Secondly, for innovation, social interaction is becoming the focal point on multiple levels and scales, as who interacts with whom matters (Lundberg, Sutherland, Blazek, Habicht & Penzenstadler, 2014; Groves & Marlow, 2016; Sørensen & Mattsson, 2016). The inner workings of a novel idea coming into existence depends on the behaviour of various people interacting with each other, their involvement, engagement, and labour. They exchange thoughts and tacit knowledge, they contribute to or are part of the development of an invention and its implementation (Fagerberg et al., 2005; Nasiri, Alleyne, Yihui & Nisar, 2016). An organization relies on its organizational structure, culture and the capacity and skills of its employees and networks to innovate (Chesbrough, 2006; Laloux, 2014). Social interactions which drive innovation are characterized by creativity at individual, team, and organizational level (Mumford, Hester & Robledo, 2012). The people involved share a deep understanding or empathy for complex processes, systems, and meanings; they evaluate and interpret, immerse themselves in requirements and needs to imagine preferred states which ought to be (Verganti, 2009; Nelson & Stolterman, 2012; Fichter, 2014). They show proximity in collaboration and co-creation, spatially and relationally, for the exchange of ideas and their further progress (Waber et al., 2014; Groves & Marlow, 2016). The importance of who is interacting and when needs to be linked to the dimension of where – in both the physical and virtual realms. When dealing with innovation, it is becoming important to consider how people act creatively, empathically and relationally as well as in spatial proximity to each other, regardless of their function or departmental belonging (Fichter, 2014; Groves & Marlow, 2016).

Thirdly, to foster innovation, the activity is shifting from process management to process design (Verganti, 2009; Martin, 2009; Lockwood & Papke, 2018). Designing a process implies a synthesizing approach, where different elements and often conflicting parts are integrated into a new whole (Nelson & Stolterman, 2012). It requires to think of organizations, their people and physical assets as a system where the parts interact with

each other. Design does not simply turn existing situations into preferred ones; it adds meaning and purpose to the new whole, which is then accessible to the people within (Simon, 1996; Verganti, 2009, Nelson & Stolterman, 2012). It escapes the linearity of process and allows for simultaneity and real-time interaction on multiple levels. Innovation processes designed as systems show an emergent property allowing ideas to evolve into innovations over time beyond a project schedule (Allen & Henn, 2007; Groves & Marlow, 2016). The awareness of process and emergence can be achieved by being visual and comprehensible, and connecting the involved, interested or unrelated actors by depicting their location and proximity spatially in a model (Allen & Henn, 2007; Lockwood & Papke, 2018). Design aims for changes in behaviour and the appropriate design of an innovation process may lead to or foster innovative behaviour (Buchanan, 2015). A systemic view of the process design helps becoming aware of the complexities and considering the dimension of time and emergence in an iterative way. It needs to be visual for awareness, communication, and engagement (Fichter, 2014; de Mozota, 2013).

Figure 1: Changing context for innovation processes: dealing with complexity, focusing on social interactions and designing processes. Author's own representation.

The 2nd Dimension - Management of Innovation over Time

Innovation research and management focus on the characteristics of innovation, which are different from business operation. Innovation research explains how innovations occur and what the drivers are, while innovation management provides the framework to manage and foster the processes (Fagerberg et al., 2005; Hauschildt, Salomo, Schultz & Kock, 2016). While it is an interdisciplinary field integrating perspectives and approaches from other areas as sociology and psychology, management is the leading domain (Fagerberg et al., 2005; Burr, 2014; Godin, 2017). In its beginnings, research and development centres shaped an era of technology-push, bringing advances in sciences and technologies from the corporate side to the market (Godin, 2017). This phase described as first generation of management of innovation processes, linear and sequential; the second generation focused on market demands and developed innovations by a close analysis of needs; the third generation pursued a combination of the two paradigms as iterative model; innovation occurred by technology-push, from companies to demands, and by market-pull, from users to companies. In its current fourth generation, the management of innovation has opened towards "a network of partners designing an integrated innovation system" (van der Duin, Ortt & Aarts, 2014, p. 489). The shift from a closed innovation paradigm, characteristic of the preceding generations, towards an open innovation paradigm has altered the relation between companies and external actors (Chesbrough, 2005). The mind-set on innovative activities has shifted from a company centric view to a dynamic network view, where people, technologies and

ideas were sourced and aligned across and outside the company's boundaries. The open innovation paradigm changed the attitude towards internally developed ideas beyond the core scope of services or products.

Innovation management in German innovation research is defined as conscious design of an innovation system, consisting of the single processes and institutions in which these processes occur (Hauschildt et al., 2016). It requires an integrative approach of leadership, resources and diffusion, distinct from R&D Management, and favours a dynamic approach and culture, in which innovation teams are encouraged to proceed for radical innovations without specified or SMART goals, which tend to be inhibitors (Hauschildt et al., 2016).

Models of innovation have tried to explain the processes behind it. In the 1960s, models started to be used and were multiplied in subsequent decades (Godin, 2017). Analytical models put "a conceptualization or theorization […] into a schema, graph or diagram." (ibid., p. 2). The process models later evolved into system models, considering the whole and parts, relations, factors, and causes. Their basic function is of a rhetorical nature; itgives form to reality or a theory, acts transcursively, advertises a conception and pretends a scientificity with a synthesizing virtue, attractiveness, abstraction and promise of success (Godin, 2017, pp. 213-215). In his analysis of models of innovation, Godin (2017, p. 181) deduces their meanings: models are simplified conceptualization of reality, a narrative of sequence of events, a paradigmatic perspective or a graphical figure in the form of chart, diagram, scheme or cycle. In its fifth meaning as a tool, models of innovation are a theoretical structuring device or a practical guide to become pragmatic, decide, check, teach and highlight important points. In contrast to other disciplines, including architecture, the innovation model in innovation research "is not an instrument to explore, manipulate, and experiment with a theory, to stimulate the world and get better theories." (Godin, 2017, p. 208). Models are used in a prescriptive and descriptive way, instead of being constructive or prospective and so creating an alternative reality (Cross 2007a). The process models show a step, phase or stage thinking of a sequence over time; systems model thus display the structure of a process, than a conception of interacting parts (Godin, 2017).

Another classification of relevance for relating architecture to innovation research, groups models in voluntaristic, contextual and interactive models. Until the turn of the millennium the prevailing understanding of voluntaristic models emphasized the individual actor (e.g. persons, organizations, R&D departments) in a linear way; contextual models outlined innovation as responses to changed circumstances and markets depending on organisational structures and industry sectors (Fichter, 2014). With increasingly dynamic markets, growing collaboration and complexity, interactive models gained in importance. They focused on holistic-systemic, process and interactive points of view, where the non-linearity and non-directed creative dynamism of the innovation process could be explained more accurately (ibid.).

In a review of innovation process design methods, 63 different approaches were mapped and analysed according concept, inner structure, and applicability (vanPatter & Pastor, 2016). As findings, graphic depictions of models started in the 1950s, but are lacking a visual clarity in respect of time and duration of each of the executed step. Roles within a process are visually not indicated nor is the human factor. The process models are ordered in six groups: creative problem solving, design, product design, service design, organizational innovation and societal innovation (ibid.). They are text-based as principle steps in acting or graphically representing the phases to be undertaken. A third dimension showing the involved actors or institutions is not included. As mentioned, models in innovation research and management are directed to prescriptive, actionable steps and processes rather than explaining the inner workings of an organization as a whole. They do not design innovation processes in a constructive way oriented towards a future innovation system of self-organized interacting parts. Though social elements have been taken into consideration since the beginnings of innovation research, the models and principles applied in practice rarely entail a dynamic, emergent, or human element. "It would be more interesting if models could be dynamic. It will make them more human" (Larry Leifer quoted in de Mozota, 2013, p. 288).

The 3rd Dimension – Architecture of Innovation Processes in Space

The growing interest by management in creative approaches for innovation processes has been focussed on disciplines such as industrial design. Architects acting at the forefront of design thinking in the past century have remained mostly unnoticed by management studies (Rowe, 1987; Dorst, 2011; Shamiyeh, 2016). The work of Schön (1983), Cross (2007b, 2013), Lawson (2005) and Lawson and Dorst (2009) refer to a large extent to architectural ways of design thinking or observe architects as case group. It is important to focus on the special characteristics of architects, trained and practiced in synthesizing a new whole out of often conflicting

and contradicting parts (Lawson 2005, Lawson & Dorst, 2009). Architecture as a profession has been intensively linked to the rise and development of different industries (Nerdinger, 2012; Rumpfhuber, 2013). The diverse field of projects architects are involved in stand in close relation to areas of management and innovation. The design and planning of a research facility require an intense deal with the underlying, projected, or yet-to-be defined processes. This creative thinking and structured work conducted to understand, design, and realize new processes, which precede the planning, have been underestimated in their value for organizational challenges, and as yet barely discussed in the scientific literature (Shamiyeh, 2007; Awan, Schneider & Till, 2011, pp. 27; Samuel, 2018). To access architecture in its relevance for innovation research and management an alternative conception is framed in the doctoral project: firstly, architectural design thinking is applicable to structuring innovation along with other design thinking approaches; secondly, the architect-client interaction contains information on vision, processes, and requirements important for redesigning an entire organization and its innovation paths. Thirdly, the focus on buildings needs to be shifted to the focus on systems and system design (Koolhaas 2004; Hyde, 2013; Luebkeman 2015). The changing context in which innovation processes are embedded – i.e. rising complexity, relevance of social interactions, and the call for design – can also be traced in the thinking and work of architects and this entails the addition of a 3rd dimension.

Architects embrace complexity and reframe it to a workable degree (Venturi, 1992; Lawson, 2005; Noennig, 2006; Gänshirt, 2012; Bachman, 2012). They exclude and include information and iterate different points of view. With parallel lines of thought they alternate between paths until a new meaning and solution unfolds (Lawson, 2005). Architecture copes with complex surroundings without simplifying and withholds contradictions inherent in conflicting goals or the contrarian requirements of clients, stakeholders, and users (Noennig, 2006; Bachman, 2012). To create a coherent whole by integrating different aspects and requirements, architecture gives order and at the same time allows disorder (Lawson & Dorst, 2009). “Simplicity” in art and architecture “is at bottom complexity” (Pallasmaa, 2014, p. 40). “To present complexity in simple ways is the designer’s noblest aspiration” (Norman 2016, p. 174). In contrast to management disciplines, architects use a 3rd dimension to cope with complex structures, relations, and interdependencies, and consider qualitative as well as quantitative information. Social interactions of people are thought together with physical area requirements and technological equipment, the form of organization – its architecture and design – is the medium to communicate meaning (HENN & WITTENSTEIN, 2016). Though the physical is dominant in the conception of built architecture, the value lies in the (invisible) art of arrangement. Applied to innovation research, this approach to complexity offers a new approach to the innovation processes of a company, integrating different parts in a multi-dimensional way while making its complex structure comprehensible to the actors involved. Embracing complexity is one of the core pieces of advice in innovation management literature – something for which architects may be well prepared (Schoeneberg, 2014; Lewrick et al., 2016).

Relations have a spatial dimension for architects. The question of who interacts with whom about what is connected to the question of when and where. Architects develop a deep understanding of people, their interrelations and interactions, their pathways and movements, and depict their proximity spatially and relationally (Pallasmaa, 2016). Organizational systems understood by architects fundamentally differ from the organizational charts in management or innovation theory. The visual and non-linear thinking of architects combined with their specific use of models provide three-dimensional access to a problem, process, or organization. Architects add a 3rd dimension to setting, organizing and transforming relations and dependencies. They graphically externalize thoughts, ideas, and knowledge in order to start a communication between the sketch, diagram, drawing, or model and the practitioner themself or other involved parties (Gänshirt, 2012; Schubert, 2014). It is less a picture of a finished idea which appears than the process of formation of an idea using a tangible medium. It is “the demonstration of an idea as well as its advent” (Leatherbarrow, 2001, p. 91). This reflection-in-action process reveals new possibilities and options, which could not be detected or observed up-front, and underline the prospective mode architects work in to transform the existing and to imagine as well as to construct a future state (Schön 1983; Lawson, 2005; Boschung & Jachelmann, 2013). While innovation management works descriptively or prescriptively, formulating a process to follow, architecture creates a frame of possibilities for the entire organization, empathically confronting people with transformation. As futurists, they are inherently optimistic that a better state can be thought of, created, realized, and operationalized (Dator, 2016; Gänshirt, 2012). This visual and spatial construction may help to broaden the view of innovation design for a company as a whole with its human actors.

Making the invisible visible is central to architecture. The architects' ability for synthesis relates to the real (world) and seeks for application in the end. This means that architects use their developed frames of complexities and their understanding of social interactions to finally design a coherent new whole (Lawson, 2005; Nönnig, 2007; Nelson & Stolterman, 2012). They abstract, represent, integrate, relate, and synthesize continuously by sketching, diagramming, planning, modelling, and prototyping: the tools they use, are tools to think and to design (Lawson, 2005; Lawson & Dorst, 2009; Gänshirt, 2012). These tools are at the same time analytical and constructive. "The ability to design," Cross (2008, p. 9) points out, depends not only on the internal depiction of an idea in the individual's mind, but "even more on being able to make external visualizations." Besides sketching as primary tool, diagrams and models are important means for designing a system (Gänshirt, 2012; Boschung & Jachelmann, 2013). In a diagram, the holistic and systems thinking of architecture becomes visible: it depicts an organization as socio-technical system by combining functional aspects of areas and processes with people, flows, interactions, and relations while not determining its final form (Boschung & Jachelmann, 2013). Diagrams reveal 'a hidden or invisible reality,' information and relations (Hnilica, 2013, p. 243). In this philosophical realm, diagrams in architecture can contain a narrative and story: they merge quantitative and qualitative information without having to be scientifically correct and extrude a metaphor in a vertical direction (Boschung & Jachelmann, 2013). The diagram stands as a concept and 'template of possibilities' which does not necessarily anticipate the building design and offers in this state valuable perspectives on organizational structures (ibid.; Dortdivanlioglu, 2018). It is "architecture's best means to engage the complexity of the real" (Allen, 1998, p. 17). At this abstract, yet constructive level, the diagram can serve as general scheme or outline for activities at the overlap of the visible and invisible. To capture and design the fuzziness of innovation processes, this may be a valuable tool.

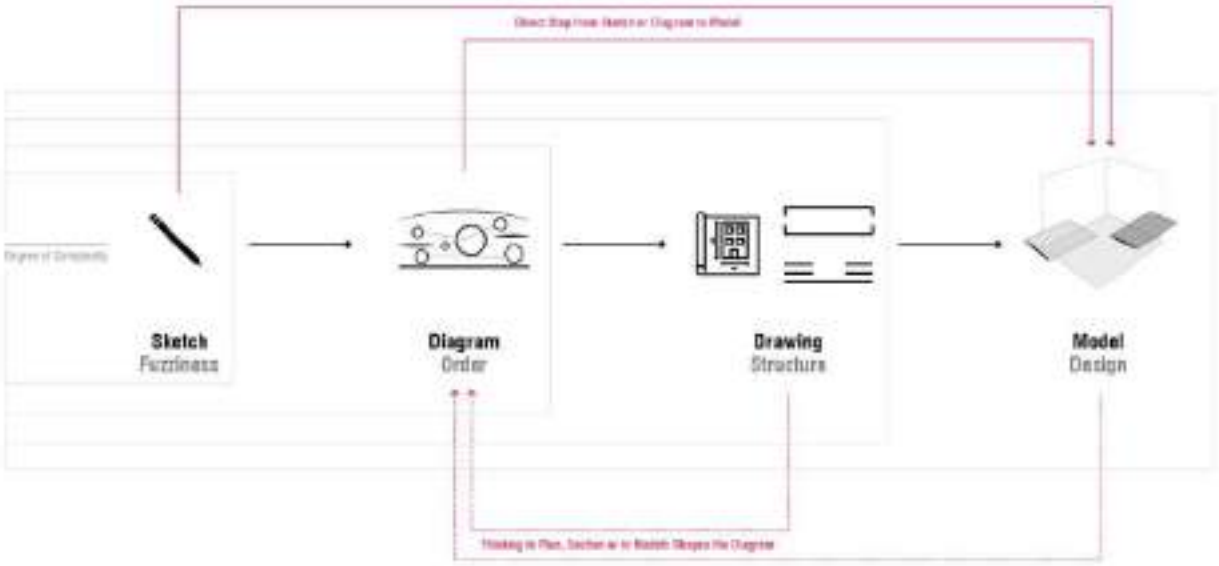

Figure 2: Design tools of architects, with interrelation and interdependencies between the tools. Author's own representation.

Models are used and understood differently in architecture than in management (Boland & Collopy, 2004). While in management the descriptive and prescriptive character in 2-D prevail, models in architecture are 3-dimensional and generative. They are used for experimenting or testing and serve as a boundary object or shared system image for communication, participation, co-creation, and presentation, both internally and externally (Doll, 2009; Gänshirt, 2012). In working models the "ephemerality of assemblies" is what allows us to add, take away, shuffle, and re-arrange parts or the entire model, while reflecting on and evaluating the conducted actions and their consequences (Wagner, 2000, p. 385). As persuasive artefacts they offer a special kind of openness, immediacy, and interpretive flexibility (Wagner, 2000, p. 388). The models also represent the prototyping mind-set of architects and show the relational and spatial proximities as well as the parallelly

and simultaneously performing parts of a whole (Gänshirt, 2012). They are abstractions and representations of the constructed real, not the final product itself, which requires the architect to continuously imagine, foresee, and think of the implications and consequences when a design is going to be built (Rittel & Webber, 1984). It speaks for a holistic approach with a long-term perspective beyond current client, user, or market demands (Maescher 2018).

Reframing complexity, understanding interactions and designing a system in an architectural way leads to a 3-dimensional conception of an organization. If this kind of thinking and tools could be applied to the design of innovation processes, new models could evolve as unique solution for a specific company. To underline this argument, two case studies will be presented, where architects have worked on architecting and designing innovation processes for small-and-medium sized companies (SMEs).

From Random and Structure to Network – 2 Case Studies

The goal in both cases was to analyse and understand the client's requirements, processes, culture, and vision and to synthesize a concept model of the future organization as the basis for a subsequent building design phase. Two SMEs were facing a major transformation and development in their structure. In the first case, an innovation factory, a successful company in mechatronics needed to enter a higher level of complexity by leveraging its innovation processes from linear to network. In the second case, a nanotechnology R&D headquarters, the successful growth of a start-up required a new state for its processes turning from random to network. Both companies were approached by an architectural consulting service called architectural programming in 2009 and in 2015, conducted with and by the author (WITTENSTEIN & HENN, 2009; attocube & HENN, 2015). Initially serving as brief for a satisfying building design, the architectural programming can be viewed as a 'research and decision-making process', which could be applied to problems detached from a physical solution (Cherry, 1999, pp. 3, 229-230). It is one goal of the doctoral project to re-direct the principles applied in architectural programming and early phases of architectural projects for the development of new organizational designs.

Mechatronics Innovation Factory / 2009[1]

As a leading company in the fields of mechatronic technologies, the capacity and competence to permanently create new ideas, develop innovative technologies, and apply them to markets has been vital. By the time of the case study in 2009, the employees were responsible for around 80% of innovation projects, while 20% were initiated by customers outside the firm. The questions were how to maintain the speed of innovation, how to achieve a share of 50% in-house and 50% externally initiated innovation projects, how to foster an innovative mindset and self-organization among employees, and, finally, how to attract international talent and expertise. The vision was to create an innovation center, where engineers, developers, and clients work together and follow the process of idea generation, development and dissemination in production.

The progress towards a 3-dimensional innovation process within the architectural consulting service consisted of six phases: information collection, linear process mapping, 3-d process visualization, sections, diagrammatic sections, and systems modelling.

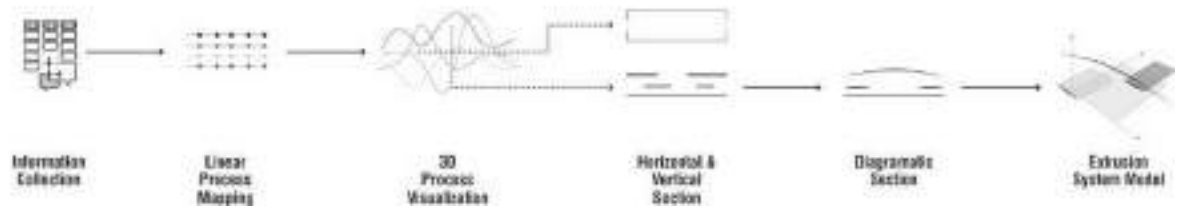

Figure. 3: 3-dimensional diagram of the organizational process in new product development and innovation. Author's own representation.

[1] The sources for the case study description and analysis are based on the author's notes and reports, presentations and models handed over by the consulted companies for research. The author was team consultant during the project in 2009, sources from internal documents released for publication are quoted with 'WITTENSTEIN & HENN, 2009.'

In the information collection phase reports and data-sheets were reframed and visualized graphically. The image of the organization changed by using different forms of visualization, which were discussed and refined in workshops. The illustrations served as boundary objects, leaving textual dependencies for visual simultaneity, and dissolving personal contributions towards commonly visible information (Boland & Collopy, 2004; Henn 2004; Peña & Parshall 2012). With an increase in information level, the visualizations were shifted from two-dimensional to a three-dimensional view, co-locating people and functions in three directions, while maintaining visibility and awareness.

The linear process mapping started from intangible elements (thoughts, ideas, knowledge) towards the physical manifestation of a finished prototype or product. It was conducted for each department and business unit, as well as for the movements of employees, customers and visitors, and for the new product development process. In a second step, each line of the processes were overlaid at the required point of interaction. As some processes needed to intersect multiple times at different stages, the 2-dimensional linear depiction reached its limits. By bending the lines in space, the architectural consulting developed a 3-D process visualization, where the joint points of intersection could be detected while not interrupting the flow line of each process. The visualization revealed a multidimensional organizational system where processes interacted in centres while remaining visible and open in-between. It led the linear thought models of organization towards an emergent system approach, where self-organization, freedom of flow, and exploration could be imagined.

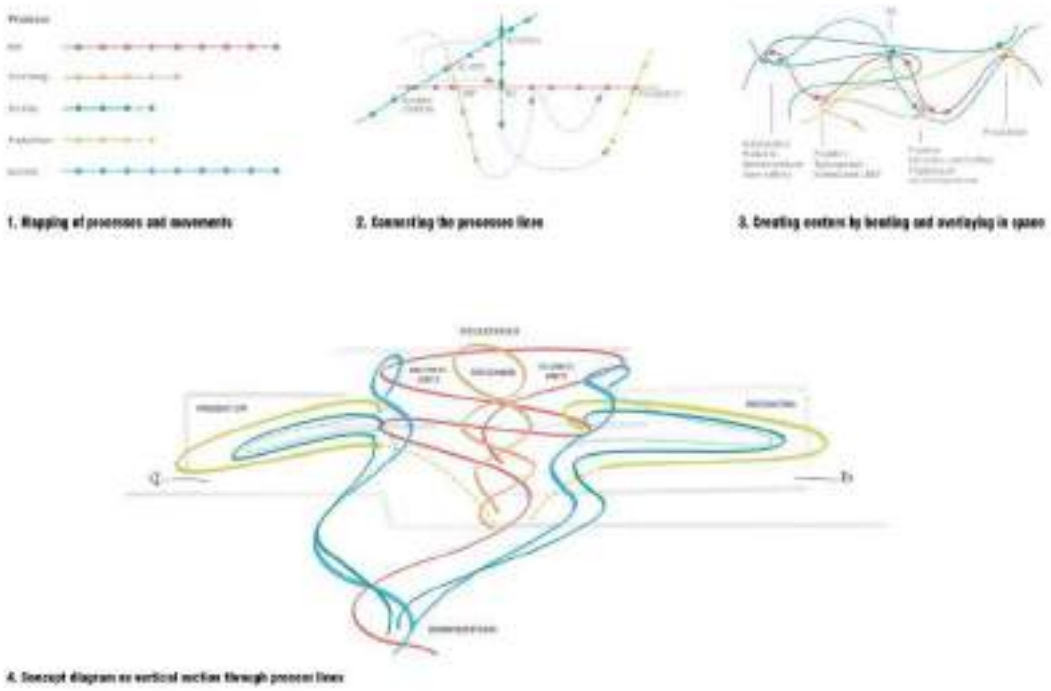

Figure 4: 3-dimensional diagram of the organizational process in new product development and innovation. Source and copyright: HENN & WITTENSTEIN AG, 2016, pp. 10-11.

The developed diagram was interpreted in a spatial dimension. By adding the elaborated information from the previous visualizations, the architects created a horizontal and vertical section through the diagram to explain the situations at intersection points. Through the 3-D arrangement of spines, the created diagrammatic section was modelled physically to show all aspects of work processes, flows, and organization of units, as well as the required spatial, technical and site requirements. It depicted for the company the future way of working and innovating in a multi-dimensional, integrative and simultaneous way. By extruding the conceptional section in different directions, the potential of the new organizational structure became visible. What formerly was depicted in a two-dimensional, linear and determined way was visible as 3-dimensional system.

Figure 5: 3-dimensional diagram of the organizational process in new product development and innovation. Source and copyright: WITTENSTEIN & HENN 2009.

Nanotechnology R&D Headquarter / 2015[2]

The start-up, founded in 2001, was in a transition phase from a grown structure of 90 people to a company of more than 175 employees. While the mechatronic company was leaving 'linearity' in processes and organization, the nanotech start-up was leaving 'dispersion.' Through the consulting of architects their vision, values and processes were reflected. The main questions in 2015 were, how to grow as company while maintaining a spirit of a community and start-up; how to achieve a share of 50% industry products and research projects (coming from 25%/75%); how to integrate management departments with innovation, research and highest-precision production; how to communicating mind-set, values, and remain attractive for researchers and high-potentials in engineering and natural sciences.

With modifications to the first case study, the process also followed six steps: information collection, process section, 3-D process visualization, section, diagrammatic sections, and systems modelling.

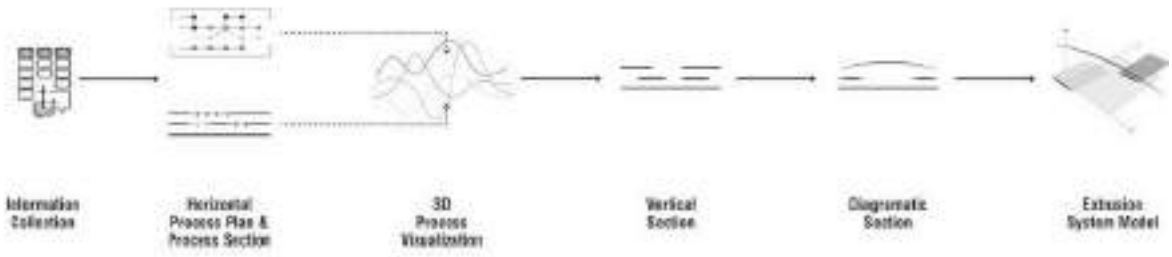

Figure 6: 3-dimensional diagram of the organizational process in new product development and innovation. Author's own representation.

The available reports and documents on the company were processed visually and enriched with the information gained through workshops and interviews with members of the board, researchers, developers and administrative staff. The process for the research and industry business were mapped in plan views and sections. The materialization of an idea was represented in plan/top view from left to right, and in section from top to bottom. The two perspectives were brought together in a 3-dimensional diagram of the organization. Employees, distance, and proximity as well as process allocation and spatial functions were considered in the model. The digitally rendered visualization was then viewed from different angles, and revised until it matched the perspectives of the board and employees.

[2] The sources for the case study description and analysis are based on the author's notes and reports, presentations and models handed over by the consulted companies for research. The author conducted the project as architect in 2015, sources from internal documents released for publication are quoted 'attocube & HENN, 2015.'

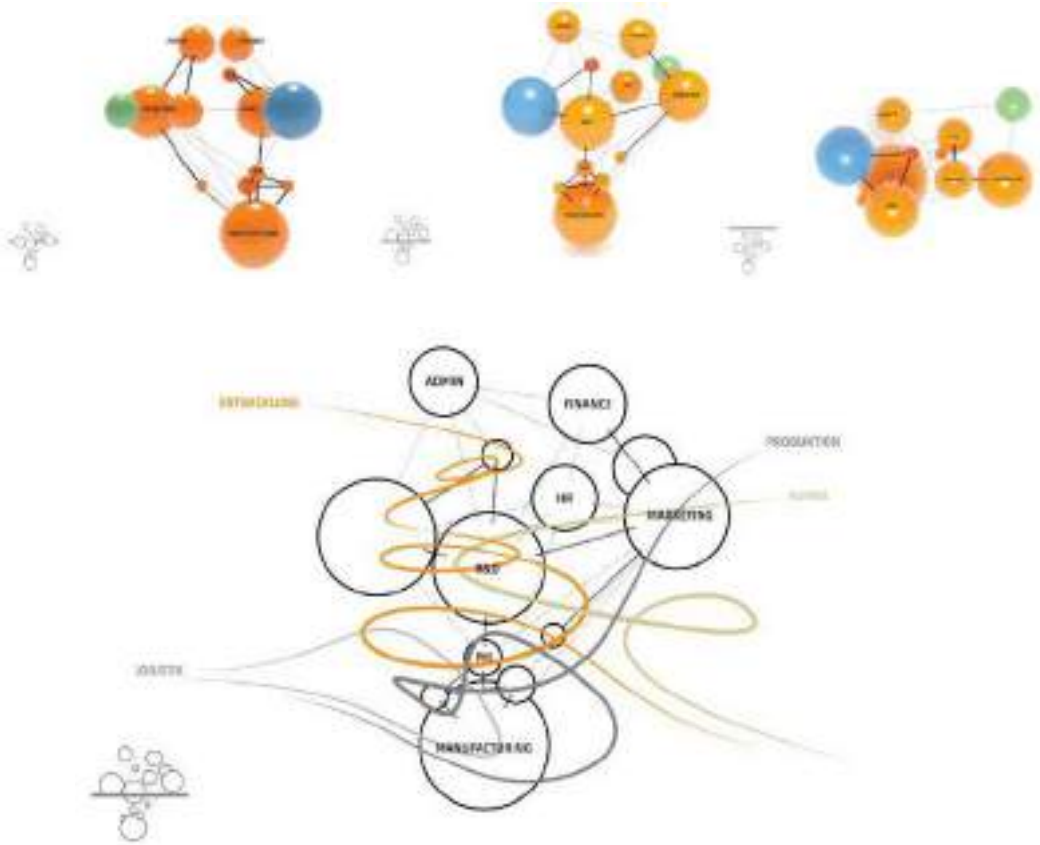

Figure 7: 3-dimensional model of employees, relation and spatial organization. Source and copyright: attocube systems & HENN, 2015.

Applying the prior elaborated process from plan view and section to the 3-D model, made the flows of interaction visible to client and architects. By cutting through the model a principle section of the entire company structure was created, which additionally displayed the values and mind-set of the company. The diagrammatic section served as intermediate structure between narrative and organization. In extruding the section in different directions, the innovation process space evolved, balancing out awareness, functions, and project flows of the company.

Further Research

As the consulting process of architects prior to a building design has not been scientifically analysed, the case studies serve as an important source in two respects. Firstly, to develop a separate view of the principles applied detached from a building focus. Secondly, to develop suitable principles and tools for implementing architectural thinking in a management and organizational design context. The visual representations of the organizations in the architectural programming are difficult to access by managerial understanding and constrained by the image of a physical building design. Though the presented works resulted in physical output, they were able to change managerial perspectives on the future organization and innovation processes. For the ongoing research it will be relevant to compare the visual and spatial approach of architects with related works from other disciplines and industries. Despite the existing text-based examples for innovation process design, new digital tools are applied in innovation management and research. Software and applications such as innotrace or innosabi foster agile innovation across companies (Lundberg et al., 2014; Innosabi, 2019). So far, a spatial-dynamic dimension for an organization as a whole has not been detected as this will be pursued in the doctoral project. By comparing existing principles and tools with architecture, is the intention is to develop an architectural approach to innovation research and management, and outline a conception of architecture as an innovation design discipline. This extended field of architecture working at a

systemic, organizational level could integrate the relational and process understanding of management with a spatial system of dynamic flows.

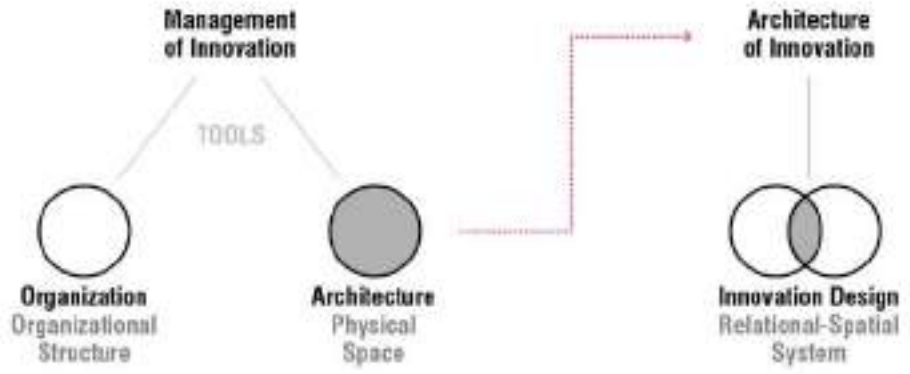

Figure 9: Re-positioning from architecture as tool to architecture as management for innovation. Architecture of innovation creates a relational-spatial system of innovation processes. Author's own representation.

To bridge communication between the two disciplines, the tools and working modes of architects need to be explicitly shown and explained. The development of further digital tools based on architects' understanding and perspectives on organizations and their innovation processes will provide additional support. An interdisciplinary project with students from information technology has recently been started to create an integrative, easy-to-use, and adaptive application. It will serve as first prototype towards creating a 3-dimensional interactive process design tool from architecture for management.

Design practices for strategic innovation in start-ups

GLAUBERT Daphna[ab]*; CHARLESWORTH Zarina[a]; NYFFELER Nathalie[a] and BERGERON Luc[b]

doi: 10.33114/adim.2019.03.300

This paper looks at the use of design practices in start-up firms for the creation of strategic advantage through product/service innovation. Start-ups face non-negligible challenges during the early-stage of development. The research questions examined to what extent design practices can provide the leverage needed to face these challenges. A 4-day *Innovation by Design Challenge* workshop provided the field for the research carried out. Participants were start-up firms each working together with two designers to form six teams. Methods used included: observation for the mapping of team activities; a short self-report questionnaire and; pre- and post-workshop semi-directed interviews with the start-ups. The findings support the idea that design practice integration into the initial development of a start-up can indeed provide a lever for success and provide the start-up with the strategic vision needed to go through the early-stage and bring their products/services to market successfully.

Keywords: Start-ups, design practice, co-design, innovation

Introduction

In a recent article on the nature and desirability of innovation, Pisano (2019, p. 19) reminds us of the difficulty that organizations have in both creating and sustaining it. Yet in a constantly changing world, innovation becomes a necessity and this even in the case of early-stage start-ups. The question is then what options are available to such firms that allow for the agility necessary for quick market response and, at the same time the creation of a competitive edge? Among the contenders one finds design practices.

This research focuses on how such practices can be made to work and leveraged strategically by an early-stage start-ups for the creation of new opportunities or to improve its product/service through the use of a human-centred approach. Young firms often do not go so far as to have well-written strategic agendas despite having an ear to the ground and an understanding of the importance of providing a product/service in line with what the market requires. Design practices can lead to “meaningful innovation [which] puts together real users’ problems and expectations with new technologies or a new use of a known technology” (Rossanese, Zilse, Arantes, & Tobias, 2017, p. 3)

There is an ever increasing need to integrate diverse areas of knowledge “where the ability to work across boundaries represents a key ingredient for competitive advantage” (Hacklin & Wallin, 2013) in which co-design and design thinking methodology play an important role and where “design thinking can be defined as the application of design methods by multidisciplinary teams to a broad range of innovation challenges” (Seidel & Fixson, 2013, p. 19). Furthermore, the integration of a design perspective means that “the emphasis is

transposed from business need to user need" (Newton & Riggs, 2016, pg 2) placing the user at the start of the design process rather than at the end.

Literature review

It has been noted, more than once, that the appropriate deployment of design resources allows a firm to achieve its organizational objectives (Gorb, 1990) and to foster value creation (Borja de Mozota, 2006). Although particularly true for large companies (Design_Council, 2007), this also applies to young structures such as start-ups. Reported research focusses largely on the implementation and use of design practices in large organisations (Bau, 2016) with a smaller body of literature reserved for small businesses (Acklin & Hugentobler, 2008; Malins, 2011; Ward, Runcie, & Morris, 2009). In large part, the design practice literature does not differentiate between established firms, large or small, and start-ups. We believe that there is indeed a difference here which has, in turn, guided our research. This section presents the challenges faced by start-ups and how design practices can provide a strategic response to them within the framework of current models and methods.

Specificities of Start-ups

Whether start-ups are presented as the result of the entrepreneurial act (Chew, 2015), or as "a human institution designed to deliver a new product or service under conditions of extreme uncertainty" (Ries, 2011, p.8) their activity focuses on the development of ideas, opportunities and the design of new products or services. All start-up firms can be seen to go through several clearly identified phases and all generally face the same challenges.

The start-up development goes through different stages that include (1) the Bootstrapping stage (2) the Seed stage and (3) the Creation stage (Radovic-Markovic & Salamzadeh, 2012). Those stages are used to transform the entrepreneur's idea into a profitable business. The objective is to position the company by demonstrating the feasibility and acceptability of its product to customers as well as its financial capacity and team management skills (Brush, Carter, Gatewood, Greene, & Hart, 2006). Companies increasingly recognize the importance of design during the early-stages, also known as the Fuzzy Front End, by using the skills of designers not only for the realization of new products/services, but also for the co-creation of concepts (Calabretta & Gemser, 2016).

In the early stages start-ups generally do not have the luxury of time nor money yet need to reduce the risk of failure to a minimum and a lack of resources can prevent the start-up from collaborating with a designer from start to finish. Working under such constraints (Glaubert, Nyffeler, & Bergeron, 2018) can contribute to the high failure rate exhibited by start-ups especially during the early-stages where the risk of failure is omnipresent.

Liedtka (2018) suggests that design practices, particularly design thinking, can be regarded as a social technology which she defines as a "blend of tools and insight applied to a work process" and goes on to suggest that "it has the potential to do for innovation exactly what TQM did for manufacturing" (p. 72), in addition to answering the challenges that firms face in the innovation process including the identification of superior solutions and the lowering of risks and costs. She joins, to a certain extent, the position taken by Acklin and Wanner (2017) that design practices are more than design but should be considered a management function, one that "embeds design or design processes in companies in order to create added value in products, services, experiences, processes and structures" (p. S471).

Despite a dearth of research on the challenges faced specifically by start-ups there seems to be a general consensus that such firms face similar challenges and ones other than those faced by established firms. Giardino, Bajwa, Wang & Abrahamsson (2015), identified ten critical challenges faced by start-ups based on a world-wide sample of 4709 start-ups and which include resource (financial, human and physical) and market related issues. This corroborates what has already been said about keeping financial and time investments down all the while paying particular attention to market needs.

Seen from this point of view it becomes clear that start-ups particularly serve to gain from collaboration between those who have competencies complementary to their own, namely, designers. And this, despite a reticence on the part of a certain category of start-ups as "budding entrepreneurs from the engineering disciplines often associate the term 'design' with art and as not relevant for their future business" (Acklin &

Wanner, 2017, p. S470). Design allows for a user-centred focus and "humanizes" (Buchanen, 2000) the technology, of importance when start-ups, particularly high-tech start-ups, are looking for investors or are in the process of addressing future clients.

The integration of design practices can be seen as a key success factor and a risk-reducing one, something of high importance for young start-ups in the early-stage (Sheppard, Kouyoumjian, Sarrazin, & Dore, 2018).

Innovation by design

As mentioned in the introduction, we live in a fast-paced world, one where innovation has become something of an overused buzzword. This banality has today's consumer taking novelty as a given and expecting to see it with ever greater frequency. Some talk about design as the latest best answer to innovation with Owen (2006) going so far as to say that design thinking "offers a way of approaching issues, problems and opportunities almost uniquely suited to innovation" (p. 3). Yet design practices alone will not suffice, nor should one imagine them as the Holy Grail to start-up success.

Both design and innovation are used with ever greater frequency, as well as interchangeably, to describe a method comprising products, services and systems. If design can indeed be seen as a resource, it is closely tied to the user and can translate into an advantage as the focus is on the human aspect versus that of the technology (Kolko, 2007). Monori, Arruda and Araujo (2015) suggest that successful innovation depends on "the understanding of user needs, competitive advantage and synergy between the company's strengths" (p. 2201).

The role of design in innovation has long been under discussion, see for example Roy (1994) for an initial discussion of how design supports innovation and Na, Evans, Zitkus, Whicher and Walters (2018) for one more recent. Its role in incremental and radical innovation was also well described by Borja de Mozota (2003).

In a recent report published the British Design Council (Benton, Miller, & Reid, 2018), design is identified as a resource for innovation with survey results showing that firms placing importance on design activities and with "design functions or facilities in-house are significantly more likely than average to have developed completely new and original products, services or processes" (p. 28). Over the past twenty years design has taken an ever-increasing role in the creation of unique and innovative marketing approaches and is increasingly seen as a method of ideation to be used by both design and non-design firms (Kolko, 2007). Today design is taking on a further element of importance as it allows for the development of products and services that have meaning for the customers and it "has the ability to add value in many ways, including economic, social, and environmental" (Lockwood, 2007, p. 91).

Despite an accrued interest in design practices, there is little empirical evidence (Malins, 2011) to support long term results of using such practices for innovation. Firms must be aware that such practices need to fit with company values and that they are but one option to choose from.

Co-design

The integration of design practices within startups requires knowledge of multidisciplinary collaboration and co-design. Indeed, they are an integral part of the design thinking methodology where different stakeholders are integrated into the project's thinking to address broader innovation challenges. The term co-design has more than one definition going from its restriction to designers alone or to a more all-encompassing definition put forth by Sanders and Stappers "co-design in a broader sense to refer to the creativity of designers and people not trained in design working together in the design process" (2008, p. 6). Such collaboration allows the firm to step back and view the project in question from an alternative point of view. In the words of Schwartz, Bransford and Sears "we think it is especially important to note that innovation often requires a movement away from what is momentarily most efficient for the individual or the organization" (2005, p. 30). This calls on the firm to invest some of its limited time resource to pause and reflect upon questions frequently asked by designers including what the purpose of the innovation is; who the target user is and; how it will be used.

Although the ideas of co-design have been around for some time now and, with the design domain, can be seen to have their roots in the participatory design movement of the 1970's (Sanders & Stappers, 2008), it would seem that industry was not ready until recently, however, to embrace these principles.

Crossing disciplinary boundaries

Taking the debate one step further we looked at the research on team composition within design practice. Much of the literature ignores the fact that design practice teams are often interdisciplinary and look more at team dynamics and successful team performance. Yet interdisciplinary teams have an additional level of complexity which should be taken into account if one is to achieve the desired "interdisciplinary knowledge integration [which] depends on the ability of individuals in teams to combine knowledge in novel ways" (Hacklin & Wallin, 2013, p.781).

In addition to the disciplinary differences that one might find among team members and, of particular interest in our research, are Ho's (2001) research findings which suggest that there is "an obvious difference between experts and novices in the way they approach the problem" (2001, p. 43). Expert designers were found to look at the design problem before using working-backward strategies to come up with design knowledge in answer to the problem whereas novice designers tended to use working-forward strategies in search of design solutions already at the outset (Ho, 2001).

In summary, what design practices today can most benefit from is teams which have the support necessary to allow for boundary-crossing by the individuals concerned to function optimally. This might take the form of models, processes, or even toolkits to help structure and allow for the integration of such practices.

Design in practice

Models and methods

By the early 2000's design practices came to be seen as a "complex thinking process of conceiving new realities, expressing the introduction of design culture and its methods into fields such as business innovation" (Tschimmel, 2012, p. 2). With this, reference to and attempts to adopt design thinking became increasing widespread. In order to facilitate the use of design thinking a number of models were created to allow for its integration into any organisation.

The most notable among these were the IDEO models which included the 3I -Inspiration, Ideation and Implementation and the Hearing, Creating, Delivering HCD models (Tschimmel, 2012). Two other important contributions to the model literature were the Double Diamond model introduced by the British Design Council (British Design Council, undated) and the Service Design Thinking (SDT) model (Stickdorn & Schneider, 2011)

As an alternative to the phase/step approach provided by the models, a number of authors, focused on the identification of key questions to be addressed during the design process. This includes research done by Austin et al. who in some early work on interdisciplinary design teams (2001) found the process to be iterative. Although no structure or method resulted from their work, they did note that without any guidance the teams studied proceeded in an ad hoc manner. Liedtka (2014) highlights the importance of what she identifies as the 'questioning period' with four essential questions to be asked: what is, what if, what wows, what works in order to create not only successful but productive teams.

Complementary to the model-based approach one also sees a number of process-related methods including that developed by Google Ventures and shown in Table 1.

Table 1: GV Design Sprint process

Day 1 **UNDERSTAND**	*Day 2* **DIVERGE**	*Day 3* **DECIDE**	*Day 4* **PROTOTYPE**	*Day 5* **VALIDATE**
• who are the users • what are their needs • what is the context • competitor review • formulate strategy	• envision • develop lots of solution • ideate	• choose the best idea • storyboard the data	• build something quick and dirty to show to users • focus on usability not making it beautiful	• show the prototype to real users outside the organisation • learn what doesn't work

The afore-mentioned process combines elements of existing models with guidance on how to proceed at each stage. This provides a framework that, for those new to design, can allow for a structured adoption process.

Finally, we now find an increasing number of design practice tool-kits available aimed at the smooth integration of design practices into business, just a few of which are listed in the references (Calabretta & Gemser, 2016; IDEO.org, 2015; Sanders & Stappers, 2013).

In summary, design practices for early-stage start-ups is a field that has not been the subject of much empirical research and one which we esteem could be a viable strategic option for such firms helping them to face typical start-up challenges. This has influenced our research focus and led us to define the following research questions:

Within the framework of a 4-day workshop open only to early-stage start-ups and designers:

1. What are the key activities used to solve a short-term design objective?
2. What is the team's perception of its productivity, collaboration and individual involvement?
3. To what extent might design practices be seen as a strategic option for start-up firms?

The answers to these questions will provide the basis for the identification of best practices with the intent to develop a method accompanied by specific tools for strategic innovation through design in start-up firms.

Methods

We chose to use action research in order to carry out this project as, more than any other paradigm, it takes the interests of all stakeholders into account (du Preez, 2011). Based on the framework set out by Dick (1993) we have followed three defined steps: *intention*, *action* and, *review*. These headings are used below to present the research carried out in what is the second iteration of the project. Results from the first iteration (Glaubert et al., 2018) allowed for the continued development of the 2nd Innovation by Design Challenge (IDC) the results of which are reported in this paper.

Intention

In order to provide an opportunity for start-up firms to test design practices as a strategic tool for competitive advantage we organized for the 2nd time, an annual a 4-day, evening-only, workshop called "Innovation by Design challenge". Our intent was to foster collaboration between start-ups and designers allowing the start-ups to improve their products/services through design practice angle. Six start-ups and twelve designers worked actively during four three-hour evening sessions over consecutive days with a final presentation one week later. This programme was designed and implemented by the School of Management and Engineering Vaud (HEIG-VD) and the ECAL/Ecole cantonale d'art de Lausanne and sponsored by a Swiss municipality (Ville de Renens) and an organisation supporting entrepreneurship in the state of Vaud (Innovaud) (Figure 1).

Action

This stage called for the implementation of the action research which, within the framework of the workshops, included active observation, informal participant feedback, the completion of a self-report questionnaire and, semi-directed interviews held with the start-ups involved.

From the first iteration of the challenge we learnt that some designers had difficulties in understanding the start-up's objectives and the short-term issues they wanted to find solutions for. As the result depended on the designer's knowledge and ability to work with the start-up this was a critical issue. In order to foster quality collaboration, we chose a more structured format with set milestones for the 2nd iteration, the results of which are presented here.

The proposed workshop drew upon two complementary models. The rationale for this being that design practices in entrepreneurial organisations alternate between open, explorative approaches on the one hand and more focused, specific ones on the other (Nguyen, 2016). The more explorative "Double Diamond" approach of the British Design Council (British Design Council, undated) has four phases: Discover, Define, Develop and Deliver, phases that allow the participant to meander. The focused method selected was the product design sprint process developed by Google Venture (Knapp & Zeratsky, 2016) a structured method using specific tools to achieve rapid prototyping within a short period of time.

Using our knowledge of the two approaches and given the five collaborative sessions at our disposal, we created four phases to structure the workshop: Reframe, Imagine, Realize and Present. These are presented below.

1. Reframe :
   Where we introduce the challenge and help to build a common understanding of the existing product and its context (clients, usability, business model, problems encountered, constraints). Then at the end of the first session all teams are asked to formalize the challenge that they want to address during the workshop. As in the previous challenge, we sent a list of questions to the start-ups to prepare prior to the first session and asked all teams to formulate the problem they wanted to solve during the workshop with two questions: HMW (How Might We) question and the value proposition question (Osterwalder & Pigneur, 2014).
2. Imagine:
   The second and the third sessions concentrates on proposing one or more solutions with a focus on customer experience and the use of the product/service, followed by the selection of one of the proposed solutions and its subsequent development.
3. Realize:
   The fourth session is dedicated to the production of visual materials (presentation, prototype) in order to help pitch the projects to the public.
4. Present :
   The fifth session is devoted to the final presentation.

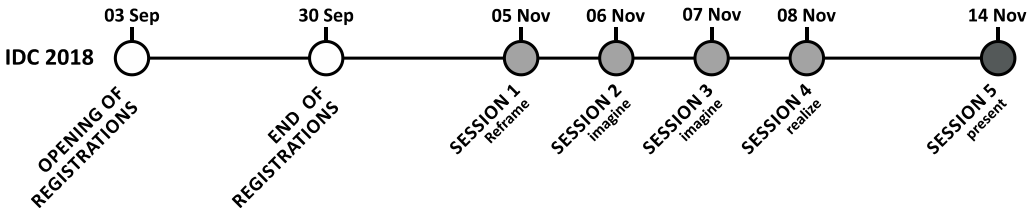

Figure 1: The entire workshop programme

Participants: In order to select the teams a call for start-ups and designers was launched between 03rd September 2018 and 30th September 2018. A total of eleven start-ups and nineteen designers applied. The criteria were the same as in the first iteration : start-ups were (1) to be located in the state of Vaud; (2) to have been founded in the last five years or to be in the creation phase and; (3) to propose an innovative project; designers were (1) to be a final-year Bachelor's or Master's student or a professional under 40 years of age. The choice of start-ups took into account the needs and short-term objectives stated on the application form. Six start-ups and twelve designers were selected for the challenge, each start-up was assigned 2 designers with complementary knowledge, experience or studies background (table 2). Indeed, the start-up challenge requires several disciplines in design to solve it. Several designers had multiple design skills and two teams (team D and F) benefited from the experience of a senior designer (having more than 10 years of experience) and with knowledge of design thinking and the strategic approach of design (Service design or experience design or MBA background).

Table 2 : Start-up workshop participant and designer profiles

Start-up	*A*	*B*	*C*	*D*	*E*	*F*
Creation	Feb, 2016	Dec, 2017	Jul, 2015	Sep, 2016	Fev, 2017	Jun, 2017
Sector of activity	Industrial Machinery and environment	Industrial machinery	Optics, mechanics, software, engineering	Drones, infra-structure	Transport	Planning and management of end-of-life data
Main offer	Machines capable of	Efficient and effective	Planar micro-	Detect drones in air	Participatory workshop on	Secure digital

	collecting lake algae and transforming it into powder.	beverage machinery	tracking system that can redirect light in various direction	traffic to avoid collisions	motorcycle and bicycle	platform that stores all important information at the end of life
Full-time employee (FT)	3	2	10	6	3	6
Needs	Present your product in a simplified way	Review the product design for production launch.	Clarify our message to our potential prospects	Redesign the digital platform	New identity to reach new customer	Invent a complete experience around an emergency card
Designer 1	Product designer	Product designer	Product designer	UX designer	Service designer	Product designer
Designer 2	Architect	Product designer	Product designer	Architect and design strategist	Product designer	Senior product designer and design strategist

Data collection : During the Challenge, we collected three data sets. The first data set was based on an observation of the activity of each team during the three first sessions. The list of the activities of each group have been quantified and classified according to the nomenclature of the phases of the double diamond model, namely discover, define, develop, deliver. Our intention was to use this data to map the creative activities and identify divergent and convergent moments. The second set of data collected during the sessions concern the perception of collaboration. Each member was asked to answer to a short self-report, 8-item questionnaire at the end of the session in order to better understand the team dynamics, their alignment on the process and their perception of the collaboration, engagement and productivity. The team B didn't answer the questionnaire the second evening, their data is excluded from our analysis. The third data set concerned the semi-structured interviews with the six start-up managers. We used an interview guide to conduct the semi-structured interviews held at two time periods: T01 = before the workshop, T02 = after the workshop. This set of data focus on the awareness of design, the role of design for the start-ups, and their expectation of the Challenge.

Review

The final stage of an action research approach calls for review. After the 1st iteration of the IDC workshop an informal review was done in order to revise and prepare for the 2nd iteration reported here. This in turn will be subject to review prior to the 3rd workshop planned for 2019.

Research findings / data analysis

The aim of the observations was to analyse the creative process of each team in order to validate and improve the tools used during the workshop sessions and identify the critical activities to foster collaboration between the start-ups and the designers.

Creative process

The observations allow us to list the activities of each team and visualize their creative process according to the double diamond model. We distinguished teams with novice designers (A, B, C, E) and teams with senior designers (D, F). As per the results, the novice designer teams do not follow the double diamond process in a linear way. Indeed, for teams A, B, E, the develop phase can occur regularly from the first S1 session and the define phase appears several times throughout the process for teams A, B, E until the last S4 session for teams

C. In addition, it is noted that teams with senior designers follow a process closer to the double diamond model with distinct phases. The discover and define phase appears in time S1 for team D and continues in S2 for team F. The develop phase extends to S2 and S3. Finally, the production phase appears in S4. This shows us that the first phase also has a relatively dense number of activities and that the definition of the in-depth problem allows us to develop solutions without having to come back to the define phase to figure out on the problem.

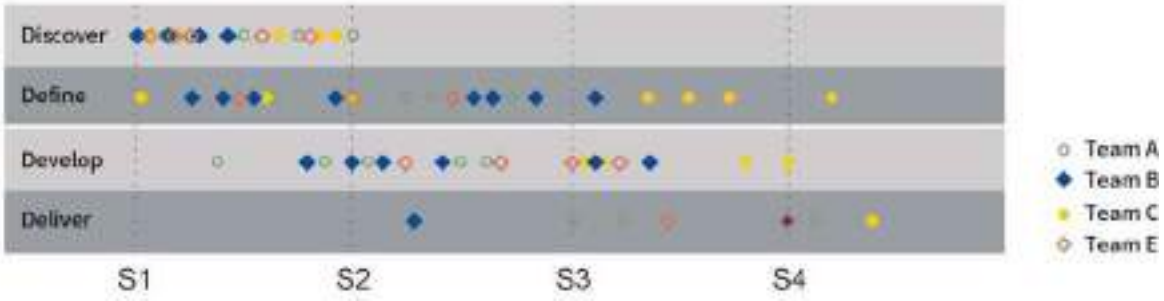

Figure 2: Mapping of the activities of novice designer's team

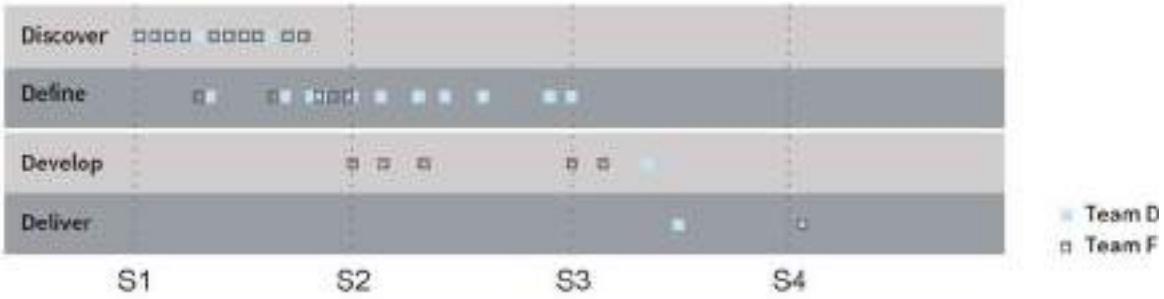

Figure 3: Mapping of the activities of senior designer's team

The management of the creative process seems to have an influence on the perception of the team production, collaboration and individual implication. The result of the questionnaire links team activities to the collective and individual perception of collaboration.

Perception of collaboration

The results show that the quality of the production is estimated lower when they enter the define phase and increases for the develop and deliver phase and that this varied from one team to another (Figure 4). For example, Team C encountered difficulties in defining the start-up's problems and needs. Their perception of their collaboration was at its lowest in S3 at which time they were still defining the problem to be solved (Figure 2). Teams E and F started the development phase in session 2 whilst Team D did not start the development phase until session 3 (Figure 3). Teams A and B followed a more iterative process and both improved and stabilized their collaboration in session 3. The data show that the teams perceive that they have performed better as a team when they agree on, and subsequently follow, a design process. Finally, the assessment of productivity, involvement and collaboration of all the teams improved at the develop and deliver phase.

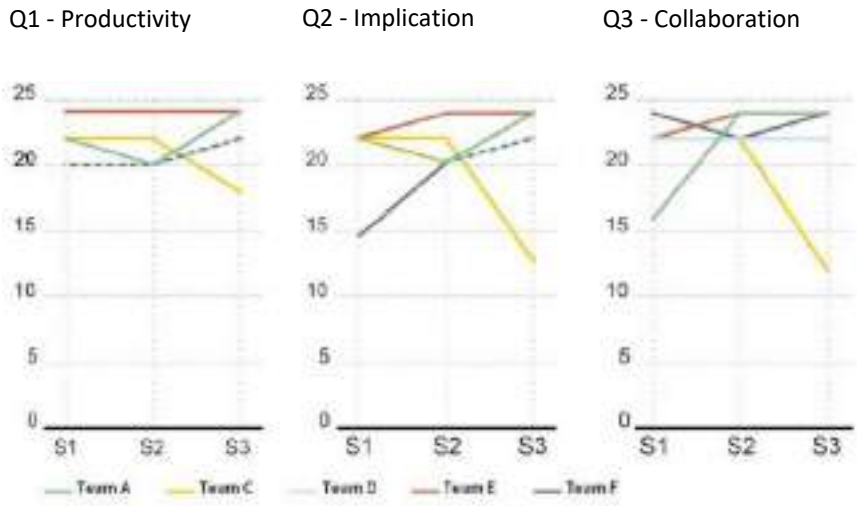

Figure 4 : Team perception of their productivity, involvement and collaboration

The analyses and themes mentioned during the different phases allowed us to see that the develop phase ends when the teams have a complete understanding of the value of the product and how it is used (competitor, stakeholders, technical, prototype, problems encountered, Unique Selling Proposition, offer); the customer segment (who the main customers are and what their needs are) and the short term objective (the problems to solve, the constraints, the deliverables). For the senior teams, they also tried to understand the business model and define the unique selling proposal or value proposition (table3).

Activities and milestones of each phase

The synthesis of the teams' activities during the program shows similarities between the teams' activities and those proposed by the sprint model. Indeed, the identification of target customers, their needs / experience, as well as dividing the challenge into sub-questions and objectives are key elements of the reframing phase. In the context of the challenge, several areas of reflection (industrial, service, digital interactions), designers also evaluate the offer, the added value of the product and its use. The difference between the models can be explained by the type of participants. Indeed, the sprint allows employees who do not have any knowledge of design to actively participate in the creative process, while in the IDC Challenge is formatted for one manager of startups with a predominance of designers. Thus, the creative process is still structured with exercises inspired from the sprint workshop model during the diverge, decide and prototype phases while the imagine and develop phases depend on the knowledge and methods used by the designers. Nevertheless, we find milestones for the development phase with the realization of prototypes, iteration, validation of the concept, distribution of tasks.

Table 3 : Synthesis of the activities during the phases

Double diamond	DISCOVER	DEFINE	DEVELOP	DELIVER	
IDC	REFRAME	REFRAME	IMAGINE	DEVELOP	PRESENT
	Understand the company context		(6) Ideas	(6) Prototyping	(6) Pitch
	(6) Company context		(6) Inspirations	(6) Iteration	
	(2) Competition		(6) Evaluation	(6) Validation of the concept	
Activities	**Understand the product value**			(6) Task distribution	
	(6) Product understanding	(2) USP		(6) Production	
	Understand how the product is used				

	(6) Usability (3) Technical aspects **Define the customer segment** (6) Customer segment **Define the short term objective** (6) Problem to solve	(2) Constraints (6) Pick a target & understand needs (6) Objectives (6) Deliverables (6) HMW		(6) Visual presentation (6) Pitch preparation

Activities	Long term goal Sprint questions Client segment Customer journey Expert interview Importance /difficulty HMW Pick a target	Inspiration Look at competitors Sketch multiple solutions Iteration	Evaluation Create one solution for the prototype Name Make a storyboard	Assign roles Prototype Put together Test Prepare the test with customer	Test with customer

Design as strategic role

The semi-structured interviews provided insight into the perception of design by start-up managers both before and after the event. Clearly the collaboration with the designers allowed the managers to understand that design had a strategic role in positioning their offer and client product acceptance (table 4).

Table 4 : Definition of design by the six managers

Before	• Cannot give a definition (3) • Solve a technical problem, a way of producing a product (2) • Link to communication, identity, marketing advertising (1) • Interact with products and take into account beauty and production criteria to differentiate from the competition (1) • Understand and meet the user's needs (1) • Visualise a process (1) • Make a shape attractive to the eye (1) • Demonstrate empathy (1)
After	• Links between technology, innovation and society (1) • Transform innovation to make it accessible (1) • Redefinition and improvement of the company's tangible and intangible values (1) • Understand a context and the needs (1) • Bring another angle of operational and strategic vision with the user to the centre (1) • Simplify a product in a pleasant and effective way (1)

Five teams believed that working with designers exceeded their expectations and allowed them to take a step back from their product and the issues they wanted to solve. Three teams reviewed the initial product and focused on support of communication of the offer. Collaboration with designers helps the start-ups on the following goals :

- A step back on the product or the issue (5)
- The creation of a tangible solution to present to customers (5)
- Simplifying the message (3)

- The integration of several design disciplines to create a coherent global project (3)

Discussion

With the Innovation by Design Challenge (IDC) we aimed to give an impulsion to start-ups by collaborating with designers on short-term objectives. The IDC was also to provide answers to our research questions. The first question had to do with the key activities used to solve a design objective in the short term. Our findings suggest that design practices can be a strategic step in the transformation of an innovative technology into a significant product by focusing on user interactions. Indeed, to solve the design challenge, the designer must define 3 main elements such as (1) the added value of the product/service, (2) who is the main customer and/or user, what are their needs, pains and motivations, (3) and how the product is used. While senior designers quickly capture these elements, young designers tend to have a more organic approach and oscillate between the definition and ideation phases, which can sometimes be difficult in terms of collaboration.

The second question that we addressed was whether such teams would be perceived by the team members as productive, collaborative and involving all team members. From what we have seen during the first two iterations of IDC, the answer is that the perception, in all categories, was positive. In line with what previous research has shown (Ward & Al. 2009), we found that introducing experienced designers to a start-up can stimulate innovation and create new opportunities. For the start-ups, working with individuals having diverse design backgrounds allowed quick results to be achieved and helped the firms to focus on their main clients.

In response to our third question, design practices were also welcomed by the IDC participants as a potential strategic option and seen to allow for the transformation of an innovation into a useful and accessible product/service for users. While market acceptance is a crucial element for the growth of start-ups, the practice of design with multiple disciplines seems to improve product consistency by focusing on the user experience. Collaboration with a designer makes it possible to make the link between the technology, the user and the context of the product/service following the phases of the creative process. Indeed, the observation of the teams allowed us to understand the collaboration process between start-ups and designers and identify key activities for product and service development. These various activities also allow us to help entrepreneurs step back, simplify the message and create an optimal product experience for users. One can say then that the practice of design consolidates the positioning of the product and validates its future acceptance by customers.

It is also of interest to note that there seems to be some correlation between the senior team process and the one developed during the product design sprint process. Collaboration between designers and start-ups is critical when it comes to understanding and defining the issue. Iterations of the ideation phase can be unproductive and create sources of frustration if the defined phase has not been well resolved beforehand. Project synthesis and scoping tools would facilitate the relationship between participants.

The results of our research suggest that the “reframe” phase could be split into 2 distinct phases : “understand” and “reframe”. The list of the activities carried out by the teams during each phase give an indication about the critical point to solve before going to the next phase (figure 6).

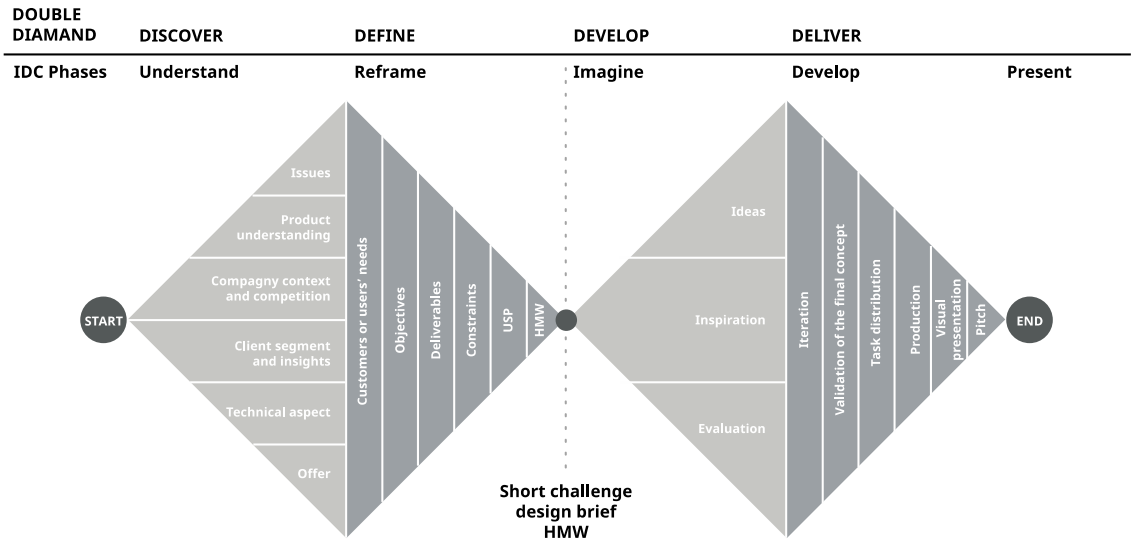

Figure 6 : Guidelines for the next programme

Conclusion

The use of interdisciplinary design teams for strategic innovation by start-up companies can indeed make a difference allowing them not only to bring potentially successful products to market but also allowing them to face up to other challenges including those of time and risk by engaging in a focussed, relatively high-speed process.

With regard to the limitations of this research presented here, only six teams participated in this study. A wider panel would be needed to achieve more generally applicable results. In the long term, the project has already been planned for 2019, and will allow us to test a more structured approach to be able to scale up the program and applied it in various incubators in the region. In terms of future developments and in order to scale up this programme we plan to (1) formalize the creative process activities into exercises, (2) find sponsors to help the start-ups finance the workshop programme, (3) create a toolkit to empower teams when collaborating.

In conclusion, success for an early stage start-up means dealing with challenges particular to such firms in a strategic manner so as to them to take their place in the market. Despite the tool-kits and models that abound, little are geared specifically towards early stage start-ups. This research has taken the specific challenges faced by early-stage start-ups as a starting point for an in situ exercise to evaluate the potential impact of design practices. The research supports the idea that such practices can indeed be included at the incubation stage of a start-up to help it better address used needs from a design perspective. Whether this will in turn impact the firm's longevity is another question but at least it provides the firm with a strong, more holistic basis, from which to move forward. While the study shows that design pratcices can become strategic for a startup, start-ups face difficulties in financing the integration of design into early stages of development, and initiatives to facilitate access to design are required.

Enhancing Collaboration: A Design Leader's Role in Managing Paradoxical Identity Tensions Through Dual Identification

COY Emma J.* and PRASCH Johanna E.

RMIT University, Australia
* corresponding author email: em.coy@rmit.edu.au
doi: 10.33114/adim.2019.04.215

As the role of design grows in prominence in the workplace, managing designers such that they can effectively collaborate in multifunctional innovation teams becomes an important consideration. We draw on social identity and paradox research to extend insights on this topic. We suggest that, to operate effectively in the workplace, designers need to experience both similarity-with and distinctiveness-from other colleagues, and that these needs are paradoxical. We argue that tensions arising from these paradoxical needs can be managed through Dual Identification – a model which promotes dual identities, allowing the fulfilment of both needs of sameness and difference. We propose that design leaders can enable Dual Identification in designers through consistent language and associated visuals, and that this will allow designers to feel secure in their identity as both a designer, and as an innovation team member. We suggest that, ultimately, this security will translate to enhanced collaboration of designers in innovation teams.

Keywords: Dual Identification, paradox, design, design leadership, collaboration

Introduction

More and more organizations are looking to integrate design and design-based practices (such as customer co-creation and visualisation) into their business processes as a way of enhancing innovation, improving customer experiences, and to gain competitive advantage (Calabretta, Gemser, & Karpen, 2016). Collaboration between designers and other innovation team members is vital for successful innovation (Calabretta, Montaña & Iglesias, 2008), yet studies indicate that designers' ways of working may be difficult to integrate with other, well-established and traditional management ways of working (Beverland & Farrelly, 2007; Carlgren, Elmquist, & Rauth, 2016; Calabretta, Gemser, & Wijnberg, 2017). Scholars note that this difference in ways of working can affect individual designer identity (Ahuja, Nikolova, & Clegg, 2017; Elsbach & Caldwell-Wenman, 2015; Gotsi, Andriopoulos, Lewis, & Ingram, 2010), which can hamper collaborative activities at the team level (Elsbach & Flynn, 2013) and ultimately impact innovation outcomes (Lovelace, Shapiro, & Weingart, 2001). We develop four propositions that together work to enhance collaboration between designers and other team members within multi-functional innovation teams.

Drawing on social identity - including Dual Identification - and paradox literatures, we propose that design leaders (i.e., a leader or manager of designers) can enact a specific leadership strategy known in the literature

as ‘Dual Identification’. This strategy enables designers to identify both as (1) a ‘designer’ and (2) an ‘innovation team member’ simultaneously and allows the individual designer to manage their paradoxical identity tensions of similarity vs distinctiveness. We propose that this Dual Identification strategy will allow designers to experience greater identity security, resulting in enhanced collaboration between designers and other team members in multi-functional innovation teams. We also suggest that the use of consistent language and associated visuals can act as a cue to enable Dual Identification. We propose that design leaders can enact this strategy in order to induce Dual Identification at the individual designer level. We suggest that the impact at the individual designer level then translates to enhanced collaboration with other team members, such that the impact of Dual Identification at the individual level is also experienced at the team level through harmonization and collaboration with other innovation team members.

While scholars have suggested the importance of self-concepts and identification in a workplace context (e.g., Alvesson & Willmott, 2002; Elsbach & Flynn, 2013; Hogg & Terry, 2000), none have yet introduced a dual identification model as a way of enhancing collaboration within a multi-functional team. Further, while scholars have addressed identity paradoxes, and suggest that management of paradoxical identities is required to enhance outcomes (e.g., Cugnasen, 2017; Gotsi et al., 2010), they have not proposed Dual Identification as a management strategy. With this paper, we aim to integrate and extend the literature on both Dual Identification and paradox.

Our paper first addresses the design context, describing designer identity needs at the individual level that require specific design leadership. We suggest that needs of similarity vs distinctiveness are paradoxical, and argue that design leaders can induce Dual Identification to assist individual designers manage the associated paradoxical tensions. We follow up with further propositions, suggesting that design leaders can enable Dual Identification through the use of consistent language and accompanying visuals, and that in doing so, they may enhance collaboration at the team level between designers and other members within an innovation team. We follow previous scholars (e.g., Gibson & Birkinshaw, 2004) in an understanding that management of paradoxes at an individual level can contribute to a team-level finding. Due to the multi-level impact of Dual Identification, our propositions span both the individual and team levels of the organization. We highlight the role of design leaders, proposing that they play a crucial role in establishing the groundwork for individual designers to contribute effectively at the team level. We close with some suggested directions for future research.

Designers: Individual Identity Needs

Creativity and design skills form an essential part of multi-functional innovation teams (Calabretta et al., 2016; Lovelace et al., 2001). The Co-general manager of Alessi, a leading design-led organization, suggests that designers’ “intuition and sensitivity are considered more effective than traditional market research in capturing latent unexpressed needs and in shaping new product typologies” (Ravasi & Lojacono, 2005, p. 59).

However, designers differ from other innovation team members in their ways of working (Calabretta et al., 2017; Carlgren et al., 2016; Elsbach & Flynn, 2013) and in the style of management and leadership that they need to perform effectively (Gotsi et al., 2010). Research suggests that leaders must tailor their approach specifically to designers to fully realize the benefits of designers and design ways of working (Calabretta et al., 2008; Ravasi & Lojacono, 2005). Scholars advocate for greater understanding of the needs of designers (DeFillippi, Grabher, & Jones, 2007) in order to understand how to manage and lead them (Michlewski, 2008). This is particularly relevant in our context, as scholars note the importance of collaboration between team members and harmonization between ways of working on innovation projects (Calabretta et al., 2016; Calabretta et al., 2017; Miron-Spektor, Erez, & Naveh, 2011).

A designer’s identity can be multifaceted (Ahuja et al., 2017; Owen, 2006). On the one hand, a designer may align to a creative, free-spirit identity, pushing boundaries through artistic expression (Gotsi et al., 2010). Yet on the other hand, a designer who operates in an organizational innovation setting must work within the constraints and boundaries of the organization, making a contribution to organizational goals and financial targets (Beverland & Farrelly, 2007; Michlewski, 2008). We suggest that this contrast in identities illustrates the need for designers to experience both similarity-with and distinctiveness-from their other innovation team member colleagues - a ‘creative free-spirit’ identity will allow the designer to experience differences from others, thus protecting their individuality, whereas a ‘one of the team' identity will allow the designer to experience similarities, enhancing their sense of belonging.

According to literature (e.g., Brewer, 1991; Shore et al., 2011), an individual naturally looks for similarities between themselves and others in order to achieve a sense of belonging. However, they simultaneously look for distinctiveness between themselves and others to protect the uniqueness of their personal identity. Thus, designers may seek to identify as a (1) 'designer', highlighting their personal creativity, or identify as an (2) 'innovation team member', highlighting their role as part of a wider team. The former identification emphasizes difference through a unique contribution, the latter identification emphasizes a connection to their innovation colleagues, working within the same constraints as everyone else.

Paradox: Individual Identity Tensions of Similarity vs Distinctiveness

We follow paradox scholars (e.g., Cugnasen, 2017) in suggesting that needs for similarity and distinctiveness are paradoxical. A paradox relates to "contradictory yet interrelated elements - elements that seem logical in isolation but absurd and irrational when appearing simultaneously" (Lewis, 2000, p. 760). The ability to combine two separate and opposite concepts (such as the need to experience both similarity and distinctiveness concurrently) in a both/and way - rather than making an either/or choice between the concepts (known as paradox poles) - is known as adopting a paradox perspective (Smith & Lewis, 2011). Paradox literature indicates that tensions are inherent to paradoxes, and will always be felt, requiring ongoing management (Smith & Lewis, 2011). While managing paradoxes beneficially can enhance (and embed) performance outcomes, literature warns that paradoxical tensions that are managed poorly can have a detrimental impact, embedding negative responses in a cyclical manner (Smith & Lewis, 2011). We address specifically the paradox of similarity vs distinctiveness at the individual level.

The identity needs of similarity vs distinctiveness are opposite yet interrelated because an increase in 'similarity' necessarily results in a reduction of 'distinctiveness'. Thus activities designed to boost one pole will consistently detract from the other. Meeting both needs of similarity and distinctiveness therefore presents a challenge to individuals. In a study of an organizational merger, Langley and colleagues (2012) find that, to meet these identity needs, employees would make an effort to reassert distinctiveness when presented with organizational initiatives promoting similarity. Applied to our context, when the designer is encouraged to promote a sense of belonging and meet their need for similarity, highlighting their (2) 'innovation team member' identity, this would lead to a greater need of distinctiveness, or relevance of the (1) 'designer' identity. Literature notes that these identity paradoxes which juxtapose a team and individual level identity form a "paradox of belonging" (Lewis, 2000).

As with other forms of organizational paradox, paradoxes of belonging involve inherent tensions between the opposite poles of similarity and distinctiveness. These tensions will be ongoing as the actions to experience differentiation (e.g., by identifying as (1) a 'designer') necessarily affect any actions to experience similarity (e.g., by identifying as (2) an 'innovation team member'). Scholars agree that paradoxical tensions can never be fully resolved; however, tensions can be managed to achieve beneficial outcomes (Lewis, 2000; Smith & Lewis, 2000).

There are various strategies suggested in the literature to manage paradoxical poles and associated tensions. For example, a number of scholars find that "temporal separation" (Poole & Van de Ven, 1989, p. 566) - focussing on one pole and then the other - can enable a both/and outcome over time. Particularly for paradoxes of belonging, studies find that organizations engage in oscillation strategies, and with varying degrees of success and tension management (e.g., Ashforth & Reingen, 2014; Cugnasen, 2017; Huq, Reay, & Chriem, 2017).

In a study of a natural food cooperative, Ashforth and Reingen (2014) find that most members identified as either an idealist or a pragmatist, and that each of the two factions projected values onto the other faction. This large divide within the organization prevented them from engaging in synthetic both/and solutions. However, they were able to meet some of the values of both factions over time by oscillating an emphasis on one faction, and then the other.

Similarly, Gotsi and colleagues (2010) find that creatives don different "hats" in order to differentiate between their consultant (commercial) and artist (creative) identities and separate the roles in space and time. Scholars also find that managerial support may be required for a weaker (Huq et al., 2017) or lower status (Cugnasen, 2017) pole in order to support both/and outcomes. In their study of police detectives, Cuganesan (2017) notes that the balance between similarity and distinctiveness tensions is elusive, and difficult to sustain for all parties.

As Poole and Van de Ven (1989) indicate in their seminal paper, temporal separation of poles can be difficult to achieve as there may be no clear indicator for when a change is required. This can mean that one pole of the paradox becomes over-weighed with emphasis (Cugnesen, 2017), drowning out the requirements of the opposite pole, and exacerbating tensions between the poles (Smith & Lewis, 2011).

In a notable exception (which does not find the paradox of belonging managed through temporal separation), Stadtler and Van Wassenhove (2016) find that, in a study of disaster relief workers engaging in co-opetition (co-operation with competitors), actors developed a nested identity - that is they identify as 'a member of their own organization', yet within a second identity of 'a member of the disaster relief team'. However, identity literature suggests that nested identities may be problematic in the event that relations between the groups become destructive (Hornsey & Hogg, 2000).

We propose a specific strategy for managing tensions and overcoming the fractious nature of paradoxes of belonging, which synthesises the poles in a both/and way allowing identity needs of similarity and distinctiveness to be met and experienced at the same time. We describe this strategy of Dual Identification in the next subsection.

Dual Identification: An Individual-level Paradox Management Strategy

Known as "creative solutions" (Lüscher & Lewis, 2008) or "novel approaches" (Smith & Besharov, 2017) in the literature, a synthesis of both paradox poles is achieved in a way that otherwise may not have been thought to be possible due to the illogical nature of trying to combine the two opposites. Synthesis approaches represent a way of combining the opposing concepts in such a manner as to honour both concepts, consisting of both/and poles in equal measure at the same time (Lüscher & Lewis, 2008). For example, Gotsi and colleagues (2010) find that, whilst also undergoing practices which separate their roles, creatives may apply an identity label of "practical artist" in order to synthesize the paradoxical poles of creative vs commercial merit under a single identity.

A review of the literature on self-categorization has surfaced the notion of enacting dual identities, and we propose that this may serve as a synthesis of the paradoxical poles of similarity and distinctiveness. Building on Social Identity Approach (Tajfel & Turner, 1986; Turner, Hogg, Reicher, & Wetherell, 1987) and individual identity needs for sameness and difference (Brewer, 1991), Dovidio, Validzic and Gaertner (1998) conceive of an approach where individuals self-categorize and identify at two levels: (1) a concrete categorization highlighting a subordinate identity, which is nested within (2) an abstract categorization highlighting a second, superordinate identity. Dual Identification, as labelled by Hornsey and Hogg (2000), allows an individual to experience two identities at the same time - for example both (1) 'designer' at the concrete level and (2) 'innovation team member' at the abstract level - such that both similarity-with and distinctiveness-from is experienced simultaneously.

Abstract categorization into a superordinate group is characterized by targeting the overall picture, whilst concrete categorization into a subordinate group focuses on details. For example, abstract categorization would allow us to see the forest, whereas concrete categorization would induce a focus on the trees. In our context, individuals would self-categorize as an innovation team member (abstract superordinate group level) in order to feel that they are similar and part of the team, or as a designer (at a more concrete, subordinate group level) in order to feel that they are different and unique (from other superordinate group members).

Self-categorizing at both subordinate and superordinate levels simultaneously paradoxically allows individuals to experience both similarity-with and distinctiveness-from at the same time. While the individual is exacerbating similarity by adhering to a superordinate category, the individual is also exacerbating distinctiveness by adhering to a subordinate category. We interpret Dual Identification as a synthesis of these paradoxical poles due to the simultaneous presence of both similarity and distinctiveness. This model does not favour one identity over the other in the manner of temporal separation, suggesting that one has precedence over the other at any given time, but offers a dual identification of both identities at the same time. Thus:

Proposition 1: Dual Identification serves as a paradox management strategy, representing a synthesis of the paradoxical poles of similarity and distinctiveness.

We specifically present enacting dual identification as a paradox management strategy. As tensions of similarity vs distinctiveness in individuals emerge, we propose that enacting Dual Identification will assist individuals to feel the security and sense of belonging associated with the categorization process. This

certainty is expected to ease paradoxical tensions, removing the sense of "stuckness" that is associated with paradoxes (Lüscher & Lewis, 2008) by providing a way for the individual to experience both similarity and distinctiveness simultaneously.

Our proposition draws on Stadtler and Van Wassenhove's (2016) study, which finds that the nested identity allows disaster relief workers to engage in co-operation in what would otherwise be a competitive environment. Their study also notes that the organizational context, and most specifically the leadership from the CEOs set the "tone from the top" (p. 671), allowing the workers the freedom to engage in co-operative efforts.

Design leaders: Inducing Dual Identification in Individual Designers

Alvesson and Willmott (2002) highlight the role of managers in employee 'identity work' (i.e., "establishing both who one is and who one is not"; Watson, 2009, p. 446), indicating that leadership engagement with such work can positively influence workplace behaviours and enhance organizational outcomes. Leaders who engage in identity work with employees can regulate employees' identities, thus helping to reduce anxiety. However, in some cases such identity regulation can become overly constraining or dominating, limiting space for critical reflection (Alvesson & Willmott, 2002). In a study on Dual Identification, Leonardelli and Toh (2011) find that "procedural justice" (i.e., fair and equal treatment of subordinate groups) mediated cooperation effects. This suggests that leaders have a specific responsibility to enact Dual Identification in such a way that creates a fair workplace for all employees.

Design leaders must be sensitive to the style of management and leadership that designers need to perform effectively (Gotsi et al., 2010). We suggest that leadership limitations of engaging with identity work, such as unfairness or dominating approaches, will be especially constraining for designers who benefit from creative freedom (Calabretta et al., 2008; Ravasi & Lojacono, 2005), and as such emphasises the need for design leaders to engage in effective regulation of identity at the designer level.

Andriopoulos and colleagues (2017) find that within New Product Design teams, team members respond to promotion-focussed "benevolent dictatorship" management, such that designers want to be given a high degree of freedom with strong leadership. Other studies find complex identity requirements on the part of designers (Ahuja et al., 2017; Elsbach & Flynn, 2013; Gotsi et al., 2010). While designers want to be supported in their ability to make a specific artistic contribution (Elsbach & Caldwell-Wenman, 2015), literature also finds that this can lead to excessive "prima donna" distinctiveness (Gotsi et al., 2010), making them difficult and uncollaborative team members (Elsbach & Flynn, 2013). These tensions of similarity vs distinctiveness must ultimately be managed in order to avoid the vicious cycles associated with unmanaged paradoxical tensions.

As with all paradoxes, tensions related to identity needs for both similarity and distinctiveness will continue to be experienced by individual designers, and cannot be managed through a once-off approach. One of the reasons for this ongoing tension is because self-categorization is fluid and context-specific (Hogg & Terry, 2000; Hornsey, 2008), meaning that individuals may re-categorize (i.e., contemplate an alternative category) themselves into different groups and adhere to different identities in the event that other identity cues become active.

Literature emphasises the role of leaders in managing paradoxical tensions. For example, Cugnasen (2017) describes how, specifically in paradoxes of similarity vs distinctiveness, senior managers work with employees to manage tensions and engage in identity work with them. Similarly, Gotsi and colleagues (2010) find that, in a study of New Product Design consultancies, managers engage strategies to help creative designers with their identity work. While paradoxical tensions can be felt across the organization at multiple levels, scholars place specific emphasis on leaders to manage the paradoxical strategy and associated tensions (e.g., Knight & Paroutis, 2018; Smith, 2014; Smith, Binns, & Tushman, 2010). They suggest that a contingency either/or approach in leadership is insufficient to keep pace with today's dynamic ways of working (Smith, 2014; Smith et al., 2010).

These works further highlight the role of design leaders in enabling Dual Identification in designers in order to manage the ongoing paradoxical tensions of similarity and distinctiveness in designers. Thus:

Proposition 2: Design leaders who implement Dual Identification can manage tensions of similarity vs difference in designers.

We propose that by understanding Dual Identification is the outcome, design leaders can support designers in the workplace by helping them to engage with both (1) 'designer' and (2) 'innovation team member' identities. Dual Identification acts as a strategy to manage paradoxical tensions of similarity vs distinctiveness, easing tensions by meeting both/and identity needs and enabling designers to feel secure in their identity. We suggest that design leaders can do this by consistently activating both (1) the identity of the creative designer and (2) the identity of the innovation team member at the same time.

Identity Cues: Activating Dual Identification in Individuals

The use of identity cues is an important factor in activating an identity and generating saliency of dual identities, prompting individuals to adopt a relevant identity. Identity cues found in the literature include: actions (Ashforth, Harrison &, Corley , 2008), visuals (e.g., Prasch, Blijlevens, Schoormans, & Carbon, 2018; Hornsey & Hogg, 2000; González & Brown, 2003), physical location (Ashforth & Mael, 1989), and language (Elgendi et al., 2018).

The use of imagery to promote an identity is a theme in Dual Identification. For example, Hornsey and Hogg (2000) use photographs, coloured t-shirts and badges to promote identification. Prasch and colleagues (2018) find that presenting images of the subordinate categories to be activated, whilst encouraging the individual to organize those subordinate categories in a common superordinate category, can induce Dual Identification (e.g., Prasch et al., 2018). Literature also suggests that consistent imagery, such as company or team logos, can form management symbols and activate identity (Ashforth & Mael, 1989).

Paradox literature offers the use of language as a strategy to manage paradoxical tensions (Bednarek, Paroutis, & Sillince, 2016; Jarzabkowski & Lê, 2016; Sheep et al., 2017). In Lewis' (2000) seminal work, she identifies that language allows actors a way in which to think about paradoxes. Specifically, the language which is used to define concepts, allows for delineation of boundaries between what is and is not part of the concept.

In a study of two merging organizations facing a paradox of belonging, Sheep and colleagues (2017) find that actors use specific language to "talk into being" (p. 463) their paradoxical circumstances, such that the language which is used allows the interpretation of the concept and therefore suggests a way forward, justifying paths of action or inaction. Gotsi and colleagues (2010) suggest that consistency of communication from management can aid the integration of commercial vs creative identities. Other scholars studying paradoxes of belonging find that lengthy back and forth discussion is used by actors as a way of confronting paradoxical tensions (e.g., Ashforth & Reingen, 2014; Huq et al., 2017).

Further, Bednarek and colleagues (2017) find that rhetoric – persuasive discourse and argumentation – allows actors to engage in the "constant dynamic work" (p. 85) of generating both/and outcomes. Jarzabkowski and Sillince (2007) suggest that rhetoric that is context-specific and internally consistent can be effective in generating employee commitment to strategic goals. And finally, Jarzabkowski and Lê (2016) note that the use of humorous language can either shift or embed individual responses to tensions.

Drawing on both identity and paradox literatures, we find themes of both imagery and language. Thus:

Proposition 3: Design leaders that use consistent language and accompanying visual symbols which support specific identity work may enable Dual Identification in designers.

Consistently referring to identities in a both/and way through language and supported communications (e.g., through the use of phrases such as: "designers as part of our innovation team", "innovation team designers", etc.) may act as a way of contextualizing both/and in way that makes it accessible as a means of identity categorization. Further, these words may form management symbols that specifically cue work-related identities (Ashforth & Mael, 1989). Accompanying the words with specific imagery in a consistent manner may reinforce this cue, such that it forms both a language and visual identity cue.

Further, accessibility of categories can be influenced by long-term effects such as chronic use, meaning frequent activation of particular categories (Hornsey, 2008). Therefore, frequent use of dual categories may also contribute to the accessibility of Dual Identification as a means of identification. That is, the more an individual is prompted to access dual categories in relation to their identity, the more likely they may be to use the dual categorization. Hence, repeated use of particular phrasing and visuals may be used to form an identity cue that specifically enables an individual to adopt a dual categorization.

Enhanced Collaboration: Impact of Dual Identification at the Team Level

Social identity literature indicates that self-categorization has two main advantages for the individual, namely self-enhancement and uncertainty reduction (e.g., Hogg & Terry, 2000). Self-categorization into a group is accompanied by an assimilation to the group and the according perceptions, attitudes and normative behaviour. Hence, self-categorization reduces uncertainty by helping the individual to feel secure in their place within that group, and also the wider society (Hogg & Terry, 2000).

Despite the positive effects on the individual, self-categorization is associated with negative group effects such as ingroup bias. Ingroup bias is 'a form of favoritism toward one's own group or derogation of another group' (Spears, 2007, p. 2). Social Identity Approach postulates that the social groups that individuals categorize themselves into strongly influence their self-concepts (Hogg & Reid, 2006). Hence, out of a desire for positive and secure self-concepts, individuals are motivated to think of their own group in a positive way (Tajfel & Turner, 1979).

Groups differ in terms of power and/or status, and this hierarchy is usually perceived as changeable (Tajfel & Turner, 1979). Because groups are only conceived through a comparison with other groups (Tajfel & Turner, 1979), achieving or maintaining a positive distinctiveness (i.e., my group is better than your group) between groups helps to maintain positive self-concepts (Tajfel & Turner, 1979). In this way, social categorization can automatically lead to ingroup bias (Chen & Li, 2009). Individuals engage in different strategies in order to achieve or maintain a positive distinctiveness between their own ingroup and relevant other groups (according to their perceived hierarchy). These strategies can be roughly divided into two camps with one approach featuring relaxed and celebratory behaviours such as ingroup solidarity and benign intergroup competition, and the other approach being characterised by fear and destructiveness, featuring strategies like prejudice and discrimination (Hornsey, 2008).

A critical factor explaining the activation of a strategy may be identity threat (Hornsey, 2008). The literature differentiates various forms of threats to identity, for example a possible loss of status or indistinct intergroup boundaries (Hornsey & Hogg, 2000). Put in a workplace context, working together with out-group members can blur group boundaries and induce perceived threat to the own identity. This can then lead to prejudice and discrimination as a way of strengthening group boundaries (Hornsey & Hogg, 2000), thereby reducing cooperation and collaboration efforts with outgroup members. In this way, collaborative efforts can be specifically dictated by how an individual self-categorizes themselves and others (e.g., Elsbach & Flynn, 2013). Thus, individual identity work specifically affects team level outcomes.

Dual Identification addresses this issue of reduced cooperation and collaboration. It tries to foster the benefits of self-categorizing into two different groups (or identities) simultaneously. The induced dual categorization leads to a state in which both identities (i.e., both, the subordinate and the superordinate identity) are acknowledged and promoted (Hornsey & Hogg, 2000). Encouraging individuals to (re-)categorize at a superordinate level aims to re-introduce the former outgroup members as part of a new, more abstract, ingroup and therefore promotes the idea of sameness among these group members at the superordinate level. The self-categorization as an ingroup member enhances the similarity to other ingroup members (Turner & Reynolds, 2001) and extends trust to fellow ingroup members (Insko, Schopler, Hoyle, Dardis, & Graetz, 1990). Keeping the original group salient through the re-categorization process works to prevent perceived identity threat (Hornsey & Hogg, 2000). This way, as Ashforth and colleagues (2008) put it, "a strong superordinate identity mitigates ingroup bias by uniting groups under a common banner" (p. 349), without inducing identity threat and associated negative behaviours such as prejudice and discrimination.

It is this specific nature of Dual Identification - the concurrent experiencing both identities - that works to reduce ingroup bias (Dovidio et al., 1998), facilitating the creation of an environment of inclusion (Shore et al., 2011) and the development of social harmony (Hornsey & Hogg, 2000), thereby enhancing collaboration. Social inclusion is not only associated with positive consequences for individuals within organizations such as higher job satisfaction (Acquavita, Pittman, Gibbons, & Castellanos-Brown, 2009), and enhanced work attitudes and psychological health (Hitlan, Cliffton, & DeSoto, 2006). Further, social inclusion can enhance team engagement (Nembhard & Edmondson, 2006) and is found to be a prerequisite for employees eliciting their full contributions to their work team or their organisation (Ferdman & Sagiv, 2012). More specifically, social categorization in the context of Dual Identification in the workplace has been found to increase intergroup collaboration with expatriates (Leonardelli & Toh, 2011).

Paradox literature supports this, with findings that suggest a paradox strategy can enable enhanced integration and cooperation (e.g., Calabretta et al., 2017; Stadtler & Van Wassenhove, 2016). Calabretta and colleagues (2017) find that alternation of practices and adoption of a paradox perspective at a team level can help to integrate decision-making on both rationality and intuition in innovation teams. In a study of interprofessional collaboration in a health setting, Huq and colleagues (2017) note that interprofessional collaboration can itself be paradoxical due to the different ways of working that are engaged by the different groups of professionals. The research finds that a paradox perspective allows for the protection of the paradox (i.e., that both poles are important and equal) and suggests that "looking beyond the poles to focus on desired outcomes" (Huq et al., 2017, p. 529) can enable both/and outcomes for health patients.

Literature supports the view that identification can enable cooperation and harmonization in teams, and that management of paradoxes can enable collaboration. Thus:

Proposition 4: Dual Identification in designers will enhance collaboration in multi-functional innovation teams that include designers.

We propose that managing paradoxical identity tensions within the multi-functional team through Dual Identification will promote inclusion, increase ingroup bias at the superordinate abstract group level, and reduce intergroup prejudice and discrimination between designers and other innovation team members. We suggest that identifying at both, the concrete subordinate group level, and at the abstract superordinate group level, has particular relevance for designers because in addition to having designer-specific individual identity needs, their multi-functional innovation team must also operate as a collaborative team. As Calabretta and colleagues (2008) note in their study of design-oriented companies: "Team spirit is not simply a question of working together. It implies individuals' identification with the team as a whole, and with other members of the team" (Calabretta et al., 2008, p. 388). As tensions of similarity vs distinctiveness in individuals emerge, we argue that enacting Dual Identification will assist individuals to feel the certainty and security associated with the categorization process, and that this may subsequently enhance collaboration.

Future Research

In bringing together the literature on Dual Identification and paradox, we hope to inspire further insights in both areas of academic interest. While we have placed our research specifically in a design and innovation context with an understanding that designers have specific identity needs, we also see an opportunity for the cross-pollination of paradox and Dual Identification literatures to be applied to other types of multi-functional teams and/or identity contexts.

At this conceptual stage, findings are theoretical only, and further research is needed to empirically test our propositions, including our assertion of enhanced collaboration in this specific design and innovation context. Future research should concentrate on specific applications of Dual Identification through experimentation in order to assess the most effective way of activating dual identities in the workplace. While we suggest the use of consistent language and imagery, and prior research on Dual Identification has provided promising results through other strategies (Dovidio et al., 1998; Hornsey & Hogg, 2000) such as a memory game (Prasch et al., 2018), we acknowledge that other methods of generating salience in these identities may work just as effectively. We encourage scholars to draw on suggestions from both identity and paradox literatures to form their hypotheses. For example, could font type in written communications have any effect on inducing of Dual Identification?

Different methods should be empirically tested and compared their effectiveness. This way, design leaders could be presented with valuable tools to include in their management of multifunctional innovation teams. Future studies may also create other, context-specific methods to enable Dual Identification for example, within other workplace teams, sporting teams, or other group contexts. Further, through application and research in a variety of settings, scholars may also be able to determine how effective Dual Identification is as a paradox management strategy.

While our research currently highlights the role of design leaders, it could also be that future studies find that actors who are not leaders can play a vital role in enabling Dual Identification. For example, identity literature identifies "prototypical" group members (actors which display an embodiment of group norms; Hogg & Terry, 2000), and we note that, following a prototypical role model may also influence the adoption of Dual Identification in actors.

Conclusion

We seek to enhance collaboration in multi-functional innovation teams, through a greater understanding of the identity needs of designers. We propose that design leaders can engage the use of consistent language and accompanying visuals as an identity cue to enable Dual Identification in designers and manage paradoxical identity tensions of similarity vs distinctiveness. We suggest that design leaders play a key role in understanding the identity needs of designers, and that in doing so, they can enhance collaboration for improved innovation outcomes.

Through this work, we generate additional insights into both Dual Identification (and social identity) and paradox literatures. We hope to stimulate academic interest and discussion surrounding the intersection of these two areas, as well as inspire further empirical research which tests and refines our propositions.

Design artefacts as flexible and persuasive tools for customer-centric innovation

WECHSLER Jacqueline (Jax)[ab]* and SCHWEITZER Jochen[b]

doi: 10.33114/adim.2019.05.208

More organisations are adopting customer-centric innovation practices to increase business value; however, very little is known about the factors driving customer-centric innovation or the conditions under which innovation succeeds. Similarly, very little is known about the role of design artefacts as inputs in customer-centric innovation processes or as instruments that support the organisational change required for successful change. A practice-led case study was conducted to examine the role of design artefacts and to demonstrate how they are flexible and persuasive tools that mediate the social and intertwined demands of customer-centric innovation strategies. Five distinct roles of design artefacts are proposed and their value in contributing to innovation and organisational change are considered.

Keywords: design artefacts, design methods, customer-centricity, organisational change

Introduction

As a key strategic resource, the capacity to innovate has become increasingly important to commercial, non-commercial and government organisations globally. This valuable approach can improve people's wellbeing, their relationship with the environment, organisational efficacy and profitability. Much can be achieved by adopting a customer-centric approach to innovation; however, many challenges still remain (Bucolo, Wrigley & Matthews, 2012). Recent research has shown that this approach involves many aspects and relationships; for example, it can involve design processes (Dorst, 2011) and design mindsets (Schweitzer, Groeger & Sobel, 2016). Little is known about the role of design artefacts in supporting an organisation to be customer focused or the changes that need to be implemented when such a strategy is adopted.

Adding to the complexity of these issues, to date, definitions of artefacts have mostly been vague. Researchers widely agree that artefacts are essential to 'getting things done' in organisations (Knorr Cetina, 1997; Orlikowski, 2002); however, very little is known about how managers successfully use and produce design artefacts (both at the organisational and individual levels) when pursuing innovation and implementing any associated change processes. We define design artefacts as visual artefacts used within innovation and design processes and any visual objects towards which and with which individuals act. This includes only artefacts that have been made during the design process such as prototypes, customer journey maps and wire-frames and it does not include artefacts that constitute a final product or service.

We conducted a single instrumental case study (Stake, 1995) that sought to improve the ordering and activation services related to complex information technology and telecommunications products. We adopted

ethnographic and practice-led design research approaches to undertake an investigation of situated design practices in a complex practice context (Mafe & Brown, 2006). Our case study considered the role of design artefacts in relation to their social contexts. By doing so, we clarified the mediatory roles of design artefacts within customer-centric innovation processes and highlighted the potential of design artefacts to support organisational change.

Theoretical background

Customer-centricity and organisational change

Human-centred innovation is based upon 'customer insights' or the knowledge gained by interacting directly with consumers to understand their values and meaning-based needs (Beckman & Barry, 2007). In business practice, human-centred innovation' is also referred to as 'customer-centred innovation' or 'customer-centricity'. Design professionals have long used ethnographic research approaches within design practice; however, more recently, innovation and management writers have also advocated for the adoption of ethnographic approaches in relation to customer-centricity (Beckman & Barry, 2007; Liedtka & Ogilvie, 2011). Previous research has shown that design processes and artefacts are commonly applied within the business context and that design practices and tools add value to businesses (Leung et al., 2016). Numerous studies focusing on customer-centricity have shown that the application of design tools and methods (e.g., 'personas', 'prototyping', 'scenarios' and 'customer journey maps') are endemic in design practice. These valuable methods provide deep insights into customer needs and inform human-centred innovation processes (Manning, Bodine & Bernoff, 2012; Schrage, 2006). Further, customer-centricity is critical to gaining a competitive advantage in business (Galbraith, 2005; Manning, Bodine & Bernoff, 2012).

However, in both the design and business literature (and in practice), understandings of how customer-centricity is enabled within organisations are limited (Johnston & Kong, 2011). Adopting a customer-centric perspective, requires epistemological and attitudinal shifts (Dunne, 2011). Thus, if customer-centred innovation is to be achieved, organisational transformation is also required. This could include changes to culture, processes and structure that are both challenging and time consuming. Recent studies identified some of the relationships between design (thinking) practices and organisational change and culture (Buchanan, 2015; Elsbach & Stigliani, 2018). However, understandings of the role of design artefacts in facilitating changes towards customer-centricity remain limited.

Design artefacts as boundary objects

Design artefacts help to get things done. Previous research has shown that material artefacts play important mediatory and enabling roles in organisational and inter-organisational innovation processes (Rafaeli & Vinai-Yavetz, 2004a, 2006). The effects of different artefacts (e.g., Gantt charts, texts and documents, visual representations and drawings) have been analysed. Such artefacts can be used in organisational learning, knowledge and management (Hutchins, 1995; Wenger, 1998, 2000) or as collaboration enablers (Star and Griesemer, 1989), coordination devices (Henderson, 1991) and as socio-material objects that mediate the social and material nature of work practices (Orlikowski, 2002, 2006, 2007). However, previous studies have largely focused on how materiality and artefacts support product development processes.

Among people, artefacts facilitate knowledge sharing and transformation and play practical, political and persuasive roles (Kimble, Grenier & Goglio-Primard., 2010). The idea of an 'artefact as a boundary object' explains the different roles of artefacts and the implicit functions of an artefact in social mediation. Boundary objects refer to the brokering and boundary spanning capabilities of artefacts across functional domains within collaborative work (Star & Griesemer, 1989). Boundary objects create a shared language for individuals and allows individuals to represent their knowledge. Boundary objects also provide individuals with a concrete means for specifying and learning about any differences, dependencies and what is new across a given (knowledge) boundary. Additionally, boundary objects facilitate the process by which individuals transform the knowledge being used and apply what they know to transform existing problem-related knowledge (Carlile, 2006).

Carlile (2002) outlined the two key tenets of boundary object artefacts: i) boundary objects are practical, as they enable a shared means of representation and a specification of any differences at the boundary; and ii) boundary objects are political, as they facilitate knowledge transformation. Thus, if innovation requires

boundary spanning, the act of deciding which artefacts to share and with whom and when could be both a practical and political decision. Wenger (2000) conceptualised these decisions as brokering or processes of translation, coordination and alignment between perspectives. Brokers move knowledge from one place to another and bring back news from the forefront (Wenger, 2000).

Designers as knowledge brokers

Designers who create and employ artefacts can be considered 'knowledge brokers' (Hargadon & Sutton, 2000), who use boundary objects to broker customer-centric knowledge. Designers use artefacts as conscription devices (Henderson, 1999) to enlist participation in organisational settings. Wagner (2000) discussed the significant and persuasive roles of artefacts in collaborative work. Similarly, artefacts are also critical to customer-centric innovation contexts in which they function to mediate social and political processes and collective actions.

Understandings of the enabling roles of artefacts in organisational contexts is well established; however, understandings of the enabling roles of artefacts in organisations attempting to move towards customer-centricity remains limited and vague. Thus, this case study sought to determine if and how design artefacts could be used to support the organisational change required to design and deliver customer-centric products and services. To answer these questions, we adopted a theoretic perspective of design artefacts as boundary objects and acted from the understanding that the designer is the knowledge broker in the context of organisational change towards customer-centricity. We also examined the role of design artefacts as flexible tools that mediate the social and interlinked demands of innovation initiatives in a specific organisation.

Studying how designers (and non-designers) consider and use design artefacts will increase knowledge of the enabling and mediatory roles of both design practices and artefacts in complex social innovation contexts (the very situation that countless organisations are presently facing). The central objective of our research was to gain a better understanding of how design artefacts function to facilitate and motivate collective action and enable communication and transformation.

Methodology

A single in-depth case study was conducted to examine the role of design artefacts and understand whether and how they support customer-centric innovation. The organisation selected for the case study had a confident strategic intention to pursue customer-centricity. This allowed us to undertake a deep analysis of the contextual factors affecting the roles of a range of artefacts.

We also adopted a researcher-as-instrument (Robson, 1995) approach. Under this approach, the researcher was the lead designer of the case project and the researcher's relationships with those being investigated were examined (MacDonald, 1994). Multiple data collection methods and sources were employed, including participant observation, qualitative interviews, document collection and the use of thick descriptions (Geertz, 1973). Additional data sources included intranet and public website content, emails, field notes, physical artefacts, memorandums and artefacts produced by other designers for other projects.

Sampling was opportunistic (Miles & Huberman, 1994). This was not ideal; however, due to the covert nature of the study, it was the only approach available. The researcher's manager was aware of the study. The research was hired as a contractor and her manager felt that it was simpler to keep the study covert and anonymise all data. In the early phase, we had limited access to conduct interviews with diverse organisational members, most notably members of the senior leadership team. These interviews provided insights based on a restricted representation of perspectives. To gain further valuable insights, we also obtained additional perspectives from stakeholders at different levels of seniority, including general managers, mid-level managers, project leads, contractors and specialist permanent staff. At the end of the project we assumed an overt role. This allowed us to conduct further interviews with the participants of the final project presentation, who had been invited to participate in the study.

Semi-structured interview guides and a detailed research protocol (Yin, 2003) were used to conduct a total of 13 interviews over two years. The majority of interviews occurred within three months of the final delivery of the project results. Follow-up interviews were also conducted with three participants some five to six months after the project had been delivered.

The activities and contextual factors associated with the defined activity systems (i.e., the individual, team, project and organisational activities and contextual factors) were considered during data collection and analysis. Participants were asked to describe any challenges they experienced when undertaking their work activities. This question enabled participants to explicate any contradictions located within the different activity systems (Engeström, 1999). Data were collected and iteratively analysed over an 18-month period that comprised three distinct phases, each of which used different approaches. The reason there was a long duration for data collection was because the project took 12 months to get funded.

For the data analysis, a constructivist grounded theory approach was adopted (Mills, Bonner and Francis, 2006), as the study relied on predefined theoretical concepts. Different analytical procedures were applied to each phase of the research, including concurrent collection and the coding and double coding of data (Krefting, 1991). The researcher was the sole data analyst.

The case: Redesigning online order and activation processes

This case study was conducted at an Australian ASX-listed company with over 40,000 employees. The company offers a broad range of technology products and services. Two years before the project commenced, the company had appointed a chief executive officer who was committed to building a customer-centric organisation. The organisation were commonly employing human-centred design approaches for product and service development and had several dedicated design teams. While this context created favorable conditions for design experimentation, it also creates a limitation for replicability of the fi

The business strategy motivating this project was to improve the online ordering capability of a specific group of business-to-business customers, who were responsible for on selling products. The project team adopted a customer-centric approach to design new online ordering and activation services. The researcher was hired as a 'customer-centred design lead' to work with the internal user experience group for five months.

The objective of the project was to deliver a conceptual design, including wire-frames (i.e., blueprints or visual specifications for online services) to improve online ordering. The project deliverable would support the development of a business case study so that a project team could be established, and the solution brought to market.

The key sponsor of the project was the design director; however, there was an implied and strategic obligation to also connect with other stakeholders who would potentially fund and build the suggested solution. Given that the lead designer's tenure at the company was short, it was also important that the knowledge related to this project was codified and transferred in an accessible way.

- **The Listening Phase.** During this phase, the design team set out to i) understand the current processes for ordering and activating products as experienced by internal staff and customers; ii) consider existing challenges with internal systems that may be common to both staff and customer groups; iii) understand customer work contexts and their dependent organisational processes; and iv) understand customer challenges and needs. The team used 'affinity diagramming' to gain insights and show that the current ordering systems and processes required improvement.
- **The Defining Phase.** During this phase, the lead designer created artefacts for 'design synthesis' and 'reflection-in-action'. Specifically, the designer considered the information needs of different stakeholders and created distinct artefacts to satisfy specific information needs and preferences. During this phase, team members engaged in iterative sketching and conducted a workshop with 10 business customers, where participants reviewed and refined preliminary sketches for a web portal. The team then transformed the designs into more detailed wire-frames.
- **The Delivery Phase.** During this phrase, the project outcomes were shared in a meeting with 40 internal stakeholders via video and telephone conferences. The project deliverables were hosted on a website that could be accessed online during the meeting.

Table 1 summarises the different activities and artefacts associated with the different phases of the project and Table 2 lists the project artefacts as they were shared.

Table 1. Activities and artefacts delivered in different project phases.

PHASE	*ACTIVITY*	*ARTEFACTS*
Listening Phase	Stakeholder qualitative research	Research report
Defining Phase	Data synthesis and artefact creation Iterative sketching (wire-frames) Codesign workshop	Opportunity maps Personas Customer journey maps Research videos Infographic Function overview Wire-frames User stories Video prototype Future storyboard Quick Wins
Delivery Phase	Communication of findings and deliverables via email and a presentation	PowerPoint presentation HTML deliverables site

Table 2. Overview of project artefacts.

ARTEFACT	*DESCRIPTION*
Research report	The research report communicated the key insights about the user group mapped to the associated findings and recommendations. Insights comprised broad generalisations. The findings provided evidence of the insights. Additional information was provided and recommendations (e.g., suggestions of things to change or do) were made to address the insights and findings. The artefacts documented the findings and substantiated the design recommendations in a format common to the organisation.
Opportunity map	Visual maps were constructed to understand customer work activities. The initial freehand sketches were later translated into designed artefacts. One illustrates the activities of the customers and the other identifies high-level capabilities to support these activities, including a summary of the benefits to the organisation. Initially created as conceptual tools to consider and synthesis customer needs, these maps were used to document and communicate the work activities of customers and identify opportunities for service improvement.
Persona	Three personas were created to reflect three different customer types based on the type (and complexity) of the products sold. Personas were intended to inform future design work relating to both this initiative and these customers.
Customer journey maps	Data from the internal workshop and qualitative interviews were translated into customer journey maps, including maps of the tasks, artefacts, systems and tools used. Customers' needs, pain-points and opportunities were then mapped to the different stages of the customer journey. Three maps representing the ordering and activation processes for three distinct products communicated the complexity of the existing processes. The maps provided a framework for the organisation to reconsider associated processes and systems.
Infographic	The infographic translated complex quantitative data to a broad audience group in an accessible way. It presented the number of support calls made to the customer call centre, information about the associated revenue derived by the organisation in relation to each product and the number of customers per state. It illustrated statistics

ARTEFACT	*DESCRIPTION*
	by showing that i) the customer group contributed a significant amount of revenue to the organisation; and ii) if the organisation improved their ordering services, the call centres would become more efficient and the organisation's net revenue would consequently increase. This artefact was a persuasive artefact, as it illustrated the potential value of investing in a revised online ordering service.
Research video	Two 1.5-minute research videos were created on the qualitative research that was undertaken. Each video displayed 8–10 verbatim quotes from various staff and customer research participants. These videos sought to create empathy for customers and simply and persuasively communicate the issues consumers encountered when ordering products. The videos revealed issues with the current ordering processes and which tools were onerous.
Function overview	The function overview provided a brief summary of the functions for the recommended portal. It mapped opportunities identified in the opportunity maps. It sought to provide an easily digestible overview of the proposed organisation's service capabilities.
Wire-frames	A series of annotated wire-frames were delivered as a PDF file to visually communicate the features of the portal rather than specific patterns and interactions.
Video prototype	In the video prototype, a user called 'Janine' talked the audience through an animation of wire-frames, describing a proposed system in terms of its benefits. These benefits addressed many of the pain-points expressed by other artefacts (e.g., the journey maps and personas). The lead designer was of the view that wire-frames were not easily accessible to non-technical audiences. Thus, the video prototype was created to present the designs in an accessible way that was appropriate to a broad range of stakeholders.
User stories	Agile user stories (e.g., 'As a customer I can check the status of an order, so that I can arrange access for technicians installing network infrastructure') were set out in an Excel spread sheet to correspond with the features in the wire-frames. The user stories sought to communicate the scope of the design and required technical integration to enable the development of the project management staff.
Quick wins	In an Excel spread sheet, the quick wins (i.e., the actions that the organisation could implement immediately to improve the existing service for a group) were listed. All of these quick wins could be executed immediately and without funding.
Future storyboard	Two future storyboards (depicting the scenarios in use) showed a tracking feature and a mobile ordering process using a tablet. These artefacts communicate service concepts in relation to their use context.

Data Analysis and Propositions

We found that the use of design artefacts in customer-centric innovation activities leads to organisational change. Design artefacts play an important role in organisational change, support social mediation and are critical in enabling and mediating change. We contend that design artefacts have five significant and distinct socio-political and sociocultural roles. Specifically, we argue that design artefacts: i) act as customer empathy enablers; ii) act as collaboration facilitators and activators; iii) provide reflective sense-making frameworks; iv) are persuasive tools; and v) are design and customer-centric knowledge communicators. We explore each of these five roles and discuss their relationships with customer-centric innovation and organisational change in relation to the case study, making five propositions. These roles pertain to use by designers as well as other organisational members.

Proposition 1: Design artefacts function as customer empathy enablers

Participants in this study agreed that adopting a customer-centric perspective was vital to company processes; however, like participants in previous studies (e.g., Galbraith, 2005, Shah et al., 2006, Meyer & Schwager,

2007), the participants in the present study did perceive the shift towards customer-centricity as challenging. Participants also reported that creating project artefacts (e.g., personas), rather than writing bullet point lists for Power Point presentations, gave the customer research a human voice and face and communicated customers' frustrations and needs in an accessible and engaging way. Personas were considered particularly instructive in communicating information about customers' behaviours and qualitative and behavioural information from customers' perspectives.

When reviewing the videos created from customer interviews, another key artefact in the study, participants noted that they felt more directly engaged with the artefacts and unlike documents, which have to be read, it was impossible to scan videos. Videos evoked much more direct exposure to customer pain-points. Notably, the use of first person verbatim quotes facilitated customer empathy while the visual artefacts motivated sharing between formal and informal social networks. Thus, evidence was found for the effectiveness of design artefacts and their value in understanding customers and creating empathy. Additionally, participants noted that the engaging visual formats would be useful in aiding cultural change within the organisation.

Other authors have considered how design artefacts can evoke feelings of empathy (e.g. Van Rijn et al., 2011). However, in this case study, we found that organisational outcomes required the collective participation of many people and that empathy was not only valuable within the design team, but also affected people involved in other projects. Due to their aesthetic dimensions, design artefacts link with subjective emotions, empathy, intuition and judgement (Fulton Suri, 2008; Rafaeli & Vilnai-Yavetz, 2004b). Participants in the current study noted how the novel visual formats of the artefacts motivated them to share information with their colleagues. The rich visual design of the artefacts addressed a number of issues related to less engaging formats and encouraged feelings of customer empathy across broad organisational audiences.

Customer empathy encourages customer-centric judgements, behaviours and the advocacy required to implement innovative changes, such as changes to processes and organisational structures (Manning, Bodine and Bernoff, 2012). As a connectedness organising mechanism, empathy can assist staff members to recognise the interconnectedness and inter-relationships between collective actions (Pavlovich & Krahnke, 2012). Empathy also facilitates shared meanings that can create, sustain or change organisational cultures (Cook & Yarrow, 1993).

It is contended that design artefacts can motivate customer-centric collective actions by facilitating far-reaching empathy for customers and enabling customer-centric judgements and behaviours. Design artefacts can shift thinking from matters of sheer usability towards a deeper understanding of human dignity and thus positively affect the thoughts and actions of individuals (Buchanan, 2015) in support of customer-centric collective outcomes.

Proposition 2: Design artefacts facilitate and activate collaboration

Participants in this study reported that collaborations among cross-functional business groups were critical to innovation processes. In this case study, participation in the project activities was mostly voluntary; however, the design artefacts also activated the involvement of non-designers in the company. Many participants noted that encouraging other colleagues to contribute and their overall engagement with and advocacy for the innovation initiatives was both critical and challenging.

Artefacts, such as videos and presentations, were shared with managers from other areas to communicate issues related to poor customer experiences and gain their support. After the project was completed, some artefacts stimulated the interest of several other stakeholders in the project and its outcomes. This ultimately led to the development of more ideas and associated change processes.

Using the artefacts to activate collaboration and participation in the innovation context of the project was critical. Motivated by human agency (Maidique, 1980; Rogers, 1995), team members became change agents who enacted change by interacting and networking within and across the organisation. Thus, it appears that by creating empathy, the artefacts motivated and activated collaborations.

Thus, the artefacts mediated the dialogue between designers and other members of the organisation by codifying and communicating knowledge. Visual artefacts (e.g., customer journey maps) provided the bases for discussions about customer-centric changes beyond the project context. For example, one process improvement specialist stated that she would use artefacts within workshops as a 'springboard' for conversations about improvements related to other associated processes.

Artefacts transform understandings and actions by enabling people to identify contradictions and uncertainties related to organisational processes (Engeström, 2001). Artefacts are not merely static knowledge repositories (Carlile, 2002); rather, artefacts are dynamic and active tools. Individuals use 'artefacts of knowing' (Ewenstein and Whyte, 2007) to exemplify, translate and contribute to their understandings. When mediated by artefacts, knowledge and activity and communicative actions (Orlikowski, 2002) transform and facilitate innovation (Dasgupta & Gupta, 2009; du Plessis, 2007). Proposition 2 describes the mediatory and enabling role of artefacts.

Proposition 3: Design artefacts provide reflective sense-making frameworks

We observed that members of the project team used artefacts as reflective sense-making tools to understand, frame problems and communicate. Sense-making refers to the process by which individuals or groups make sense of information. The artefacts (e.g., the opportunity maps or journey maps) created for this project assisted non-design staff members to understand and appreciate new models for thinking about customers and the difficulties that customers face using the current products and services.

For example, the lead designer created opportunity maps and personas to help demonstrate the work practices of customers and conceptualise how the organisation could add value to these practises for customers. These artefacts were initially used to understand the context and needs of customers; however, they evolved throughout various consultations until they ultimately served as a framework for reflection and a synthesis of key customer tasks, needs and improvement opportunities. Thus, the artefacts became structures through which the design team could reflect and refine their understandings of the project. Similarly, the journey maps were used to combine different data into one visual artefact over time. This enabled the team to synthesise, consider and talk and gain insights into the data and allowed non-design staff members to understand current user experiences and related systems. The journey map was used by another staff member, working in an operational capacity, to 'springboard' conversation about process changes in workshops not related to the digital product.

The value of visual practices in sense-making and synthesis is well established (Kolko, 2010; Krippendorff, 1989). Such practices enhance sense-making processes by making the abstract more concrete, improving communication, building knowledge and enabling complex and non-tangible concepts to be understood (Michela and Floricel, 2012; Oster, 2009).

The visual artefacts in this study aided sense-making, shifted mental models and supported organisational change processes (Senge et al., 2005). Further, sharing within and between organisational networks led to collective sense-making (Orlikowski, 2002). The design artefacts provided cognitive frameworks to various actors, supported problem-framing processes (Beckman & Barry, 2007; Dorst, 2011) and enabled the organisation to identify and solve customer problems and innovate. Thus, as suggested by Proposition 3, artefacts are valuable 'things-to-think-with' (Brandt, 2007).

Proposition 4: Design artefacts play persuasive roles

In the case study, artefacts assumed an implicit persuasive role. From executives to the frontline staff delivering the products or services, from the staff involved with implementation to customers—every stakeholder needs to be engaged, informed or convinced in some way at some point. Team members employed artefacts as persuasive tools. For example, some team members used the artefacts to encourage senior executives to fund the project while others used the artefacts to support their recommendations.

Additionally, team members found that the artefacts were very effective in communicating key issues and complex financial information. For example, the infographic clearly showed the financial benefits related to funding the proposed platform while the videos provided evidence as to why the ordering service needed to be improved. Wagner (2000) suggests 'persuasive artefact', however, her observation is based on collaborative architectural work within a single community of practice. Conversely, in the present study, we observed that artefacts enable social mediations between communities of practice across long-term innovation initiatives.

This study also revealed how artefacts play political roles. It was challenging to engage different stakeholders early on in the project. One participant emphasised the importance of gaining support from the 'right' stakeholders to progress a project and noted that the videos had been very helpful in increasing the interests of stakeholders. Many reported that collaboration was challenging to orchestrate between different business

units within the organisation. The research videos were used to persuade an executive to prioritise this program and mandate that his staff engage with the design team. Thus, brokering artefacts to stakeholders at different times represents a political activity (Carlile, 2002; Kimble, Grenier & Goglio-Primard, 2010). It has been suggested that politics only play out during the final phases of a project (Carlile, 2004); however, we found that politics and the management of social relations were significant throughout the project. Thus, artefacts play important, persuasive roles in the innovation, design and implementation phases of projects. Artefacts also affect project advocacy, project continuation, consensus building, knowledge sharing and organisational change processes.

Proposition 5: Design artefacts effectively communicate customer-centric and design knowledge

In this case study, the project participants used artefacts to effectively communicate a customer-centric perspective. For example, the participants showed videos of customer interviews to executives, national sales staff and call centre representatives to demonstrate customers' perspectives. Both videos and personas were used to educate new staff about customer characteristics and needs. Further, even after the project had finished, members of the organisation continued to use the same artefacts to describe key customer attributes. Management theory supports the role of artefacts in organisational learning. Indeed, organisational learning often rests upon social processes that are mediated by artefacts (Boreham & Morgan, 2004; Weick & Roberts, 1993).

The artefacts were also used tactically (to explain the 'how') and strategically (to help individuals to envision 'what could be'). For example, a conceptual video prototype, which had been created to explain the design concept to staff members with no or limited technical knowledge, was later used to share a customer-centric vision to the organisation. Thus, artefacts can function to motivate action, enable strategy (Spee and Jarzabkowski, 2009) and bridge current and future states. Artefacts are often used to share a future vision, activate participation, collaboration, advocacy and internal alignment because of their engaging visual form. In the case study, the artefacts linked specific actions or outcomes to a broader strategic narrative.

When artefacts are shared voluntarily and talked about widely, they can become mechanisms to express culture and enact change (Carlile, 2006). For example, in this case study, participants recalled how they learnt about the project 'road show' via formal and informal networks. This illustrates the social character of knowledge sharing and the value of social networks in distributing knowledge within organisations (Dasgupta and Gupta, 2009; 1995; Lave & Wenger, 1991). Artefacts can become symbols of a new customer-centric culture (Boreham & Morgan, 2004) merely by being discussed. Thus, design artefacts appear to strengthen informal work relationships, organisational learning and cultural transformations towards customer-centricity.

Overall, we found that customer-centric knowledge, expressed via engaging and accessible design artefacts, provided the organisation with new and effective boundary objects, which allowed people to engage with, talk through and discuss customer-centricity. Thus, artefacts played enabling roles, acted as change agents and supported innovation and transformation.

Conclusion

This study sought to explore the value of design artefacts in creating customer-centric organisations. In this paper, five distinct roles of artefacts were considered. By virtue of their rich, visual, novel and engaging formats, artefacts are likely to be shared more easily in informal organisational arrangements (e.g., among cross-functional teams). Artefacts provide an accessible and applicable way to communicate tacit needs and other customer-centric insights. Artefacts inspire customer-centric behaviours and stimulate cultural shifts in organisations. Thus, our findings generally showed the value of design artefacts in customer-centric organisational change. However, further empirical research is required to validate the propositions developed in this paper and to determine the conditions under which design artefacts enable customer-centric organisational change.

Our research raises a number of questions about the factors and capabilities needed to transition to customer-centricity using design artefacts. Factors such as knowledge management capabilities, organisational culture and absorptive capacity (Cohen & Levinthal, 1990) could affect the ability of design artefacts to impact organisational transformations. Additionally, artefacts need to be recognised and promoted by leadership

(Aftab 2012). Executive support for the use of design artefacts shows their widespread use and effects (Bailey, 2012).

Organisations need to develop the necessary capabilities to use design artefacts as mediatory and enabling tools. Training and participation in design processes can facilitate familiarity with customer-centric design artefacts (Junginger, 2005). For example, this case study informed the creation of a pedagogical framework that was designed to support the development of design artefacts (Wechsler, 2017).

Designerly innovation tools, such as canvases, are widely used for facilitating team and collaboration processes. This paper outlines the potential design space of such innovation canvases. Based on a systematic analysis of 123 existing canvases we developed a morphological box that distinguishes between six different parameters identified as relevant: (1) addressed process step, (2) involved media, (3) sequence of use, (4) available instructions, (5) number of elements, and (6) design specifics, as well as possible choices among them. The analysis also yielded several research gaps. Furthermore, we present an in-depth discussion of the possible theoretical underpinnings of innovation canvases and summarize them in a theoretical framework. The results of this paper provide references for other researchers and practitioners to better understand working mechanisms and fields of application of existing canvases and for developing such visual innovation tools for their own purposes.

Keywords: Visual Innovation Tools, Canvas, Design Management, Innovation, Review Paper

Introduction

Since the introduction of the 'Business Model Generation' book in 2010 (Osterwalder & Pigneur, 2010), the related poster-based Business Model Canvas (BMC) is widely used in companies and startups for "describing, designing, challenging, inventing, and pivoting business models" in a co-creation approach (Strategyzer, n.d.). The Business Model Canvas is a poster-based graphical framework consisting of several boxes ('building blocks') that can be filled by the users according to printed prompts. The provided framework deconstructs the overly complex task of developing a business model into smaller components, which simplifies the process also for non-experts. This novel approach completely changed the way how business ideas and business plans are developed. Writing an entire business plan had been particularly challenging for startups and founders who did not have a business background, whereas the BMC provided some sort of guided shortcut.

We consider the Business Model Canvas a designerly innovation tool because (a) it guides the creation of something new—in this case an innovative business model, (b) it is presented in a designerly form—a graphical framework, and (c) it facilitates co-creation processes with different stakeholders or within diverse design teams—an approach typical for the design thinking and service design disciplines.

The Business Model Canvas has become a quasi-standard innovation tool for founders and innovators who want to flesh out their business ideas. According to the inventors, by today the Business Model Canvas is used by more than 5 million people worldwide (Strategyzer, n.d.). It comes as no surprise that the canvas approach has been picked up by innovators from various disciplines. As of today, Roberts (2016) has collected a total of

100 canvases for different purposes in his Blog. It seems that there exists a canvas for almost any business- or innovation-related activity.

We define a canvas as a two-dimensional, poster-based tool that guides a heterogenous team with a particular challenge or task. Typically, it is presented a graphical framework that decomposes a complex topic into several smaller clusters, and hence offers simplification and guidance. A canvas provides blank areas to be filled by the users, in order to invite co-creation activities and team work. However, the overview of 100 canvases collected by Roberts (2016) revealed that although many canvases follow the basic structure of the BMC, there exist minor or major differences in number of boxes, alignment, use of symbols or visual metaphors, use of color, provided instructions, and so on. This *design space* is the focus of our study. We define a design space as the conceptual solution space including various design parameters and the possible choices among them (Maclean & McKerlie, 1995).

However, relatively little research has been undertaken yet, to deconstruct the visual elements of a canvas and to explain their working mechanisms and theoretical underpinnings. Such information might help users identify the appropriate tool for their own innovation purposes and hence improve their innovation efforts. This paper tries to provide the readers with the required information for these tasks. Hence, the following research questions guided our study:

> *(1) What parameters and possible design choices (that is, the design space) exist for visual innovation canvases?*
>
> *(2) What are possible theoretical underpinnings that could explain the impact of particular canvas designs?*
>
> *(3) What research gaps can be found when looking at existing innovation canvases?*

We start this paper by presenting a brief overview of related work on visual canvases. Afterwards, we describe our methodological approach: We developed our data source of 123 canvases by expanding the existing list of 100 canvases (Roberts, 2016) through a systematic literature search to include also scientifically developed canvases. Subsequently, we describe the artefact analysis process of the included 123 canvases. The contribution of this paper is spread over the subsequent three sections: (1) The section *Design Space of Innovation Canvases* presents a morphological box that outlines the design space of visual canvases, according to six emerging categories. This morphological box was derived iteratively by a systematic artefact analysis of 123 existing canvases. (2) In the section *Canvas Analysis Results* we report on insights gained from the quantitative analysis of the 123 canvases and present several identified research gaps. (3) To illustrate the possible benefits and working mechanisms of a canvas, we present a *Theoretical Framework of Canvases* that constitutes a bricolage of related theories that form the theoretical underpinning of the impact and usefulness of visual canvases. We conclude by discussing the limitations of this work and potentials for future research.

Related Work

Many visual innovation tools follow the example of the Business Model Canvas (Osterwalder & Pigneur, 2010) and present a one-page, poster-based canvas with several graphical boxes and prompts to be filled with specific information, either handwritten or using sticky notes. They are often intended for collaborative team work (involving approximately 5–6 people) and displayed wall-mounted. Often, they are accompanied by printed instructions—in the case of the Business Model Canvas, the users are offered an entire book (Osterwalder & Pigneur, 2010), explaining the usage of the canvas in detail. When looking at other innovation tools there are several that also follow a canvas-approach and a similar layout as the Business Model Canvas but address different topics. For example, the Project Canvas (Habermann, 2014) was developed to strategically plan a project, Business Model You (Clark, Osterwalder, & Pigneur, 2012) facilitates some sort of self-reflected career planning, The Team Alignment Map (Avdiji, Elikan, Missonier, & Pigneur, 2018; 'Team Alignment Map', n.d.) facilitates team building, and the Value Proposition Canvas (Osterwalder, Pigneur, Bernarda, & Smith, 2014) focuses on identifying user needs and matching the benefits of the service or product.

In the design field, graphical frameworks and poster-based canvases are commonly used tools for example to elaborate intangible services, such as Service Blueprints (Shostack, 1984), or to map user journeys. Some approaches expand the canvas paradigm further in various directions. For example Joyce and Paquin (2016)

added several vertical and horizontal layers to the Business Model Canvas in order to expand its scope. But there are also visual innovation tools that follow a completely different layout and involve different media. For example, Lego® Serious Play (Lego Serious Play, 2006; Kristiansen & Rasmussen, 2014) makes use of Lego bricks in order to build three-dimensional representations of business ideas or other mental models, working with metaphors. Usually it needs a trained facilitator to guide the very flexible approach. The method does not provide templates or canvases but rather suggests to work in three-dimensional metaphors and spontaneously create one's own canvas, if required. SAP Mosaic (SAP AppHaus, n.d.) lets users create their own canvas on brown paper. Some tools also involve other media, such as digital extensions, stickers, or inspirational card sets.

For the user this broad variety of existing canvases and other innovation tools can be quite confusing. It might be difficult to choose the appropriate tool for one's own purpose, and even more challenging to develop one's own tool, if an appropriate solution is not yet existing or if a customized tool appears to be necessary. Avdiji, Elikan, Missonier and Pigneur (2018) suggest three principles for developing visual canvases, such as the Business Model Canvas, namely (1) ontology-creation, (2) creating a shared visualization, and (3) provide collaboration possibilities. However, they do not provide any particular guidance on how to exactly design those tools. Eppler and his colleagues (Martin J. Eppler, 2003; Martin J. Eppler & Hoffmann, 2013; Martin J. Eppler & Kernbach, 2016) presented various research studies on visual representations with a particular focus on digitally enhanced visual tools. Eppler (Martin J. Eppler, 2003) discussed the advantages of visual metaphors in templates for the communication of knowledge. Eppler and Kernbach (2016) introduced the term 'Dynagram' for dynamic, software-based diagrams that facilitate team interactions in design thinking processes. Specifically, they investigate a diagram's capability to capture knowledge, to facilitate team discussions, and to provide added value in the joint analysis. Eppler and Hoffmann (2013) presented a set of visual solutions for developing business models, found in literature. To the best of our knowledge there exists no systematic overview of different parameters for visual canvases, which we present in this paper. Our suggested morphological box can be considered a foundation for the future development of canvases by outlining the relevant parameters and possible design options

Methodology

Data Source of 123 Canvases

The sample of 123 canvases that were included for our analysis were selected based on a three-step search process, as shown in Figure 1: First, we included the 100 canvases provided in the 'Canvas Collection' by Roberts (2016), which he collected based on a co-creation approach together with the readers of his Blog. Second, we conducted a systematic literature search within the Scopus database with the search terms "Canvas AND innovat*", which resulted in a total of 315 sources. Through this procedure we wanted to identify additional innovation-related canvases that were discussed (but not developed) by the scientific community. In a third step, we conducted another literature search in the Scopus database with the search term „Canvas AND Introduc*", which returned 393 sources. Through this step we wanted to identify additional canvases that were newly developed by the scientific community.

The resulting 708 additional sources were narrowed down to 49 through discipline filtering within Scopus and through title- and abstract-based analysis (selection criteria A). We excluded non-related disciplines (such as medicine, music, or chemistry), sources that addressed canvases in a metaphorical, artistic, or archaeological sense (e.g. "painting on a blank canvas") , as well as sources that discussed canvases in different media ("human skin as a canvas for tattoos", "textiles as canvas for embroidery", "digital canvases", etc.). This step left us with 20 sources, which were then analysed through full-text analysis (selection criteria B). Here, we excluded sources that simply applied existing canvases such as the BMC (e.g. as a case study), as well as sources that misleadingly labelled other types of diagrams as canvases (e.g. simple metrices or synthesis models that were not intended for poster-based printouts and collaborative activities). Any variation of an existing canvas was considered a new one. An additional co-citation analysis yielded in another 7 sources that were included. Finally, we excluded 4 redundant papers from all three steps (selection criteria C). this entire process yielded in 123 canvases that were included in our final analysis. Figure 1 illustrates our systematic search and analysis funnel.

Artefact Analysis

Subsequently, we followed a systematic artefact analysis process as suggested by Froschauer and Lueger (Froschauer, 2009; Froschauer & Lueger, 2016), which consists of three steps: (1) Descriptive analysis of the artefact (materiality, inner structure, and conditions for existence), (2) Analysis of embedded meaning in the organisation (social relevance, contextual analysis), and (3) reconstruction of underlying organisational structures (production, effects and functions, use). In the first step we analysed the visible structure and appearance of the 123 canvases (number of elements, layout, colours, etc.). In the second step we analysed the artefact in terms of its social context and meaning. This step involved interpretations of assumed usage scenarios, based on given instructions (if any), and the canvas title. More specifically, we located the intended usage of the artefact in one particular stage of the innovation process. In the third step, we analysed potential team behaviour and motivations through the canvas, based on visible prompts, trigger questions, and visual metaphors (if any). Insights about the production process of the canvas could be inferred through the presence of supplementary publications (if any). If a production date was mentioned on the canvas or in the publication, this was recorded as well.

The artefact analysis was conducted by two researchers in an iterative process. While going through the list of 123 canvases we coded each canvas according to emerging categories. These categories were recorded in a table and updated iteratively, whenever a new category emerged. Any disagreements between the two researchers were discussed until an agreement was found.

The artefact analysis revealed that several canvases were not related to any innovation activities or processes. Instead, they addressed general managerial issues, such as project planning, team building, or change management, as well as other topics unrelated to innovation, such as ethics. We excluded a total of 55 canvases that addressed such unrelated areas from our final evaluation, because we were particularly interested in the capabilities of a canvas to facilitate *innovation* processes. Figure 1 illustrates the entire literature search and analysis funnel.

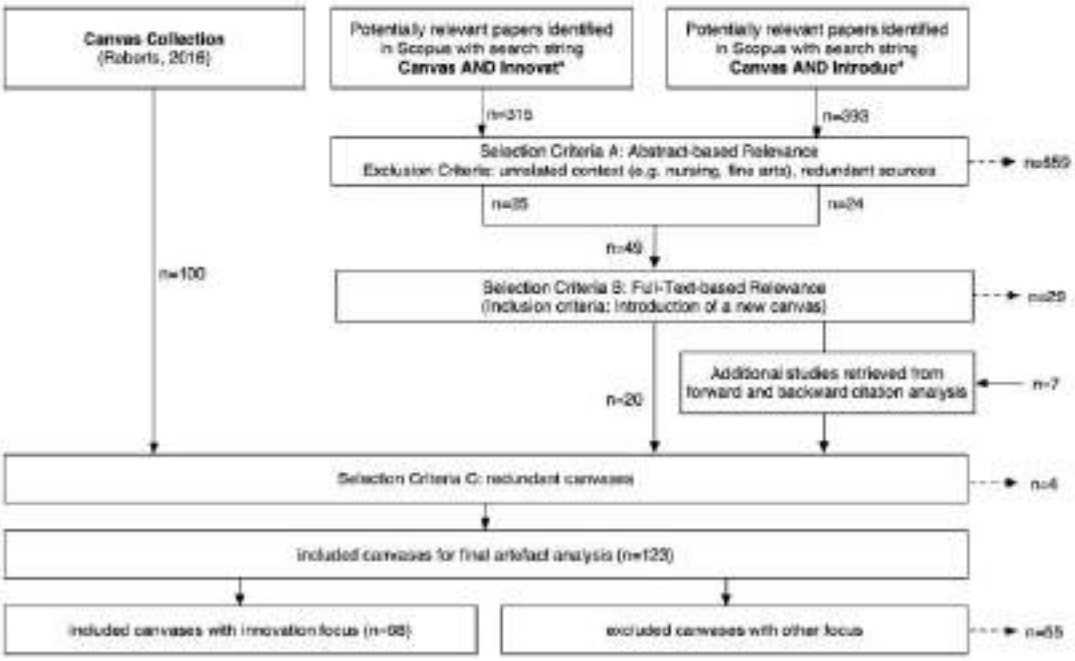

Figure 1: Illustration of the search and analysis process.

In the following section, we summarize the resulting insights from the artefact analysis of 68 innovation-related canvases in a framework. The emerging categories identified as relevant were aligned in a morphological box that constitutes the *Design Space of Innovation Canvases*. It can be used to analyse and localise an existing canvas, or to develop ideas for a new canvas design.

The Design Space of Innovation Canvases

This section presents the design space of visual innovation canvases as a framework outlining six design parameters: (1) the addressed step within the innovation process, (2) involved media, (3) sequence of use, (4) provided instructions, (5) number of elements, and (6) design specifics. These categories were developed iteratively by extracting the respective occurrences from the analyzed 123 canvases. Figure 2 shows the framework as a morphological box that outlines the design space of visual canvases and serves as a tool to guide canvas-related design decisions. The six categories are described in the following subsections.

Parameter	Possible Choices								
Process Step	FFE Research	FFE Synthesis	FFE Ideation	NPD Refining	NPD Prototype	NPD Test	C Assessment	C Business Model	C Sales
Media	Handwriting/Sketching		Post-it		Stickers		Cards	Computer Support	
Sequence	Numbers			Arrows			None		
Instructions	None		Printed within Element		Printed outside Element			Supplementary Guide	
Elements	3–6		7–8		Exactly 9		10–14	15+	
Design Specifics	Icons		Checklists		Color-Code		Visual Metaphor	Integrated Framework	

Figure 2: Morphological box, outlining the different categories that constitute the design space of visual canvases

Step of the Innovation Process

The first category locates the canvas within one or more process step of the innovation process. According to Koen et al. (2002) the innovation process can be divided into three phases: the fuzzy front end (FFE), the new product development (NPD), and the commercialization (C) of the innovation. Each phase is characterized by several sub-steps that could be facilitated through a visual innovation tool. According to this, we distinguish between nine process steps. Within the FFE phase we define (1) research, (2) analysis and synthesis, and (3) ideation; within the NPD phase we define (4) idea refinement and selection, (5) idea prototyping, and (6) evaluation and iteration of a developed solution; and within the commercialization phase we define (7) risk assessment, (8) business model generation, and (9) sales and marketing. This list does not imply that the process steps are to be executed consecutively. Instead, they can also include iteration loops, as suggested for example by the design thinking process (e.g. Brown, 2008). In that case, switching between canvases to elaborate different steps of the process, is possible and encouraged. Nevertheless, it is important for the tool to clearly address one or several process steps in order to communicate to the users, when to use the tool for what purpose. Also, the targeted process step might determine specific design decisions of the tool. For example, research or ideation tools will need empty spaces to be filled with insights or ideas by the users, whereas analysis or evaluation tools will need a more structured presetting like checkboxes or assessment frameworks.

Media / Additional Input

This category distinguishes between different media input. The simplest form of working with a canvas would be to write or sketch manually into the given areas. However, many canvases allow to use more flexible post-it notes and hence provide boxes that match the standardized post-it size. Only a few canvases provide additional tools, such as exemplary pictures, stickers, card sets with trigger questions, or the like. Another form of media support could be digital enhancement. Some canvases provide a digital counterpart or extension, to allow customizing of labels or remote team work.

Suggested Sequence

This category includes three possible options: Some canvases suggested a specific sequence of filling the different areas by either providing (1) strict numbers, or (2) more subtle graphical indicators, such as arrows or hierarchical flow charts. (3) Other canvases did not suggest any particular order but rather a flexible and spontaneous sequence, as the participants would see fit.

Instructions

Most innovation canvases need some sort of instructions. These could be (1) printed within the boxes itself, (2) added as a legend outside the canvas elements, or (3) provided as separate guidelines, for example as printed brochures or books, or as a video tutorial.

Number of Elements

Many canvases follow the example of the BMC and provide exactly 9 elements, either as building blocks or other shapes, each addressing one issue within the overarching canvas topic. Other canvases address simpler topics, and hence limit the number of elements, whereas canvases for more complex issues need more elements. The range spans from a minimum of 3 to a maximum of 28. In the morphological box we decided to provide five clusters, according to the identified distribution outlined in our analysis (see subsequent section, Figure 5).

Design Specifics

The analyzed innovation canvases involved various design elements: (1) Icons and symbols provide a visual reference and help to support the meaning of specific canvas areas. (2) Checklists, checkboxes, and rating scales invite the assessment of existing solutions as well categorical or ordinal input. (3) A color code (for example through the use of colored Post-It notes, stickers, or colored areas on the canvas) might add meaning and structure to the entered data. (4) Visual metaphors can activate a specific mind-set or motivate participation. Moreover, they might help users to better understand the goal of the canvas and provide connections between the individual elements. (5) Integrated (subordinate) graphical frameworks provide structures that can help organize information within or in between elements.

Figure 3 illustrates the applicability of the morphological box by exemplarily mapping it to the Business Model Canvas. The used choices of the BMC are marked in dark grey. Similarly, the reader can use the morphological box to analyze any other existing canvas, as well as for selecting possible options when designing a new one.

Parameter	Possible Choices								
Process Step	FFE Research	FFE Synthesis	FFE Ideation	NPD Refining	NPD Prototype	NPD Test	C Assessment	C Business Model	C Sales
Media	Handwriting/Sketching		Post-it		Stickers		Cards	Computer Support	
Sequence	Numbers			Arrows				None	
Instructions	None		Printed within Element		Printed outside Element			Supplementary Guide	
Elements	3–6		7–8		Exactly 9		10–14	15+	
Design Specifics	Icons		Checklists		Color-Code		Visual Metaphor	Integrated Framework	

Figure 3: The design space of the Business Model Canvas (respective design choices marked in grey).

Canvas Analysis Results

The following section presents selected insights from the artefact analysis. Figure 4 shows a bar chart outlining the addressed process steps within the innovation process, or other addressed aspects, respectively. It reveals that 68 of the analysed canvases are intended to facilitate some steps of the innovation process. Most of them support the development of business models (n=24) and the idea refinement phase (n=24), followed by synthesis/analysis canvases (n=13) and canvases addressing the sales/marketing stage (n=12). Only a few canvases addressed the research phase (n=3), risk assessment (n=2), ideation (n=8), prototyping (n= 5) and test/iteration (n=8), which shows a persisting potential for new tools in these areas. For the subsequent analyses we include only the 68 innovation-related canvases and exclude the remaining 55 unrelated sources.

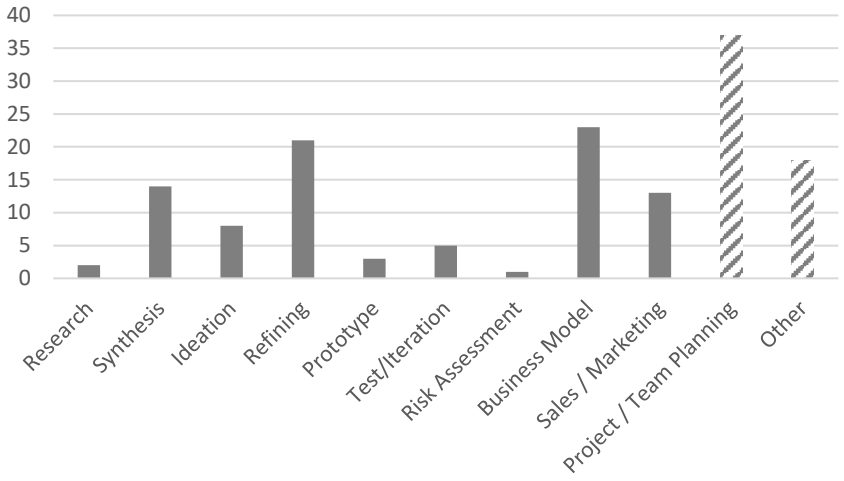

Figure 4: Distribution of canvases addressing different process steps; more than one possible (n=123).

Figure 5 shows the distribution of the number of building blocks or other elements on the different canvases. It illustrates that most canvases follow the example of the BMC with exactly nine elements. The maximum number of elements on one canvas was 28 (the "Big Idea Canvas", the minimum number was 3 (the "Requirements Engineering Canvas").

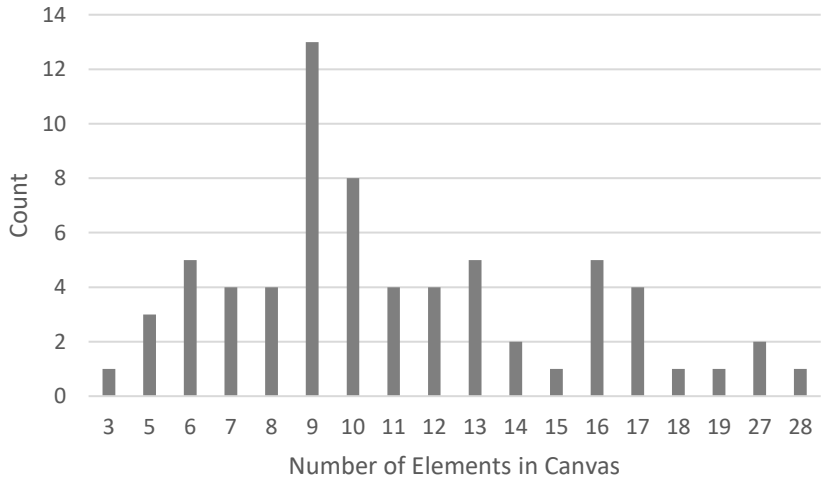

Figure 5: Number of elements on the different canvases (n=68, innovation canvases only).

Figure 6 illustrates the average number of elements on a canvas according to the targeted process step. It becomes evident that some tasks might be more complex and hence require more elements, such as the Testing/Iteration phase (average number of elements = 15), whereas other tasks seem to be less complex and manage with fewer elements, such as the Research or Risk Assessment phases (average number of elements = 7).

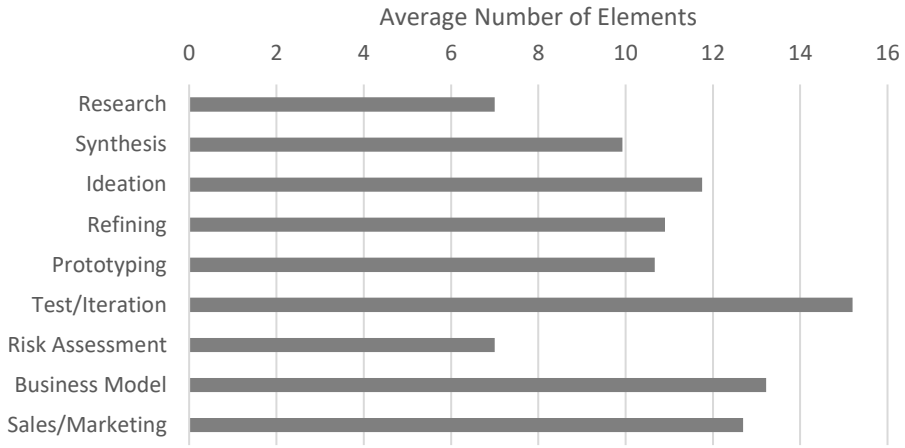

Figure 6: Average number of elements according to the addressed process step (n=68, innovation canvases only).

The following other insights could be derived through our analysis: A sequential order was only suggested on roughly one third of the innovation canvases (n=21). Half of the innovation canvases made use of icons or symbols (n=34) whereas the rest did not make use of any visual support. The potentials of color-coding and visual metaphors seemed to be not utilized to their full potentials (use of color-coding: n=18; use of visual metaphors: n=7). While the vast majority of canvases was using the standard rectangular building blocks (n=57), 11 canvases abstain from the typical building block structure and use other shapes, ranging from abstract diamonds, pie elements or (semi) circles, to concrete figures like a bridge or a face. 27 canvases showed a combination of rectangular boxes and other shapes. Some canvases also incorporated subtle structuring elements, such as arrows indicating a specific direction of use, or process maps that suggested a particular arrangement of data.

All these aspects warrant further investigation and consideration. The possible impact of variations in color-coding, visual metaphors, sequences, or instructions could be investigated through experimental studies. The analysis of any correlations between aspects (e.g. the appearance of particular design characteristics in different process steps) also warrants further investigation and is dedicated to future work.

A Theoretical Framework of Canvases

As pointed out by Avdiji et al. (2018), most developments of visual canvases are not following a scientific process but serve more a trial and error approach. In an application situation it might be sufficient to know what kind of tool is working in which context and under which conditions. However, if we want to know why one tool works in one situation and not in another we need to find out more about causal relationships of tools and human behavior. There is not one single theory but rather an abundance of theories on human behavior, developed from different disciplines with different foci, such as psychology, sociology, ethnography, and many more. In addition, different units of analysis such as individuals, groups, and organizations need to be addressed. Based on this 'bricolage of existing theories', we claim three inter-connected theoretical frameworks contributing to building the skeleton to understand, explain, and predict human behavior.

In the following subsection we extend this theoretical framework by seven possible functions or working mechanisms of a visual canvas. Figure 7 juxtaposes these functions with the existing theories in a framework, consisting of 3 main categories and 7 subcategories. Additional literature is presented that might be able to explain those suggested working mechanisms of an innovation canvas.

Figure 7: Theoretical Framework of innovation canvases; outlining the possible working mechanisms.

Cognitive-Perceptual Level of Information Processing.

This level includes memory, learning, and knowledge acquisition, as well as cognitive biases such as fixation, which is the inappropriate repetition of existing solutions (Purcell & Gero, 1996; Cardoso & Badke-Schaub, 2011). Dalsgaard (2017) provided a framework of 'instruments of inquiry', in which he outlined that tools or instruments can guide the designers' perception and understanding of design problems and solutions.

(1) Extended memory. The visual canvas can serve as an extended memory. Knowledge and information can be captured and visually stored. The externalization of previously tacit (design) knowledge on a canvas facilitates knowledge exchange between team members and facilitates memorization of relevant information (Müller & Thoring, 2010). Moreover, a canvas can serve as some kind of checklist that ensures that no step will be forgotten (Gawande, 2010).

(2) Thinking facilitator. The visual canvas can act as a facilitator for the thinking process, for example, by providing a step-by-step instruction when to do what. In this case, the tool should provide clear guidelines, such as a numbered order of subsequent steps. Similarly, it can be a source of inspiration, for example by providing trigger questions or exemplary solutions. However, one should be aware that such inspirations can also limit or manipulate the creative output of the users, which can lead to fixation (Purcell & Gero, 1996). Moreover, a canvas might act as an 'eye-contact deflector' (Kajimura & Nomura, 2016) and that way protect certain cognitive control processes from turning off during group work. Furthermore, according to the Dreyfus and Dreyfus model of skill acquisition (Dreyfus & Dreyfus, 1980), templates and step-by-step instructions can be useful for novices whereas experts often prefer an intuitive approach to problem solving. As Liedtka (2018) pointed out „structure and linearity help managers try and adjust to […] new behaviors", which she called "the beauty of structure".

Emotional-Motivational Level of the Individual Needs.

The emotional-motivational level of individual needs includes the mutual influence of persons how to feel accepted, and also the need for control. For an overview of individual needs structure, Maslow's motivation theory (Maslow, 1943), and 'motivation theory reconsidered' (Landy & Becker, 1987) can serve as a reference.

(3) Platform for ideas. A visual canvas can serve as a platform for ideas and insights by providing (empty) space(s). People often express a tendency to fill a given space to make it look complete, a phenomenon similar to the 'Zeigarnik effect' (Zeigarnik, 1938), which suggests that people feel the urgency to complete an unfinished task. If, for example, a canvas provides a fixed number of boxes to be filled, the user might want to fill all of these boxes. Hence, the size of the tool itself might also determine the amount of output. The rectangular shape of building blocks can be easily filled with post-it notes, whereas differently shaped areas might hinder this attempt.

(4) Motivator. A well-designed visual canvas might be able to increase individual motivation. It can encourage people to share their ideas and insights and increase engagement and commitment. For example, a canvas might be able to motivate all participants to share their ideas, also those who are shy or reluctant. This assumption can be supported, for example, by studies suggesting that brainwriting outperforms brainstorming (Heslin, 2009). If the tool itself demonstrates some designerly effort, the chances are high that the users will also spend their own effort when filling it. The co-created output might also increase loyalty towards the team and the result, because one might better relate to the jointly developed solution. When designing a visual tool, you might want to consider options to engage all involved participants, for example by providing dedicated space per participant, or by assigning specific team roles.

Social Influence and Mutual Interaction.

The level of social influence (Flache et al., 2017) and mutual interaction includes the communication of and within the team. Here, all three streams come together—the individual need for control meets the need for a shared understanding in the team and the exchange of information according to the respective goal of the innovation tools.

(5) Shared mental model. The visual canvas can facilitate the creation of a shared mental model. According to Badke-Schaub et al. (2007) mental models are simplified (not necessarily accurate) representations of the real world in our heads. If a team performs on a joint innovation project, a common understanding and a synchronized mental model is crucial for the project success. A visual tool can facilitate the creation and balancing of such a shared mental model.

(6) Boundary object. A visual canvas can facilitate team discussions and serve as a boundary object. Boundary objects are information that are plastic enough to be adapted and interpreted differently by different communities, but robust enough to maintain informational integrity (Star & Griesemer, 1989). They are standardized forms that provide a shared format for solving problems across different functional settings (Carlile, 2002) and hence support distributed cognition by eliciting and capturing tacit knowledge through interactions with the object (Henderson, 1991). A visual canvas represents such a standardized form that can help a team to produce records of mental thought outside of the individual memory, by providing means for others to interact, critic, and build upon the ideas, and by establishing a common language of understanding (Fischer, Giaccardi, Eden, Sugimoto, & Ye, 2005). This can allow knowledge sharing and coordination of a discussion in heterogeneous teams, even without consensus (Bechky, 2003), by allowing sketching and visual framing of concepts that can then be discussed. Moreover, giving and receiving explanations (Ross & Cousins, 1995) through interaction with a canvas might be able to enhance mutual understanding of the problem.

(7) Presentation and communication tool. The visual canvas can be used as a presentation or communication tool, for example to justify an idea towards clients, co-workers, or superiors. In this case, the visual tool should provide a clear structure, outlining possible benefits, and encourage legibility (e.g. of handwritten notes). Moreover, a canvas can facilitate storytelling and hence foster the exchange of organizational knowledge (Connell, Klein, & Meyer, 2004). Team discussions along a visual collaboration tool can facilitate abductive inference (Lombrozo, 2012), which is the main component for innovation. At the same time, a visual canvas can gather people together and involve different stakeholders in workshop settings. According to Conversation Theory (Pask, 1976), participants engage in conversation where everyone finds a ‘corner’ (a building block within the canvas) and a space for getting to say (or teach) something to the group. Participants are not only filling boxes, but learning from the group and encouraged to teach something back to the group.

Discussion

Implications

As outlined above, visual innovation canvases can provide various benefits. They can facilitate information processing, individual motivation, and team interaction. A canvas might increase the quantity of a team’s output as well as their time-efficiency. Visual structures and prompts can invite participation and reduce unnecessary discussions on what strategy to pursue (because this is already suggested by the tool). Complex tasks are simplified, which facilitates thinking processes. Interdisciplinary teams, who do not have a common understanding and possibly different levels of expertise, might find a canvas helpful to facilitate communication and foster engagement. The same applies for presenting concepts to clients or other stakeholders.

However, the vast choice of existing canvases might overstrain the user. The question, which of the existing tools would be the right choice for a specific purpose, how to use those tools, or how to adapt them for one’s own requirements, might become a challenge. Sometimes it might be inevitable to design a new visual tool, because an adequate solution is not yet available. Although there exist many canvases for various aspects, our analysis showed that the available tools for particular tasks of the innovation process (e.g. research, risk assessment, etc.) are limited. Consequently, with regards to our research questions stated earlier, this paper provides the following theoretical and practical implications:

(1) The presented morphological box outlines the relevant parameters that mark the possible design space of visual canvases, and hence provide a guidance for other researchers and practitioners to either select or design an innovation canvas. It helps the users to identify which aspects are relevant for their task and compare these with existing canvases. When designing a new canvas, they can select from the provided parameters and compose them into a desired template for their own purposes.

(2) The presented theoretical framework of visual canvases provides helpful insights on the working mechanisms and theoretical underpinning of canvases that allow for a goal-oriented and appropriate application and development of canvases.

(3) The results of the canvas analysis yielded rich insights on existing research gaps that could be tackled in future research.

Risks and Challenges

Despite the apparent popularity of visual innovation tools and their helpful benefits that we discussed in this paper, we would like to pose some critical thoughts. Developing a visual canvas requires a lot of skills in terms of both, conceptual and designerly expertise. Avdiji et al. (2018) expressed their concern about the lack of scientific rigor for the development of many visual canvases that are available today. Our systematic literature search showed, though, that a multitude of canvases is in fact scientifically developed, evaluated, and published in peer-reviewed sources. Nevertheless, we want to emphasize that a reflective development of a canvas, possibly involving an evaluation study following an action research approach (Lewin, 1946), can secure a rigorous foundation. For a well-grounded conceptual base for developing such visual tools, we refer the reader to Kolko's work on visual synthesis models (Kolko, 2011). Adding to that, we would like to express our concerns about the possible lack of aesthetics and design expertise for some existing visual tools. The list of 100 visual canvases collected by Roberts (2016) reveals the oversimplified design of some of these canvases, partly neglecting basic design rules that could be found, for example, in the seminal works of Tufte (1990, 2001) and Bertin (2011), or in the work of Moody (2009). Bresciani and Eppler (2015) outlined several pitfalls of visual representations, for example, over-complexity or over-simplification, as well as misleading or cryptic decoding challenges. Furthermore, we see a tendency—especially in the design thinking field—of what we like to call 'templatism'—the overly use of templates for almost any given task without questioning or reflecting on its appropriateness. This might be reflected by the illusion that the right tool would magically solve the problem without any additional effort of its users—a phenomenon called the "Candy Man effect, where executives longing for easy, sure-fired innovation" (Barry, 2017). We argue that a template can only guide a thoughtful process but cannot compensate for a possible lack of conceptual underpinning and careful research. Finally, we would like to emphasize the risk of fixation effects when relying heavily on visual innovation tools. The concept of fixation describes inappropriate repetition of existing solutions; (e.g. Purcell & Gero, 1996; Cardoso & Badke-Schaub, 2011). Rigid structures of a visual tool might limit the creativity of the users and lead to foreseeable or biased results.

Limitations and Future Work

One limitation of this study is that it partly relies on the rather arbitrary canvas collection by Roberts (2016). However, to the best of our knowledge, there exists no other compilation of canvases, yet. We expanded the existing canvas collection through a systematic literature search, which yielded our final list of 123 included canvases. We argue that this number of analyzed sources was sufficient to develop a theoretical framework and to derive criteria for canvas designs, even if the list of included canvases might not be exhaustive.

Potentials for future research can be found in exploring the opportunities of digitally enhanced canvases. Digitally supported tools might allow for easy individualization and mass-tailoring of visual tools. Also, team-based discussions with a large number of participants, time-delayed and/or simultaneous discussions, and remote interactions would be possible through digital facilitation. Comi and Eppler (2011) demonstrated in an experimental study that software-supported visual facilitation outperforms poster-based collaboration in terms of team performance and participants' satisfaction with the inter-organizational meetings. Similar results were presented by Eppler, Öste and Bresciani (2013). These studies warrant further research into developing software-based visual innovation tools.

Furthermore, additional research is needed to investigate the conceptual impact of innovation canvases. The question whether such tools actually improve innovation processes and the outcome's quality, is not yet fully

answered. However, the evaluation of the effectiveness of the 123 analysed canvases is beyond the scope of this paper and will be tackled in future work.

Finally, we want to distill the insights of this study into some basic design principles for developing innovation canvases. This would extend the presented morphological box and theoretical framework towards a more practical tool for applied research and practice.

doi: 10.33114/adim.2019.07.310

This article discusses the use of low-resolution prototypes and storytelling as tools for planning and building simulated interactive experiences as a part of an exploratory method of user-centered research. We contextualize the concept of low-resolution prototyping and storytelling, present its insertion in the method and discuss its relevance to design user-centered experiences. The results suggest that using low-resolution prototypes and storytelling to create immersive experiences to validate products/services enable a deep understanding about users, which is an important perspective to design driven-innovation, considering that people do not buy products and services, but meanings. The combination of both tools gives the researchers a qualified amount of data that covers what the user consciously speaks, automatically does and unconsciously expresses. Using the proposed method companies will be able to identify the value perceived by customers, in order to create a better experience.

Keywords: design research, user experience, low-resolution prototypes, storytelling

Introduction

In the context of experience, Design has the purpose to enable the conditions for creating experiences in a planned way. The understanding of how experiences occur and how objects become emotional triggers opens space for new product design opportunities that are meaningful and relevant in people's lives (Forlizzi, Disalvo, & Hanington, 2003). Considering the relationship between people and the products and services they consume, the experience will draw in the emotions, beliefs, and expectations that occur before, during and after consumption (Chammas, Quaresma, & Mont'alvão, 2015).

In order to design experiences, it is necessary to involve the users in the design process, not only by questioning them about their needs and motivations but also by providing an environment in which they can imagine themselves in future scenarios related to the project's context. By actively involving customers in the innovation process, it is possible to get specific information about needs and desires, in order to translate this into products insights (Kaplan & Haenlein, 2006). But the more innovative these products are, the more they will challenge the organization's ability to take them further (Carlgren, Elmquist, & Rauth, 2016).

To do so, low-resolution prototypes - physical representations of early conceptual models (Kaya, Alacam, Findik, & Balcisoy, 2018) - enable the creation of a complete simulation environment where users can interact with the product or service that is being designed, validated or tested, and freely express their perceptions. In

this way, the researcher can dialogue, question and observe conscious and unconscious behaviors that could generate insights for the project. In order to be immersive, this simulation must be planned and applied based on narratives that describe the universe of the project and integrate the hypotheses to be confirmed. When consumers are living the experience, more-original ideas can be discovered (Liedtka, 2018).

Therefore, this article discusses the use of storytelling and low-resolution prototypes (also called low-fidelity prototyping) as tools for planning and building simulated interactive experiences as a part of an exploratory method of user-centered research. This method was conceived and applied during joint investigations executed by HP Inc. Brazil R&D Center and Tecnopuc Crialab, the creativity laboratory of the Pontifical Catholic University of Rio Grande do Sul - Brazil. This method is oriented to the initial stages of the product development process, and allows users to imagine themselves in a future context through fictitious environments and scenarios in the scope of ideation. In this article, we intend to contextualize the concept of storytelling and low-resolution prototyping, to present the method, to discuss how storytelling and low-resolution prototyping can help create a better experience, and finally to discuss its relevance to design user-centered experiences.

Low-resolution prototypes for simulated experiences

Prototyping is an activity that has received considerable attention in the product development process since the adoption of Design Thinking in several business areas (Elveruma, Weloa, & Tronvoll, 2016). The understanding of the design process in the business and development domains has been extended, so using low-resolution prototypes in the early stages of design has become an important practice. In contrast to the traditional role of the prototype in engineering processes, the prototype in the design process, especially of products, has a more exploratory role (Elveruma *et al.,* 2016).

Using prototypes, designers and project teams create concrete representations of design concepts, taking them out of the conceptual space of their minds and materializing them beyond graphical representations. These prototypes, even when done in a rudimentary way, facilitate the communication of concepts and ideas, both among the design team and with users and stakeholders (Orr, 2015). These traditional prototypes can serve many useful purposes in product development processes, but since they often require a high commitment of financial, human, and time resources, they are often seen as an obstacle to final production (Savoia, 2011; Orr, 2015). Its use can help to test and validate the potential market of new ideas in a concrete and objective way; however, it is common to invest weeks, months or years and large amounts of financial resources, which makes this process difficult, expensive and time-consuming.

Low-resolution prototypes, on the other hand, involve fewer costs and reduced time to obtain the necessary information that will allow the project to move to the next phase (Figure 1). In order to achieve a good physical representation of an idea, the tools and materials used to prototype must be simple to use and easy to manipulate (Kaya *et al.,* 2018). Constructed with basic materials (from cardboard to bottle caps), these materialized concepts have many benefits: for Pernice (2016), with low-resolution prototyping, more time can be spent exploring interactions with the product/service, without technical restrictions. In addition, necessary changes are made faster so it's possible to quickly perform several test sessions and apply adjustments needed to re-test the product/service in iterative cycles. Low-resolution prototypes also exert less pressure on users. As the product/service is not yet concluded, users do not feel the obligation to be successful in the tests and are more likely to express any negative reactions. This effect also applies to the design team; necessary changes in the product/service are made more naturally since it is understood that the project is still under construction and can be modified (Pernice, 2016).

Referring to low-resolution prototypes, Savoia (2011) brings the concept of "pretotyping". For this author, between abstract ideas and suitable prototypes there are the pretotypes, low-resolution prototypes that are still in the initial phase, and that help to collect valuable market data and product/service usage information for decision-making regarding the continuity of the project, for a fraction of the cost of prototypes, since they can be developed in a few hours, using few resources. The pretotypes allow design teams to fail quickly so a quick recovery can be achieved with enough time, money, energy and enthusiasm to explore new adjustments in the project until achieving a model that really has value for people (Savoia, 2011).

Figure 1: Example of product low-resolution pretotype. source: the authors.

According to Orr (2015), the prototype can be categorized into three different groups: prototypes of adjustment, prototypes of shape or prototypes of function. Adjustment prototypes are designed to test fittings, assemblies, and manufacturing peculiarities. The shape prototypes are intended to test the aesthetics of final products. Finally, function prototypes are developed to test specific product and/or system functionalities. These three categories are not exclusive, because in many projects it is necessary to test more than one dimension of the product simultaneously. However, from an experience perspective, it is understood that the interaction between the user and a product/service transcends its form and function, and also involves environmental aspects, senses, motor and mental abilities, intentions, expectations, desires, values and previous experiences (Freire, 2009). Experience is the result of the interaction between people, products, and the context in which this interaction takes place - and must be functional, determined, engaging, attractive, and memorable. Thus, in the context of this research, a fourth category of prototypes is also visualized: the prototypes for the conception of experiments (Figure 2).

Figure 2: Example of low-resolution prototypes. source: the authors.

In this process, using a low-resolution prototype creates a easily simulated environment in which the user has the experience of using the product/service being designed, validated, or tested. Through narratives that report the different situations of use that are previewed in the project, during the experience simulation the user can freely make decisions, perform actions and manifest their perceptions. To discuss the construction of these narratives, it is interesting to start with an overview of concepts and applications of storytelling.

Storytelling as the driver of experiences simulations

Stories are a natural and flexible way of communicating. Its effectiveness ranges from its use in teaching, as a means to help people to remember information, to a good form of entertainment (Quesenbery & Brooks, 2010). Stories are told through the generations to educate, inspire and motivate. They reflect how people usually tell things about themselves, about other people, places, cultures, and experiences. Telling (and listening) stories naturally makes people more receptive to new ideas and perspectives (Beverland, 2009).

The use of stories as communication means is not limited to the personal level. At the professional level, whether for teachers, organizational leaders or scientists, there are many ways and opportunities to use storytelling. In a classroom, stories can be used to explain the content in a playful and didactic way. In a judgment, a story can be told by a lawyer as a means of promoting jury empathy and exposing the defense view (Meyer, 2014). In Design, storytelling is used as a method to elaborate usage scenarios, for the creation of personas and as part of other tools used in projects that involve the user experience (Quesenbery & Brooks, 2010; Frandoloso, Gonçalves, & Fialho, 2017).

For Quesenbery and Brooks (2010), stories have many applications in the design of experiences: they can describe a context, such as stories that tell a person's journey; they can illustrate problems and pain points, explaining why a new experience is needed; or they can launch points for a discussion, explore design concepts and describe the impact of new projects (Quesenbery & Brooks, 2010). When used in experience simulations with low-resolution prototypes, they are written to describe a context or situation of use of a product and/or a service. In this case, the narratives help in understanding the circumstances and variables related to the project, since they not only describe a sequence of events but also help to explain the reasons and motivations of these events.

Because they have a particular structure that describes cause-and-effect relationships between events that occur in a particular period, impacting specific people (Dahlstrom, 2014), narratives are important tools to interact with users. Good storytelling is interactive; it is like a conversation in which the storyteller and audience participate together, and are engaged to the point to feel part of the narrative. In addition, storytelling does not bring too much detail - on the contrary, it purposely leaves gaps that will be filled by the viewer's imagination, so that it builds up parts of the story (Quesenbery & Brooks, 2010). This active and dynamic aspects of storytelling make it essential for the design of experiences.

Considering these concepts, in the following pages we discuss how low-resolution prototyping and storytelling can be applied in a user-centered research method, as important tools used to create the stories that will be told to users and experienced by them in interactive experiences simulations, in the context of products and/or services development projects.

Low-resolution prototyping and storytelling for user-centered research

As user experience becomes central to the design process, it is necessary to establish means by which designers and users can act as equal partners, which impacts not only the results of the design process but also the design goals. In order to design new products and services, users' participation is essential, so they can contribute with their vision about what is being developed and act as collaborators in the design process. So, under these premises, Tecnopuc Crialab's design team developed a user-centered design research method[1] focused - but not restricted - on the initial stages of a technological product/service development process. This method was created in collaboration with HP Brazil R&D, in order to involve users in some stages of the development process and to encourage them to become co-creators in the design process (Figure 3).

[1] *The complete method was published in the Brazilian journal Human Factor Design (HFD, v.8, n.15, p. 98-113, March 2019).*

Considering our goal with this article, we will briefly explain the method and then focus on the role of low-resolution prototype and storytelling.

Figure 3: Complete diagram of user-centered research method. source: the authors.

About the Method

The method comprises four phases: Context, Plan, Action, and Analysis. The first phase, CONTEXT, is about understanding the project environment. It defines the research main goal and the directions to be followed in order to make the experience happen. Every process should start with a contextualization because it allows us to understand the project universe and the user profile, who will be the main actor in this process. As in our experience design, management and development teams will work together, decisions regarding this phase must be made in a joint effort. This initial phase is also important to clarify the research context, which can be driven by the idea of a product to be developed, by a product to be validated or a launched product to be evaluated.

According to Pine and Gilmore (1998), the potential commercial success of product/services depends, in addition to other factors, on the experiences it provides - and therefore understanding the consumer needs and their motivations is essential to create meaningful and memorable experiences. In order to do that, we carry out desk research (exploratory research in academic bases and websites in order to investigate cultural, behavioral and market aspects related to the project) and we create personas, user journeys and empathy maps.

As we are using a user-centered approach, we need tools that are focused on explaining and detailing the user's profile and needs related to the product or service. Because of their fictitious, specific, concrete representations of target user's characteristic (Pruitt & Adlin, 2006) personas potentially can help address some of the issues with current user-centered approaches (Miaskiewicz & Kozar, 2011). Also, user journeys and empathy maps can help us immerse on the user's world so we can create a meaningful experience for the user. Based on this, we define the research hypotheses that will be validated with the experiment application. The CONTEXT stage creates the necessary basis for the following method phases since it gathers all the information necessary for the effective design of the experiment.

The PLAN phase consists of planning the simulated experience to be applied. In this phase, the low-resolution prototype and storytelling will have an important role. We start this phase writing the narrative that is going to guide the experience (storytelling), based on the hypotheses, behavior settings (Wicker, 1987), and technologies previously defined, and we consolidate it as text or as a storyboard. How the storytelling will be built-up is also an important aspect to be considered. In our experience working with different teams, with different backgrounds, storyboards tend to help put everyone on the same page and focus on planning the same experience.

With the narratives already defined, the scripts and the protocols must be prepared. They consist in each step the researcher must take to conduct the experiment: this includes welcome the participants and explain how the experiment will be, ask them to sign the image use authorization (or any other document), make initial questions, propose the tasks that the participant should perform, observe it, and make the final questions. Our goal is to compare people's behavior during the experiment and find patterns in their behavior in order to generate products/services insights. To be able to do that, in the scripts, every step must be clear and detailed, including the researcher's lines and the questions that will be done before, during and/or after the experiment

in a semi-structured script. It is also relevant to consider support tools to the interviews that are going to be used in specific points of the interaction. These tools can be used by the participant and the researcher together, helping the user to imagine hypothetical scenarios and to demonstrate their thoughts, opinions, and feelings. Some examples of support tools are paper cards with future scenarios, image sorting (Kumar, 2013), emotional response test (Memoria, 2006; Meurer, 2014), among others.

After the scripts, we initiate the construction of the environment where the experience simulation is going to happen, building the low-resolution prototypes (Figure 4). We need to make the conceptual representation of the product/service tangible to be tested or validated. Also, to be able to create an immersive and playful experience that will stimulate the user's imagination for future scenarios where they perform the requested actions. The low-resolution prototype is done considering the narratives that were previously created.

With the scenarios built, we start the participant's call to action. The users are recruited considering the profile defined in the CONTEXT phase. The recruitment does not necessarily need to be started at this stage but must be finalized before starting the next step.

The third phase of the method, ACTION, aims the experiment application. In this phase, a pilot with a few users is initially applied, to verify the research protocols and all the operations. Once this verification is done, the experiment will be applied according to the participants' schedules. We usually apply it in short iteration rounds, so we can make protocols reviews and, if necessary, apply new pilots. Possible adjustments may occur in these reevaluation steps and we should consider that in the final analyses. Throughout the application rounds, it is also important to make sure that all the media are being recorded, so all the experiences can be analyzed at the end of the research.

Figure 4: Examples of experience simulation using low-resolution scenario and product prototyping. source: the authors.

The last phase of the method, ANALYSIS, refers to the analysis of the data collected with the application of the simulation of the experience. The data collected is analyzed qualitatively because it allows the description of the complexity of the phenomena related to the subject of study (Flick, 2009; Gibbs, 2009). In this phase, all audios are transcribed and snapshots of recorded videos are selected. We strongly suggested the use of two video cameras to record the user in different angles. This preparation of data is important to posteriorly cross texts from the transcriptions and images from videos.

Then, the shreds of evidence collected with different media are crossed and categorized. Then, the results are analyzed. By the end of the analysis, results are compiled and design principles are generated. Design principles propose to transform insights into project recommendations and indicators/guidelines for the development of a solution related to the experience that is being designed (Kumar, 2013).

By using this structure, this method allows constant iterations along its application and predicts these iterations especially in its central phases – plan and action. Enabling iterations means that the plan of the experience can be reviewed at any moment, which will impact in the simulation of the experience simulation with the users, which can result in a new process of investigation. This new investigation can be of a new premise to be explored, or about a reformulated old one. The method, that is user-centered and developed in

the context of experience design, is oriented to design research processes with great potential of participation of designers, other team members, and users, and qualifies the stages of an investigation and problem definition in projects.

Storytelling and Low-resolution prototype for Innovative Simulated Experiences

As mentioned, the low-resolution prototype and storytelling will play an important role in the PLAN phase of the proposed method. This phase starts with narrative writing using the information gathered in the previous phase. This previous information is essential to bring meaning to the story. To write the narrative we needed to establish some directions. So, we reviewed the branding storytelling framework from Smith (2012). As Smith's framework is focused on creating branding narratives, we adapted it to focus on the simulation of experiences (Figure 5). As the original framework, ours consists of three stages: environment, experience, and outcomes.

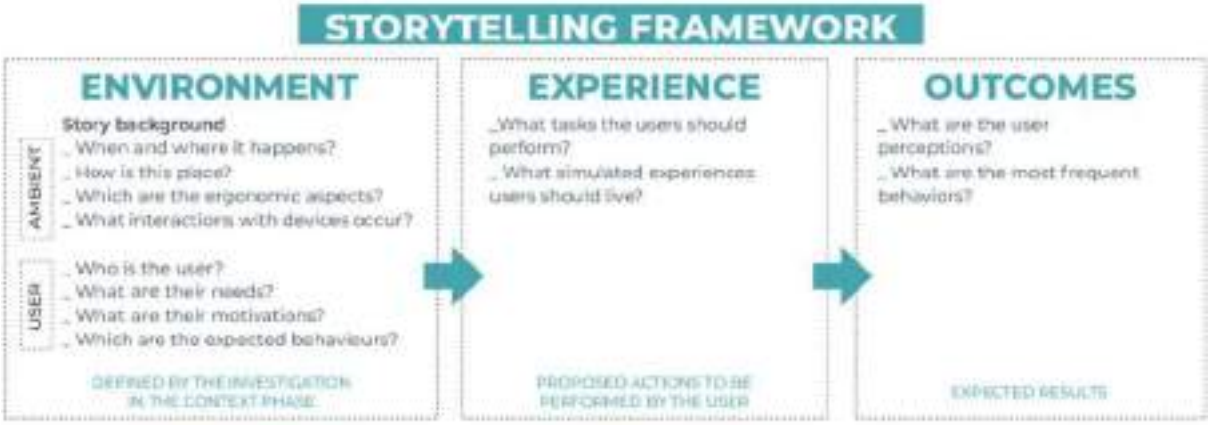

Figure 5: Storytelling framework, adapted from Smith (2012). source: the authors.

On the ENVIRONMENT stage, the goal is to define the experiment background. Every experiment we planned, we had to make related decisions about where the story will be placed and who are the users that will interact with it. In order to do that, we planned considering two main aspects: ambient and user. In the ambient phase, we answer questions like when and where the experiment happens? How is this place? Which are the ergonomic aspects? What interactions occur? But we also needed to have a better understanding of the user who will be interacting in this space. For that, we answer questions like who is the user? What are their needs? What are their motivations? Which are the expected behaviors?

Having all these answers makes it possible for us to visualize what needed to be done and start designing the first sketch (Figure 6). Besides telling the atmosphere of the story, this information also defines exactly what is going to be built: what kind of devices, how many of them, what the ideal distribution of elements to compose the environment, and other needed information. In addition, in this stage, we gather the information regarding the user profile (as their needs, motivations and expected behaviors that were previously investigated) to address it in the tasks that users are going to perform in the simulated experience. The user profile is also considered for the recruitment of participants who will be invited to the experience.

Figure 6: Sketch for an ambient with low-resolution prototypes. source: the authors.

On the EXPERIENCE stage, we define the tasks that users are going to perform in the experience. These tasks can be very detailed (when the intention is to test the relevance of a product and/or service, or its usability), or can be very broad (when the intention is to understand behaviors or cultural aspects). These tasks can be consolidated as text and/or storyboards, and are the base to the scripts and protocols that are followed by the researcher to conduct the experience. If in the ENVIRONMENT phase we are focused on the context of the narrative, the experience phase is related to the action step, where the user is the center of it. Based on Smith's (2012) framework, we also separate the defining tasks step from the contextualization one when designing narratives. So, decisions made on the environment phase will guide the tasks definition, but only after finishing the environment phase is it possible to define coherent and consistent tasks for the user. In our experience, the second stage will demand not only general storytelling knowledge to be accomplished but also a deep understanding of the user and the story you want them to experience.

Finally, the OUTCOMES stage consists of the end of the experience. In Smith's (2012) original framework, the end of the narrative presents the story's main point, but because we are focusing on understanding experiences, the end of the story is determined by the user. How they decide to end the experience is an important result and can help us confirm or refute a hypothesis. Based on the research goal, it is possible to define expected results, especially when the intention is to validate an idea, a product and/or a service. In this case, there is an expected result that, if attended, the hypotheses are confirmed. On the other hand, if the expected results are contradictory, the hypotheses are refused and new hypotheses can be defined.

As the results are uncertain, we must emphasize that the narrative is not immutable, and can be adapted and reviewed as much as necessary. The narrative aims to tell the stories that will be experienced by users, and that simulates the context where the user is going to use the real product and/or service in the future. When it is well explored, it captures and maintains the user's attention and generates interest and enthusiasm. Because of that, it must be detailed enough to help the user to go deep into the immersion - so it must include the product and/or service to be tested and all its context of use (Denning, 2005).

Figure 7: Construction of the ambient where the experience simulation is going to occur. source: the authors.

Although the storytelling can be an important player when building experiences for users, it cannot do everything by itself. Besides creating a consistent narrative, in order to have users completely immersed in an experience, it is necessary to build scenarios to make them feel that they are truly living and making the tasks we need them to perform. Also, it may be risky to make project decisions based only on user interaction with the product prototype without an understanding of the context of use of the product - that is why the prototyping of the scenario is essential for the completeness of the experience and the identification of the contextual factors that direct the use of the product.

The low-resolution prototyping of the product/service is necessary not only to test functionalities, ergonomic issues and other aspects of the product itself but also to investigate the meaning this product has to the user and how relevant it is in the user's life. As the low-resolution prototypes has the advantage of bringing a playful aspect to the experience, the user feels more comfortable doing the simulations and easily talks about their perceptions, motivations, and concerns. So, after creating the experience narrative, we build scenarios, devices, and what else is necessary to make the story happens. As in this phase, we already have protocols and scripts done, we need to think about how to make the planned flow possible and what kind of scenario will be assembled.

In our past experiences using this method, most of the time our focus is on testing technologies and understanding how people interact with it. So, we need to build an environment where these products would really take place. For us, this is where the storytelling makes sense. All the interaction we planned is tested when a user interacts with a real size prototype and express their behaviors, beliefs, doubts, and concerns about the product/service they are testing.

Using low-resolution prototypes at this point of our method allows us to make users live the interaction in a simulated environment where they feel free to express themselves. As said before, because we are using simple and cheap materials, interacting in a simulated environment, the participants do not feel the pressure to like the product or any resentfulness in telling what they are really thinking. These insights are very valuable when defining projects directions.

Simultaneously with the low-resolution prototype construction, we define the media recording set - that can be in video, audio, and photography, for example. It is interesting to do that while the prototypes are made, to choose the best angles to position the cameras aiming for a better recording of facial and body expressions of

participants, but also to not make the user uncomfortable with being recorded. This material will be really important when the analyses phase starts.

The use of narratives and low-resolution prototypes allows us to make more certain decisions when it comes to product/services directions. We know it is possible to make products validation only using storyboards (or any other method), but in order to simulate the real experience, low-resolution prototypes are necessary. People can imagine scenarios and tell how they would feel. However, living a simulated experience will get deeper on feelings and behavior, because the participants are not thinking about what they would do in a hypothetical situation. In this case, the participants are living it, and behaving in a really close way to how they would do in a real situation.

Findings and discussion

In eight applications with this method, it was possible to collect feedback from 180 participants about their perceptions and feelings. On that, 75% of participants reported they enjoyed immersing themselves in experience simulations to evaluate them. The fictitious built scenario and products, the script (storytelling) conducted by the researcher and the clear willingness of the researcher for the user's contribution in imagining, were mentioned as facilitators for evaluating the experience. Besides that, 60% of the participants mentioned that despite being a visibly fictitious ambient, the environment gave them a good sense of reality.

We noticed that the playful aspect of low-resolution prototyping allowed the user to feel more at ease to express their perceptions and opinions, without suffering unconscious influences derived from brands or products already known by him. By simulating interactions with simple prototypes, the comments made by the participants become more spontaneous, without much prior elaboration before the speech, and therefore more reliable to their feelings and opinions. Moreover, the recognition of the real environment associated to the playfulness of its look helped them to imagine unknown situations. One of the participants said *"It was beyond my expectations, I was really able to feel in a real environment, in my own bathroom, and I felt stimulated to imagine interactions I don't have nowadays"*. Another one said *"I felt I was immersed in a real situation that felt concrete, even though I was simulating technological interactions with pen and paper"*.

There are probably two main reasons for this. The first one is connected to the playfulness of the scenario, which gives people the feeling that this is a product under construction and they can really contribute to it. The second reason is related to user's ideation. Because they are not in a real environment, they are not limited by what already exists or it is possible to create. One of the participants mentioned that there is a lot of difference between simulating it in a real environment or in one made of cardboard. He felt freer to express his ideas because everything was possible, an argument already brought by Savoia (2011), when he approaches the concept of pretotyping.

The use of storytelling to predefine narratives aims to tell stories that will be experienced by users in a relevant way to assist them in their immersion on the simulated experience, involving the interaction with the product being validated and sharing ideas and knowledge in a persuasive way. In this sense, storytelling is essential for the experience to take place in depth. When the storytelling is followed by low-resolution prototypes it makes it possible for participants to really immerse on the experiment. The big advantage of it is to let the user finish the story that is being told. When they are performing the activities, they can imagine this situation in their daily lives, and express how they would behave and feel when actually using these concepts (or future products) that are being validated. For Liedtka (2018) this is probably the surest route to win consumers support and involve them in the process of generating ideas, in order to improve solutions.

It was also noticed that the use of low-resolution prototyping brings advantages even before the stage of application of the simulations with users. Considering that this is a quick way of materializing ideas, the design of prototypes helps design teams to see more clearly the product/service they are designing once they "build to think". In this way, when building the prototype, the designers can imagine different situations of use that can interfere in the experience of the user, being possible to ponder possible qualities of the prototypes. The act of building becomes part of the process of ideation. Still, from this perspective, the low-resolution prototyping is advantageous within the proposed method because it allows numerous iterative cycles. Paraphrasing Savoia (2011), one can thus fail faster, recover quickly, make necessary adjustments and restart the experiment cycle - and with this process, find out what the real value that the product or service in question has for the users.

Finally, one of the interviewees stated that even though he was working in technology, the experience was valuable to make him think about things that are indirectly related to the interaction, such as issues related to privacy, trust and data storage that could influence features in the product development process. So, the creation of basic, low-cost artifacts that will capture the essential features of users experience results in more-accurate assessments of value, because helping people “pre-experience” something can stimulate this type of feeling (Liedtka, 2018).

Final considerations

The use of narratives, prototypes, and simulations are important factors in the process of getting the user immersed in the experience, which leads to co-creation since it encourages the user to talk more about their perceptions, opinions, feelings, and ideas. As people are driven by a fear of mistakes, they focus more on preventing errors than on seizing opportunities (Liedtka, 2018). So, living experiences in simulated environments can output that. Besides that, low-resolution prototypes represent low costs in terms of material and technological resources, which enable new applications of the experience simulation whenever necessary in the product/service development process, making it easier for the whole team to restart when necessary.

As for the context of the application of low-resolution prototyping, this has been used in investigations in the field of technological products, which have physical objects and different environments of use. However, the potential for the tool is also perceived in the context of service design, with the same intention of simulating experiences. In addition, even though prototyping was described as a tool to be used specifically in the “plan” and “action” phases of the presented method (when the simulation of the experience is constructed and applied), it is strongly recommended to be used in other phases of the method. Considering the previously mentioned premise of "build to think", prototyping can be used in other phases where it is necessary to ideate about the problem or make representations that help the design team think or present a concept.

Moreover, we can highlight storytelling as an important tool used in conjunction with prototypes. Scripts are elaborated to all moments of user participation in the simulation, from the arrival of the user to the research site until their exit, in a dynamic and active way. They are used as interactive guidelines for the interactions and happen during the simulation like a conversation between the researcher and the user, which is engaged to the point that he or she feels part of the narrative. These guidelines purposely do not bring too much detail, so the user will fill the gaps with their own imagination, adding to the story pieces of evidence that will influence the design of the experience. The combination of both tools gives the researchers a qualified amount of data that covers what the users consciously speak, automatically does and unconsciously expresses.

It is understood that within the presented method, the construction of prototypes of products and its environments have important sub-phases that can still be explored in future studies. The application of different techniques for the construction of narratives, and the insertion of new tools to support research still present potential for study and detailing in future publications. Also, we can go further on understanding the differences in having a narrative that the user can finish when experimenting or have a complete narrative with the end already defined previously by the researcher.

Involving the participant in the low-resolution prototyping construction could also be a research phase. This would make co-creation reality in different phases of the method and not only the results that come from the experiment would have the users look, but the whole planned experience. Although this method has been used several times in the context of our projects, there is still space for more testing. More methods and tools can be incorporated into each phase. However, we claim that the application of our method can definitely be a first step to co-create and get insights for projects in different areas. It can be used by small companies and in projects with low budget and short time.

Finally, design role as a main contributor for innovation is a clear point (Acklin, 2010; Bertola, Vacca, Colombi, Iannilli, & Augello, 2016; Brigitte Borja de Mozota, 2015; de Goey, Hilletofth, & Eriksson, 2017; Kumar, 2009; Liu, Liu, & Zhang, 2018; Moroni, Arruda, and Araujo, 2015; Tidd and Bessant, 2013; Verganti, 2006; von Stamm, 2003), and design-driven innovation involves an understanding that people do not buy products and services, but meanings (Verganti, 2006). In this context, using a user-centered research method is an easy way to complete the task of finding meanings. Using the proposed method, companies will be able to identify the value perceived by customers, and by iteration phases, create a better experience.

Service Design Creating Value for Industrial Corporates through AI Proofs of Concept

JYLKÄS Titta[ab]*; KUURE Essi[a] and MIETTINEN Satu[a]

doi: 10.33114/adim.2019.08.322

The field of service design has set practices that are useful during servitization transformations intended to help businesses respond to customers' rising expectations regarding the value of the service experience itself. As businesses increasingly pursue service development alongside product development, they need new ways of working and of evaluating solutions. Simultaneously, technological advances open avenues to new services and ways of interacting with customers. This paper draws on two workshop case studies of artificial intelligence (AI) assistant projects to examine service design in the industrial context. Through these case studies, the paper illustrates how proof of concept (PoC) is used at different project stages and explores how service design can support creation of PoCs in large industrial corporate contexts. The findings reveal the aspects of PoC as embodied experiencing of intangible AI concepts, the creation of PoCs through conversations, and the role of PoCs in industrial service design process.

Keywords: industrial service design, proof of concept, AI assistants, embodiment, corporate context

Introduction

Service design plays an ever-increasing role in industrial corporate contexts. This paper explores how service design can add value by creating proofs of concept (PoCs). A PoC is 'evidence, typically deriving from an experiment or pilot project, which demonstrates that a design concept, business proposal, etc. is feasible'.[1] As a way of concretising early-stage ideas, PoCs play an important role in the industrial service design process, helping to communicate the intangible value of service concepts. This paper asks how service design contributes to creating PoCs in industrial corporate contexts.

Service design has become increasingly important in industries that previously focused on manufacturing, reflecting the long-term trend of economies that focus on the exchange of services beyond exchange of physical goods (Vargo & Lusch, 2004, 10). This shift affects companies' production, strategies and structures, and many organizations have begun to expand their businesses by offering product-related services and gaining increasing revenues from service business (Lightfoot, Baines & Smart, 2013). For companies engaged in such change, service design introduces design thinking and processes to the development processes, products and services of the company as well as to the company's employees. The use of design has evolved in industrial contexts beyond actual product or service design to become one of the skills required for multi-professional innovation and for running a service business. The role of design is important in contributing

[1] https://en.oxforddictionaries.com/definition/proof_of_concept

facilitatory methods that enable teams to use creative confidence and expertise when creating new service-driven solutions.

With advances in 'servitization' (e.g. Lay, 2014) and 'servitizing' (Gray, 2013), companies must transition to delivering services successfully through product-service systems (PSS; e.g. Guidat et al., 2014). Creating valuable offerings within this context requires organizations to change their business models, processes and procedures as well as shifting the mind set of their employees and the nature of their relationships with customers and suppliers (Roy & Baxter, 2009) towards service-oriented innovation. Service design practices support and co-create this change; the service designer must synthesize solutions based on comparison of different needs, points of view and socio-cultural models (Morelli, 2003).

The concurrent development areas of service design are often complex and abstract, even in industrial contexts where services are connected to a physical product. It can be challenging to track and quantify services that are experienced subjectively (e.g. Meyer & Schwager, 2007), and methods of understanding user experiences in non-numeric ways can support the development and evaluation of service offerings. The availability of many competing services means that customers increasingly expect both high-quality content and interaction and around-the-clock convenient service access. Digital service channels allow companies to continuously serve customers, and advances in technologies like artificial intelligence (AI) make it possible to engage users in conversation with no actual human involvement on the service provider side. The intangible nature of AI-enabled conversational service interfaces, such as AI assistants, requires service value creation to take on new forms. Service design methods used for concretizing and making it possible to experience such intangible solutions are important means for developing concepts for new technologically enabled services that can be tested and evaluated.

As industry's use of service design increases, new ways of understanding the design process are needed to support implementation and maintenance of services in different organizational departments. One of the challenges relates to how newly generated ideas, concepts and solutions can be communicated, shared and implemented more efficiently and transparently in large, multinational and department-focused companies. One way of supporting service design in such contexts is the execution and use of PoCs. PoCs can be used in different phases of the service design process, from ideation to testing, to demonstrate the value of a product or service (Rauth et al. 2014).

The remainder of this paper is organized as follows. First, the paper presents an overview of the current state of service design work in large industrial corporations. Then, the paper introduces findings from two workshop case studies that consider the creation of PoCs in AI assistant design projects. By focusing on service design methods, the paper discusses the two case studies as examples of how PoCs have been used at different stages of the industrial service design process. The first workshop case study illustrates how embodiment and drama may be used to develop a PoC AI that is intended to create a new type of customer-AI interaction. Specifically, the case study explores voice interaction and conversational interface as a means of proving a concept's viability. The second workshop case study also utilizes AI as a base technology: a PoC of a chatbot is tested via involvement of potential users. Three main topics emerge from the analysis of these two workshop case studies and are presented in the findings: embodiment in experiencing the intangibility of AI assistants, service value through conversations, and PoCs in the industrial service design process. The paper concludes with lessons learned from the case studies and reflects them to define the role of service design in industrial contexts.

Service Design in Industry

Industrial service design refers to service design practiced in an industrial context, often inside an organization. According to Miettinen (2016), 'industrial service design is embedded in existing corporate structures and processes', where the service designer negotiates and initiates service design within the frame and constraints set by the organization. Industrial service design supports transformation towards more agile working methods and an iterative process for service development, enabling the organization to meet increasing demands from customers and the service market. To enable this, service design thinking must be a cross-cutting process that supports lowering of silos and flattening of hierarchies.

Beyond the traditional 'double diamond' model of the design process, Miettinen (2016) identified the following steps in the industrial service design process: (1) the pre-process, including strategic thinking and internal marketing; (2) running pilots with the team; and (3) scaling up the service solution. Service design in

the industrial context must be highly adaptable to find its way into the everyday practices and processes of existing design and innovation teams. The adaptation of service design in an organization is needed to support human-centred thinking and the creation of customer-oriented service journeys.

In industrial contexts, the service design process rarely begins from a predefined brief; rather, it typically involves a process of strategic thinking and collaboration within the organization, culminating in a project description. Before a project gets underway, it must be aligned with internal stakeholders and decision makers. This commonly involves presenting the project's goals and objectives, as well as outlining the resources required, to groups of stakeholders before a decision is made to proceed with the project. For this purpose, it is also helpful to be able to demonstrate that the project has business potential and can address real needs.

In seeking project approval, service designers often initiate PoCs or pilots to demonstrate the viability and feasibility of a topic, idea or concept. During piloting, it is important to refer to the original strategic alignment and planning to ensure that the project is moving in the right direction. The scope of a pilot or PoC can vary: PoCs are often small-scale or short-term efforts that enable the team to assess certain features of the project, while a pilot often follows more detailed concept development. Pilots are usually a test phase involving a limited number of users and often a limited set of service features. PoCs and pilots enable the team to identify both limitations and opportunities for development and support refinement before scaling up to a public customer solution.

Depending on the organization, scaling up may include internal processes such as IT development and data security. For the service designer, it is important to know the required steps inside the organization in order to successfully scale the service and launch it for customers and responsible business units. Beyond individual services, the challenge is often to see the big picture of individual service actions as a sequence of touchpoints that may seem disconnected from an industry perspective but make more sense as a single process for the customer. According to Miettinen (2016), a 'sequence of well-designed actions constructs a unified service experience', and a customer experience framework can be used to develop services and touchpoints within a unified service system.

AI Assistants

AI has been in development since the 1950s, but advances in AI in the past decade have made it more visible to the general public. While AI still exhibits a rather narrow definition of intelligence, it has proven valuable in the field of digital services. AI streamlines the analysis of large amounts of data and provides new ways for humans and machines to interact, such as AI assistants.

An AI assistant is a virtual system that utilizes AI technology to understand a customer's request based on written or spoken words. The assistant can also function as a service interface (Shevat, 2017) to support users in everyday tasks (Jolley, 2016; Afshar, 2017). The technology underlying AI is used to understand human behaviour and needs, and to allow the AI assistant to communicate responses back to users via conversations using natural language. As AI assistants such as Siri from Apple and Alexa from Amazon have begun to infiltrate the market in recent years, brand and service interaction is transitioning from touch-based interactions with applications towards conversational interaction (Gartner, 2016).

An AI assistant can take many forms and play many roles in delivery of a digital service. Frontend services can be facilitated through an AI assistant interface that is in direct contact with users, simplifying user tasks such as getting info on your next trip[2], ordering items[3] or organizing meetings[4]. In other cases, an AI assistant can be a backend resource, for example by assisting a human service agent in accessing relevant information, carrying out rapid analysis or giving suggestions on service actions based on accessible data (Gartner, 2019).

Regardless of the role, each type of AI assistant has a clearly defined purpose with regard to how it contributes value to a service. To achieve its purpose, an AI assistant requires a certain level of intelligence and ability that allows it to understand the user's need and respond to that need accordingly. Creating an AI assistant involves multiple aspects beyond the technology. An AI assistant commonly comprises selected service functions, the

[2] Many travel agencies such as Expedia and airlines like KLM have a chatbot for providing travel information to their customers.

[3] For example, Amazon Alexa.

[4] For example, x.ai (https://x.ai).

information provided or collected, frontend customer interface(s) including voice, text and visuals, and the assistant's character as well as the required technology and intelligence in the backend. As an AI assistant is likely to be seen as the voice of a brand, it is important to consider what expectations and meanings it creates for the brand. In other words, an AI assistant's character and behaviour are likely to influence how the brand is seen by customers.

Designing the assistant's character includes defining its personality, behaviour, appearance and tone of voice. In many cases, the assistant is also given a name and a backstory that defines who it is and how it behaves. All the designed aspects of an AI assistant are eventually communicated to users primarily through conversations. Compared to other digital service interfaces, such as websites, apps or display screens, an AI assistant relies primarily on spoken or written language.

Research methods and data

The research data come from two workshop case studies and includes images, field notes and documented personal reflections of the authors as service designers in the workshops. Both of the workshops were held with one large international organization but each had a different focus in terms of purpose, process, outcomes and people involved. The workshops were facilitated by service designers; Case Study 1 was run by internal service designers, while Case Study 2 included external service design support.

Table 1: Description of workshop case studies

	Case Study 1	*Case Study 2*
Focus	Future-oriented concept for AI assistant	AI assistant for customer service using a chatbot
Workshop description	1 day 12 participants Internal	1 day 6 users External
Workshop aim	Ideation and development of a concept	Testing of initial version of AI assistant with potential customers
Key methods	Personas Future visioning Role-play	Usability testing
Purpose of PoC	To prove the potential of new business areas	To prove user acceptance and to collect feedback for further development

- Case Study 1 focused on the creation of a future-oriented concept for an AI assistant. The workshop was constructed around a common view of a service landscape and future scenarios in order to explore the boundaries and possibilities of solutions that the case organization might offer to their customers. The content of the envisaged solution was created through customer journey enactment and mapping.
- Case Study 2 was a customer workshop held as part of a project to develop an AI assistant. Six potential customers were invited to participate in the workshop to test the initial concept by exploring content areas covered by the assistant and trying out the conversation interface. The workshop was an important step in proving that the concept could meet customer expectations so that a finished product could be developed.

As this paper's primary concern is to analyse workshop processes in order to study the constructs that constitute a proof of concept in an industrial service design context and AI-enabled services, further detail about the content and topics of the projects is not of immediate relevance. This also preserves the confidentiality of the workshop content and outcomes. The following three sections describe the findings emerging from analysis of the workshop case studies and discuss the roles and aims of the PoCs in each workshop.

Findings

Embodiment in experiencing the intangibility of AI assistants

The goal of the first workshop was to better understand users in future service settings where an AI personal assistant can enable new types of services. The workshop initially adopted an ecosystem perspective to develop a common vision of the scope of service opportunities the company might seize within the projected timeframe. Based on three future scenarios, this service ecosystem (Banoun et al., 2016) was used to frame ideation of the assistant and the customer services it might offer. Common methods of enhancing the exploration of possibilities for service interactions include experience prototyping (e.g. Buchenau & Fulton Suri, 2000; Rontti, 2016), role-playing (e.g. Iacucci, Kuutti, & Ranta, 2000), bodystorming (e.g. Oulasvirta et al., 2002) and service prototyping (e.g. Blomkvist, 2014; Rontti et al., 2012; Miettinen et al., 2012).

The method of role-play was used in the workshop in combination with pre-defined persona profiles (Blomqwist, 2002). The characteristics of the personas guided the workshop participants to take on roles as users in the role-play and explore through embodiment the actions and reactions the user might have in the future service situation. As a starting point for ideation, participants listed possible tasks that the persona might undertake in their everyday life. The tasks were then taken into the SINCO (Service Innovation Corner) service stage (Miettinen, Kuure, Rontti, & Lindström, 2012), using digital backgrounds, sounds and physical props to set a scene for a service situation. While situations from the customer journey were acted out, one participant would adopt the role of the AI assistant and would be visible to the 'customer' only through its voice and selected visual cues. The insights and ideas developed through this enactment were collected and used to generate a user journey map (Temkin, 2010) showing possible user actions, the function of each service, and the interaction between the user and the AI assistant.

Embodied design methods were instrumental in understanding the interactions and proving the value of the service from a customer perspective. Technologies people use in their everyday activities fundamentally shape how those activities might be done, and it is thus critical for designers and participants to understand those practices (Robertson & Simonsen, 2012). Although the workshop was internal to the development team and actual potential users were not involved, the enactment of service situations enabled the participants to adopt the user's point of view and thus experience the service situations from the user's perspective. Role-playing is widely recognized as a powerful method for observing and discovering aspects and elements of service (Buchenau & Fulton Suri, 2000). However, empathizing with someone else's role differs from using experience prototyping to experience the service subjectively for oneself (Miettinen et al., 2012). Previous studies have also confirmed that it is beneficial to involve company representatives directly in acting out new service concepts. This deepens their insight into the new idea and into the user experience, enabling them to evaluate the service experience from the user's point of view rather than as an outsider.

In AI assistant services where service content may only be expressed through language, it becomes crucial to involve the user in the design and development process. Creating a PoC for the assistant is one way to collect relevant user feedback to enable an incremental and iterative design and development process. As an element of service delivery, an AI assistant is likely to appear somewhat abstract, and without a concrete embodiment of the solution, it may be difficult to convey what it might be like to interact with such a service entity. In this case, the embodied service situations can be considered as proofs of concept. The workshop focused on potential services five or more years in the future based on assumptions of certain improvements in AI technology. Therefore, participants also had the freedom to imagine interactions that current technology might not yet support. Because the technology does not yet exist, it was considered more efficient to first prototype and evaluate the interaction through human-to-human role-play. This kind of exploration leaves space for improvisation and new findings, which human-centred service design encourages (Penin & Tonkinwise, 2009).

Service Value through Conversations

The second workshop was part of the process of designing an AI assistant for customer service support. The overall process followed the steps of use case definition for the assistant and design of the assistant's personality. The use cases were transformed into conversation flows in a website chat window that used the final technology but did not include the final user interface (UI) design. Six potential users were invited to the workshop to test the initial version of the assistant and to offer feedback to inform future development. The

test version of the assistant included AI skills for natural language understanding and processing, enabling the assistant to understand the user's needs and match those needs to defined responses or specific conversation flows. Six different use cases were included in the conversation content that underwent usability testing.

The aim of the workshop was to evaluate the service value an AI assistant can bring to users in the form of language. Character design elements, such as personality and traits, were included in the proof of concept along with the conversation content. The participants were asked to provide feedback on how they perceived the assistant's appearance and personality—for example, its level of politeness and use of words—and the value of the content it provides. Using laptops, participants tested the assistant on a test website through a chat window. Before starting the interaction with the assistant, a service scenario with a specific user goal was explained to the participants; they were then asked to start a text chat conversation with the assistant in whatever way they considered appropriate to the situation. The conversations were logged, and later in the workshop, the conversations were analysed and discussed together with the participants.

Providing service content purely through machine-generated conversation is still a rather new format for service providers. In order to test and evaluate the value of such service content, a PoC with the actual technology provided a means of communicating the content to users and receiving their feedback. The tests revealed the limitations in the content and conversation flows but also confirmed customers' willingness to interact with an AI assistant when it offers them concrete value. This might include simplifying a service process, taking over tasks that would otherwise require more effort on the part of the customer or providing easy access to information that might not otherwise be available to the customer.

PoCs in the Industrial Service Design Process

PoCs can serve multiple purposes in the service design process. In the first case study, a PoC was used as a form of ideation together with embodied design methods; it was also used to provide evidence of the intangible value of the AI assistant. The workshop was located in the discovery phase of the service design process and was used to collect more information about the possibilities of a service area that could be covered by an AI assistant in the defined future setting. As the workshop was also intended to communicate the potential value of the project to internal stakeholders, it can be also connected to the 'pre-process phase of strategic thinking and internal marketing' identified by Miettinen (2016) as one of the characteristic steps of the industrial service design process.

PoCs can support internal team communication. Design activities involve not just thinking or pure creativity but also communicating what design is or what it could be in ways that are understandable to others (Knight, 2012). Industrial service design supports understanding user actions and technologies in actual settings collaboratively and pragmatically rather than through abstractions. This supports mutual learning (Kuure & Miettinen, 2013) and idea sharing. Through improvisation and spontaneity, service design can work as 'communicative activities in ordinary conversation inside the organisations´ (Larsen & Friis, 2005). In the workshops, the use of PoCs that could be experienced allowed the participants to work from the same page, enabling easier, faster team work. After the workshop, the PoCs were also used in internal communication in the company to help other stakeholders understand the aims of the project and to generate the support needed to gain management approval to continue the project.

PoCs are often used as fast, efficient small-scale tests. They do not need to be publicized but can remain internal to the organization and can be used to further define the future direction of service development. Therefore, they are also useful prior to larger scale pilots that require the service to be in a close-to-finished state and that require a larger group of users involved in the testing. Running pilots is one of the characteristics of industrial service design processes (Miettinen, 2016), and this is where the second workshop case study can be located.

When the service is delivered through a conversational interface with an AI, the ability to experience the PoC is important in understanding how the service answers the needs of the user, how the value is created and delivered, and how the interaction fits as a service action with the larger view of the service journey the organization provides to their customers. An AI assistant can be seen as a single service touchpoint that complements the other steps in the service journey. By keeping in mind the larger picture, including the connections to other service actions, throughout the service design process, designers can ensure that the AI assistant has an established and verified place in the service offered to the customer.

Discussion

The workshop case studies show that PoCs serve different purposes at different stages of the industrial service design process, allowing the investigation, for instance, of customer needs, business potential, technical feasibility or the match between content and user expectations. Among the benefits of using a PoC in this context is that it provides early feedback from users or internal stakeholders about whether the project is going in the right direction. A PoC also makes the design target more concrete by giving it a functional form, whether through role-play or using the actual technology; such concretization enables stakeholders to discuss and evaluate the idea, concept, vision or strategy that the PoC represents. The case studies and the use of service design to illustrate these features in PoCs are a valuable contribution to industrial service design research (Miettinen, 2016). Further, including PoCs in the service design process adds value to experience prototyping (Buchenau & Fulton Suri, 2000).

Clearly, design PoCs also have some limitations. As they often demonstrate only one part of a wider solution, it is arguable whether a design PoC provides a sufficient basis for decision making. One PoC alone may not prove the case for an entire project, making it crucial to understand how and why the PoC is created in the first place. Especially in industrial contexts, winning the support of partners and internal sponsors is crucial for project continuity (Miettinen, 2016). To secure support for a project, it is essential to know what speaks to the relevant audience.

Depending on the decision makers and the design process stage, the focus of PoCs must be adjusted to acquire the insights needed at that particular step in the design process. At the outset, customer feedback on the initial idea may be the most worthwhile first step; PoCs with preliminary UI ideas can help to trigger customer comments and feedback. At the development stage, a technical PoC integrating a 'click dummy' prototype may offer more insights for addressing development backlogs. In many cases, a PoC is also used simply to assess the adaptability of existing technologies or service solutions to the concept.

Use of a PoC in industrial service design is an iterative process, and several PoCs may be needed before reaching a final concept and implementing the solution. Ultimately, based on the project stage, the project team must define the aim of the PoC, how it should be built to achieve that aim and how success of the results will be measured. As noted above, creating PoCs can be a crucial step in ensuring project continuity as it can provide concrete proof of areas of opportunity. Nevertheless, a PoC may not be comprehensive in itself, and combining it with other forms of insight such as customer testing, market research or business analysis can provide the information needed for decision making in relation to project direction and further development.

A variety of skills are needed to develop PoCs appropriate to the project stage. In addition to service design skills, technical expertise is necessary to create PoCs of the requisite quality, especially for digital service channels. A good sense of what is technically possible and the best means of achieving project goals with the available tools and skills is also important. What can reasonably be tested, what form of PoC best fits the project stage, and how to connect the process of creating a PoC to the existing organizational processes should be determined through collaboration and discussion among the project-owning business unit, service designers and technical experts.

Conclusions

Proofs of concept play an important role in AI assistant design projects, as they allow evaluating, testing and communicating the value of services. Service design supports the creation of design PoCs by incorporating the views of different stakeholders into clear goals through concretization and visualization and by facilitating collaboration among involved teams and experts. By introducing service design methods for ideation, prototyping and testing, insights and learnings from PoCs can help designers articulate concrete opportunity areas, development requirements or action plans for a project's next steps.

Depending on the intended purpose, a PoC may be more technical; in such cases, the role of service design is to keep the customer viewpoint in mind, avoiding technology-first development that risks developing solutions with no clear usability target. The strengths of service design include an understanding of customer needs and expectations, and the ability to utilize that knowledge to evaluate PoC outcomes plays an important role in clarifying insights and incorporating them into the project's next iteration.

Drawing on two examples of the use of PoCs in AI assistant projects, this paper illustrates how the purpose of a PoC can vary according to the project stage and goals. There is a tradition of utilizing PoCs in fields such as

business and IT development; in industrial contexts, where projects are often interdisciplinary, it may likewise be useful to have a tool that has a common meaning for everyone. At the same time, the tool can be used in different ways, and service design can open new opportunities by introducing methodologies such as embodiment to deliver concrete and meaningful outcomes without significant investments of time and money.

As the data set of the paper is limited to two case studies, further research is needed to show the full potential of using PoCs in the design of AI-enabled services in industrial contexts. However, the research shows the value of AI PoCs in the discovery, ideation and testing phases of AI assistant projects. PoCs can concretize intangible AIs and allow users and stakeholders to better understand the meaning of conversational service delivery. They can also point the way to further development directions for the solution. In the future, AI PoCs might also support earlier and more direct involvement of users in industrial service design projects through digital channels, thus overcoming the organizational boundaries that typically exist today.

Disruptive Innovation Ecosystems: Reconceptualising Innovation Ecosystems

NTHUBU Badziili*; RICHARDS Daniel and CRUICKSHANK Leon

Lancaster University, United Kingdom

doi: 10.33114/adim.2019.09.318

Ecosystems are valuable in creating diverse and collaborative environments that enable businesses to innovate in ways that are much more difficult without them. However, business managers can be reluctant to participate in building ecosystems mainly due to lack of understanding. Specifically, businesses can be uncomfortable sharing resources, data, intellectual property and secrets with other ecosystem actors. Drawing on inter-disciplinary perspectives from literature, we use a 'design focused ecosystem thinking' to propose a new type of Disruptive Innovation Ecosystem (DIE). Firstly, we discuss the significance of adopting innovation ecosystems to create shared value. Secondly, we conceptualize a new type of DIE and propose steps on how DIEs can be created and fostered. Finally, we discuss DIE roles in relation to Amazon, Apple, Uber, and Siemens ecosystem cases. This paper offers a new type of DIE design process which may be leveraged by businesses towards building sustainable innovation ecosystems.

Keywords: Innovation ecosystem, Disruptive Innovation, Disruptive Innovation Ecosystem, Design, Shared Value

Introduction

The word 'ecosystem' originates from the domain of biology, and it defines the interaction and interdependence of living organisms within their environment (Jucevičius & Grumadaitė, 2014; Ferdinand & Meyer, 2017; Su, Zheng & Chen, 2018). In business, an ecosystem is defined as a network of actors who are guided by shared goals to create market and customer-focused solutions (Lyman, Ref & Wright, 2018). Recently, business and innovation literature has started to use 'ecosystems' as metaphors to explain the process of innovation (Shaw & Allen, 2016), subsequently leading to the ubiquitous use of the term 'innovation ecosystems' which means the constellation of actors connected in a web-like system to co-create, deliver and appropriate value (Hwang & Horowitt, 2012; Iansiti & Levien, 2004; Rabelo & Bernus, 2015; Tsujimoto, Kajikawa, Tomita & Matsumoto, 2017; Lyman et al., 2018; Russell & Smorodinskaya, 2018; Dedehayir & Seppänen, 2015; Dedehayir, Ortt & Seppanen, 2017).

Innovation ecosystem actors collaborate to offer innovations in the form of new systems, new products, technologies and services to customers. Wal-Mart, Amazon, ALIBABA, Apple, eBay, Google, and Microsoft are some of the few examples of firms who successfully applied the concept of innovation ecosystems in the past (Lyman et al., 2018). The internet makes it easier for larger and denser innovation ecosystems to grow in ways that were more difficult without the internet (Rong, Hu, Lin & Shi, 2015; Zhongmin, 2018; Wu, Wu & Si, 2016; Yan & Guan, 2018). In the context of this study, we discuss innovation ecosystems as systems of shared value

creation. However, before we discuss innovation ecosystems lets look at how Chesbrough, Vanhaverbeke, and West (2008) describe open innovations:

> *The use of purposive inflows and outflows of knowledge to accelerate internal innovation, and expand the markets for external use of innovation, respectively. (Chesbrough et al., 2008, p. 2).*

Chesbrough et al., (2008) claim that opening the innovation process by leveraging information flows from outside firm boundaries and sharing data with other actors and or competitors can profit the firm, and Cruickshank (2014) expand on the claims by signaling the significance of managing information flows to increase profit. Consequently, opening the innovation process to create shared value is achieved through innovation ecosystems. Best and Koria (2017) posit that shared value is the unexpected solutions arising from innovation ecosystems. We continue from the latter perspective and Rabelo and Bernus (2015) innovation ecosystem life cycle processes. To support these ongoing works of building sustainable innovation ecosystems, we follow a design focused ecosystem thinking to develop a new kind of DIE associated with mutual survival of innovation ecosystem actors within disruptive environments. Disruptive innovation occurs when established customers of mainstream products, services or systems leave and start using a different offering, often produced by a less established company (Valkokari, Seppanen, Mantyla & Jylha-Ollila, 2017; Christensen, Raynor & Mcdonald, 2015; Christensen, 2013; 1997).

Ecosystems empower businesses to innovate together to create shared value (Lyman et al., 2018; Senyo, Liu & Effah, 2019; Adner, 2017; Russell and Smorodinskaya, 2018; Bosch and Olsson, 2018). However, as higher numbers of actors become interconnected, interrelationships can become unclear and evolve in unpredictable ways (Gomes, Facin, Salerno & Ikenami, 2016). Real-world ecosystems provide a milieu of interconnected actors where businesses can leverage vast resources to create new offerings. Nevertheless, how designers and business leaders use innovation ecosystems to develop sustainable offerings is less understood (Shaw & Allen, 2016; Lyman et al., 2018). Specifically, managing disruptive innovations within ecosystems remain a significant challenge (Gomes et al., 2016; Dedehayir et al., 2017; Valkokari et al., 2017). It is essential to discuss the emergence and role of innovation ecosystems within business growth (Mortati & Cruickshank, 2011), and towards the delivery of disruptive innovations (Dedehayir, Mäkinen, & Roland, 2016). Best and koria (2017) opened a conversation around how silent designers may help create unexpected solutions from ecosystem ambiguities. These ambiguities are opportunities that are difficult to find through linear systems or models (Best & Koria, 2017; Lester & Piore, 2004).

While organizations are generally set up to create profits as their primary function (Russell & Smorodinskaya, 2018), throughout this paper, we emphasize that shared value associated with mutual survival of ecosystem actors is becoming crucial. Organizations and governments make huge investments across the globe towards the development of innovation ecosystems, but there is a dramatic shortfall in achieving set targets (Rabelo & Bernus, 2015). These shortfalls are partly ascribed to actor's insufficient readiness and lack of knowledge and awareness about operating within ecosystems (Lyman et al., 2018; Rabelo & Bernus, 2015; Iansiti & Levien, 2004). Since ecosystems are regarded as 'new thinking' for value creation in today's interconnected world (Russell & Smorodinskaya, 2018; Lyman et al., 2018), it is urgent to comprehend the process of innovation ecosystems in creating and delivering shared value. Lyman et al., (2018) and Senyo et al., (2019) observe that though some business managers appreciate the significance of adopting ecosystems, they can be reluctant to participate due to fear of relinquishing control and sharing resource, data and intellectual property with other actors or competitors.

This paper discusses some major innovation ecosystem challenges and conceptualizes a new type of disruptive innovation ecosystem (DIE), which may be a fundamental design process for DIEs. Secondly, we propose steps on how DIEs can be created and fostered. Through the ecosystem approach, we posit how DIEs may be fostered to emerge and create viable connections amongst entities by drawing insights from literature on ecosystem emergence and disruptive innovation (Gawer & Cusumano, 2014; Dedehayir et al., 2016; Iansiti & Levien, 2004; Adner & Kapoor, 2016; Adner, 2017; Christensen, Raynor & Mcdonald, 2017; Valkokari et al., 2017). Thirdly, we discuss and visualise ecosystem roles by using Amazon, Apple, Uber and Siemens innovation ecosystem case studies.

This paper is divided into four sections. The second section discusses innovation ecosystems and disruptive innovation concepts. The third section proposes a new DIE and visualises DIE roles. In the last section, we outline the main conclusions and future direction of the study.

Innovation Ecosystems and Disruptive Innovations

Challenges of designing viable innovation ecosystems

Innovation ecosystems can be useful for developing creative solutions to problems. However, thriving ecosystems often emerge organically and can be difficult to build from scratch. It would be vital to be able to design and build them from scratch, but the dynamics and behavior of innovation ecosystems can be difficult to understand (Roundy, Bradshaw & Brockman, 2018). To appreciate the structure of innovation ecosystems, it is generally explained in terms of either hub-centered star structures as shown in Figure 1(A), or flat mesh-like structures as shown in Figure 1(B) and are further elaborated in previous literature (Mazhelis, Luoma & Warma, 2012). This typology defines the power diffusion and challenges associated with managing connections within the ecosystem network roles which will be discussed thoroughly in the third section of this paper.

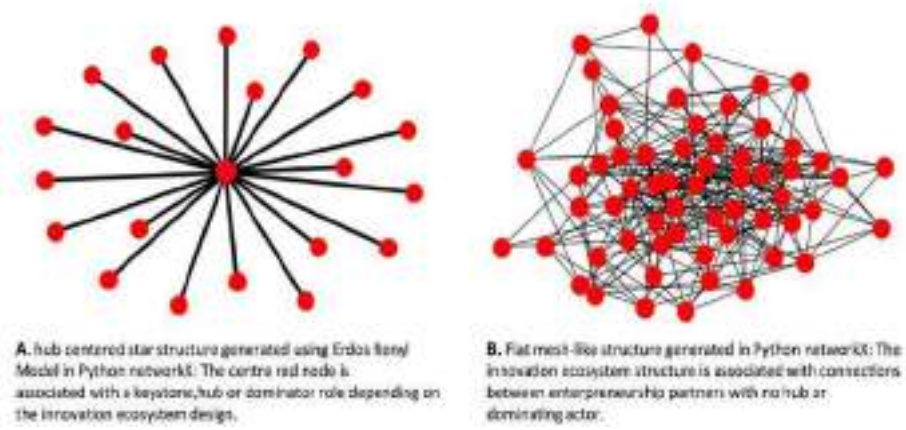

Figure 1: A typological visualization of innovation ecosystems: Showing A (star-shaped structure) and B (flat mesh-like structure).

Meanwhile, the openness of innovation ecosystems is usually seen as a management challenge more especially when dealing with many actors possessing different characteristics (Masys & Bennett, 2016), and contrasting socioeconomic and leadership models (Barile, Lusch,Reynoso, Saviano & Spohrer, 2016; Russell & Smorodinskaya, 2018; Mortati & Cruickshank, 2012). However, Best and koria (2017) argue that designers may leverage from these supposedly problematic areas of innovation ecosystems to create unexpected solutions and improve ecosystem adaptability. Adaptability in the context of our study means the ability of the innovation ecosystem to adjust to new conditions imposed by the external environmental forces. Innovation ecosystems are exposed to rapidly changing environmental factors (Hwang & Horowitt, 2012; Iansiti & Levien, 2004), and characterized by ambiguities (Ferdinand & Meyer, 2017; Best & Koria, 2017).

It is difficult for leading and incumbent firms to evolve their innovation ecosystems and re-design their systems to cope with disruptive innovation, some examples of failed ecosystems include Intel (Iyer, Lee & Venkatraman, 2006), IBM (Christensen, 1997) and Nokia (Iyer et al., 2006). The challenges affecting the evolution of business ecosystems also affect the development of innovation ecosystems, albeit more ambiguous. The ambiguity of innovation ecosystems is partly explained in Christensen's case study writings (Christensen, 2014; Christensen, 2013; 1997), though the author's theory is inclined towards creating firms competitive advantage instead of innovation ecosystems shared value creation. Christensen (1997) explains that incumbent firms fail to respond promptly to disruptions thus allowing entrants to grow and ultimately taking their customers. Market disruptions challenge the business as usual ecosystems, in most cases causing the ecosystem networks to collapse when faced with entrant disruptive ecosystems (Christensen et al., 2015). The impact of entrant disruption to actors connected to incumbent ecosystems seems to be unclear from Christensen's description (Dedehayir et al., 2017).

While innovation ecosystem challenges are well acknowledged in management research (Dedehayir et al., 2016; Lenkenhoff et al., 2018), disruptive innovation ecosystems related problems are less discussed and less

predictable (Dedehayir et al., 2017), although we argue that they are more intricate due to the complex nitty-gritty of managing disruptive innovations and innovation ecosystems. Hwang and Horowitt (2012) claim that innovation ecosystems need not be forced to exist, but rather emerge from a designed and shaped environment where they may thrive. The design and form of Innovation ecosystems are likened to the rainforest which does not predetermine the new biological species but provides the right environmental factors to foster emergence (Hwang & Horowitt, 2012; Shaw & Allen, 2016). Howkins share the same view and apply it to the emergence of creative ecologies (Howkins, 2010).

Identifying the right environmental factors for the design and formation of viable innovation ecosystems is one of the primary challenge confronting ecosystem designers today, just as it is challenging to plan for disruptive technologies (Christensen, 1997). In order to build successful innovation ecosystems, we need to consider the interdependence and interconnectedness of actors, individual actor models, strategic roles, evolution process, actor heterogeneity, and environmental factors. These are vital precursors for designing viable innovation ecosystems. These precursors may shift the attention from managing competition to coopetition as observed in (Isckia & Lescop, 2009; Ferdinand and Meyer, 2017).

To optimize shared value within innovation ecosystems, the theory of weak ties albeit old (Granovetter, 1973), may aid innovation and creativity within ecosystems. Mixing unreliable ties (weak ties) with reliable and established ties (strong ties) may provide new avenues for disruptive innovation (Cruickshank, 2010). The theory suggests that actors who are weakly linked to a network are most likely to provide the most valuable information for innovation as shown in Figure 2. However, in practice, weak nodes in networks are usually forgotten or ignored, but Hwang and Horowitt (2012) buttress that Google and Facebook were not distinguishable from weed in a rainforest or unwanted trees a few years ago, but today they are the most valuable amongst the search engines and social media platforms respectively. As shown in Figure 2, Ignoring the weak ties between IE-A and IE-C may lead to insufficient use of high-value data from both communities. Finding useful ways to take advantage of weak ties in designing innovation ecosystems is a great challenge and opportunity for designers.

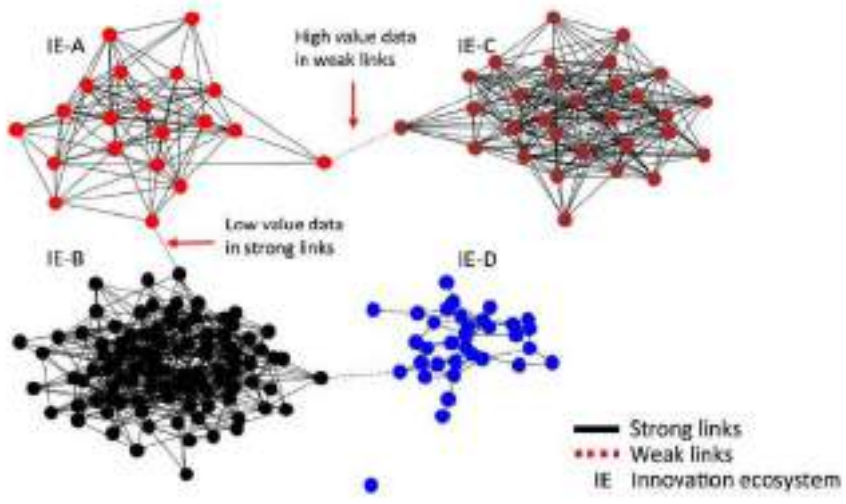

Figure 2: Visualisation of weak ties vs. strong ties: IE-A link to IE-C represents a weak tie which connects to information outside immediate group, hence, high-value data for innovation. IE- A link to IE-B represent a strong tie which connects actors to data within the group, thus present low-value data for innovation.

To address the challenges, we propose a new kind of 'disruptive innovation ecosystem (DIE),' which is a combination of disruptive innovation and innovation ecosystem constructs.

Disruptive Innovation Ecosystems (DIEs)

What is a DIE?

'Disruptive innovation ecosystem (DIE)' is proposed here as an innovation ecosystem capable of delivering disruptive innovations. James F. Moore was the first author to coin the term 'business ecosystem' which

according to Su et al., (2018) and, Gratacap and Isckia (2013) have been extensively applied to innovation management research in the past. Moore's concept of business ecosystems has continually evolved into explaining social networks and community structures (Ansari, Garud & Kumaraswamy, 2016; Su et al., 2018; Elena & Avasilcai, 2016; Gratacap & Isckia, 2013). Today, understanding interrelationships within SMEs, digital spaces, government policies, communities, and prosumers may be critical than ever before. Businesses are slowly harnessing the power of ecosystems in developing their business models (Lyman et al., 2018). Examples of bubbling disruptive innovation ecosystems are Uber and Lyft in the taxi business, Airbnb and Breather in hotel business (Libert, Wind & Fenley, 2014; Smith, 2016), and Apple iPhone in the smartphone business (Valkokari et al., 2017).

Though the theory of disruptive innovations continues to be explored in business management, business managers and strategists remain unaware of the possible remedies of disruptive threats in their incumbent innovation ecosystems (Christensen et al., 2015; Lyman et al., 2018; Khanagha, Ramezan, Mihalache & Volberda, 2018). While it is difficult to prescribe what needs to be done to tackle the disruptive threats from entrants' ecosystems as argued in (Ozalp, Cennamo & Gawer, 2018; Dedehayir et al., 2017), Christensen et al., (2015) suggests that instead of incumbent firms competing directly with entrant firms, they may consider forming separate divisions to explore new disruptive models. Furthermore, Khanagha et al., (2018) suggest experimentations with disruptive innovations. We submit that experimenting with DIEs requires a design process and designers to build the process. Who are these designers?, How can they design DIEs?, What roles may DIE actors assume?

Designers of DIEs

Designers are divergent thinkers (Hernández, Cooper, Tether & Murphy, 2018), and dealing with ecosystems is a problem of a divergent nature where designers may provide solutions to build sustainable DIEs. Therefore, a DIE designer maybe anyone with a divergent mindset, willing to look beyond the boundaries of a system towards creating customer experiences by leveraging DIE ambiguities. When designing DIEs, one cannot just look at individual actions, the designer influences the design of the holistic DIE environment and form that connects the actors to the same objective, attract new actors and ultimately enable DIE to emerge and thrive. The designer may be the brain behind innovation ecosystems, clusters, value networks, and other social network structures. Building this kind of DIE is not easy. Researchers previously proposed business ecosystem designs but to no definite agreeable structure (Gomes et al., 2016; Rabelo & Bernus, 2015; Valkokari et al., 2017), and developed tools for modelling innovation ecosystems (Walrave, Talmar, Podoynitsyna, Romme & Verbong, 2018; Talmar, Walrave, Podoynitsyna, Holmstrom & Romme, 2018). Challenges associated with DIE ambiguities may be addressed by following a DIE design process to create unexpected solutions. As shown in Figure 3, designers may use weak ties between communities of DIEs to leverage these relationship properties or recipes of design to create new solutions. For example, IE-F is weakly connected to IE-D, the two communities may use the weak tie as a bridge to leverage information on both sides to create new offerings.

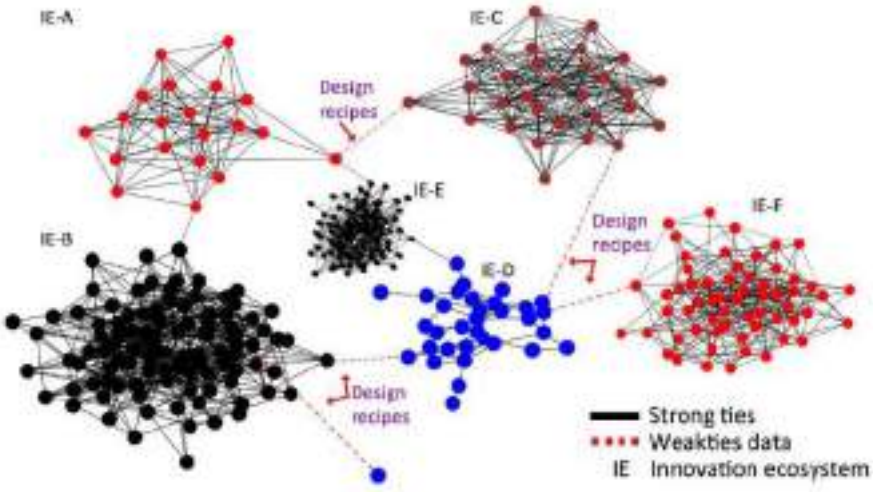

Figure 3: Showing innovation ecosystem community (A, B, C, D, E, F) weak ties and where designers of DIEs may leverage ambiguous data of weak ties to identify design recipes for innovation.

Designing DIEs

Design is the process that transforms new ideas and technologies into new usable systems, products, and services for customers (Hernández et al., 2018). Customers in case of DIEs may include co-innovators, distributors, retailers, end customers and others who are part of the DIE. Since design science is seen as a tool to gain competitive advantage in new radical innovations (Laureate & Spence, 2017), it can help the ecosystem actors to work collaboratively past specific firm challenges to ecosystems (Lockwood, 2018). Considering there is nothing like a single recipe for a thriving innovation ecosystem (Rabelo & Bernus, 2015), designing this kind of DIE embodies a creative process based on shared value to create, develop and define new products, services or systems that represents change. This may be a laborious exercise since innovation ecosystems do not have a formal structure of operation (Dedehayir et al., 2016). To constantly redesign shared value within Innovation ecosystems, we visualize the ideal ecosystem design approach shown in Figure 4 to aid the process of developing DIEs.

We draw insights from the fundamentals of open systems (Input-process-output) and show how this axiom interrelate with DIE factors. These interrelations may lead to unpredictable and unexpected DIE outputs. Understanding these interrelationships and environmental factors is crucial to DIE design process. As shown in Figure 4, DIE business models are interlinked to the DIE vision through customer demands and market needs. Market needs, DIE data, DIE network interrelationships, DIE shared vision, DIE material, and information flows are all crucial precursors for the design of viable DIEs. During the implementation stage, DIEs evolve in different shapes and forms depending on the disruptive innovations, value streams, new technology, information exchange, the culture of actors, talents and other factors as shown in Figure 4. Since DIEs form is evolving rapidly, it is challenging to develop a one size fit-all perspective. Our approach emphasizes understanding inputs, process, and environmental factors, which self-organize and evolve with time. Therefore, we argue that what is paramount is to position the designer at the early stages of DIE initiation, to influence the DIE evolution, management and sustainability.

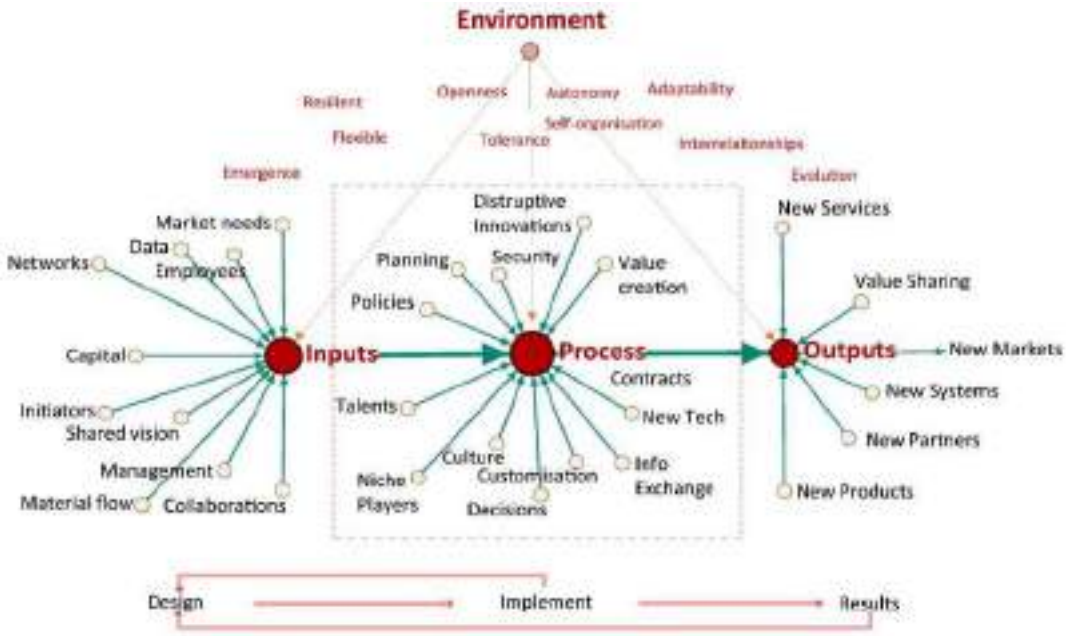

Figure 4: Ecosystem design approach: Showing Inputs, processes, environmental factors leading to DIE outputs.

Actors aiming to start DIEs are confronted with many questions such as how to start, whom to begin with and when to start. These questions cannot be answered through a literature review alone. The openness of DIEs makes them fuzzy to design just like developing ecosystems as noted in (Dedehayir et al., 2016), hence the need to understand the evolution stages and factors that are likely to shape and influence the design of DIEs. Moore (1993) proposed a four-phase life cycle (birth, expansion, leadership, and self-renewal) in developing business ecosystems, which was later expanded by Rong, Liu, and Shi (2011) as follows; 1. Emergence, 2. Diversifying, 3. Converging, 4. Consolidating, 5. Renewing. We propose DIE design process stages and visualize the model as shown in Figure 5.

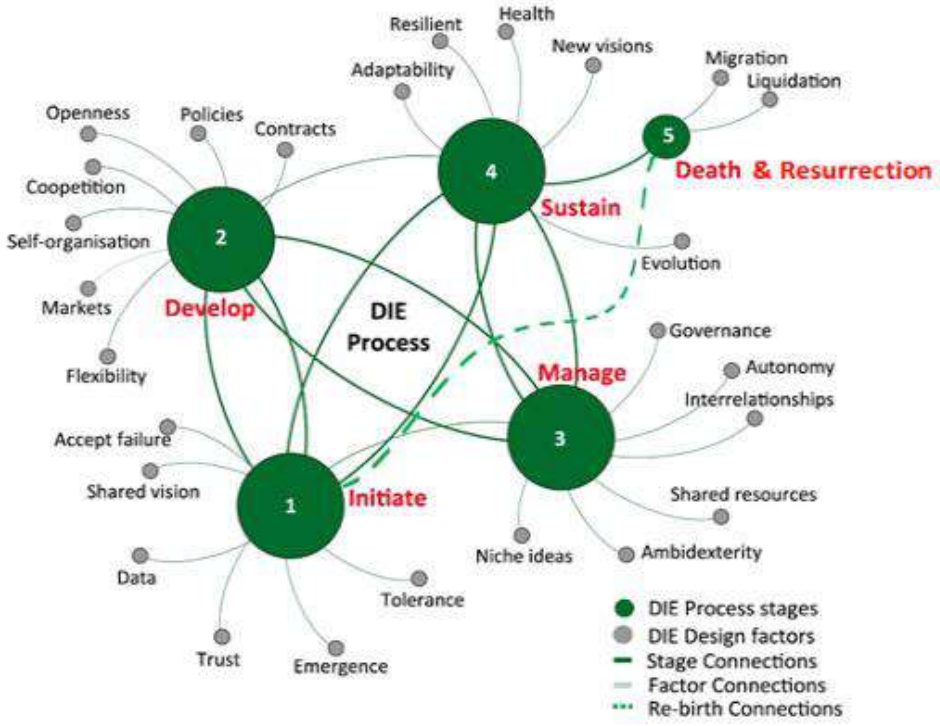

Figure 1: DIE process: Showing the non-linear interconnections between stages: 1. Initiation (information flow; 1-2 ,1-4, 1-3, 1-5), 2. Development (information flow; 2-1, 2-3, 2-4), 3. Management(information flow; 3-2, 3-4), 4. Sustainability (4-1, 4-3, 4-5) and 5. Death and resurrection (information flow; 5-1).

DIE Initiation

As astutely argued by Christensen (1997), established firms usually wait for disruptive technology to be established in mainstream markets. In the past, IBM waited carefully for the unfolding of the market (Moore, 1993), but today it may be risky to wait. Therefore, the first consideration for DIEs design is to initiate the value proposition around the emerging new market needs. Defining value proposition is meant to initiate the process of collaboration as outlined in (Adner, 2017). The ecosystem initiators actuate the process of coalescence. It is at this initiation stage that trust, tolerance, data sharing, emergence, and shared visions are cultivated to build open connections as shown in Figure 5.

The value proposition is based on information flow, money, interrelationships and materials as described in (Parolini, 1999). Just like the flow of nutrients in the rainforest (Shaw & Allen, 2016; Hwang & Horowitt, 2012), we argue that data flow is the resource that links stakeholders of the DIEs. It is crucial at the initiation stage to establish potential roles or nodes in the DIE structure. Some researchers suggested actors who may be essential at this early stage of building innovation ecosystems such as Suppliers, manufacturers, users, universities and research centers, entrepreneurs, regulators (Cusumano & Gawer, 2003; Li & Garnsey, 2014; Dedehayir et al., 2016; Rabelo & Bernus, 2015).

We propose that the design of DIEs may be approached from the main players who possess a shared vision complemented by other actors. The leader may recruit actors and ensure their autonomy and diversity of ideas. The initiator may offer some incentives to attract more actors to the DIE. Moore (1993) defines the initiation stage as the birth stage, Rabelo and Bernus (2015) identify this stage as the seed phase. We emphasize that this initiation stage cultivates a nourishing environment for adaptable DIEs to emerge.

We argue that the use of weak ties to increase the network density may also increase interaction within DIEs, hence increasing disruptive innovation streams. Weak ties connect actors of differing capabilities, unlike strong ties as shown in Figure 3 above. The amorphous bridges created by weak ties (Baer, 2010), are valuable to the design of DIEs because they may increase network density and access to information outside core actors. The increase in density of non-linear interrelationships is proportional to an increase in ecosystem

efficiency (Ivanova & Leydesdorff, 2015). It is not about choosing the right actors during the design process but rather stimulating DIE environment, just like in nurturing the rainforest as observed in (Hwang & Horowitt, 2012). The initiation stage is more about defining the DIE vision, business case, market roadmap based on the critical environmental factors shown in Figure 5.

DIE Development

We expect the initiated DIE to expand in terms of coopetition dynamics. Instead of competing with new DIEs it may be fruitful to explore weak ties to bridge the information gap between the DIEs and foster coopetition. The development of DIEs can be supported by friendly government policies at this stage to enhance coopetition and information exchange between actors. Searching for new territories to create and capture new markets by recruiting niche players may further develop the DIE network. To attract new players, DIE actors may establish unambiguous value creation and appropriation guidelines which are open and public following suggestions from (Rong et al., 2015; Dedehayir et al., 2016). Though these suggestions are not designed explicitly for disruptive environments, we argue that they apply to the development stage of DIEs. Open relational contracts for shared value are encouraged to lessen conflicts and disgruntlement within DIEs.

DIEs may attract new players by first growing demand for their niche products and services. This may be possible through the design of innovation ecosystems. At this point, disruptive players can be recruited to expand the niche creating streams. Developing DIEs may involve planning, testing and piloting in the market. To grow the market, the DIE architecture is designed for future scaling and evolvability. Therefore it must be flexible and adaptable to environmental changes which are often unpredictable and ambiguous. DIE designers may also consider third-party opportunities to develop the ecosystem. Amazon benefits a lot from third-party proceeds due to its open ecosystem architecture (Isckia, 2009).

DIE Management

Detailed literature investigated by Gomes et al. (2016) indicates challenges in the management of disruptive innovations within ecosystems. We posit that a design-focused approach can help manage DIEs. In Lyman et al., (2018), 50 % of managers believe that they do not have the capacity to manage business ecosystems. The autonomy of actors to operate in multiple and horizontal ways enabled by shared assets may limit linear management tendencies as demonstrated in (Lyman et al., 2018; Iansiti & Levien, 2004; Power & Jerjian, 2001; Gemici & Alpkan, 2015). Management in DIEs implies, inter alia, the coordinated sharing of resources as opposed to hierarchical coordination. Sharing of DIE resources lead to the creation of shared value. The main players may directly coordinate by initializing niche and smart technologies and influencing DIE actors to innovate through a shared vision. Linear management styles are discouraged at this stage because DIEs are intended to create unexpected opportunities horizontally.

Management of DIEs may focus on nurturing the DIE environment to accommodate the heterogeneity of business models. The firm focused business ecosystem concept such as Moore (1993) at this stage emphasizes control of value streams, which may not be an ideal strategy for managing innovation ecosystems in today's business milieu. Blackberry ecosystem's collapse is attributed to lack of designing an effective strategy to manage its innovation ecosystem (Jacobides, 2013). We propose a ‘win-win’ kind of collaborative activities and strongly discourage ‘big brother’ mentality in sharing resources for innovation. This can be achieved through an elaborate strategic DIE role structure.

DIE Sustainability

At this stage, DIE actors may decide to revamp the activities of the network in line with new visions to tackle new disruptions which may be affecting the health and adaptability of the DIE as shown in Figure 5. The DIE is expected to ail with time and become less efficient. DIEs can resuscitate ailing networks by recruiting niche actors in their systems, who can be used to experiment on disruptive innovations until value interrelationships are fully developed. The theory of weak ties may be useful in expanding nodes towards actors outside the DIE community to increase information pathways for innovation or design recipes as shown in Figure 3 above. We reiterate that weak ties may increase the DIE resilience and adaptation leading to sustainability of disruptive innovations, in fact utilising weak tie data reduces destructive competition and increases shared value amongst heterogeneous communities.

DIE Death and resurrection

If DIEs fail to sustain its shared value at stage 4, it may cease to exist as a DIE by either a large part of the actors migrating to other DIEs or liquidating as individual entities, pulling others along with them. To survive the storms from competing ecosystems, DIEs may seek to slow the growth of new ecosystems by negotiating to collaborate partly or wholly, or worst-case scenario re-structure their DIE architectures to accommodate new players. However, the death of one DIE may lead to the emergence of another as shown by the dotted line in Figure 5 (relationship 5-1). Competition within DIE actors may lead to the destruction of the entire DIE and resurrection of a new type of DIE. DIEs may be dominated by either a keystone, dominator, hub landlord or niche actor. In the following section, we explore and visualise these DIE roles in detail.

Strategic roles in DIEs

Even though ecosystem roles are sometimes naturally emergent rather than prescribed (Dedehayir et al., 2016), it is crucial to understand the actor's roles in developing and sustaining DIEs. This can be achieved by understanding individual DIE actor capabilities they contribute towards shared value. Additionally, the power dynamics between actors need to be established to characterize DIE interconnections. To discuss the DIE roles, we re-imagine Iansiti and Levien (2004) strategic roles (Keystones, Dominators, hub landlord, and niche players) and generate visualizations to represent DIE roles. We then discuss Amazon, Apple, Uber, and Siemens case studies as examples of DIEs. We use graph visualisations to represent abstract properties like relationships, power, and interactions between DIE actors in a simple way to aid quick understanding of roles.

We use python tools to produce graph visualisations using random comma-separated values (CSV) data to facilitate ease of comparing main roles within DIEs following the visualisation framework as shown in Figure 6. Python libraries dedicated to graph visualisation such as Matplotlib, NumPy, and Networkx are used to demonstrate how actors (nodes) relate (edges) to each other in terms of position, connection and influence. CSV data is created depending on the description of each DIE role (keystones, dominators, hub landlords, and niche players) to represent nodes and edges of graphs. Larger nodes and higher connections represent more importance and influence in DIE network graph.

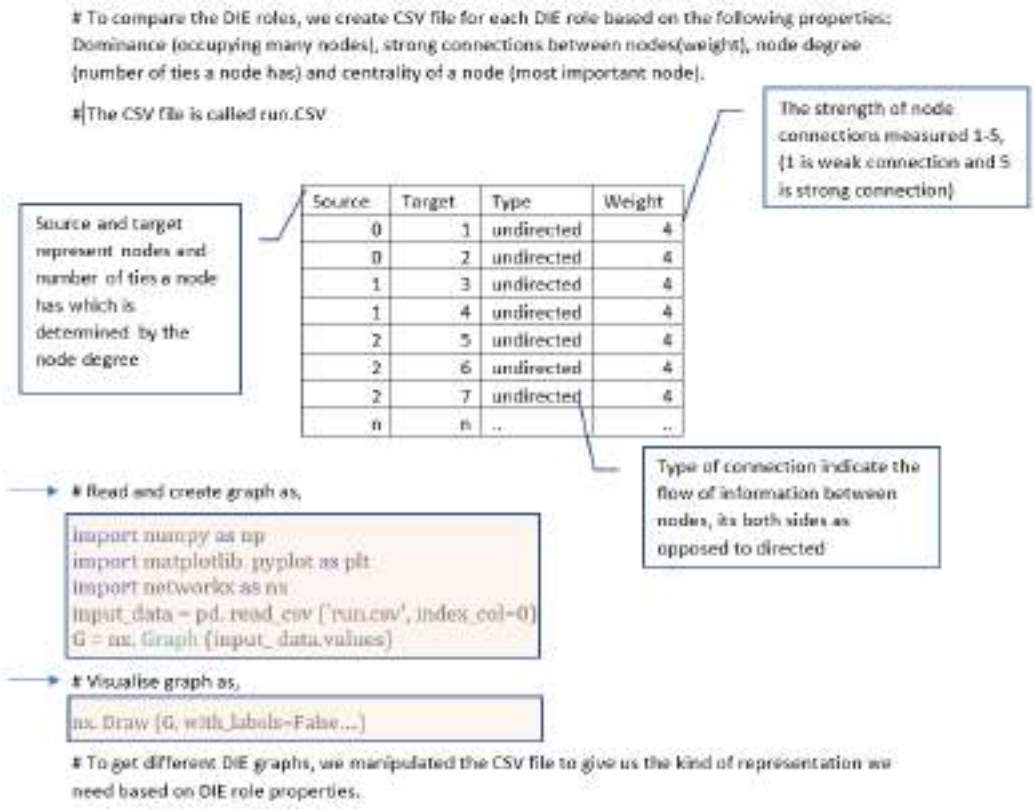

Figure 2: DIE visualization framework showing the basic procedure taken to visualize actors' roles using CSV data and represent their difference in terms of node importance, connection and influence.

DIE Keystones

A keystone is an important and influential node that promotes stability, health and shared resources with other DIE actors. Just like in the context of business ecosystems (Rong et al., 2015; Iansiti & Levien, 2004; Hwang & Horowitt, 2012), DIEs cultivate co-evolution, creativity, and innovation by providing an open innovation environment. Removing the keystone node shown in Figure 7 may negatively affect the shared value. As shown in Figure 7, Keystones are represented in large nodes and edges occupying few positions in DIE networks. The remaining positions (small nodes and edges) are available to be occupied by other actors, thus dispersing power and authority across the network. By occupying the central positions, keystone nodes support innovations through the provision of DIE resources. Keystone node is trustworthy and has a good market reputation (Isckia & Lescop, 2009).

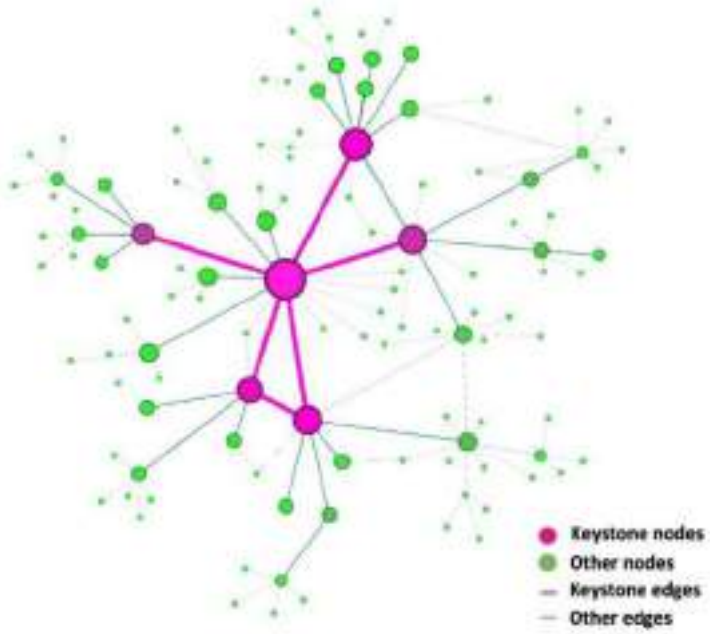

Figure 3: Visualization of a DIE Keystone role: Keystone positions occupy the center nodes and connect through keystone edges to the rest of the network. Keystone positions are few in the network to lessen control and dominance.

Amazon as a keystone

The growth of Amazon is attributed to its innovation ecosystem (Isckia & Lescop, 2009). Amazon as a keystone focuses on creating opportunities for other actors to access and leverage unlimited resources (Mazhelis et al., 2012; Gratacap & Isckia, 2013), without contributing to huge platform-specific investments (Zhu & Liu, 2018). Amazon maintains the autonomy of its partners pricing policies unlike other platform leaders such as Wal-Mart and Apple (Moore, 1996; Zhu & Liu, 2018). Amazon integrates niche players within its ecosystem platforms as thus creating more value through web services and e-business incubation (Isckia & Lescop, 2009). Amazon has an excellent reputation for sacrificing profit for growth by fostering open-innovation within third-party players (Zhu & Liu, 2018). Therefore, Amazon appears to be a good example of a DIE keystone actor.

DIE Dominators

Dominators are DIE actors who have high control of value creation and capture streams in the network. Dominators are distinguished from Keystones through metrics of physical size as shown in Figure 8, one dominating actor occupying all positions indicated in large nodes (dominating nodes) in the network. Unlike keystones, dominators stifle diversity by the massive presence in the network and control most of the innovation streams (Dedehayir et al., 2016). Consequently, dominators within the DIE network may create and extract most of the value, thus starving its ecosystem. The behavior of dominators may limit the DIE to respond to external shocks and may eventually collapse the entire DIE.

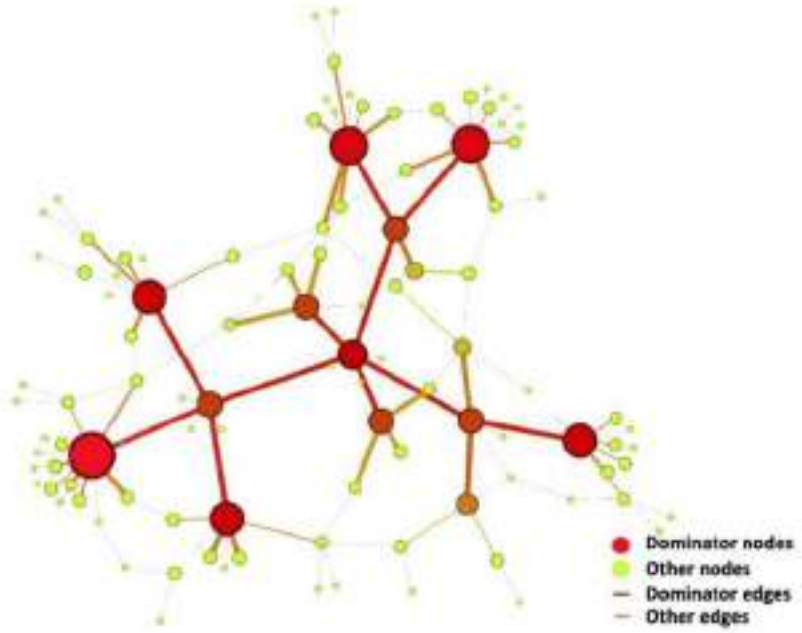

Figure 4: Visualization of a DIE Dominator role: Dominator positions occupy the large nodes and connect through thick edges to the rest of the network. Dominator positions are many in the network to increase control and dominance.

Apple as a dominator

Unlike Amazon, we observe that Apple maybe extracting more value from the ecosystem by dominating its innovation networks. This is seen in (Valkokari, 2015; Jacobides, 2013) as a dominating factor. Apple maybe controlling the ecosystem by inhabiting value creating nodes as shown in Figure 8. Distinct from the Amazon ecosystem, Apple has been consistently reluctant to share value with others through licensing third-party developers. Though the company recently started supporting third-party apps, Apple continues to thwart third-party efforts by continually releasing new operating systems (Zhu & Liu, 2018; Song, 2010), whereas Amazon encourages the growth of third-party players. Though Apple has managed to navigate the disruptions in the smartphone business while maintaining a moat on its incumbent services (Back, 2014), it may be beneficial to open its innovation ecosystem further to support and create shared value to guarantee Apple DIE sustainability.

DIE Hub Landlords

Hub landlords are DIE actors who invest in value extraction only. As shown in Figure 9 hub landlords occupy few nodes in the entire innovation ecosystem shown in large nodes and thick edges. Actors holding hub positions are often faced with temptations to exploit their central hub position for short term gain to the detriment of other actors (Iyer et al., 2006). Dominators control value creation and capture most of it whereas hub landlords choose not to participate in the value creation, instead eschews control of networks and invest in value extraction only as elaborated in (Song, 2010), eventually turning successful keystones into hub landlords.

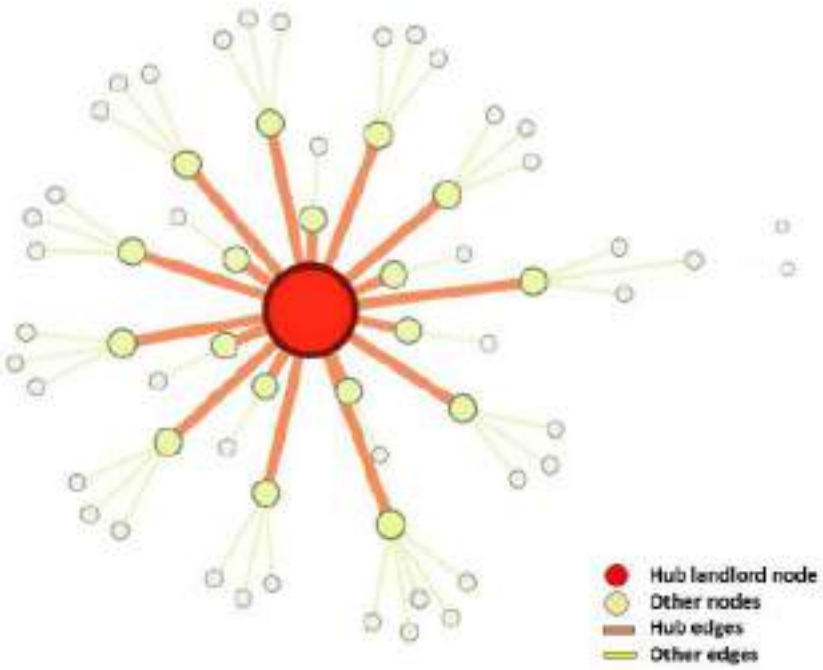

Figure 5: Visualization of a DIE Hub landlord role: Hub landlord positions are few in the network to avoid control of value creation but increase value extraction as shown by its position in the network and value extraction edges.

Uber as a Hub landlord

Uber relies on other people's automobiles by merely providing the hauling app to facilitate the sharing of actors' assets (Libert et al., 2014). Uber leverages dormant automobiles into valuable assets for drivers and riders (Smith, 2016). However, most of the value generated by drivers and customers are reported to be going towards Uber (Bensinger, 2017; Berger, Chen & Frey, 2018). Consequently, drivers and riders appear to be resentful over Uber's value extraction and its inability to improve their well-being within the ecosystem (Ridester, 2018; Bensinger, 2017). Uber appears to be benefiting immensely from its ecosystem (Hall, Palsson & Price, 2018; Farrell & Bensinger, 2018).

Since Uber is not yet a public entity, its pricing algorithm is not publicly shared (Jiao, 2018), and it remains unclear as to how much is the actual unit cost per ride (Mims, 2017). Bensinger (2017) note that it is possible for Uber to lower fixed fees and commission charges to boost driver's income. To sustain its ecosystem, Uber may need to look at its fixed costs and commission, and factor in maintenance costs, road charges and other charges associated with the drivers to turn it into a keystone player.

DIE Niche

While keystones provide a platform for innovation, niche players add value to the platforms by innovating (Rong et al., 2015). As shown in Figure 10, niche players have a meager physical presence in the DIE network yet collectively can create high-value solutions. Keystones rely on the presence of niche players to remain attractive to new actors. Niche players develop unique products and services different from what others do by leveraging resources provided by keystone players (Galateanu & Avasilcai, 2016).

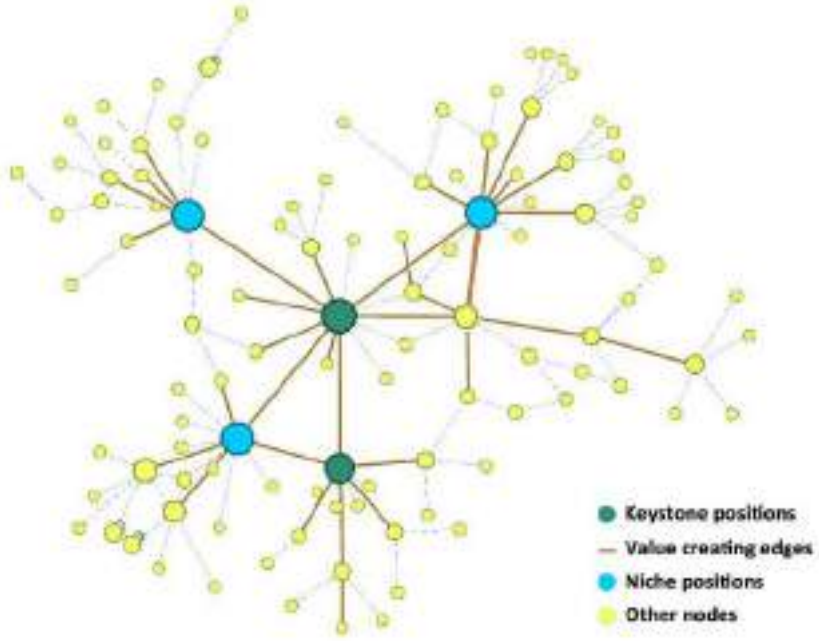

Figure 6: Visualization of a DIE Niche role: Niche positions occupy the nodes located at the busiest points in the network. Niche positions are few in the network to contribute to innovation and creativity.

Siemens as a Niche

Adidas and Siemens are working towards forming something which may be likened to DIE niche service, to build an intelligent manufacturing speed factory. The factory is intended to make use of the power of customization in manufacturing shoes faster than using traditional or conventional methods (Lyman et al., 2018). Adidas as a keystone is leveraging the specialized services of Siemens within its ecosystem to transform their factory. By digitizing the factory, the DIE may produce new technological innovations and customizations faster than ever before as noted in (Adidas, Siemens Partner in Digital Production, 2017). In the Adidas speed factory DIE, Siemens occupies a niche position.

Conclusions

This discussion paper has two significant contributions. Firstly, it adds to the discussion of ecosystems as a new strategy to promote disruptive innovations by reconceptualizing a new type of DIE. Secondly, it visualizes and compares strategic ecosystem roles with case studies. Through these contributions, we explained how DIEs could be created and fostered. We identified the following steps as key towards designing viable DIEs; 1. Initiate, 2. Develop, 3. Manage, 4. Sustain, 5. Death and resurrection. The study positions a designer as the key actor in the development of a viable DIE.

The practical implications of understanding DIEs and positioning designers within the DIE design process may aid continuous re-design of DIEs to suit the ever-changing economic reforms in policy, SMEs business models, school's curriculum, entrepreneurs and individual businesses. Understanding design and emergence conditions may help enterprises to better leverage DIEs in creating sustainable solutions. This paper provides a lens for future empirical research strategies and methods. The limitation of this study is that it is based on a conceptual discourse merely focusing on theoretical discussions with no practical examination.

Further work is now needed to explore current DIEs to establish how ecologies are likely to influence change in future business models, particularly in developing nations. It would be interesting to provide an empirical investigation on how DIEs are designed, evolved, managed and sustained to contribute to shared value. To develop our work on DIEs, we will be engaging with businesses in developed and developing nations to support our new DIE concept with empirical work.

doi: 10.33114/adim.2019.10.387

In the last decade, online shopping has become increasingly popular, as evidenced in the global growth of e-commerce and m-commerce. Alongside these developments, it is important to ensure customer satisfaction and requirements. The integration of smart technologies with service design and applications introducing the virtual fitting room are on the increase and are contributing to the fierce competition between online retailers. However, there is little understanding about the most effective way to use this technology and how it can transform services touchpoints, particularly for fashion brands. Considering this, the current study compares and contrasts virtual fitting room models found in the literature with examples from popular websites. This paper introduces the concept of the salesperson in the virtual fitting room and provides recommendations as to how this can be explored in the future, from a design perspective.

Keywords: Virtual Fitting Room, Salesperson, Service Dominant Logic, Fashion Brands

Introduction

In the last decade, online shopping has become increasingly popular, as evidenced in the global growth of e-commerce and m-commerce. Alongside these developments, it is important to ensure customer satisfaction. Applications introducing the virtual fitting room have been on the rise nourishing the fierce competition between online retailers. Today, consumers can try clothes on from their homes, without having to go into a physical store. This provides another layer of complexity for the overall consumer experience on e-commerce websites. Systems like triMirror[1], for example, provide a personalised experience for consumers, allowing them to try clothes on a 3D avatar with the same body features as the consumer.

Online shopping offers a dominant alternative to traditional retail shopping, rendering imperative for online retailers to seek ways to improve customer experiences (Mallapragada, Chandukala and Liu, 2016). Improving the customer experiences online can be particularly challenging for fashion brands, where the product aesthetics and product fit matter. Recent literature identified wrong size or bad fit of online cloths as key obstacles to online shopping (Liu, Burns and Hou, 2013; Syazwan, Noraidah and Tengku, 2018). One way of improving customer experiences for fashion brands would be to introduce virtual technology systems that would allow customers to virtually try on the selected garments. This idea, however, presents a number of

challenges as virtual systems need to be useful and easy to use in order to create positive customer experiences (Kang, 2014).

Considering these trends in shopping and the current challenges posed by 3D virtual rooms, the aim of this paper is to make recommendations to fashion retailers to integrate virtual rooms into their services. It focuses specifically on the role of the sales person who is crucial for improving the quality of the shopping experience, as it is the sales person who can also co-create with the customer (Le Meunier-FitzHugh, Baumann, Palmer and Wilson, 2011). Although online fashion retailers use 3D fitting rooms on their websites, there is little reflection on and research into how they can be improved and what could make consumers use this type of tool. For example, have the fashion brands developed strategies to use 3D virtual fitting rooms, and if so, how can they be improved, both of which are research questions that guide this study.

Following an in-depth literature review, this paper compares and contrasts virtual fitting rooms from the marketing literature and websites that work closely with fashion brands, such as; *Metail*, *Model my Outfit*, *3d-a-porter*, *SenseMi, triMirror*. The contribution of this paper is a critical review of the literature in this area and recommendations for the application of 3D virtual fitting rooms in fashion service design, including a discussion on the role of the salesperson in this context.

Literature Review

The 3D Virtual Fitting Room

Although the 3D technology had a slow start in the fashion industry and only in the last few years fashion brands have made efforts to adopt this technology in retailing (Clarke and Wilhelm, 2011), nowadays, most of the virtual fitting rooms seek to incorporate 3D technology. The 3D technique provides a 360 degree view of the model and aims to increase customised demand (Olaru, Spanachi, Filipescu and Salistean, 2014) and improve efficiency in the purchasing process (Lee, Ma, and Choi, 2013). The virtual 3D fitting room constitutes an interactive platform between the fashion brand and the customer that aims to reduce the bad fit rate and enhance overall confidence and satisfaction in the purchasing process (Lee et al., 2013).

Different from 2D environments that are flat by nature, 3D worlds provide another dimension of interaction (depth); this tends to be associated with the perception of realism since our world is 3D by nature (Cao, 2014). If applied in interactive media, 3D has the potential to change consumers perceptions. For instance, high realism perceptions tend to influence brand preferences positively (Grigorovici and Constantin, 2004).

The virtual fitting system allows customers to select and virtually try on different clothes. Customers simply need to create a private profile and add their body measurements or choose an avatar close to their body type. Studies have shown that compared with traditional stores, online retailers that use virtual technology tools are able to increase interaction on their website and increase online apparel sales (Lee et al., 2013). However, at the same time, having a 3D fitting room in the website does not imply that consumers would have an enjoyable experience. It is possible that consumers are not familiar with the technology, thus the use of the virtual fitting room is simply depends on the actual usefulness of the tool (Kang 2014). Consumers would use the virtual fitting room with a purpose (to buy the product), and not because it could be enjoyable. The use of the virtual fitting room may also depend on the customers level of ego involvement. Customers with a high level of ego involvement are found more inclined to use the virtual fitting room (Kang, 2014). Similarly, in a recent study on the use of virtual fitting rooms on fashion brand websites, (Beck and Crie, 2018) found virtual fitting rooms to significantly increase customers intention to buy the product and customers intention to demonstrate superiority through the quality experience created by this tool. On the basis of all the above considerations, using the virtual fitting rooms to create compelling brand experiences for the fashion customers can be considered crucial in the online setting.

Brand experiences

The proliferation of brands in the marketplace has increased customers choice set of brand options. Nowadays customers are empowered to choose among various brand options and have ample options to switch. In this competitive and dynamic environment one of the key concerns for marketers is how to design brand strategies that build and support brand commitment. Past literature has examined various drivers of brand commitment, but much of the recent literature has focused on brand experience as a key driver of brand commitment (Brakus, Schmitt, Zarantonello, 2009; Das, Agarwal, Malhotra and Varshneya, 2019). Brand

experience provides critical points of interaction for multisensory stimulations that can engage customers with a brand (Das et al., 2019).

Brand experiences are also defined as "subjective, internal consumer responses (sensations, feelings, and cognitions) and behavioural responses evoked by brand-related stimuli that are part of the brand's design and identity, packaging, communications and environments" (Brakus et al., 2009, p.53). In other words, brand experiences are the outcome of consumers perceptual or behavioural interactions with various brand stimuli such as logos, colour, packaging and advertisements (Das et al., 2019). Brand experiences can also lead to pleasurable behavioural and attitudinal outcomes i.e., high perceived brand value, brand endorsement, brand commitment (Brakus et al., 2009) aversion from switching to alternative brands (Chaudhuri and Holbrook, 2001), repeat purchase and habitual behaviour (Zarantonello and Schmitt, 2010). Intuitively, a positive brand experience would lead to brand commitment (Das et al., 2019). However, there are arguments in the literature to suggest that the relationship is mediated by cognitive and affective aspects (e.g., relationship quality, credibility and emotions) (Francisco -Maffezzolli et al., 2014). In a recent study on the antecedents to brand commitment in the apparel industry, (Das et al., 2019) found brand passion to mediate the relationship between brand experience and brand commitment. Based on the attachment-aversion theory the more the perceived brand and self-distance and the notable the brand meaning is the more consumers feel connected to the brand (Das et al., 2019), which can in turn lead to a stronger need for attachment with the brand i.e., brand passion (Albert, Merunka and Valette-Florence, 2013).

Since brand experience is about creating multisensorial experiences through different stimulations (Das et al., 2019), it provides ways for consumers to engage with the brand. Thus, 3D virtual fitting environments could provide more in-depth experiences for consumers. In fact, developing customer engagement opportunities is crucial to improve the quality of online shopping (Ha and Stoel, 2012). This can also improve the experience consumers have with the brand. For instance, interactivity, presence and immersion can influence brand experience (Mollen and Wilson, 2010). However, this does not mean that high interactive websites would necessarily be engaging for consumers. As stated by Mollen and Wilson (2010), a website can have many interactive features, but if it is not relevant for the consumer, it will not create consumer engagement. Thus, 3D virtual rooms need to have a clear purpose.

There is also an opportunity for fashion brands to explore consumer satisfaction in online environments. In his principal work on the cognitive antecedents and consequences of satisfaction decisions, Oliver (1980), define satisfaction as customers psychological response following the post-purchase experience of the product compared with the pre-purchase expectations. Thus, narrowing the gap between what customers perceive and what customers expect is a key point to achieve the success in online retailing. Fierce competition between online stores, makes it necessary for retailers to look for a new breakthrough and make some changes that can not only attract potential customers but also minimize companies' cost. Thus, by adding more multisensorial layers of interaction could impact the quality of the shopping experience.

Quality of the Shopping Experience

A large body of previous literature shows the importance of understanding customers individual needs as well as their attitudes and satisfaction level with online purchasing (Mosteller, Donthu, and Eroglu, 2014). Many people have been dissatisfied with their online shopping experience mainly due to the bad fit of the clothes following the purchase (Cordier et al., 2003; Liu et al., 2013). A key element to attract more customers to meet their individual satisfaction and finally develop their intention of online shopping is to increase the quality of their shopping experiences (Ha and Stoel, 2012). The quality of online shopping is defined as consumers' attitudes and viewpoints on what e-retailers provide them both in product and service (Ha and Stoel, 2012; Shiau and Luo, 2012). Past studies have focused on the use of virtual technology to reinforce consumers' purchasing intention. For instance, Lau et al., (2013) have found a positive relationship between the attraction to the site and the use of virtual technology. Virtual technology was found to significantly change the online experience from the in-store experience. The focus on the quality of experience is fundamental since the interactive element of 3D virtual fitting rooms alone is not enough to convey consumer engagement (Mollen and Wilson, 2010; Kang, 2014). In order to improve the use of 3D virtual fitting rooms, service providers need to consider a combination of usefulness with consumer perceived value. For instance, online retailers could reinforce "good value for money", by providing price comparisons within the 3D virtual fitting room (Kang, 2014). Another way to improve service quality using virtual technologies online is through the use of chronological interactions. This perspective coined as *narrative experience* could influence consumers through content, graphic style and navigation structure (Huang and Liu, 2014). In fact the way the information is

presented to the consumer through different types of media influences the way consumers search for information (Klein, 1998). Thus, if searching for information takes time and effort and if the media is not accessible, then it would ultimately influence consumer decision-making in a negative way. Thus, if by using a 3D virtual fitting room it is not possible to find relevant information and if the experience is not seamless, then consumers would not perceive it as beneficial. Therefore, the quality of the shopping experience is related to both pragmatic and hedonic aspects of the service. That is, the features of the service (through characteristics like content, presentation, functionality and interactivity) would evoke both pragmatic and hedonic perceptions (Hassenzahl, 2005). For instance, pragmatic aspects are utilitarian and related to the manipulation of the service/product, whereas hedonic aspects are related to pleasure and attributes such as stimulation, identification and evocation (of memories) (Hassenzahl, 2005). This means that for an effective use of 3D Virtual Fitting Rooms in fashion websites and mobile apps, usability and pleasurable experiences should be key challenges. However, this might be attached to the familiarity with the device and context. For example, consumers might shop via mobile/tablets or using a computer desk at home (or work). Thus, these variables are also important to consider.

From a service design perspective, it is crucial to consider experiential touchpoints points. In this case, there are three spaces that compose service experience: backstage, frontstage (or frontline) and auditorium (the actual customer experience and customers) (Zomerdijk and Voss, 2010). In this case, the frontstage is composed of physical environment, service employees and the service delivery. If considering that e-commerce utilises a virtual environment, then this changes the service frontstage considerably. In the case of fashion retailers, this aspect overlooks the role of the sales person. Thus, this shows a potential limitation and opportunity for 3D virtual fitting rooms to improve.

The Value of the Salesperson in the Shopping Experience

A service oriented organisation requires by its nature personal interaction between salesperson and customer. The role of the salesperson is continually developing following the changes in the environment. The global marketing shift from Goods Dominant Logic (G-D) to Service Dominant (S-D) logic had fundamental implications for the role of the salesperson in the sales process and overall customer shopping experience. Adopting the S-D logic requires staff to develop additional skills that will elicit needs at both the values in exchange and value in use stage. This new sales process goes beyond selling goods and services to co-produce attributes of the customer usage process (Le Meunier-FitzHugh, Baumann, Palmer and Wilson, 2011).

Traditionally the sales process required the salespeople to persuade customers to buy the business goods and services (Sharma 2007). The more complex modern sales environment demands creating value by delivering integrated solutions (Brady, Davies and Gann, 2005), which means selling a combination of products and services adjusted to satisfy customers' particular needs (Davies, Brady and Hobday, 2007). The advent of relationship marketing and S-D logic requires sales staff to become more sensitive to the needs of their customers, adjust integrated solutions for specific customer groups. Under the new customer centric logic (S-D logic) the salesperson is responsible for aligning the internal and external resources to satisfy customer needs and build long-lasting relationships with the customer (Sheth and Sharma, 2008). Therefore, the salesperson has various roles, i.e., trusted partner that seeks to provide solutions, customer consultant and relationship manager (Sharma, 2007). The salesperson with his ability to co-create the customer shopping experience and at the same time communicate views of the product to underpin product/service innovations constitutes a strategic capability for the business (Le Meunier-FitzHugh et al., 2011). In fact, the importance of co-creation of value in services that utilise smart technologies has been emphasised repeatedly and should be addressed as an important research agenda in service design. The success of the future organisations will dependent on their ability to create new business models based on smart devices provision and shift from product-based to solution-based models (Wuenderlich, Heinonen, Ostrom, Patricio, Sousa, Voss and Lemmink, 2015).

The concept of value under the S-D logic is also context specific and relative to the other experiences, not only determined by the customer (Vargo and Lusch, 2004; Vargo and Lusch, 2008). Therefore, it is proposed that introducing the salesperson in the virtual fitting room would enhance that experience. However, there is limited or no research in this area. Thus, this study aims to address this gap and to explore the current and potential future applications of 3D fitting rooms by fashion brands.

Methodology

The study used the key words “3D fitting system”, “Virtual fitting room” “Virtual Dressing Room” and narrowed down the focus of analysis on several key conceptual papers i.e., Cordier, F., Seo, H. and Magnenat-Thalmann, N. (2003). Made to Measure Technologies for an Online Clothing Store. *Journal of IEEE Computer Graphics and Applications, 23*, (1),38-48. Pereira, F. Silva, C. and Aves, M. (2011). Virtual Fitting Room Augmented Reality Techniques for e-Commerce. *in Enterprise Information Systems* , *220*, 62-71. Zuo, P. and Zhao, Y. (2011). A design of 3D Modelling virtual fitting project for online shopping, Industrial Engineering and Engineering Management (IEEM), 1893-1897. The study also compared and contrasted five virtual fitting room websites, i.e., *Metail*, *Model my Outfit*, *3d-a-porter*, *SenseMi, triMirror* which are accessible in fashion retail market. For that, we have analysed the main design features from the websites’ services and their applications. We have looked at the main page and areas that describe the services provided by the 3D virtual fitting room tools. These were summarised in Table 1.

Findings and Discussion

A review of the literature has highlighted several important studies. Zuo and Zhao (2011) have designed a clear frame chart to explain step by step the process of how consumers can input their body measurements, choose the clothes they like and try them on. Cordier et al. (2003) have established a web application architecture based on existing models and 3D technology for online clothing store. In a more recent study Pereira et al., (2011) proposed a framework by applying a virtual fitting room for online retailing in three different contexts i.e., Augmented Reality (AR), Computer Vision and Image Processing (Pereira et al., 2011). They also put forward the application of virtual dressing room flowchart which uses “Upper Body Detector” and “Hand Detector” to display the new dress.

Zuo and Zhao’s (2011) model focuses on the detailed measurements in order to give consumers a more accurate selection of clothes size. In a similar line, Cordier et al., (2003) established an integrated web application architecture for online clothing store with includes clothing design, pattern derivation and 3D fitting service and attaches great importance to body measurement. Pereira et al., (2011), on the other hand, showed that the virtual fitting room can apply Augmented Reality (AR)techniques to online retailing; although this technique does not require the user to manually input their measurement, it uses a specialised digital cameras and Adobe Flash technologies, which might be difficult for middle aged people or people with low technical knowledge to use it. All three papers as well as more recent papers following the 6th International Conference on Electrical Engineering and Informatics (ICEEI) in 2017, focus on simplifying the user interface of the virtual fitting room for the user, but with no consideration for the humanising aspect of the virtual fitting room. Syazwan, Noraidah, Tengku (2018), following a systematic procedure of searching related literature on virtual fitting rooms, also confirmed the main issues to be the usability and profound emotional elements connected with the application. Syazwan et al. (2018) proposed a new virtual fitting room model based on the Unified Theory of Acceptance and the Use of Technology that aims to enhance usage intention through effectiveness, efficiency, satisfaction of usage and positive emotional arousal. However, the latter conceptual paper does not provide empirical evidence on how to achieve this. On the other hand, recent marketing literature examines the role of the virtual fitting room as a tool to increase online and offline exploratory behaviour, patronage and purchase intentions. Beck and Crie (2018) have found that the virtual fitting room specifically increases curiosity about the product, intention to patronise (online and offline) and intention to purchase (online and offline). The latter strengthens the importance of the virtual fitting room in the quality of customer experience and the quest for further research on the subject.

Whilst analysing virtual fitting room websites, we have encountered many similarities within the services provided by each website. All websites provided the service of 3D fitting room for both online and physical stores. Personalisation was an important design feature provided by these websites. For example, in the website *Metail*, customers can enter their measurements and edit skin colour and hair style and choose to virtually try on clothes from a variety of fashion brands. Similarly, the *Model my Outfit* virtual dressing room allows consumers to create a personal avatar and try on clothes from different fashion collections. In both cases, customers have to enter their measurements manually, while at the same time there is no point of contact with the brand or other customers to enhance the engagement with the medium or to reinforce confidence over the purchase process (see Table 1). This might be an issue that should be tackled in a long-term since consumer engagement should be a key concept for brands to succeed. Thus, by just having a

cutting edge technology as part of the service might not be enough for 3D virtual fitting room providers to survive competition and the market.

For example, in 2010 “Fits.me”, a robotics application virtual fitting room, was the first to partner with the UK luxury shirt retailer Hawes and Curtis to assist customers to virtually try on a mannequin before buying the product. Following the introduction of the virtual fitting room, Hawes and Curtis’ return rate dropped substantially from its already low rate of 4% to 2,99% (Baldwin, 2016). The virtual fitting room start-up “Fits.me” closed in 2018, three years after it was bought by the Ratuken Group (Fits.me, 2018). This shows that although there is a huge trend towards the use of 3D virtual fitting rooms in online retail, it might be difficult to scale and sustain this type of service in a long-term. Compared to the other websites mentioned in our analysis (*Metail*, *Model my Outfit*, *3d-a-porter*, *SenseMi* and *triMirror*), Fits.me has not included a variation of tools and it is possible that because of that the company had to shut down in 2018. Thus, possible reason for the closure of Fits.me could be the potential for innovation. If considering the other websites cited in our analysis (Table 1), none of the services mentioned the capacity to include the salesperson within the offered services. In fact, the tools mentioned by the websites in Table 1 are quite similar and it is difficult to distinguish their unique selling points, which may rely on technological advances such as algorithms or 3D body scanning. However, none of the websites analysed have specified developments on the services provided to the online and physical retail stores and brands. Therefore, there is still a huge potential for companies to invest on the development of services and touchpoints that utilise this technology with more proficiency. This could include new services and possibly new partnerships with brands and design consultants. Also, there could be a potential to develop tailored services according to different types of products and brands across the globe.

Table 1. A Comparison of Virtual Fitting Websites and Digital Services in the UK

Virtual fitting websites and digital services	**Design features**	**Reference**
Metail	3D virtual body representations that consumers can access online through mobile phones and websites. The service also provides data analytics for fashion retailers	https://metail.com/
Model my Outfit	3D virtual body representations that could be personalised according to different body shapes that consumers can select from a list	http://myvirtualmodel.com/
3D-a-porter	3D body scanning, magic mirrors and 3D virtual fitting services. Most services can be used from distance and online (consumers are not required to visit the physical store)	http://3d-a-porter.com/services/3d-virtual-fitting-room/
SenseMi	Online fitting room for websites, virtual dressing mirror, virtual makeover and smart table in stores. It uses augmented reality features, using camera and 3D projections	http://sensemi.com/
triMirror	In-store and online experiences for consumers through 3D virtual clothes and mobile solutions. This tool uses algorithms and 3D modelling to provide precision	https://www.trimirror.com/

Recommendations and future work

Although there are few studies examining the effects of salespersons to consumers (Rapp, Baker, Bachrach, Ogilvie and Skinner Beitelspacher, 2015), our work is the first to focus on the relevance of a digital salesperson in the virtual fitting room. A recent development by Amazon strengthens the argument for further research on the merits and challenges of having a salesperson in the fitting room. In 2017 Amazon launched Amazon's Echo Look camera (Alexa), a personal robot stylist that helps the customers choose clothes that best fit their body type and accentuate their best features. This study offers initial insights into the merits and challenges of the virtual fitting room and although the research design is appropriate for the nascent state of the virtual fitting room, future research should seek to refine the use of the salesperson in the virtual fitting room, once the latter has been more widely adopted in practice. The current status of many virtual fitting room websites, is largely dysfunctional with many customers lacking the technological skills hesitating to use them. Customers will either have to have a ruler at hand to take their measures, or know their figure and choose from basic but not specific mannequin types. The mechanical instead of emotional nature of the medium often results in lack of trust as customers need to input their measurements individually, and yet no technical support and no recommendations by anyone, the experience may result in loosing time without any gain. Despite all the challenges, such tools as the virtual fitting room are found to increase online intention to try, and even patronise behaviour and enhance purchase intentions (Beck and Crie, 2018). The additional feature of a salesperson in the virtual fitting room is believed to enhance the aesthetics of the online store, particularly for luxury brands. The present study answers to the quest of fashion brands on how to maintain uniqueness and convenience. Liu et al., (2013) study highlighted convenience as the key motivating factor influencing customers shopping desire. The virtual fitting room can be particularly convenient way of trying on clothes for customers who are not located close to the luxury stores and is not convenient to access them. The present study also compliments existing literature on how image interactivity can improve the online brand experience (Beuckels and Hudders, 2016) and transfer the traditional sensory experience into the online environment (Okonkwo, 2009). Li, Daugherty and Biocca (2001) found that interactivity features on websites enhance the value of the product and promote customer engagement. Altarteer, Charissis, Harrison and Chan, (2013) in their research on the interactive virtual reality shopping and the impact in luxury brands found that 3D models of luxury goods enrich the user experience and lead to higher levels of trust. Beuckels and Hudders (2016) recommend to online luxury retailers a more interactive approach through the use of 3 dimensional visualisation, increasing luxuriousness of the product indirectly, leading in higher levels of involvement and enjoyment for the customer. The presence of the salesperson in the virtual fitting room would promote engagement with the brand, strengthen customer's trust in the purchase process and reduce the returns because of bad fit. The customer-salesperson relationship is particularly valuable for fashion brands, as apparel brands are hugely popular, people tend to display strong feelings of attachment often translated to brand passion and managers are recently putting more effort to create and maintain emotional attachment to apparel brands (Das et al., 2019). Several service design recommendations on how to achieve this, include an avatar. The salesperson could be represented by an avatar that could give suggestions for the user. For example, the presence of an avatar in games can evoke positive attitudes towards a brand, particularly across cultures (Choi, Yoon and Taylor, 2015). This means that the presence of a 3D avatar in the 3D virtual fitting room would also need to be tailored according to the users' needs. It is also possible that this could change according to the perceptions towards the character considering gender, voice, behaviour and level of realism. If fact, the level of realism or human-likeness is another aspect to consider. For example, people who perceive human-like "robots" (or 3D images) as "humans" would have a positive attitude towards it, but then this attitude would reach a state in which the perception of human-likeness would decrease and people would feel "strange" about, evoking a sense of repulse towards it (Mori, MacDorman and Kageki, 2012). Another option could be adding the salesperson in form of recorded videos, which would have then a "real" person giving advices. This could be done by real personal stylists or even celebrities. Thus, future research in the area is needed in order to understand which technique is more efficient in order to improve service design of 3D virtual fitting rooms.

Another design recommendation is related to usefulness and familiarity with the 3D fitting room application. For example, consumers might not use the 3D fitting room if it is perceived as "difficult" to use. This aspect focuses the evaluation of this tool around usability issues. Considering this, it would be necessary to develop a set of usability guidelines for 3D fitting rooms. However, usability alone does not guarantee the success of the use of these digital tools. For example, consumers need to feel that these 3D projections are also projections of themselves. Thus, online fashion retailers could benefit from the collection of personal data including not

only body measurements but also personality aspects. Although this could evoke a high sense of ego involvement (Kang, 2014), it would also reflect issues around data privacy. Thus, an ethical and "transparent" 3D fitting room tool is also required. Another suggestion is the recording of personal preferences in order to provide a narrative experience. Websites tend to do this by using previous purchase data to give suggestions. In the case of 3D fitting room, this information could be recorded straightaway and linked to other personal data.

Other design suggestions could be the addition of 3D fitting rooms in Virtual Reality (VR) using headsets (see Figure 1). In the VR environment, consumers could experience the simulation of a "real" fitting room. The difference is that consumers could personalize the fitting room by adding their own features. For example, the fitting room could have a mirror and the decoration from the consumer's bedroom. A salesperson, in this case could be an avatar inside the VR room experience, giving suggestions of outfits, similar to a personal fashion expert. Consumers could also choose to have a salesperson or not talking to them. It could be possible that with future developments in the VR area, consumers could also share their VR room with family and friends.

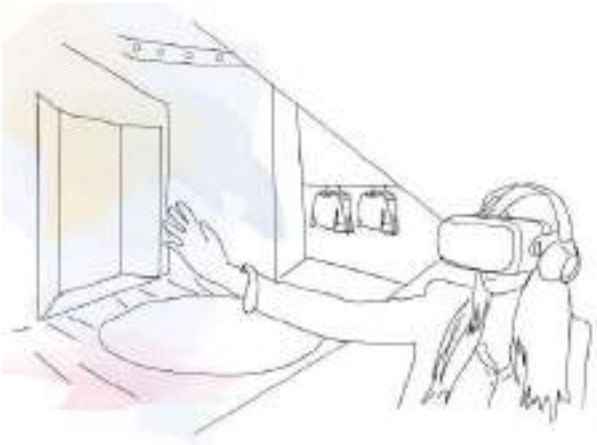

Figure 2 VR fitting room experience

Future work in this area could address the relationship between the 3D projections and the sense of ego-involvement, particularly through the engagement with the avatar. As mentioned before, a potential research could consider the application of the 3D fitting room in VR applications. This could evoke a sense of belonging and it could influence consumer's purchase intentions. The utilization of 3D virtual fitting rooms could also transform the in-store experience (physical). For example, studies could compare the differences between the real fitting room and the virtual one, highlighting its benefits for the overall consumer experience. It is possible that if the online fitting room becomes each time more immersive, then in-store fitting rooms would need to be transformed or perhaps adapted to include digital touchpoints. For instance, the mirror in the in-store physical fitting room in-store could be connected to the Internet and could give the consumer advices (see Figure 2). Similar systems have been suggested using Artificial Intelligence (AI). For example, consumers can get recommendations from a virtual agent through personalized algorithms (Fu, Liu, Jia, Ma, Meng and Huang, 2017). This opens possibilities for researchers and practitioners to "humanize" algorithms and make them similar to real-world salesperson. Smart mirrors could also enable consumers to call friends and family to ask for their opinion whilst choosing a specific outfit (using services like Skype or social media channels). This could also impact other niche businesses such as for outfits designed for a specific event, such as weddings. With the adoption of this type of technology, it might be possible that consumers could try wedding outfits without having to leave their homes and get them perfectly fitted for the special occasion.

Figure 2 Magic mirror

There are many opportunities to expand this research. For example, the websites and services analysed in our paper did not mention the role of the salesperson in 3D virtual fitting room and the possible connection with other people (e.g. family and friends, personal stylists and so on). This can be a key research agenda for future studies in the impact of virtual technologies in fashion online retailing and brand experience. Other opportunities could explore both technological and behavioural sides of the impact of 3D virtual fitting rooms. For example, designers could collaborate with developers and create prototypes of new 3D virtual fitting rooms that have different types of potential. At the same time, designers can also study the impact of such technologies on consumer behaviour, analysing their engagement and brand experience. Thus, this paper could be a starting point for research in this area. We also expect this paper would be of interest for service providers and designers, willing to explore the potential of 3D virtual fitting rooms, powered by the development of new technologies such as VR and AR.

doi: 10.33114/adim.2019.11.263

In recent years, the way organizations innovate and develop new solutions has changed considerably. Moving from 'behind the closed doors' style of innovating to open innovation where collaboration with outsiders is encouraged, organizations are in the pursuit of more effective ways to accelerate their innovation outcomes. As a result, organizations are establishing creative and entrepreneurial ecosystems, which not only empower employees but also involve many others to co-create new solutions. In this paper, we present a methodology for organizing hackathons, i.e. competition-based events where small teams work over a short period of time to ideate, design, prototype and test their ideas following a user-centric approach to solve a specific challenge. This paper also provides insights into two different hackathons organized in the United Kingdom, and Mexico, as well as a series of 5 hackathons organized in Argentina, Mexico, Switzerland, United Kingdom and in Senegal.

Keywords: Co-creation, Hackathon, Open Innovation, Design Thinking, Case Study

Introduction

Inventiveness, innovativeness and creativity run in our blood, but as we start growing up, influenced by our environment and the people that surround us, we change the way we see things and the way we think about them. But this happens to organizations as well. As they evolve from a startup to an established, large organization the challenges of maintaining the speed and frequency with which the organization innovates slow down and/or become less risky, less bold, less disruptive, and more easily replicable by the competition (Mootee, 2013 & Golob et al., 2015).

Not long ago, industrial leaders believed that the greatest opportunity to leave the competition behind was to invest heavily in internal R&D. The idea was to have vast R&D resources, leading talent and strong, top-level support carry out all innovation activities behind closed doors until new products - the seeds of the innovation process - were mature enough and ready to be launched to the market (Figure 1: Closed Innovation). It was believed that only those organizations would be able to keep up with the pace of change and innovation (Tucci, Afuah & Viscusi, 2018).

Fast forward 30 years or so, the situation in most industries is quite different. Organizations around the world have moved, or are moving, from inward-focused, 'closed' innovation to open innovation as proposed in Figure 1. Opening up the innovation processes and making its walls permeable, decisively encourages the use and exchange of external ideas, technologies, knowledge, talent, resources and more (Chesbrough, 2006). In

part, this can be achieved through the organization of co-creation events that are often referred to as hackathons, ideathons or innovation days. Once industry-specific coding sprints, they recently overtook the world of entrepreneurs, startups and, lately, large corporations (Cobham et al., 2017; Spaulding & Caimi, 2016; Di Fiore, 2013; Altringer, 2013). The word hackathon is composed of 2 parts: hack and marathon. The word hack refers to the creative problem-solving, designing, prototyping and tackling of the challenge, while the word marathon indicates the intensity of the event.

In a nutshell, a hackathon is an event with an element of competition, where participants work in teams over a set and short period of time to ideate, collaborate, design, rapidly prototype, test, iterate and pitch their solutions to a determined challenge. And since hackathons are time-limited events, they best fit the earliest stages of the lean innovation process, where the market is unknown or not yet well-defined, and many ideas are welcome to be tested using user-centric and Lean Startup concepts.

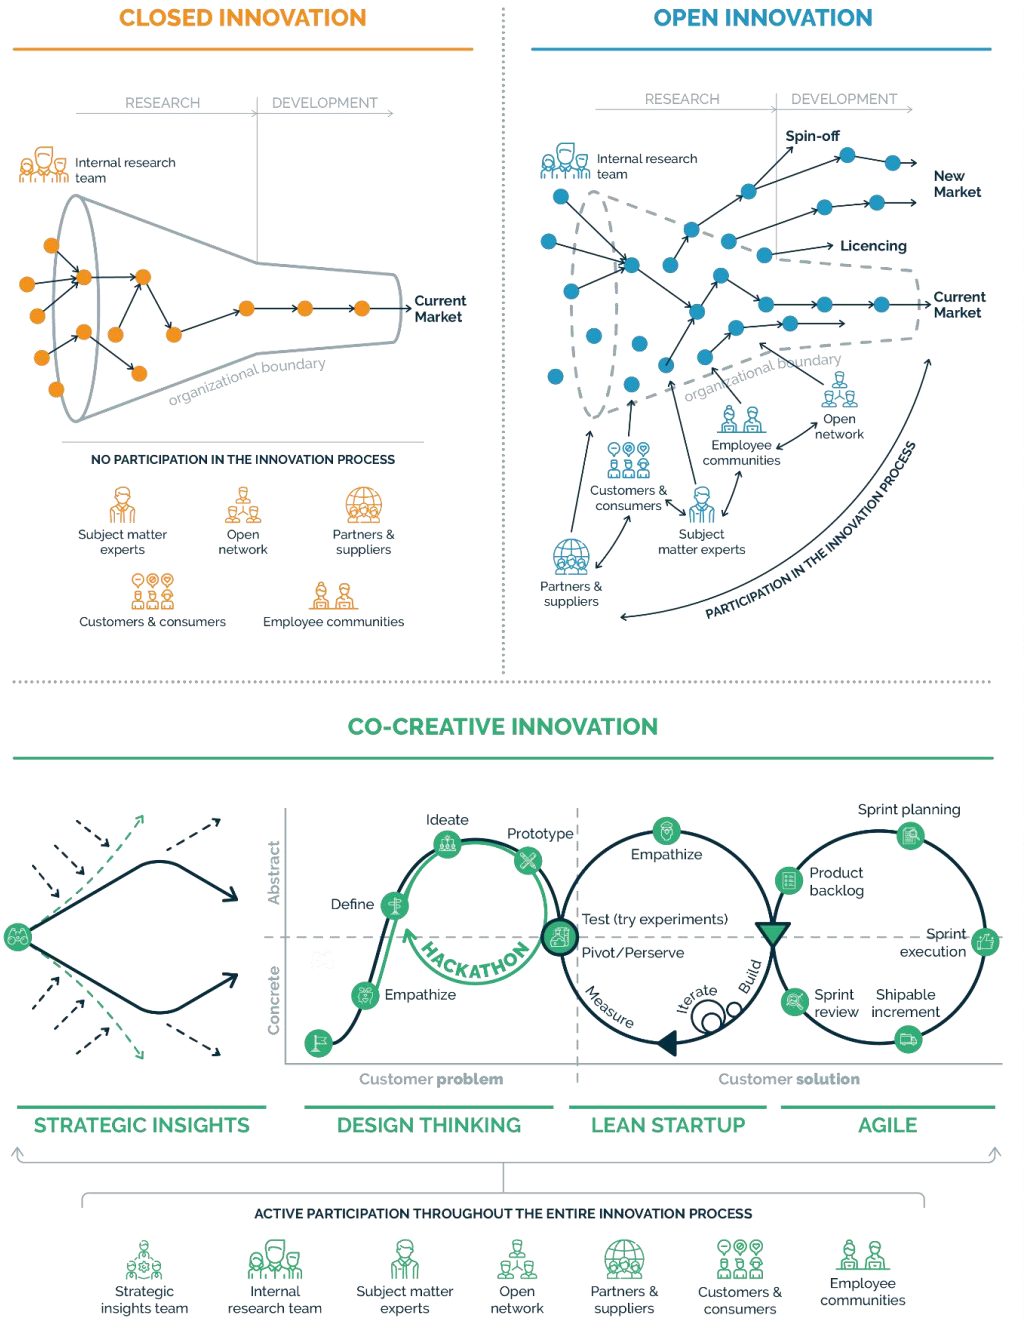

Figure 1: Comparing Closed Innovation, Open Innovation and Lean Innovation processes (adapted from Chesbrough, 2006; Optimus BT, 2010; and Gartner, 2016)

Chesbrough (2006) described open innovation as a concept where valuable ideas can come from both inside as well as outside the organization, and can, similarly, be pushed to the market from inside as well as outside the organization. Open innovation assigns the same priority or level of importance to external ideas and routes to the market as to internal ones. This hybrid concept provides an environment where innovative ideas and new products are underpinned solely by innate creativity and knowledge from within the four walls of the organization's R&D. This open environment actively seeks for collaborations reaching far outside the organization's R&D in order to co-create with partners, suppliers and even customers (Chao, 2012). However, making such a paradigmatic shift in the way organization operates its innovation ecosystem is not easy and requires unwavering leadership support and a structured approach.

LAA's Lean Innovation Model (Figure 2) relies on years of research, where different models from well-known authors and practitioners, as well as cases of successful lean innovation implementations in leading organizations, were studied and analysed (Flores, 2014). The resulting Lean Innovation Model consists of 12 enablers structured in 4 key building blocks and serves as a reference to support organizations in the creation of their lean innovation roadmaps (Flores et al., 2017).

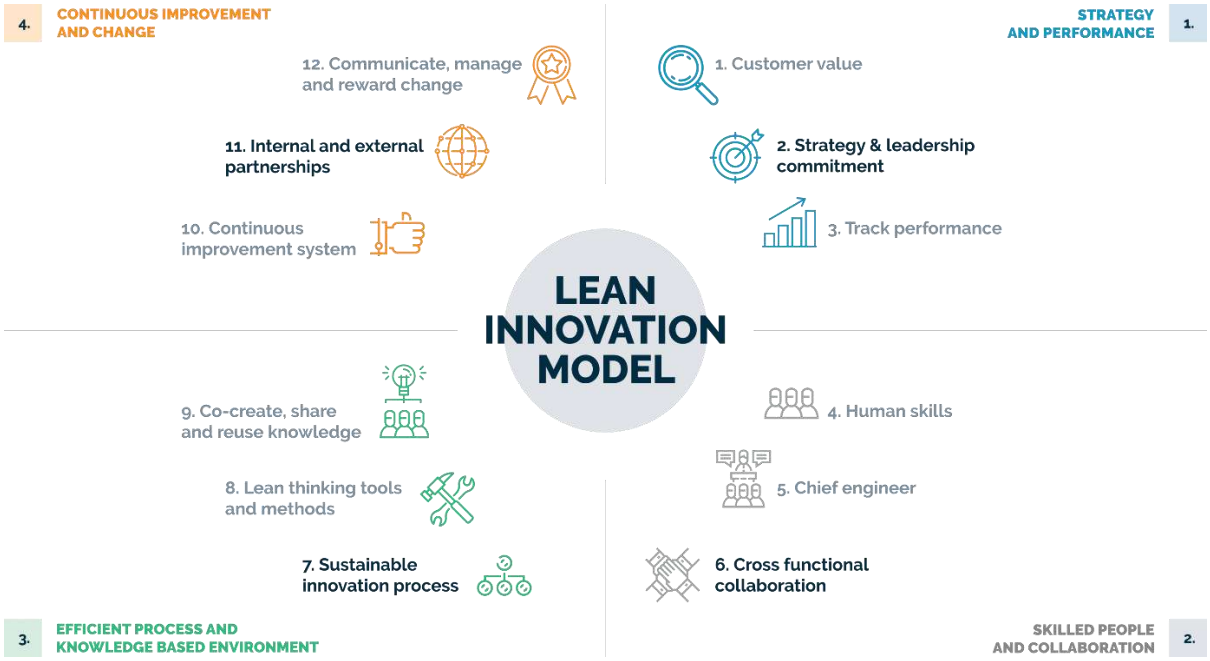

Figure 2: Lean Innovation Model with highlighted enablers for organizing hackathons (Flores, 2014)

The aim of the Lean Innovation Model is to provide a framework to help practitioners discover the various innovation practices, which could be methodologies, tools or techniques, such as open innovation, co-creation and others. In particular, the organization of co-creation events falls under the 4 enablers, as highlighted in Figure 2:

- **Strategy & leadership commitment:** For co-creation events to be successful, they require: 1) to be aligned with the organization's vision to determine strategic challenges for the event, 2) support from the leadership to communicate the seriousness of the intent to potential participants, and 3) to ensure the results have the potential to grow and become real projects.
- **Cross-functional collaboration:** Experts from the same domain can only come up with ideas situated around their area of expertise. Therefore, a wide diversity of participants is encouraged to ensure that out-of-the-box ideas emerge. It is key that employees interact with external participants during the co-creation events.
- **Sustainable innovation process:** To run a successful co-creation event, a simple, yet impactful innovation process is required. Commonly used methodologies for such events are Design Thinking, Lean Startup, Scrum, or a combination of these.
- **Internal and external partnerships:** Forming partnerships to organize co-creation events make a big difference in whether the event will be a success or just another mediocre workshop. Partners include

anyone from venue providers, support teams and photographers, to facilitators, subject matter experts, speakers and judges.

Hackathons leverage the creative and intellectual capacity of the crowd to generate a range of ideas that are crossing the organization's borders in order to not only accelerate innovation and refresh the portfolio of ideas, but to bring employees from different departments closer together (Flores et al., 2017; and Spaulding & Caimi, 2016).

Table 1: Innovation benefits resulting from organizing a hackathon (adapted from Flores et al., 2018)

12	**Enables rapid development & the testing of ideas**	**9**										
13	Provides a time-intense innovation environment	4										
14	IP development	5										
15	Uses a simple, yet impactful innovation process	5										
16	Frontloads the innovation process	3										

17	Fuels the organization's innovation pipeline with already somewhat validated and prioritized ideas	2										
18	User-centric lean innovation tools and techniques	3										
BUILDING BLOCK 4: CONTINUOUS IMPROVEMENT AND CHANGE												
19	Intensive co-creation & radical collaboration	5										
20	Enables organizational change	6										

Table 1 compares the benefits of organizing a hackathon proposed by different authors, including those identified during the organization and execution of the three Hackathons, which were organized according to the four building blocks of the Lean Innovation Model and the proposed methodology shown in Figure 1.

From the analysis, it can be observed that literature generally agrees that hackathons help to accelerate innovation, provide a creative and more stimulating environment for employees and enable rapid development and testing of ideas. Interestingly only one publication besides our own findings highlights that hackathons help to fuel the organization's innovation pipeline with already somewhat validated and prioritized ideas. Similarly, only two other publications beyond our findings from the CEMEX Hackathon highlight hackathons as potential or partial means of frontloading the innovation process.

By integrating several practices identified with the Lean Innovation Model as a framework and using the findings from the literature as well as our experience in organizing hackathons (LAA, 2018), a step-by-step methodology for the preparation and execution of hackathons has been developed.

The paper is structured into four core sections, starting by the introduction (above) where literature and the need for business hackathons are explored, followed by the methodology for organizing business hackathons and the three case studies, before concluding the paper in findings and future work.

Methodology for organizing business hackathons

As described in the introduction of this paper, hackathons are co-creation events purposefully designed to utilize diverse mindsets, tackle complex challenges and create new business opportunities. However, to provide such an environment, any hackathon needs to be carefully planned, executed and wrapped up. From selecting the venue and the room layout (Rattner, 2017; Dam & Siang, 2018) to appointing the facilitator, determining the program (Amabile & Khaire, 2008) and selecting the awards (Bays et al., 2009), every detail influences the creativity and innovation potential of the participants.

A literature review highlighted some of the core areas of organizing co-creation events, covering mainly generic hackathons and not corporate ones (Cisco, 2015; Rissola et al., 2017; Tauberer, 2016; InfoSupport, 2017). Although most steps are transversal, the reasons, the planning and the alignment approach tend to differ. In addition, most of the literature still focuses on industry-specific events, largely on software development and digital technologies.

To ensure co-creation events deliver benefits for the host-organization as well as the participants attending, the LAA team defined a three-stage methodology that covers in detail: 1) the pre-hackathon planning, 2) the execution, and the 3) post-hackathon stage. The steps of the proposed methodology are shown in Figure 3.

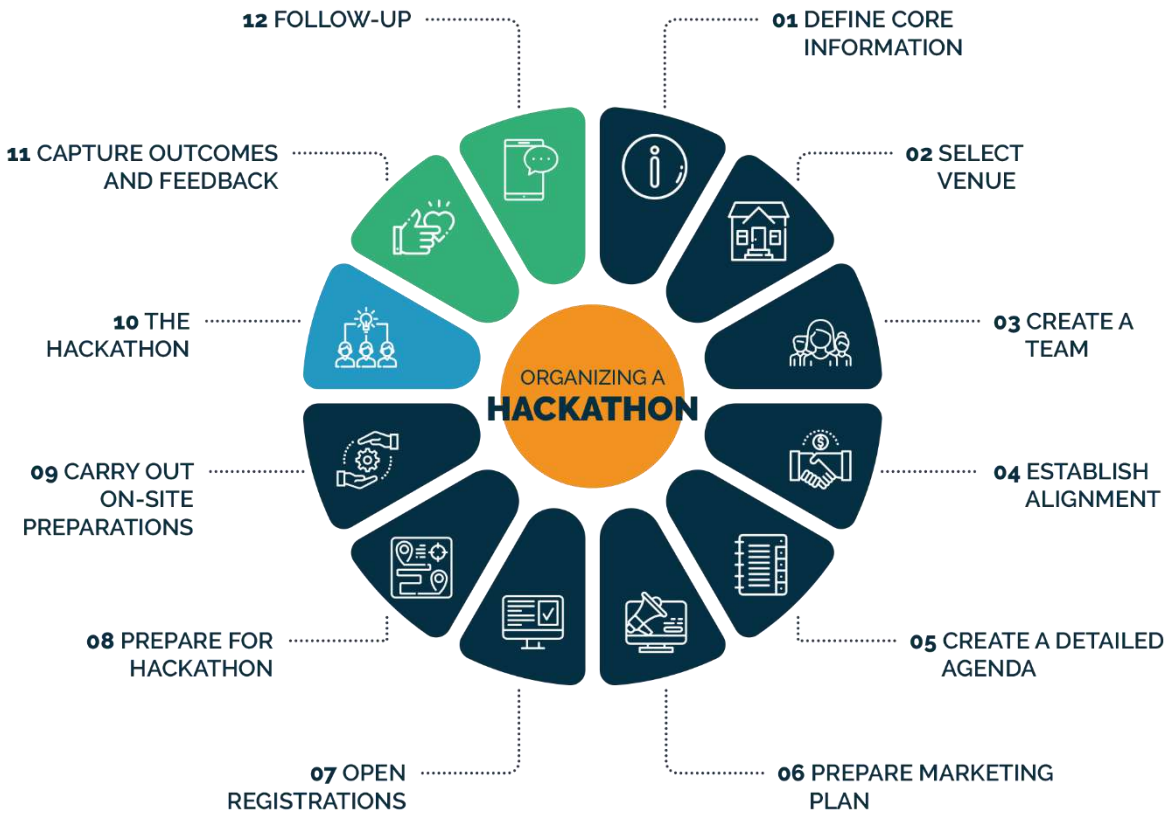

Figure 3: Methodology for organizing co-creation workshops in a corporate setting (Flores et al. 2018)

The methodology consists of three main stages: **pre-hackathon (preparation) stage**, the **hackathon (execution) stage** and **post-hackathon (reflection) stage**. In this paper, authors provide an in-depth overview of the preparation stage and use the case study section of this paper to outline the activities carried out during the execution stage. The reflection stage is also briefly described.

Pre-hackathon stage (planning)

The planning stage is the first and most critical stage when organizing a hackathon. It consists of 9 steps (as observed in Figure 3), starting from (1) defining the core information such as the aim and objectives, the expected outcomes, the theme or topic, the challenge, the date and duration, the target group (participants), the location and the budget. Having pinned these details down, a suitable (2) venue needs to be identified and a (3) team must be formed. As mentioned above, the venue needs to 'scream innovation and creativity' in order to maximize the diversity and originality of ideas and prototypes the participants will develop. Another important aspect of selecting a venue is the catering service; the continuous supply of food and drinks for such events is a must in order to keep the energy level high. However, the selection of the venue is only one part of the success, the other being the team that will help organize and execute the hackathon. While smaller hackathons need less time and people to organize, larger hackathons (100+ participants) require a dedicated, or "core" team (Cisco, 2015). Hackathons do require an extended team, including facilitators, subject matter experts, presenters and workshop leaders, judges and technical and support teams. Each individual plays a specific role before and, especially, during the event. For example, facilitators will be involved in planning the program in the pre-hackathon stage and will be leading teams of participants through the design and problem-solving process during the execution stage. Presenters and workshop leaders might also be involved in the planning stage but will play a crucial role in setting the scene and equipping participants with the needed knowledge at specific times during the hackathon. The core team will co-determine the evaluation criteria and protocol for the awards ceremony, identifying judges who, during the hackathon, will be carefully observing and evaluating how teams work and the ideas they develop. For more specific challenges, subject matter experts are needed in order to advise teams during the hackathon, help them with specific questions or dilemmas, and provide insights, knowledge and experiences, thus enabling teams to develop better prototypes

(InfoSupport, 2017). To ensure such a diverse group of people works together smoothly and delivers value, (4) team alignment must be achieved (including alignment with the sponsoring organization).

Hackathons also require a process to ensure the expected results are obtained in such a short time. Coding and software development hackathons typically consider the Scrum process to 'walk through' a design cycle. On the other hand, business and corporate hackathons usually follow a design thinking methodology to guide the teams through the day(s). Design thinking works extremely well in the business hackathon setting because it starts by deep-diving into the problem (challenge) through user interviews, observation and research. This provides strong foundations, rooted in real, human needs, to build ideas and prototypes on.

Design Thinking is a human-centred approach used to creatively and holistically solve complex problems in an iterative and collaborative manner (Brown, 2008). The design thinking process created by Stanford Design School (d.School, 2013) is structured into five-phases: Empathize, Define, Ideate, Prototype, and Test.

Using design thinking as the process to follow during the execution of hackathons, ultimately sets the back spine of the (5) co-creation program. While the program depends on the duration of the hackathon, the challenge, the expected outcomes, the facilitators, as well as the targeted audience, the core elements remain the same across the events. The typical structure of the hackathon program includes opening speeches and icebreakers, followed by the stages of the design processes (with lunch and coffee breaks, as well as occasional energizing activities), and concludes with the submission and presentation of prototypes to the judges and audience. The final act of the hackathon is the awards ceremony where winners are announced, and awards handed to the best team(s) or idea(s).

The following two steps of the hackathon organization methodology focus on (6) the promotion and marketing of the hackathon, and (7) handling the registrations. Whether the hackathon is being organized for an internal (in-company), external (open to the public) or mixed audience, getting the right participants will have an impact on the quality of the outcomes. Both activities need to be planned well ahead of the actual date of the event in order to ensure the news reach the largest audience possible and allow enough time to apply (InfoSupport, 2017). Both the promotion and registration processes are the first touchpoints the potential participants will have with the hackathon experience. While the promotion messages should be aligned with the challenge of the hackathon, the registration process should be set up in a user-friendly and simple way.

The last two steps of the pre-hackathon stage occur after registration is closed but before the hackathon day. During the final (8) preparation, the team will ensure that all presentations and speeches are ready, prototyping material is available, templates and visual guides are printed, the pre-work for participants is selected and distributed, the promotional material (such as T-Shirts, hats, mugs, pens, notepads, power banks, etc.) is ordered in the right quantities, and the venue and other suppliers (photographers, cameramen, doodlers and scribblers) have all the information needed. A day or two before the actual event, (9) on-site preparations are required. These include audio-visual checks, setting up the room layouts and workshop spaces, setting up the registration and welcome desk, printing the participants' badges, putting together welcome kits for participants, doing a trial run of presentations and speeches, and more.

The hackathon stage (execution)

After the official welcome and the initial presentation of the hackathon challenge, teams start working on the Empathize phase, were participants conduct preliminary research on the topic and engage with end-users and other stakeholders through interviews. Moving to the second phase, teams try to make sense of what they just learned through the interviews and research, by defining the problem they are going to address. While the hackathon provides the challenge, the underlying problem is identified through the analysis of data collected in the Empathize phase. With a clear problem statement, teams enter the third phase where they start brainstorming about potential ideas that could solve that problem and continue by ranking these ideas. The important notion at this stage is that ideation is not so much about the quality, but rather about the quantity of ideas. This is where teams should explore anything from conventional to entirely blue-sky options. What follows is a series of iterations, where teams start by developing a prototype for the selected idea, before testing it with the stakeholders. In a two-day hackathon, this is where day one typically ends. In the morning of the second day, teams undergo at least one more iteration, modifying their prototypes based on the feedback they received the previous day. With the updated prototype, teams will test it again with the end-users and apply final modifications before presenting it to the judges, as shown in Figure 4.

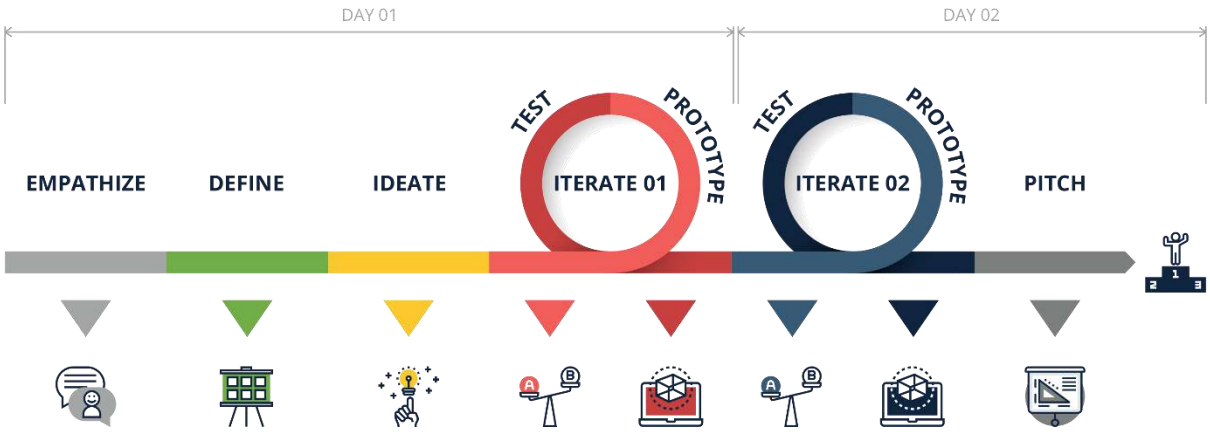

Figure 4: Design thinking processes proposed for a two-day hackathon event (Flores et al., 2018)

To support the execution of a business hackathon authors have developed new, or customized existing well-known tools and methods from design thinking. Some of the tools were redesigned to become templates that participating teams could use, others were used and moderated by hackathon facilitators. Table 2 highlights the tools used throughout the three hackathons, further classified according to the Design Thinking stage in which they were used.

Table 2: Tools and Methods applied by facilitators during the three hackathons

STAGE	#	TOOL / METHOD	The tool was () used in the:		
			CEMEX Hackathon	**MeXXTI Hackathon**	**DT Olympics**
Pre-hackathon	1	**Prework** *(familiarization with the hackathon topic - reading and video material is provided before the hackathon)*			
Empathize	2	**Challenge Specific Trends Analysis** *(organizers conducted research to collect, visualize and present trends & challenges relevant for the hackathon)*			
	3	**User interview** *(contextual interview to gain insight & understanding of users or customer pains, challenges, desires, etc.)*			
Define	4	**Personas** *(a fictional character that represents a customer segment and captures key findings from the empathize stage)*			
	5	**Empathy Map** *(capturing what persona sees, hears, says and think – this furthers the understanding of the persona & its challenges)*			
	6	**"How Might We?" Question** *(helps to define the problem that needs to be solved in a form of an actionable question)*			
Ideate	7	**Silent brainstorming** *(participants brainstorming individually for a short period of time before a group reflection – works best in 2 or 3 rounds)*			
	8	**Group brainstorming** *(participants share their ideas on post-it notes as soon as they write them, essentially enabling team members to build on ideas of instantaneously each other)*			
	9	**Crazy eight brainstorming** *(participants sketch 8 ideas in 8 minutes – guiding questions such as "how would Google solve that?" can be used)*			
	10	**Superpowers brainstorming** *(participants brainstorm ideas based on the assumption of having certain superpowers, e.g. Superman's flying ability)*			
	11	**Brainstorming reflection and voting** *(reflection is usually done after each round of brainstorming to ensure all team members are aware of all ideas before the doting system is used to vote for the best or craziest idea)*			

Prototype	12	**Paper prototyping** *(using paper, cardboard, scissors, glue, etc. to actually build a physical prototype of the solution or part of it)*
	13	**Wireframe and mock-up prototyping** *(using sketching and drawing techniques to rapidly develop and design user interfaces – typically for apps or websites)*
	14	**Roleplaying** *(like in a theatre, act-out the service or part of it to demonstrate how it works)*
	15	**Desktop walkthrough** *(using cut-out shapes or LEGO bricks to "play-out" a service or experience on the table-top)*
	16	**Blended prototypes** *(a combination of prototypes such as wireframes and roleplay to better convey the message/solution)*
Present	17	**Pitching** *(typically a pitch-deck coupled with the prototype demonstration and short (3-7min) presentation)*

While these 17 tools and methods were used during the three hackathons, facilitators are free to use any tool or method at their disposal to ensure their teams work most efficiently, have fun and produce the best possible result. Similarly, not all facilitators used all the tools mentioned in Table 2. Authors recognize that stronger consistency would help academic analysis, yet, in a hackathon, tools and methods are merely means to help teams work together better and navigate through the innovation process. Therefore, people come before teams and hence facilitators can deploy the tool, they see most fit for the given stage or challenge.

Post-hackathon stage (reflection)

Hackathons are high-energy events, which is the reason why post-hackathon work is often neglected. However, it is strongly recommended to also invest time in this last phase, where the organizing team arranges lessons learned sessions to analyse ideas, patterns and prototypes, and set in motion the wheels for establishing a project or projects based on the winning solutions. The organizing team also collects, structures and stores the outcomes of the event, prepares follow-up work and gets ready for post-hackathon promotion activities. It is important to highlight that leadership support is essential if the seeds of ideas from the hackathon are to sprout into full-grown projects.

Three hackathon case studies

Over the course of 2018, the Lean Analytics Association have organized and carried out 3 separate hackathon events, where one event, the so-called Design Thinking Olympics consisted of 5 individual hackathons. Therefore, this section provides insights into the experience of 7 hackathons for accelerating innovation and rapid generation of ideas.

Case study 01: CEMEX Mobilization Hackathon: Innovating at speed requires engaged employees

On February 9th and 10th 2018, the Lean Analytics Association organized and facilitated the first CEMEX Hackathon featuring over 130 people out of which 101 were participants: 67 CEMEX employees from 9 countries and 34 post-graduate students from 9 leading universities. This intense co-creation event was held in Cambridge, UK and welcomed anyone with a passion for innovation as well as design thinkers to collaboratively solve a challenge that aimed to increase employee engagement, motivation and mobilization, thus developing a new innovative culture in CEMEX.

Thirteen teams of 6 to 8 participants composed of CEMEX employees and students were formed and each team was assigned facilitators from the Lean Analytics Association or one of the 3 Universities (EPFL, Cambridge University and Cranfield University). In addition, one CEMEX employee per team was selected to document and store the generated insights, ideas, and knowledge.

Before the teams kicked-off with their work, hackathon organizers and sponsors delivered the opening presentations, formally opening the hackathon challenge, providing the background information about the

company and challenge itself, introducing the agenda for the two days, and providing a brief training on the design process for the hackathon.

Teams started the journey by doing contextual research and carrying out interviews with CEMEX employees. Using the insights from research and interviews, teams built the persona, a fictive representation of a real person that fits the profile of the segment of people that the challenge is affecting. Furthermore, they developed an empathy map for that persona in order to determine the underlying problem of the hackathon challenge. The idea of the problem statement is to pinpoint the challenge down to one problem based on the learnings and insights from the Empathize step (the first step of Design Thinking methodology; see Figure 4). There might be many problems that are resulting in the challenge, but for the two-day hackathon, teams had to focus on one. In the following step, teams used various brainstorming techniques as devised by facilitators, to come up with as many ideas as possible, before reviewing and ranking them. The idea that received the highest number of votes was prototyped in the fourth step. Teams used various prototyping techniques to manifest their ideas into demonstrators, mainly through the use of paper prototyping, storytelling, roleplaying, wireframing and mock-ups. During the prototyping step, teams had the opportunity to work with three artists from the Starfish Taylor to better visualize their ideas. At the end of the day, each team was given 2 minutes to demonstrate their prototypes to the judges and other teams, who provided their feedback through an interactive voting system. With that, the first day of the CEMEX Mobilization Hackathon came to pass.

The teams kicked off the morning of the second day with a discussion about the feedback received on the previous evening. Based on the new insights, they had to decide either to start modifying their existing concept or make a pivot and select a different idea from their ideation board (which they created during the third step of the Design Thinking Methodology; see Figure 4). All prototypes had to be completed by the end of lunchtime when teams were given time to prepare their final pitches and demonstrations. The hackathon closed after an international jury conveyed, unanimously selected the three winning teams, and announced the winners at the awards ceremony. The winning team received the award of 3,000 GBP and the opportunity to develop their solution further in CEMEX, while the second and third teams received 2,000 GBP and 1,000 GBP respectively.

Authors observed a great level of energy (see highlights from the even in Figure 5), motivation and determination from all participants, who also showed significant interest in the topics of innovation, co-creation and in creative problem-solving. They have collectively generated approximately 1300 high-level ideas, used over 10,000 post-it notes, created 24 prototypes in total, and delivered 13 pitches. In two days, participants collectively put over 1900 man-hours into dedicated problem solving and innovation, which is the equivalent of 1.1 years of one full-time employee. However, this number is presented only to demonstrate how much effort can be achieved in two, focused, days, as the diversity of ideas and vastness of experiences and skills cannot be compared (Flores et al., 2017; and Spaulding & Caimi, 2016).

Michel Andre, the UK Country President at CEMEX, one of the event's key stakeholders, sponsor and judge of the hackathon was well impressed with what was achieved in two days. He wrote, "*What a learning experience! Incredible engagement and passion demonstrated by all participants! Several great ideas being incorporated in our innovation model.*"

Figure 5: Highlights from the CEMEX Innovation Mobilization Hackathon (Cambridge, UK)

Case study 02: México Tierra de Innovadores: Mind the digital talent gap

As part of the first México Tierra de Innovadores (MeXXTI) conference held In Mexico City in September 2018, the Lean Analytics Association organized and facilitated a one-day Business Hackathon with 80 participants including innovation heads, managers and directors of some of the most innovative and successful Mexican companies and 20 junior high students varying from 12 to 16 years old from the Academia Aeroespacial México (Campus Tlaxcala).

One of the most recent trends in business nowadays is Digital Transformation. Many organizations are aware of it or have heard about it, yet, according to studies carried out by MIT Center for Digital Business and Capgemini Consulting, more than 3 out of 4 organizations considered in the study agree that missing digital talent and skills is one of the key obstacles towards their digital transformation (Spitzer et al., 2017). This indicates that there are many organizations trying to reduce the talent gap in their current workforce to enable their organization to be successful in their digital transformation journey and increase the competitive advantage. Therefore, the challenge of this hackathon was aimed at answering the following question: "**How might we help companies to bridge the digital challenge gap?**"

The MeXXTI Hackathon started by formulating 8 teams of 10, where each team had both students and professionals. The event was then opened with the presentation introducing the challenge, the hackathon process, the rules and the awards. While the agenda of the event followed the first four stages of the Design Thinking methodology, some changes had to be made due to a significantly shorter time as in the CEMEX Mobilization Hackathon. Therefore, the empathizing was done in two stages:

- Firstly, three companies, Airbus Defence & Space from Madrid (Spain), CEMEX from Monterrey (Mexico), and Axtel from San Pedro (Mexico), presented the need for the digital talent within their organizations and spoke about challenges they are facing in obtaining or educating it. During that stage, participants were encouraged to take notes and identify any pieces of information and insights that helped them understand the challenge from an industrial point of view.
- Secondly, participants within each team were then divided into pairs and tasked to interview each other, with the purpose of eliciting any additional needs, desires, pains, challenges or experiences related to their work and the hackathon challenge.

As in the CEMEX Mobilization Hackathon, teams then converted the generated insights into a persona, for which they also developed an empathy map. This map provides a condensed, visual overview of what persona is (1) Thinking and Feeling, (2) Seeing, (3) Saying and Doing, and (4) Hearing. Teams were now able to start defining various possible problem statements in the shape of "How might we?" questions. Table 3 displays some examples of the "How might we?" questions from one team's persona (in that case Martha, a Senior Portfolio Manager in the large international organization) in relation to the hackathon challenge:

Table 3: Examples of "How might we?" questions for the Mind the digital talent gap challenge

1.	How might we help Martha to be able to learn about the digital transformation at her own pace during her free time?
2.	How might we enable Martha to learn about digital technologies and how to apply them during lunchtime at work?
3.	How might we help Martha to recruit new people with the digital skills in her team while ensuring the work continues uninterruptedly?
4.	How might we support Martha on her path to convince the company's leadership to invest in internal training development for digital topics?
5.	**How might we help Martha to learn and keep up to date with the latest digital topics that will help her deliver new value to customer and business?**

While all five questions are relevant, by the end of the Define phase, each of the eight teams had to agree on one single question, which they were challenged to answer the same day during the following stages of design thinking. In the example above, the team selected question number 5 - highlighted in Table 1 - as their core problem statement.

Now participants began to brainstorm ideas that could answer the problem statement. Facilitators provided the teams with various brainstorming techniques, and most teams went through two brainstorming iterations. After carefully evaluating each idea, teams had to vote for one that had the biggest potential of answering the selected problem statement. In some cases, where this made sense, multiple ideas were merged into one in order to create one “superior” idea.

Having selected the idea, teams then began to develop prototypes. Most of the teams identified that some form of narrated storytelling in combination with the roleplay is the best way to convey their idea. To develop their prototypes, teams had only one and a half hour, plus an additional half an hour to prepare their demos and pitches. As the final act of the day, teams pitched their ideas to five international judges, who ranked them and their solution according to four evaluation criteria:

1. **Novelty:** How new/unique are the proposed ideas?
2. **Usefulness:** How actionable/feasible are the proposed ideas?
3. **Overall Creativity:** How creative was the team, the idea, the pitch, etc.?
4. **Pitch:** How exciting, clear and memorable was the pitch?

The judges had to select one team as the overall Hackathon Winner, as well as two winning teams for the categories of The Best Pitch and The Crazies Idea. These were announced at the awards ceremony which also marked the official closure of the México Tierra de Innovadores Conference. Figure 6 depicts some of the highlights and moments from the México Tierra de Innovadores hackathon.

Figure 6: Highlights from the México Tierra de Innovadores Hackathon in September 2018

Case study 03: Design Thinking Olympics: Mind the digital talent gap

Design Thinking Olympics is a series of international events in which teams of students from different Universities around the world work hands-on, compete, learn, innovate, prototype. The aim of the Design Thinking Olympics is to solve critical challenges for organizations and society by facilitating the discovery of innovative ideas in collaboration with students, academics, industry, governments and the wider society.

In 2018, the Lean Analytics Association organized 5 Design Thinking Olympics held at the following locations:

8. **Universidad Austral** – Buenos Aires, Argentina
9. **Cranfield University** – Cranfield, United Kingdom,
10. **EPFL** – Lausanne, Switzerland
11. **Tecnológico de Monterrey** – Monterrey, Mexico
12. **EDACY** – Dakar, Senegal

The main organizer in each location called these, Local Design Thinking Olympics. This is because the winning teams of each of the Local Design Thinking Olympics were invited to the second round in London, where the five local winning teams would pitch their solutions at the Lean Innovation Forum organized by the Lean Analytics Association, an international conference on lean thinking and innovation.

Similarly, to the México Tierra de Innovadores Hackathon, the challenge for the Design Thinking Olympics was "How to reduce the digital talent gap towards industry 4.0?" However, in the case of Design Thinking Olympics, this challenge was not to address the needs of the industry, but rather to address the needs of the students close to graduation, that in most cases still do not count with the digital talent required nowadays. Although there is awareness about this talent gap, concrete actions to reduce it are rarely taken. The aim of the Design Thinking Olympics is to solve this challenge in direct collaboration with the students and industrial partners who provide insights. Therefore, the high-level persona, (which participants further explored and enriched during their events) was loosely described as a student perusing a university degree, who is close to graduation and lacking digital skills or who will be searching for a job within 1 or 2 years.

Figure 7: Process of organizing Design Thinking Olympics

While the previous two hackathons were organized in accordance with the methodology described in Section 2 of this paper, the organization of Design Thinking Olympics required somewhat a different approach as shown in Figure 7. The first effort was to invite five universities and find industrial partners who would join the local event as subject matter experts and judges. In parallel, the details, event logistics, and the challenge had to be defined and agreed, and in March 2018 the first Local Design Thinking Olympics took place at the Universidad Austral in Buenos Aires, Argentina. Local events at the other four universities followed between April and June 2018. Each local event yielded one winning team which entered an international competition for a final prize of 2,000.00 GBP towards the idea incubation. However, to enter this competition, all teams had to undergo a second design iteration starting in July and ending in the second week of November 2018, in order to advance their prototype, and this time, test it with the real users. Throughout the second iteration, teams were given support by their local, university coaches, as well as by a global team of facilitators and mentors from the Lean Analytics Association. At the Lean Innovation Forum 2019 in London (UK), all five teams pitched (virtually or in person) their solution to a selected international jury, which used the same four evaluation criteria as in the México Tierra de Innovadores Hackathon. The competition was so close that the jury selected 2 winning teams: The team from Cranfield University (UK) and the team from Tecnológico de Monterrey (Mexico). Figure 8 shows the group photos taken during each of the local Design Thinking Olympics.

Figure 8: Design Thinking Olympics from the top down: Universidad Austral in Argentina, Cranfield University in the United Kingdom, École Polytechnique Fédérale de Lausanne (EPFL) in Switzerland, Tecnológico de Monterrey in Mexico and EDACY in Senegal.

Case study comparison

Each hackathon was organized in accordance with the methodology described in Section 2 of this paper and followed the Design Thinking Methodology. However, each hackathon has been unique and the execution of the CEMEX Hackathon, México Tierra de Innovadores Hackathon, and the Design Thinking Olympics differed from each other and from location to location. Table 4 summarizes some of the key similarities and differences in the organization and execution of the three hackathons and uses the following key: (✓) fully agree/align to the attribute, (~) somewhat agree/align to the attribute, and ( ) does not agree/align to the attribute.

Table 4: Comparing the similarities and differences of the three hackathons

#	ATTRIBUTE	CEMEX Hackathon	MeXXTI Hackathon	Design Thinking Olympics
HACKATHON PROCESS				
1	Followed Design Thinking Methodology			
2	Participants engaged in Empathy Phase			
3	Participants engaged in the Define Phase			
4	Participants engaged in the Ideate Phase			
5	Participants engaged in the Prototype Phase			
6	Participants engaged in the Test Phase	–		
7	Participants had to pitch their ideas			
8	Participants completed at least two design iterations			
9	Participants used templates to help them navigate through the process			
ORGANIZATION PROCESS				
10	Hackathon had a sponsoring company			
11	Hackathon was open to a mixed audience			–
12	Hackathon had a clearly defined challenge			
13	Participant registrations were handled online			
14	Participants had to do some pre-work or pre-reading			
15	Subject Matter Experts were involved in the hackathon		–	
16	Hackathon facilitators and the core team established alignment before the event to follow a standard approach			
17	Formal structured interviews to end-users were carried out during the Empathize phase		–	
18	Awards were provided to the winning team(s)			
19	Hackathon duration	**2 days**	**1 day**	**1 day**
20	Intense promotion to invite students to attend			
21	The voting mechanism from all participants for the first prototype to provide feedback to all teams		–	–
OUTCOMES				
22	Total number of participants	**101**	**80**	**106** [1]

23	The approximate number of generated ideas *(including duplicated, conventional and unfeasible ideas)*	**1300** [2]	**200**	**460**
23	Total number of teams	**13**	**8**	**20** [4]
25	The average number of ideas per team	**100** [3]	**25**	**23**
26	Total number of prototypes	**26** [5]	**8**	**25** [6]
27	Total number of pitches	**13**	**8**	**25** [7]
28	Percentage of students among participants	**34%**	**25%**	**100%**
29	Number of final winners	**3**	**1**	**1**
30	Further work to continue developing and deploying the solution to innovate		**—**	
31	Coding was done by some teams during the event	**—**		**—**

Notes and comments on some of the statistic represented in Table 4:

(1) The total number of participants from 5 locations. Some locations had more participants than others.

(2 & 3) Participants were asked to brainstorm ideas for 6 individual areas, had more time for ideation and went through more brainstorming rounds than in other two hackathons, hence the number of ideas and number of ideas per team is significantly higher.

(4) The total number of teams from 5 locations. Some locations had more teams than others.

(5) Each of the 13 teams developed 2 prototypes (one during the first day and the second one during the second day – the second prototype might have been a modification of the first one or a completely new one).

(6) Each of the 20 teams developed one prototype, however, 5 winning teams were asked to improve their prototypes or develop new ones during the second iteration. The second prototype might be a modification of the first one or a completely new prototype. Hence the final number of prototypes sums to 25.

(7) Each of the 20 teams had 1 pitch, but on 15th November 2018, 5 winning teams will deliver an additional 5 pitches (one per team). Hence the final number of pitches is 25.

Conclusion, challenges and future work

Growing in their popularity amongst entrepreneurial individuals as well as larger organizations, hackathons provide a means to accelerate innovation. The regular organization of internal and mixed-audience hackathons is more than just a 24-hour or 48-hour workshop; it is a change initiative with a great ROI that reaches beyond R&D. Hackathons are a scouting-ground for new talent, a test-bed for 'crazy' ideas, a place for cross-functional and cross-cultural collaboration, a means for identifying and promoting intrapreneurs, and an opportunity to create new businesses and business opportunities.

In this paper, the authors describe the methodology for the organization of corporate hackathons, which provides a three-stage, step-by-step guide covering planning, execution and post-hackathon activities. It enables organizations to prepare an event that delivers value, it helps to change the innovation landscape and it empowers participants and employees to act on the resulting ideas. Furthermore, three case studies of different hackathon events are presented and compared in order to offer deeper and somewhat quantifiable insights into these co-creation events.

However, the organization and execution of the hackathons have different challenges. Furthermore, these latter vary in existence or magnitude, depending on the hackathon type, aim, objective, scale, location, or another variable. The key nine challenges and risks the Lean Analytics Association team faced during the organization and execution of the 3 hackathons are summarized in Table 5. The key used is the following: (□□) indicates in which hackathon the challenge or risk was strongly present; (□) indicates in which hackathon the challenge or risk was present; (□) indicates in which hackathon the challenge or risk was somewhat present). The order in which the challenges appear is random and does carry any significance.

Table 5: Nine challenges and risks when organizing and executing hackathons

#	CHALLENGE OR RISK	CEMEX Hackathon	MeXXTI Hackathon	Design Thinking Olympics
1	**Obtaining the right profile of participants** *Hackathons are attractive to many people, but not all hackathons are suitable for everyone. For example, coding hackathons would struggle to produce good results if the majority of contestants would not have enough or any coding skills.*			
2	**Achieving cross team alignment** *For hackathons to run smoothly, the entire team, including facilitators, presenters, organizers, photographer, venue, catering, workshop leaders, and anyone else involved in the event, must be aligned and aware of what is happening and what needs to happen next. It is also incredibly useful if people are aware of what to do in cases when things do not go as planned.*			
3	**Pick the right and experienced team to facilitate** *Each design thinking facilitator has a different skillset or a different toolkit to offer. Also, some might be more experienced in particular areas than others and it is the organizer's responsibilities to onboard the most suitable facilitators, capable of guiding the teams from the challenge to solution.*			
4	**Timekeeping** *Hackathons are high-energy, time-intense, creative events, where participants are immersed in the design challenge, trying to solve it. This often results in trying to stretch the allocated time to its maximum or even over, in order to gain additional time to perform their activities. Depending on the planning preparations and agenda, this can be allowed, or not in cases of the strict deadline.*			
5	**Attaining unwavering commitment and trust** *This is especially true when organizing a hackathon for a specific company. Hackathons are not a standard business practice yet and, therefore, require strong collaboration, continuous communication and transparency.*			
	Selecting the right challenge/theme *Hackathons typically focus on a specific theme with a specific challenge which the participants need to solve. However, not all challenges are suitable for hackathons, therefore selecting the right ones is of ultimate importance.*			
7	**Wording the hackathon challenge/theme** *Wording the challenge in the right way is critical to a successful organization of any hackathon. It is difficult to attract the right people or ensure the teams understand what they need to do, if the initial theme or challenge is unclear to begin with.*			
8	**Ensuring design thinking stages are clear to all** *The majority of participants are attending the hackathon for the first time; therefore, the agenda needs to be defined accordingly to ensure participants have enough time to get familiar with*			

	their teammates, the challenge and each step of the design process. Workshops parallel to the hackathon (e.g. how to prototype, how to pitch, etc.) might enrich the hackathon outcomes.			
9	**Post-hackathon activities and follow-up** *During the hackathon, a vast amount of new knowledge is generated, and (some) ideas and prototypes that emerge might carry real commercial value. The challenge is, how to document, structure and store the knowledge, and how to ensure the work done during the hackathon is utilized and applied in the organization to really innovate.*			

Relying mainly on regular and transparent communication and collaboration the abovementioned challenges and risks were mitigated or eliminated during the organization, execution and reflection stages. However, further tests and observations are required to derive more concrete conclusions on how to systematically and structurally address or prevent these challenges. It is a question of future research to investigate and further quantify the outcomes, experiences and results of organizing and executing the hackathons. Therefore, authors believe that the future work should look into individual areas of the hackathon organization methodology in depth to provide more specific and comprehensive advice while continuing to measure the benefits and challenges of organizing corporate hackathons.

Acknowledgements

We thank all participants of the three hackathon events, their facilitators, subject matter experts, speakers, visual artists, support staff and sponsors. We express our special gratitude to the CEMEX team for their strong engagement and trust in the organization of the first CEMEX Hackathon in Cambridge, UK. Furthermore, we would like to thank co-organizers of the México Tierra de Innovadores conference, in particular the Premio Nacional de Tecnologia e Innovacion, and the Business Performance Institute, as well as all the partners who supported the realization of the Design Thinking Olympics together with the local Universities in the five locations: Universidad Austral in Argentina, Tecnologico de Monterrey in Mexico, Cranfield University in the UK, EPFL in Switzerland, and EDACY in Senegal.

Track 4.c Introduction: Transformation IN and BY Design Thinking

BIANCHI Mattia[a]; CANDI Marina[b]; DELL'ERA Claudio[c]; MAGISTRETTI Stefano[c]; STIGLIANI Ileana[d] and VERGANTI Roberto[c]

Scholars and practitioners are acknowledging the central role that design can play in innovation (Brown, 2009; Martin, 2009; Verganti, 2009 and 2017; Verganti and Dell'Era, 2014; Liedtka, 2013; Kolko, 2015; Kleinsmann, Valkenburg and Sluijs, 2017). Design is increasingly becoming a strategic source of competitive advantage, to the point that scholars investigate its managerial side and its impact in the creation of value (Capaldo, 2007; Dell'Era and Verganti, 2007 and 2010). Design Thinking, in particular, is making the headlines, with an extremely rapid diffusion in the practice and interest of organizations. Far from being connected with the "form" of products, Design Thinking is accepted as a formal method for creative problem solving, with the intent to foster innovation (Brown, 2009; Martin, 2009; Liedtka, 2015).

This rapid adoption of Design Thinking in practice however has not gone hand in hand with a robust development and diffusion of its theoretical underpinnings. On the practitioner side, Accenture, Deloitte, IBM, KPMG, McKinsey and PricewaterhouseCoopers rank among the most forceful players in acquiring design agencies in order to renew their offering and refresh their approach. Contemporary design thinking is booming in those industries where the digital transformation requires new competences and capabilities for developing delightful digital experiences (Calabretta and Kleinsmann, 2017). On the one hand Design Thinking describes significant transformations highlighting overlaps and synergies with emerging approaches such Design Sprint (Knapp et al., 2016), Agile (Bianchi et al., 2018) or Creative Confidence (Kelley and Kelley, 2010); on the other hand it is considered a fundamental paradigm to lead digital transformations. For this reason, the thematic track "Transformation IN and BY Design Thinking" investigates the evolution of this paradigm in relation to different theoretical lenses:

- Design Thinking and Innovation Theories
- Design Thinking and Creativity Theories
- Design Thinking and Leadership Theories
- Design Thinking and Organizational Theories

Business Empathy: A Systems Thinking Perspective

WARING Jack[a]*; PRICE Rebecca[a] and WARING Carl[b]

[a] TU Delft, Netherlands
[b] University of Derby, United Kingdom
*corresponding author e-mail: jack@jackwaring.com
doi: 10.33114/adim.2019.01.200

The strength of design is that it brings new perspectives - often referred to as 'out of the box' thinking. However, an attitudinal and methodological strength need not render the designer humble in systems-based business knowledge that improves the prospect of ideas being carried through to implementation. Systems thinking as a discipline offers designers a way to model and understand how a business works, from its processes and power structures to its people and underlying architecture. This paper proposes an incorporation of key system thinking tools including; Soft Systems Methodology, Business Architecture and Viable Systems Modelling into the design process to develop what we term business empathy. The paper contributes a system thinking perspective to an increasing body of literature regarding design innovation.

Keywords: Systems Thinking, Viable Business Model, Business Empathy, Holistic Thinking, Servitisation

Introduction

We begin with a scenario:

> *Company A* approaches a design firm with the challenge; assist our company to transform into a competitive force in an 'Industry 4.0' environment. The design firm sees immediate servitisation opportunities; both digital and physical adaptations to current product offerings. The design firm sets to work drafting and developing a series of changes. When the time comes to present these opportunities in a product-service blueprint; a glaring gap emerges. The people that work for the company have mixed views in determining the proposed value propositions and the best way to make the necessary changes. The company's business architecture simply won't support such a transformation, now or in the future. Further, it is difficult to visualise what incremental steps could be taken to optimise value during the business's evolution while mitigating risk associated with the cost of change. It becomes clear that the operational structures and systems within the organisation have not been factored within the design process to the detriment of both client and design firm.

Design (and design thinking) have provided a human-centric posture toward innovation enabling organisations to adapt to changing market conditions and absorb the shock of technological changes. However, the pace of change in Industry 4.0 requires greater attention to the necessary organisational structures to allow continued adoption. Industry 4.0 has been called the next industrial revolution, and is forecast to radically change the relationship between consumers and producers (Roblek, Meško & Krapež, 2016). This revolution will be driven

by physical objects with embedded software, driven by the internet of things (Almada-Lobo, 2015), creating a digitization of economies and society and a digital environment (Pozdnyakova, Golikov, Peters & Morozova, 2018). This mix provides business with the opportunity to gain continuous and real time feedback from operations (Roblek, Meško & Krapež, 2016) with the potential to customize and improve a value offering in a highly adaptive manner (Rymaszewska, Helo & Gunasekaran, 2017). Yet the development of Industry 4.0 also places new pressures on the internal infrastructure of an organisation - the business architecture - to afford self-awareness, self-predicting, self-reconfiguring and self-maintaining business systems (Lee, Kao & Yang, 2014).

Design is known to assist organisations to adapt to new value creation and capture mechanisms by testing deeply held assumptions (Liedtka, 2015). The popularity of design at this time is often constructed along the rhetorical narrative; *it is an age of uncertainty and therefore a prosperous time for design*. Yet gaps can emerge between a design proposal and the necessary business architecture changes to afford such transformation as we explored in our scenario. As we introduced in the scenario of *Company A*, not identifying how a business works can later impede the actionability of an idea or solution that emerges from the design process.

The following paper will look into systems thinking and identify particular tools which designers can incorporate into the design process during servitisation challenges in the context of Industry 4.0. The aim of the paper is to propose how these tools could be integrated into, and strengthen the design process of designers who operate within this context. We broaden the notion of empathising with users and stakeholders to deeply gather insights, to empathising with the logic underpinning existing structures and systems that allow an organisation to operate during explorative phases of the design process. The paper contributes systems thinking perspectives toward the design of product-service-systems in order to bridge the gap between disruption (innovation) and optimisation (implementation). Through this paper we seek not to lock design up in systematic tools, but rather expand the available means through which a designer operating in business can understand, create and implement change. We build toward implications for fourth order design that stem from greater attention to systems thinking, organisations and environments. The paper concludes with reflection upon design's increasing provenance with the business community.

Servitisation challenges of industry 4.0

Industry 4.0, as opposed to previous industrial revolutions, will see the absolute integration of instant communication into all production processes (Sukhodolov, 2018), fuelling the rise of servitisation. This has seen more organisations exploring advanced service offerings such as product service integrated solutions (PSS), with industry-based evidence suggesting it creates closer and more long term relationships with customers improving satisfaction and increasing sales (Hennik Research, 2017; ("Servitisation: The Changing Face of Manufacturing and Service", 2018)).

This shift from purely product-offerings requires organisations to think in terms of comprehensive systems with interdependent elements (Sukhodolov, 2018); and a change in the way they think about innovation. Whereas, 'pure product' was traditionally focused on technical expertise, service innovation requires human centred understanding as the products are not merely stand-alone solutions, but are used in the broader context of a users' life (Agarwal & Selen, 2015). This in turn changes the competitive landscape, where once businesses competed on technology, the new factor for success has become knowledge regarding experience; where the customer is the supplier, and the business the integrator (Burton-Jones, 2003).

While industry 4.0 is presenting these new opportunities for businesses, responding to these changes can be a challenge for businesses (Neely, 2014). Responding to the challenge of better understanding the relationship aspect with their customers organisations have been turning more towards design thinking with it being used as a strategic capability (Dell'Era; Verganti, 2010), as it is intrinsically based around human- centricity (Calabretta & Kleinsmann, 2017).

Design Thinking in the context of Servitisation

Design thinking is an approach for solving human- centred problems (Garrette, Phelps & Sibony, 2018) giving organisations a customer centric view, enabling them to deliver human-centred experiences, which fulfil emotional and functional needs which can be supported by business operations (Calabretta, Kleinsmann, 2017).

As a problem solving process with cognitive origins, design thinking can be seen as a form of abduction aimed at defining the 'What' and 'How' needed to identify a 'Result' (Dorst, 2011) which can be broadly defined in four phases including: the preparation phase, the incubation phase, the illumination phase and the verification phase (Tschimmel, 2012). The design thinking process has been represented in a number of ways including; the double diamond approach, the three I model, or the Hasso Planter Institute model (Stanford/Potsdam model) as represented in Figure 1. The notable aspect of these models is they all begin with a learning phase from defined users. The learning, or empathy stage with users is viewed as a foundation of design thinking (Garrette, Phelps & Sibony, 2018) which deepens understanding into the problem situation enabling the realisation of relevant solutions (McDonagh, 2010).

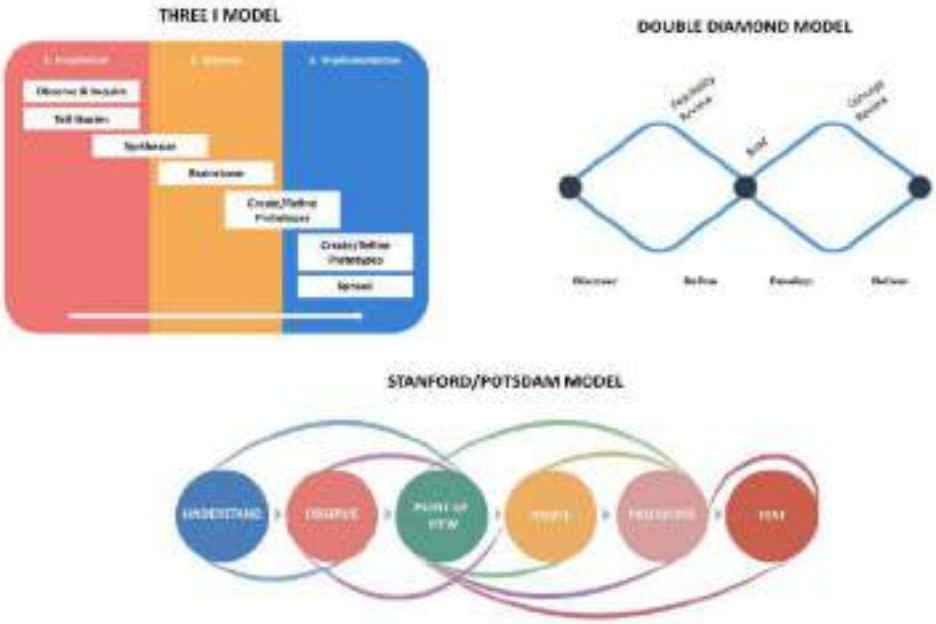

Figure 1: Design Thinking Process Models. Source: Tschimmel, 2012, redrawn

Empathy has been defined as 'perspective-taking' where one places themselves into someone else's position and adopting their perspective (Gasparini, 2015) and in the design process, focuses on key stakeholders namely the end user, within the context of the problem in order to understand their needs. In servitisation, this enables organisations to understand the customer perspective in turn creating a 'customer benefit package' (Goldstein, Johnston, Duffy & Rao, 2002). Through journey mapping and service safari's, designers can capture opportunities in existing processes (Howard, 2014) where improvements can be made to improve the user experience (Scherer, Kloeckner, Ribeiro, Pezzotta & Pirola, 2016). With this information designers can then describe a service in its constituent parts including: service product, process, place, physical evidence, people, productivity and quality, plus additional marketing elements (Goldstein, Johnston, Duffy & Rao, 2002). These are then organised into a process using a service blueprint, such as that shown in Figure 2. Through this designers can create a user centric business model, which visualises the different components and interrelations between stakeholders (Estañol et al., 2017).

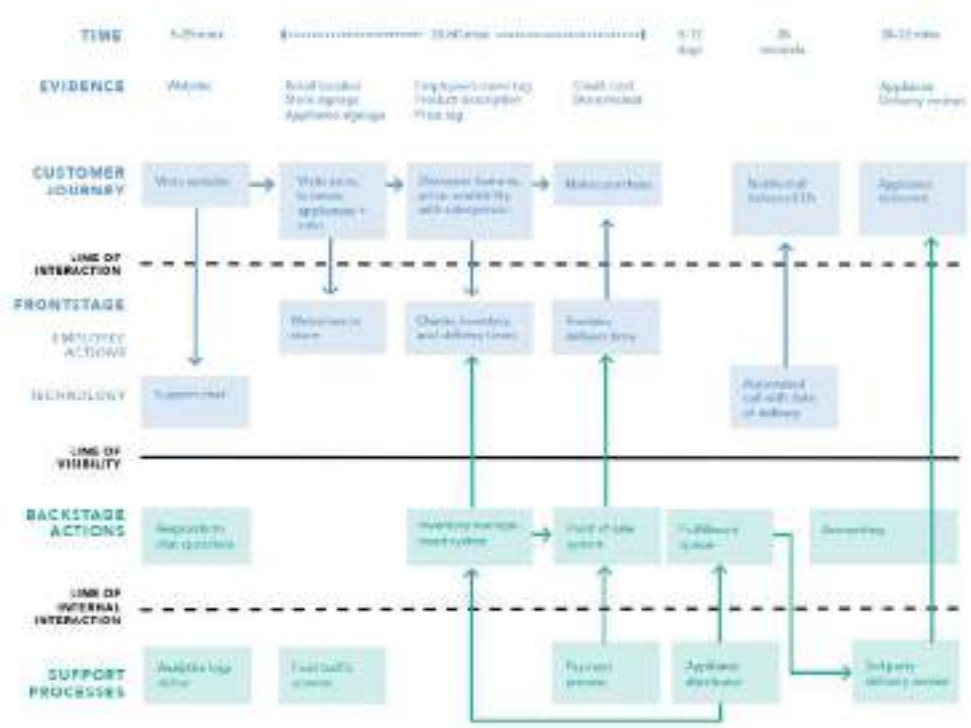

Figure 2: Example of Service Blueprint for online shopping. Source: Nielsen Norman Group, 2017

Limitations of Design Thinking

While design thinking gathers insights to propose business opportunities, these may sometimes be at odds with the current state of the organisation (Martin, 2009). In the context of servitisation, it is important that while designers should understand the user needs, they must also have an understanding of the system which the service will operate in (Calabretta, Kleinsmann, 2017). Without considering both views, the entire picture isn't complete (Kuehn, 2018), and value cannot be delivered until there is alignment between the invention and the business system (Auerswald and Branscomb, 2003). While service blueprinting outlines the requisite components an organisation needs to deliver a service, it lacks the rigorous analytical capabilities to be used to test a service within an organisation (Estañol et al., 2017). Activities up until this point can arguably be seen as product championing, which is demonstrating a problem solution fit and desirability in the market. While this is an important part of the new product development (NPD) process, failure to consider broader ramifications results in strategic neglect which is where focus has only been on desirability and viability, but not on achievability from a business perspective.

In order to avoid neglect, this requires reflecting the concept back into the business, framing it in how it contributes and impacts the business from not only market growth but on its people, processes and structures in what is known as organisational championing (Burgelman, 1983). Strategic neglect leads to what is also known as the 'valley of death' which is the result of short fallings in the organisational capabilities as well as institutional misalignment (Auerswald and Branscomb, 2003). Failure to bridge the valley can result in organisations missing the opportunity to realise value opportunities. The valley of death, as depicted in Figure 3, provides a broad view of the structures, processes, people and resources that are involved in commercially realising a solution. On the graph the y-axis indicates resource availability against the level of development on the x-axis.

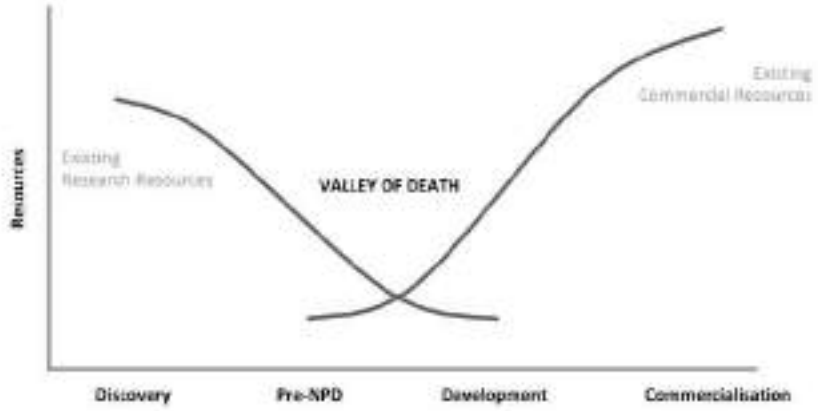

Figure 3: The Valley of Death. Source: Markham, 2002, redrawn

This gap is caused by misalignment attributed to the different perspectives which NPD professionals and organisations have (Markham, 2002). This can be seen where NPD is focused on innovation, which in its nature is disruptive; whereas a business is focused more on efficiency and stability.

Exploring Implementation Challenges in Design Practice

To better understand how this reflects in practice, exploratory interviews were conducted at a design agency currently operating in the space in assisting organisations realise the potential of industry 4.0. The agency does this by translating human insights and pairing it with technology to create new business opportunities in sectors including automotive, insurance and retail.

Interviews were conducted with 12 members of the team ranging from strategy, UX and UI design, project management and innovation consultants. Interviews, which lasted an hour and were semi-structured, asked individuals to reflect on the performance of previous projects with regards to how their work was adopted by clients; asking them to think about what was or wasn't successful. Quotes from these interviews were then coded and clustered in order to identify themes which related to why the products were or weren't adopted. It is worth noting, that the interviews only took on board the perspective of the agency, as such taking the NPD view of the valley of death. Further interviews would need to be conducted from the client side to gain an understanding from both sides of the challenge.

The projects which have been a success range from apps to physical products within a PSS and a key aspect to their success was the matching of the product to the broader context of the business. In two of these instances projects from the client were purely executional in terms of simply building the products. In these cases, the understanding as to how this would align with the organisation was already considered by the client, with pre-existing supporting business cases which gained broader organisational buy-in before development work had begun. Other successful projects had seen the agency take on a much proactive relationship with the client, where the agency had developed longer term innovation roadmaps with the client, and identified components within the business to support the agencies development work. Here the relationship with the client project sponsor in building project impetus within the business had been an important factor.

Speaking with individuals in the agency who had been involved in unsuccessful projects however, found that they viewed the client as a 'black box' and didn't fully understand the 'why' behind the projects. As such, the rationale behind projects reverted to 'common sense', from a viewpoint of what was desirable for the user, viable for the business, in terms of market fit, and what was feasible technologically. While feedback from the clients on the concepts was positive, in later feedback issues arose around business prioritisation, fit for the organisation or resource availability.

While these interviews only take into consideration the design agency perspective, the factors which affected the success or failure of these projects were related to understanding the broader context of the concept within the business. Where the broader implications of how the idea would fit into the business had been factored, either by the agency of client business, adoption and then implementation had been successful.

Those projects on the other hand, without this understanding were often lost at early stages of concept and first prototype, not making it to a pilot stage.

Disciplines for Understanding Business

As discussed by Whittington (2010), there are different approaches organisations can take with regard to process activities including either more deliberate or emergent decision making. Those which take a more emergent approach, can be seen more of as opportunistic where they look to the market to dictate decisions and their behaviour. These can be seen typically as more dynamic and responsive businesses, where taking a customer centric view is likely to be sufficient in decision making. On the other hand however, businesses with a deliberate approach which are more long term planners, look more for clear rational when making decisions. This approach considers legacy aspects within the organisation in order to inform decision making, therein making it more deliberate than opportunistic.

For organisations with a more deliberate approach, the broad range of challenges revealed in the literature review and exploratory interviews related to mindset, process and integration to the business requires a more holistic approach. A discipline such as system thinking enables designers to gain such an overview (Van Ackere, Larsen & Morecroft, 1993). It has been argued that more reductionist views such as business process engineering or service blueprints, compartmentalise processes which focuses on inventing a process from afresh (Romney, 1994). This in turn provides an artificial view of how a business works, where the subtleties between people and process are ignored (Stickland, 1996). As such, a more holistic view of an organisation through systems thinking is suited where not just the business components of a business are considered, but also the interdependencies between them are explored (Ackoff, 1999), as failure to do so typically leads to failure in the implementation stage (Cao, Clarke & Lehaney, 2000).

An Introduction to Systems Thinking

Systems thinking (we will use the acronym ST from herein) finds its roots in a number of different disciplines including philosophy, communication, control engineering and biology (Checkland, 1981). The aim of ST is to understand complex phenomena by reducing it into its elementary parts (Bertalanffy, 1950), and then looking at the interactions between these parts in order to generate a systems view (Ackoff, 1999). Unlike more reductionist methods of viewing a business (or parts of it in isolation), which aim to simplify a system; ST embraces complexity by breaking it into manageable separate elements in order to understand the interdependencies between its parts (Doleski, 2015)

When attempting to understand how a system operates, we turn to cybernetics which is the science of control within ST (Ríos, 2011). Cybernetics concerns itself with the relationships between; emergence and hierarchy, as well as communication and control within a system and how these all interrelate (Ashby, 1961; Checkland, 1991). An important cybernetics principle to consider when looking at organisations is the law of prerequisite variety or Ashby's law, which governs these two relationships. Ashby's law states:

> *For a system to be stable, the number of states that its control mechanism is capable of attaining (its variety) must be greater than or equal to the number of states in the system being controlled. (Naughton, 2017)*

This law is represented in Figure 4 and is true for any open system; whether it is biological or social (Ackoff, 1994).

When this is related to a business context for example 'a business as a system', it means that in order for a business to remain viable and deal to the variety of challenges, whether from the market or elsewhere, it must have a repertoire of responses which reflect the challenges it faces (Lockton, 2018). This variety can be seen as capabilities, information, individuals within the organisation who recognise the disruption.

Figure 5 shows how this variety is delaminated across a business system, between the external environment it operates in, the business operations and then the management of those operations. Between each of these the amount of variety differs, from the environment which has infinite variety, to the process which has less, and the management which has the least. The amount of variety is represented by the size of the 'V'. Between each of these elements exists a feedback loop which controls the communication between each element,

either amplifying or reducing the message (Beer, 1990). In reality, this can be seen by senior management creating initiatives, which are amplified through the business towards the market, and then customer feedback returning and being reduced through reporting back through the business to senior management. Between each of these entities the amount of variety which can be absorbed differs.

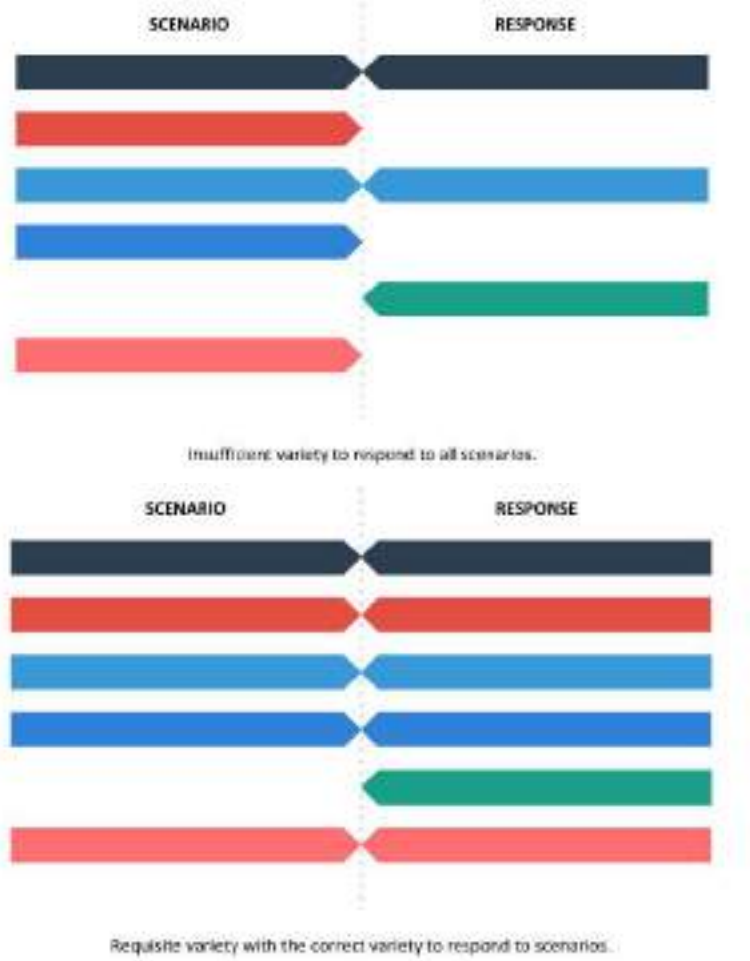

Figure 4. View of a System through Ashby's Law. Source: Lockton, 2018, redrawn

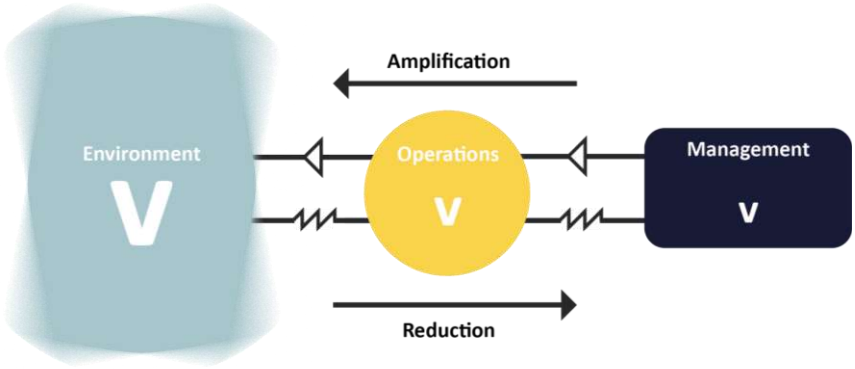

Figure 5. A View of Delamination of Variety across a Viable System. Source: Beer, 1990, redrawn

The purpose of reducing the variety is to ensure that management can focus on only what is necessary, rather than the large range of issues faced in the environment (Beer, 1990). Ashby's law states that how each part of

the system, between the environment and management is able to respond to the information in the feedback loop, determines the viability and survivability of the system. In reality the external environment is perpetually changing. Therefore, there is a constant requirement to continually monitor changes in the external environment as well as the efficacy in the management system to adapt to it.

While Ashby's law indicates how a system, such as an organisation, communicates; it doesn't provide an insight into the individuals within it, which is a critical consideration when understanding a social systems (Ackoff, 1994). As such in the discipline of system thinking a distinction in methods was created between people and processes resulting in soft and hard systems respectively. A hard system is considered something 'which has precise objectives which can be expressed in quantitative terms' (Kirk, 1995), which can be seen in disciplines such as operational research and systems engineering (Oliga, 1988). Soft system's on the other hand is related with human activities, aimed at understanding and reconciling multiple diverse and conflicting definitions of a situation; where there is no precise agreement on the objectives or outcomes (Oliga, 1988). A soft systems approach is concerned with how the system should behave, versus how it actually behaves (Kirk, 1995).

Consideration of both hard and soft perspectives in a business are important, as while a hard systems approach to a solution may appear rational to one individual, other stakeholders may have different views (Burge, 2015) which if ignored can lead to challenges.

Bringing Systems Thinking to Design Thinking

Based on this overview of aspects to consider within a business three themes have been identified which would assist a designer in understanding a business during the development of a new PSS: 1) A tool for understanding how people perceive the business; 2) A tool for understanding the capabilities which exist in an organisation; 3) A tool for understanding the interconnectivity of how a business works. These will come from hard and soft systems methodologies in addition to business architecture. The following portion of this paper will focus on a tool for each of these challenges and then how these can be incorporated into design. We will also draw on parts of the scenario in our introduction to connect to practice.

Understanding Worldviews – Soft Systems Methodology

> Scenario - 'The people that work for the company have mixed views in determining the proposed value propositions and the best way to make necessary changes'

Soft systems methodology (SSM), is a modelling approach which finds its roots in philosophy and social theory (Mingers, 2000), and is used to structure problem situations by providing a holistic view from multiple stakeholders (Checkland, 2000). It is argued by Checkland (2000) that every situation can be seen as a human situation as ultimately it is people who take action within a hard system, where all stakeholders within it have their own worldview or 'weltanschauung' which ultimately affects the performance of the hard system. This is particularly a challenge when individuals unconsciously adopt a particular perspective on a situation which may be completely opposite from another person but yet is still rational causing conflict (Mingers, 2000).

SSM aims to elicit, structure and model different individual understandings of a problem situation to create a structured debate about desirable outcomes, how to get there and the success and failure criteria. In practice SSM has been broadly used over the last 30 years within government and industry; notably within the supersonic aircraft project Concorde. In what was initially considered an Engineering challenge, with the question asked, 'how can British and French engineers logistically work together?', it was soon discovered that the challenge was not simply structural, but cultural and political. Using SSM compromises were able to be found enabling the better cohesion with the team and the eventual completion of the project (Checkland, 2000). There are four main activities within SSM which are illustrated in figure 6, and also described as follows:

1. Find the problem situation including cultural and political aspects;
2. Formulate relevant activity models
3. Debate the situation using the models and debate:
    a. Changes which could improve the situation both culturally and feasably,
    b. Accommodations between the situations.
4. Take action to bring around improvement to the situation.

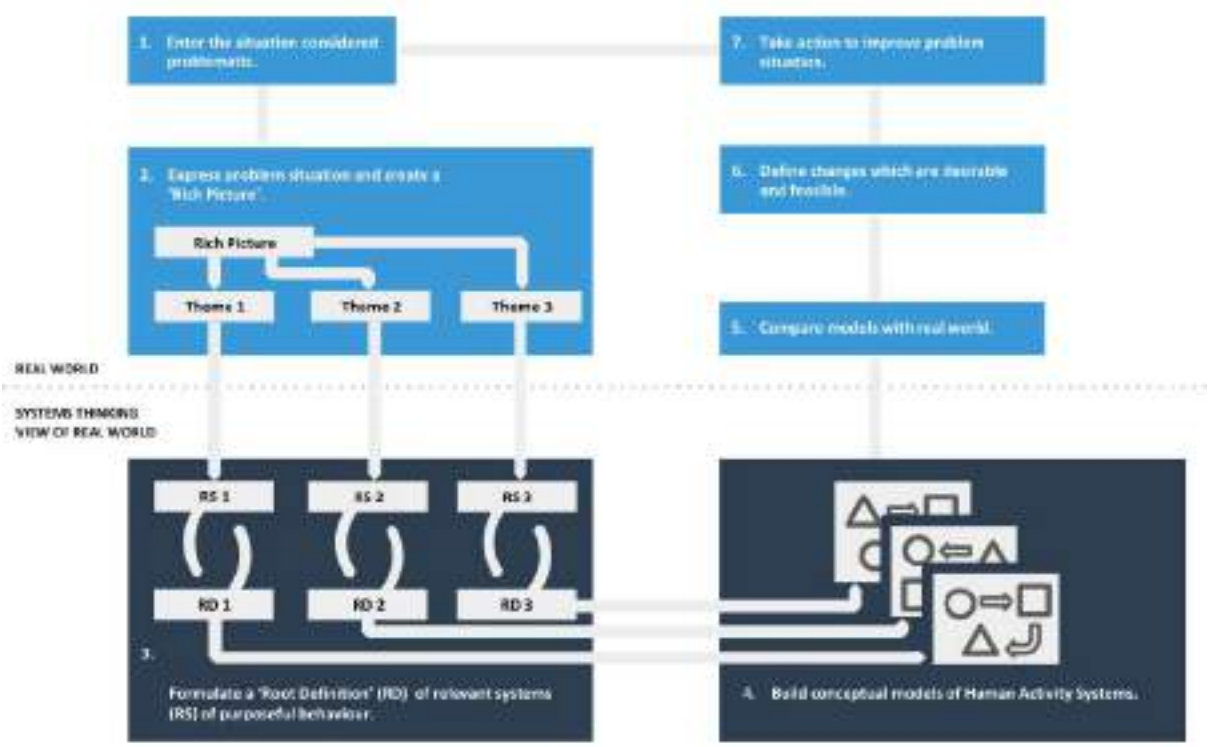

Figure 6. Soft Systems Methodology Framework. Source: Burge, 2015, redrawn

Within this process in stage 1, an understanding of the situation is created through what is known as a 'rich picture', whereby a situation is drawn by a stakeholder in the form of a flow chart from their perspective. Multiple of these are created from various stakeholders which are then compared to create 'root definitions', or points of emergence, of a problem situation (Burge, 2015).

When developing this rich picture, the shared root definition should include the following aspects, which Checkland created using the acronym CATWOE (Burge, 2015):

- Customer: The individual(s) who receive the output from the process (Pandey, 2011).
- Actors: The individuals who are involved in the execution of the process (Pandey, 2011).
- Transformation: The process of changing and input into an output (Pandey, 2011).
  eg. Operational Process
- Weltanschauung: the bigger picture and the reason for 'why' the transformation is taking place (Pandey, 2011).
- Owner: the decision maker who is concerned with the performance of the system (Burge, 2015).
- Environmental Constraints: the key external constraints that are significant to the system (Pandey, 2011).

The aim of the CATWOE analysis is to determine the; 'What to do', 'How to do it' and 'Why do it' (Checkland, 2000), which creates the rich picture of each individual allowing points of emergence and divergence to be highlighted. It is through modelling in SSM that these points of divergence can be highlighted, enabling structured debate in an effort to bring about the desired solution for all stakeholders

The benefit of such an approach to the design process is that it aims to identify the latent needs of stakeholders within a business, identifying diverse and conflicting views with an aim to find consensus. An approach such as SSM can be seen as an addition to a designers tool set, where they set out to identify the latent needs of users.

Understanding Capabilities – Business Architecture

> Scenario - 'The company's business architecture simply won't support such a transformation, now or in the future. Further, it is difficult to visualise what incremental steps could be taken to avoid the risks of inaction.'

In order for a designer to create solutions which align with the business they must understand and gain a cross sectional view of the business from its capabilities to internal value streams (Gharajedaghi, 2011; Kuehn, 2018). This can be achieved through business architecture which aims to create a multidimensional blueprint of a business from its structures to its capabilities. The aim of this is to create an objective view of the business to assist in realising strategy (Winter & Fischer, 2006), which is used as a communication tool between stakeholders to turn value propositions into actionable initiatives (Kuehn, 2018). Through this, internal capabilities can be matched to emerging market opportunities (Gharajedaghi, 2011), as illustrated in figure 7.

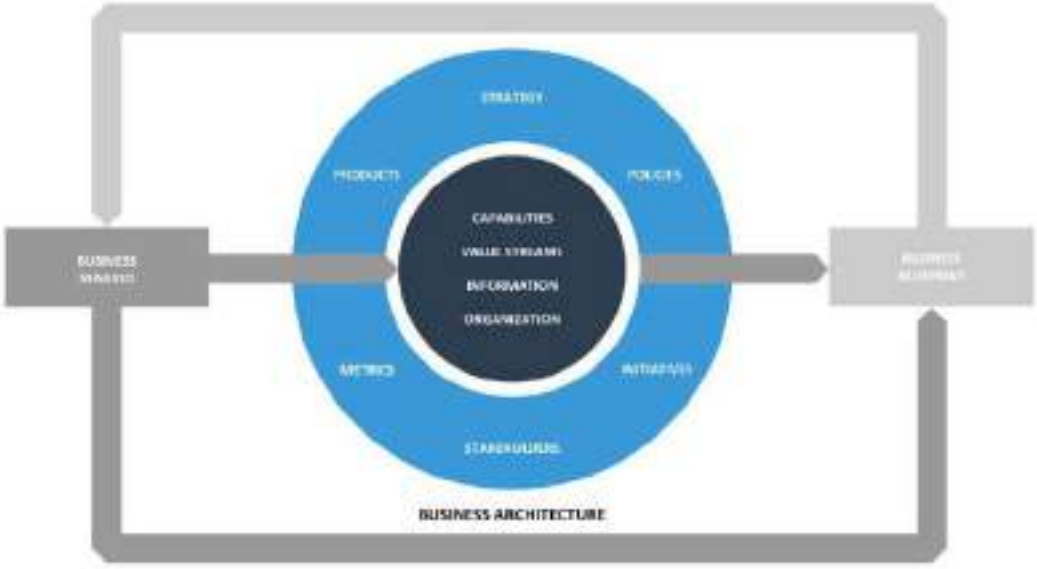

Figure 7. Business architecture flow chart. Source: Kuehn, 2018, redrawn

When the capabilities of a business are connected together through a particular value stream it is possible to understand how stakeholder value (whether internal or customer) can be delivered (Kuehn, 2018). Business architecture takes this view of a business, rather than structure as shown in Figure 8, which does not show internal relationships within the business. Instead business architecture divides these capabilities into four functions of a business including input, output, market access and control capabilities, as shown in Figure 9.

Figure 8. Structural Business Model. Source: Gharajedaghi, 2011, redrawn

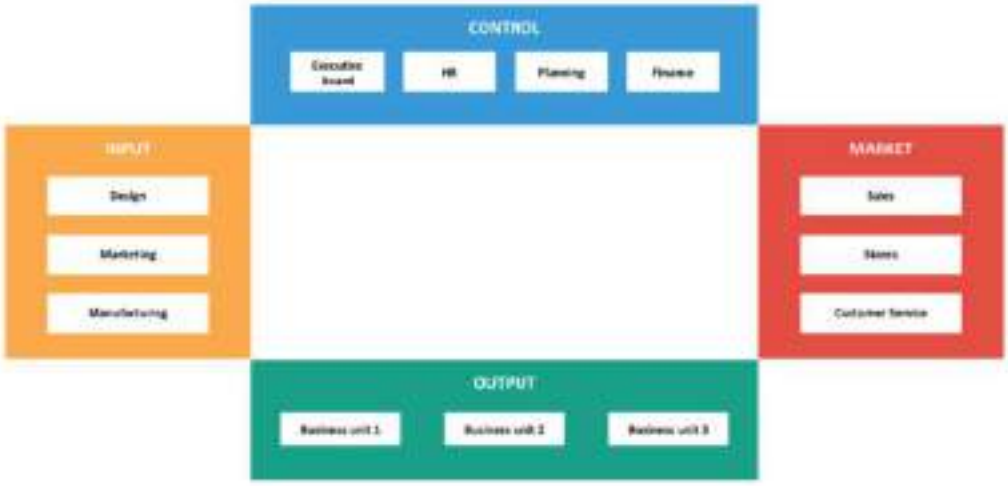

Figure 9. View of Business through capabilities. Source: Gharajedaghi, 2011, redrawn

Through identifying the various capabilities across the different spectrums, they can begin to be connected to create value streams which show the business capabilities required to deliver value as shown in figure 10. Through mapping the business this way, it allows the relationships between peer to peer groups to be seen, from input, to output to market access, allowing the necessary interfaces between capabilities to be highlighted (Gharajedaghi, 2011; Kuehn, 2018).

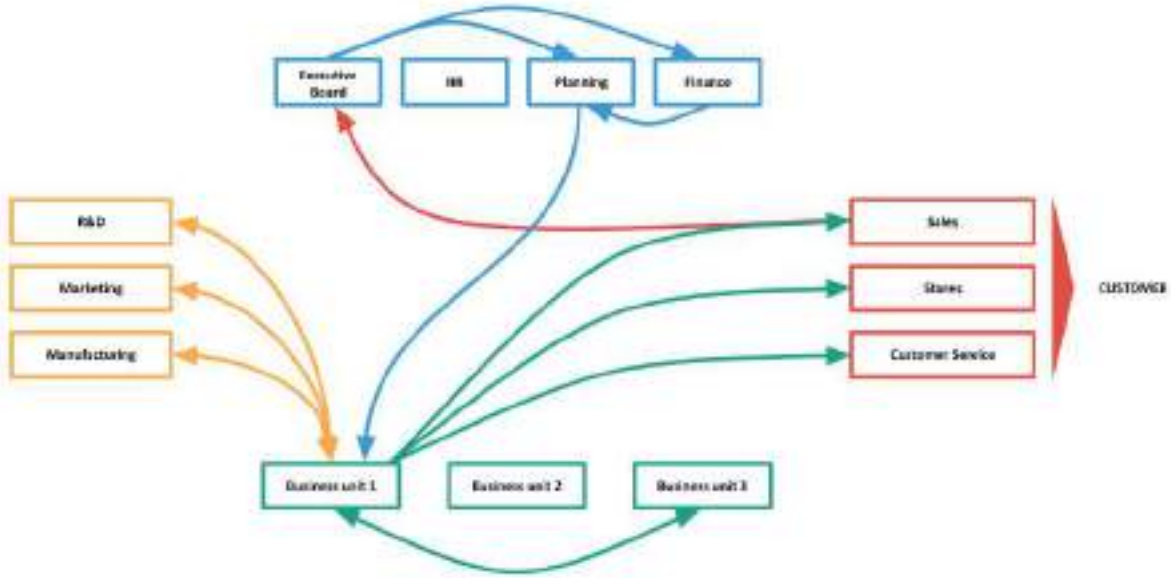

Figure 10. Example of value streams within a business. Source: Gharajedaghi, 2011, redrawn

The aim when identifying capabilities is to remain objective when defining them, as they constitute the basic DNA of a business. By remaining objective, and not tying a capability to a particular outcome, it enables designers and the organisation to reconfigure itself for any given context (Kuehn, 2018).

The benefit for designers, when developing a service blueprint for an organisation, is it allows for an objective view of the business and enables a new service proposition to be compared to existing business capabilities within the organisation. As such for a new service, a designer can propose not only a customer centric business model, but explain this within the current limitations of the organisation and also propose which capabilities will require investment, thus strengthening a service proposal.

Understanding the Workings – Viable Systems Modelling

> Scenario - 'It becomes clear that the existing operational structures and systems within the organisation and how these interdepend and interact with each other have not been factored within the design process'

Once a designer has developed a business model through business architecture, they can use viable systems modelling (VSM) which is an integrated business modeling tool (Wehinger and Herrmann, 2012) to identify deficiencies in existing business system and highlight changes which may need to be made (Hildbrand & Bodhanya, 2015). Unlike more common business models tools, which reduce complexity, an integrated model such as VSM provides a comprehensive framework that breaks down the dynamic aspect of complexity into manageable separate elements (Doleski, 2015).

This integrated business model approach breaks this down by describing all management activities through three lenses that include; Normative, Strategic and Operational management functions. These can be described as follows: Normative is described as the management of general business activities, expectations, values which steers the behaviour of the organisation; Strategic, which is based on normative aspects but steers the focus of the organisation and finally; Operational which focuses on the execution of the day to day tasks. These should all be considered concurrently rather than in isolation, in terms of how they relate to each other (Doleski, 2015).

Based on this aspect, VSM models how each of these functions behave across an organisation through five subsystems which come together to create a viable business which are noted in table 1. The definitions of these systems are identified through qualitative interviews with key stakeholders within the organisation (Hildbrand & Bodhanya, 2015). These all interact as shown in figure 11, which shows the interrelated aspects of VSM, which is essence is an extrapolation of figure 5.

Insufficient performance, missing components or issues in feedback loops between any of these aspects ultimately endangers the viability of the organisation (Hildbrand & Bodhanya, 2015). As such VSM may be applied within the context of analysis, used to run and test scenarios (such as the introduction of a new service) through a system to identify issues in a how an organisation responds. Once these issues have been identified, it enables designers to appreciate potential incompatibilities either within the design of the service or the ability of the organisation to address the requirements for the service to function.

Table 1: Systems required in a Viable Systems Model

Name	*Function*	*What is asks of the Business*
System 1 (Including S1.O (Operation) & S1.M (Management))	Operational unit activities with their direct Management, which are essential duties of an organisation. eg Sales, Logistics, Procurement etc (Hildbrand & Bodhanya, 2015).	What is happening here and now?' (Wehinger and Herrmann, 2012)
System 2 (S2)	Co-ordination of System 1 activities, limiting the principle freedom, to manage each output.	Are optimal standards being exploited for the overall system to work without constraining innovation in system 1 activities and outputs? (Lamb, 2017)
System 3 (S3)	Operational Management, Monitoring and Auditing - Ensures output from all system 1's are coordinated to deliver on broader mission of the organisation. Is responsible for optimizing resource allocation. (Wehinger and Herrmann, 2012)	'What is happening on the short term basis in operative business framework?' (Wehinger and Herrmann, 2012)
System 4 (S4)	Strategic Managment - Makes organisation aware of the current and future environment both in	'What could happen next in the environment or internally in the

	and out the organisation (Wehinger and Herrmann, 2012).	system?' (Wehinger and Herrmann, 2012)
System 5 (S5)	Normative Management - Makes decisions on policy, standards and organisational focus (Wehinger and Herrmann, 2012). Defines the mission and goals and manages the conflict of resource allocation between Systems 3 and 4.	'What should happen in the future based on all the knowledge present in the system?' (Wehinger and Herrmann, 2012)

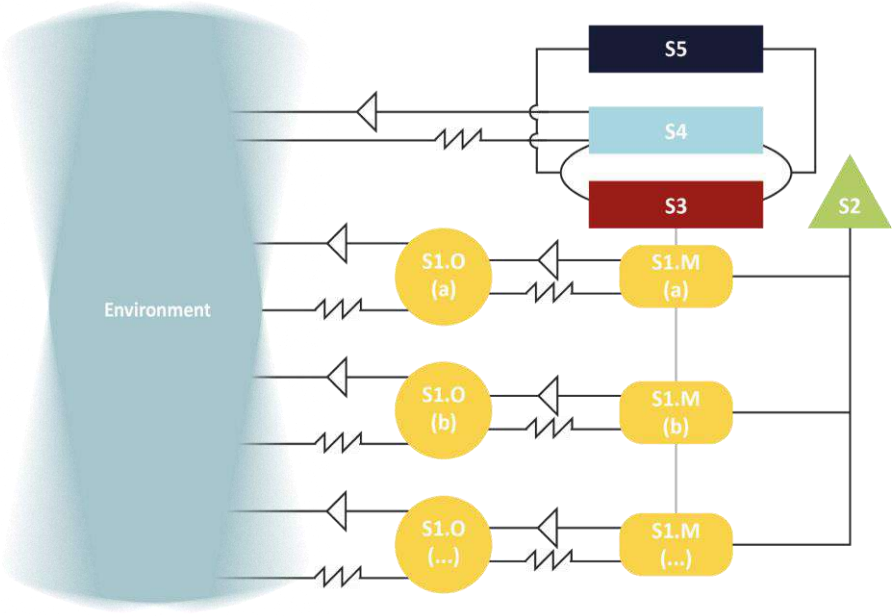

Figure 11: Viable Systems Model. Source: Beer, 1990, redrawn

VSM enables designers to gain a view of the structural recursion of command and control actions within an organisation (Espejo, 2003). Such a view enables designers to model and observe the behaviour of how an organisation reacts the environment it operates in. With such a model it enables designers to identify bottlenecks within the organisation which could limit the implementation of a new PSS solution, enabling discussion about proposed enabling solutions.

Developing Business Empathy

Through this paper we have discussed the importance of acknowledging the various complexities within a business which should be considered when developing and introduction a new PSS. While design thinking provides an insight for businesses into customer behaviour which can be translated into new value propositions, the tools which designers have to understand and articulate these overly simplify the view of a business causing challenges in adoption and subsequent adoption. In order to understand this aspect we propose designers develop what we describe as business empathy. Based on the exploration above this means taking the perspective of the business in terms of the people, processes and structures within a firm which are relevant for the implementation of a new value proposition.

The purpose of business empathy is to allow designers' to pair the knowledge of the current state of the business to a customer centric value proposition. With this information a designer can propose a minimal achievable product, from a business perspective and propose a broader program of projects which move from pure business centricity to more customer centric, or from incremental to more radical design solutions.

The ST tools outlined in table 2, aim to complement the existing tools in the designers toolbox by enabling them to populate service blueprints or business model canvases in a more considered way which reflects the current state of the business. The use of SSM, BA and VSM would enable designers to understand from the businesses perspective; the situation from the internal stakeholders perspective, the existing resources at the disposal of the business, and how the business is managed and is able to respond to new solutions/situations.

Considering how this would be used in practice, we envisage business empathy as opening the black box of how a business works, to aide designers in developing solutions which acknowledge dependencies surrounding implementation. In the case of the design agency interviewed, for projects which require organisational championing; designers would start by using SSM to gain an understanding of the expectations stakeholders had behind the project. Here designers would understand the 'why' and understand the underlying values motivating the project. This would then aide in the shaping of the idea as well as how designers would eventually articulate the value within the business.

When considering how a service would be constructed, designers would consider both the customer and business perspectives. Starting with a service blueprint approach designers would assert the core logic behind the delivery of value to the user. Using BA, designers would then reflect on the actual resources available within the firm to support the delivery of value. With this the designer would compare the customer centric service blueprint and the business centric blueprint. Comparing the two perspectives, the designer would then shape a number of options which scale between complete customer or business centricity. In doing so they create a number of options from a minimal achievable product to a completely customer centred solution. The application of VSM enables designers to take a deeper look at the organisation in terms of the monitoring or communication in order to reflect how the introduction of the new value proposition would impact the organisations processes. Again here designers are able to propose either changes to the business, or incremental solutions which will allow the business to adopt the minimal achievable proposal and adjust according.
Through the application of these tools, business empathy enables designers to discuss value propositions beyond what is simply desirable for the customer in the product championing phase, but discuss their ideas at a higher level within the business through organisational championing.

Table 2. Tools for Business Empathy

Tool	*What it does*	*When to use it*
Soft Systems Methodology	Provides a method of analysis to interpret multiple stakeholders views of situation, such that they can be objectively compared and discussed with said stakeholders.	In order to understand the expectations of a new project from multiple stakeholders (the people within the business), and identify either points of emergence of divergence. The aim here being to create a shared vision.
Business Architecture	Provides an objective view of an organisation's capabilities and value streams.	In order to gain a view of a business's capabilities to shape what supporting activities are required from the business for the value proposition.
Viable Systems Modelling	Reveals interactions and linkages of managerial regulations across an organisation as a whole.	In order to gain an understanding of the communication channels and monitoring activities within a business which the new value proposition will exist in or need to shape proposals how a system can be redesigned to absorb such new proposals.

Conclusion

As design's provenance within management continues to grow, many organisations' are looking become more customer centric. Spurned on at the eve of Industry 4.0 and the potential which IOT brings, companies are finding their old ways of working are being challenged as feedback loops between customer and business move into real-time. These challenges raise questions as to the limitations of the design process, where tools are aimed at customer experience and unpacking technological possibility, ignoring the current state of the organisation. In order to overcome this we propose business empathy as a means of understanding what happens in a business with regards to people, processes, power dynamics and capabilities. By incorporating the established tools discussed in this paper with existing design tools such as the service blueprint or the business model canvas, designers would be able to propose holistic solutions.

The addition of these tools to a designer's tool set builds on the notion that design thinking is user centric and aims to understand the customer, but now frames business as a network of stakeholders including the customer. With designers having the skill set to gain insight on user behaviour at a time when industry 4.0 brings businesses closer to their customers, the organisations who approach this also need to be understood as they will become the user of operating models proposed by designers. By using tools to empathise with businesses, it transforms the role of designers and enables them to develop a mature value proposal aiding them in bridging the valley of death. The use of these tools leads designers to a holistic view of all stakeholders engaged in the product lifecycle and service solutions, replacing prescriptive customer centric business models with a more considered joint business and stakeholder/customer centric solutions.

In order to remain sustainable, organisations' must repeatedly interpret their own operational boundaries, products and services, the environment they choose to work in and how they work within it. As Industry 4.0 has no boundaries, It will be up to organisation's to interpret what value they choose to create around this industrial evolution. Design thinking enables organisations to exploit human centric opportunities, and working with designers who have a holistic approach, will ensure the creation of solutions which reflect the specific and unique challenges of that organisation even during a volatile transition to Industry 4.0.

Research Perspectives IN THE ERA OF Transformations

The Organizational Impacts of Design Thinking used as a Toolbox for Managers or as a Theory of Design

BERGER Estelle[a]* and MERINDOL Valérie[b]

* corresponding author e-mail: e.berger@strate.design
doi: 10.33114/adim.2019.02.204

The adoption of Management Innovation in organizations is difficult to investigate. Controversies exist on the nature of Design thinking (DT), which can be used as a toolbox for managers, or as a theory of design practice. Based on a multi-case study, this article investigates the impacts brought by DT in organizations, in terms of new practices and roles played by designers. Referring to various definitions of DT and its relation to Design, this article proposes a framework articulating the objectives of DT as Management Innovation and its adoption. The results show two intertwined factors: the fit between the cultural, technical and political dimensions of the organization, and the profile of the change agent, designer or not.

Keywords: Design Thinking, Management Innovation, Organizational Culture, Change Agent

Introduction

Management innovation introduces new management practices and processes that are significantly different from the existing norms operating in an organization. If the variety of these innovations and their multiple contributions to the companies' performance has been examined in-depth (Damanpour and Aravind, 2012), their adoption and impacts on the functioning of organizations have been poorly analyzed (Volberda and al., 2014). The management innovations are most of the time put under pressure when introduced in companies (Birkinshaw and al., 2008), and go hand in hand with change management (Damanpour and Aravind, 2012). Outlining the contours of a management innovation and assessing its actual degree of novelty are both complex (Adam-Ledunois and Damart, 2017; Mignon and al., 2017; Volberda and Van den Boch, 2013). Depending on the context in which management innovation is implemented, its new principles and practices are more or less aligned with the initial key features of organizations (Ansari and al., 2010). The degree of rupture brought by a management innovation is therefore analyzed based on its diffusion and adaptation trajectory.

Design Thinking (DT) is a representative case of management innovation whose outlines (Rauth and al., 2014) and degree of novelty in organizations (Carlgren and al., 2016a) are complex to assess. While it is often described as a set of practices for acquiring new innovation capacities (Schmiedgen and al., 2015), the concept of DT remains unclear and may refer to a cognitive style, a theory of design activity or a resource for organizations (Kimbell, 2011) depending on the situation. This debate on its definition and its relationship to the professional practices of designers creates a tension in the assessment of DT as a management innovation. Some consider it to be profoundly transformative for the organization (Brown, 2009), while others approach it as a complementary managerial tool (Verganti, 2009; Mahmoud-Jouini and al., 2016). In one case, the designer's skills are essential to apply and disseminate DT (Walter and Baxter, 2008), while in the other case his practices

are regarded as easily appropriable by managers (Verganti, 2017). Our research question is therefore: what are the organizational impacts of Design Thinking used as a management innovation in companies?

Conceptual frame

The outlines of Design Thinking as Management Innovation

DT results from a formalization of the designers' mode of reasoning (Archer, 1979). It takes its inspiration from their thinking patterns and practices to formulate and solve unstructured problems (Brown, 2009; Johansson-Sköldberg and al., 2013; Kimbell, 2011). Carlgren and al. (2016a, 2016b) and Walter and Baxter (2008) have identified the key practices:

- Multidisciplinarity, i.e. the integration of numerous fields of knowledge, including imagination. DT lies on abductive reasoning: it is about questioning a variety of concepts and their connection with others in terms of a concrete reality that is meant to be transformed (Cross, 2011).
- An exploration approach focused on people's experience (Brown, 2009). Users are at the heart of problem framing and solving, with the help of field observation and/or co-creation.
- The materialization of ideas, reflected in the use of visualization, experimentation and prototyping very early in the exploration process, not limited to technical performance and functionality (Kimbell, 2011).

In view of these practices, DT would constitute a mixed management innovation as presented by Le Roy and al. (2013). On the one hand because it renews the way companies explore, and thus produce knowledge (Mahmoud-Jouini and al. 2016). On the other hand because it impacts the processes, roles and relationships of the different kinds of expertise. It thus tends to bring together specialties and functions of the organization that were previously separated (Brown, 2009; Jahnke, 2013).

This identification of DT as a mixed management innovation depends strongly on how the links between DT and Design are regarded. Thus, Kimbell (2011) highlights two types of relationships: while DT is seen by some as the basis of a general theory on Design, others regard it only as a simplified approach to designers' practices and ways of thinking. Our hypothesis is that this tension between DT as a reflexive foundation for Design discipline or as a managerial practice has strong implications on the measure of the impacts brought by DT in organizations.

The nature of the impacts associated with DT

Depending on the relationship between Design Thinking and Design

Some authors consider DT as a toolbox for managers (Boland and Collopy, 2004), relatively detached from the cognitive capacities and know-how of designers (Deserti and Rizzo, 2014; Verganti, 2017). It is therefore not very transformative, especially regarding the relationships between stakeholders, often applied only in exploration phases. It can be utilized as a method that can be used in a flexible way in order to solve new problems (Krupp and al., 2017) and help to overcome a lack of agility, creativity and ability to explore (Deserti and Rizzo, 2014; Verganti, 2017; Krupp and al., 2017). In this perspective, DT would represent a management innovation with a local impact: integrating into existing and well-defined innovation processes, contributing to their improvement. Although the way knowledge is produced is evolving, the relationships between the stakeholders and organizational functions would not be fundamentally transformed (Verganti, 2009). In this context, the key practices associated with DT would be applied in a flexible or even loose manner (Verganti, 2017).

When DT prefigures a general theory of Design, it represents on the contrary a key step in the transformation of the corporate culture, to put Design and user-centred innovation at the heart of its activity (Walter and Baxter, 2008; Liedtka and al., 2013). As a vector of organizational transformation, DT then aims to fundamentally change the whole process from exploration to exploitation of ideas (Rauth, 2014; Walter and Baxter, 2008; Carlgren and al., 2016a). From this perspective, the potential impacts of DT could be global. It thus features all the characteristics of a mixed management innovation, changing not only the modes of knowledge production, but also the relationships within the company. Many authors point out that adopting DT by systematizing its key practices would lead to major changes: reduction of organizational silos and

adoption of decision-making methods based on a mix between rationality and intuition, at all levels of the company (Brown, 2009; Carlgren and al., 2016b).

This is why we are putting forward the following proposals:

Proposal 1: When DT is considered as a managerial tool detached from Design, it introduces a low degree of novelty, limited to a local scale of the organization.

Proposal 2: When DT is considered as the basis of a general theory of Design, it is disruptive for the organization as a whole, both in its way of generating knowledge and in its relationships.

Depending on the organizational context

The greater the degree of disruption potentially brought about by a management innovation, the greater the problems of organizational alignment increase. Consequently, its content is adapted or altered (Volberda and al., 2013, 2014). Ansari and al. (2010) propose to consider technology, culture and power relations as the key components of organizational contexts. A poor alignment of management innovation with these three dimensions would imply a strong potential breakthrough and difficult adoption. The authors conclude that the adoption trajectories of a management innovation vary according to its adequacy to the context. A technical gap would require a moderate adaptation of innovative practices. If the gap is cultural, innovative practices would be tailored but more broadly adapted within the organization. Finally, a political gap would create an ambivalent movement to strengthen innovative practices and compromise their widespread adoption within the company (Ansari and al., 2010). From this perspective, the local or global adoption of management innovation and its degree of disruption depend on the ability to manage "gaps" with the organizational context (Volberda and al., 2014).

The issues of alignment with the organizational context are presented in the academic literature in different ways depending on the definition of DT. When the latter is seen as a toolbox detached from the Design, the problems appear to be weak, because the practices and methods would be sufficiently flexible and therefore adjustable to adapt to the managers' working methods. Deserti and Rizzo (2014) conclude that the adoption of DT as a managerial tool does not really alter the way large companies operate on a technical, cultural or political level. For example, the materialization of ideas during DT workshops can be based on the use of techniques that are not very different from the practices and thought patterns usually used by managers (brainstorming, mind mapping, use scenarios). Verganti (2017) points out that, in companies with a technology-push approach, DT would help to consider users' experience earlier in the exploration process, without transforming the engineers' way of thinking and problem solving. DT would also be consistent with an organizational culture based on market-pull, as it makes it possible to start from customers' needs. In the statistical approach to marketing, DT would bring a focus on the experiential.

However, while the adoption of DT as a toolbox does not fundamentally change the company's culture it may still have unexpected impacts on internal power relationships. Thus, some authors tend to show a negative impact on the internal legitimacy of the Design department, when there is one (Rauth and al., 2014). The adoption of DT would thus devalue the expertise of designers by giving the impression that their added value compared to the tools and methods of DT is low. For Verganti (2009), it would tend to limit designers' role to aesthetics. In the same perspective, Norman (2010) argues for the abandonment of the concept of DT, considered harmful to the recognition of professional designers in companies. That is why we make the following proposals:

Proposal 3: When DT is seen as a toolbox detached from the Design, practices are developed in a flexible way to align with the technical, cultural and political dimensions of the organization.

Proposal 4: When DT is perceived as a toolbox detached from Design, it can have an undesirable effect on the position of the company's professional designers, by downgrading their expertise.

Conversely, when DT prefigures a general theory of Design, it implies a systematic adoption of key practices (Walter and Baxter, 2008) that may contradict the traditional functioning of established companies. First of all, from a technical point of view, DT brings tools that are new for managers in order to materialize ideas (such as drawing, video or other forms of rapid, physical and virtual prototyping). From a cultural point of view, DT, which reflects the practices of designers, carries reasoning schemes that are not very compatible with those of managers of large companies. Decisions on exploration projects are usually concentrated within the chain of command, and based on rational criteria. On the contrary, DT is based on employees' autonomy and includes intuition in the decision-making process (Carlgren and al., 2006b). Some authors such as Beverland (2005) and

Rylander (2009) go further by pointing out that, in companies where innovation processes are structured by a market-pull and/or techno-push approach, the adoption of DT is likely to be interpreted as a challenge to reasoning patterns and the dominant roles of marketing and/or engineering. With its ability to manage multidisciplinary teams and adopt abductive thinking, Design would then gradually take on a central role in the innovation process, to the detriment of other functions. It thus acts as a "glue" orchestrating all practices in the organization (Walter and Baxter, 2008). Since the cognitive skills and abilities needed to mobilize and operationalize DT at this scale are difficult to acquire (Carlgren and al. 2016b), designers would naturally become key in the innovation process (Walter and Baxter, 2008; Brown, 2009). DT as a transitional phase towards a Design centred corporate culture would thus represent a technical, cultural and political break with the models of established companies. That is why we make the following proposals:

Proposal 5: When DT is considered as the foundation of a general theory of Design, it implies a strict application of its key practices, which are at odds with the technical, cultural and political dimensions of established companies.

Proposal 6: When DT is considered as the foundation of a theory of Design, its adoption reinforces the role of designers and the Design function in the company's innovation processes.

Table 1: Synthesis of proposals from the literature

DT as	*Type of Management Innovation*	*Adoption of key practices*	*Degree of rupture to the context (technical, cultural, political)*	*Impact on the Design function*
Toolbox for managers (Verganti, 2017, 2009; Deserti and Rizzo, 2014)	Local and non-mixed (limited to the production of knowledge)	In a flexible and loose way	Little rupture	Work of specialist or even devaluation of Design expertise
Theory of Design (Brown, 2009 ; Walter and Baxter, 2008 ; Carlgren and al., 2016a and b)	Global and mixed (evolution in the production ok knowledge and relationships)	In a complete and correlated approach to the designers' mode of reasoning	Potentially in strong rupture	Highlighting of designers' meta-competence and at the heart of innovation

Methodology

We used a qualitative method based on a multi-case study (Yin, 2009), allowing to study complex phenomena whose explanation is intrinsically linked to the interaction between a variety of dimensions, actions and relationships (Langley and Royer, 2006). The selected approach is based on abduction, an iterative process of enriching the theory based on data collected on the field (Thomas, 2010). The abductive method can lead to the reformulation of certain proposals resulting from theoretical concepts as well as the emergence of new ones (Gehman and al., 2017). The research protocol followed the precepts of grounded theory (Strauss and Corbin, 1990).

24 semi-structured interviews were conducted with 22 employees from four companies, lasting between 45 and 120 minutes each. We interviewed managers who are non-designers (14) and designers (8). They were three types of profiles: (top) manager in charge of introducing DT in the organization, project manager using DT, and designer (when this is a different person). Data was collected in two phases. A first series of 12 interviews was carried out between 2015 and 2016 in the context of research projects aiming to study the innovation practices and organizational transformation. However, the researchers were not involved in an action research approach to deploy DT initiatives in the companies studied. The interviews allowed identifying the innovation practices and cultures as well as the use of DT and the implementation of Engineering, Marketing and Design functions in change management. 12 new interviewed were specifically conducted in 2017, in order to complement initial data on the links between DT and Design, as part of their adoption by companies.

The interviews were recorded and transcribed by each researcher separately. The analysis process was shared. The coding process was shared, based on the concepts provided in the literature review supra. Iterations generated preliminary results that allowed identifying the level of adoption of DT according to the

organizational context. The coding singled out the practices and objectives associated with DT, as well as the degree and nature of the ruptures brought in the organization, regarding new practices and the design function. The second round of interviews aimed at “theoretical saturation” and generated more “groundness”. Theoretical saturation was not completed until reaching a convergence in coding superior to 90%.

Case study analysis

Presentation of the companies and their Design Thinking initiatives

Companies were selected based on the characteristics that underpin their organizational culture, and the diversity of DT's initiatives over the past five years or more. They all have in common a strong hierarchy, as well as a verticalization of functions and a relatively large silo structure. On the other hand, other criteria differ according to the companies: the place of techno-push and market-pull approaches, which are reflected in the predominance of R&D engineering and/or marketing in the innovation process, as well as the existence of a Design function prior to or concomitant with DT initiatives. These points are summarized in Table 2.

In two cases, Air Liquide and SEB Group, DT represents a creative method used by managers in new user-centred innovation laboratories. As for EDF and Carrefour, on the other hand, DT is at the heart of a company transformation project aimed at integrating design practices more broadly. In the case of Carrefour, the concept of Design Management is even preferred to that of DT, to highlight the strategic value of Design that must permeate all the company's activities.

Table 2: Presentation of companies studied

Company	*Initial culture before the use of DT*	*Design Function*	*Initiatives and objectives associated with DT*
Air Liquide Gas production and associated services	Techno-push (90% engineer)	Non-existent Initially recruiting of a Designer at the I-Lab (2015)	DT as a toolkit for user-centered innovation. Used to enhance creativity in the I-Lab, Innovation laboratory created in 2013 (18 people). Goal: develop radical innovation
Carrefour Mass market	Market-pull Limited scope for innovation	Design Center created in 2009 (30 people, led by a Designer) strategic for innovation	DT as a mode of reasoning associated with professional Design skills. Advocacy led by the Design Centre since 2008. Goal: build up a corporate culture and strategic vision focused on users’ experience
EDF Electricity production and supply	Techno-push	Innovation Hub created in 2000, integrating 12 designers (since 2012) + 3 Innovation Catalysts: DT experts in the group	DT as transversal skills for all innovation activities. Used in intrapreneurial projects, fablab (I2R) and contests in the Innovation Hub since 2012. Goal: cultural transformation to better take into account societal issues
SEB Conception and production of small household appliance	Double approach: techno-push and market-pull	Institutionalized function (44 designers) but limited to product design	DT as a toolkit for interdisciplinary work. Used to enhance creativity in the SEBLab, an innovation laboratory created in 2013 (3 people). Goal: support the group’s business units with rapid prototyping and innovation acceleration

New practices associated with Design Thinking according to the assigned objectives

In all cases, DT-based initiatives involve approaches that focus on users’ experience, multidisciplinarity, and the rapid implementation of ideas (including prototyping). For SEB and Air Liquide, DT is a creative toolkit for developing exploratory projects in the SEBLab and I-Lab innovation laboratories.

When we asked the business units what they needed, [...] people told us about thinking of use, desirability... They also talked about the need to work in co-construction with the other functions of the company. All of them put a name to the methods they wanted to develop inside the SEBLab [...] and most often it was Design Thinking. [SEBLab Manager]

Therefore the goal is to bring new practices, easily usable by managers to complement the existing exploration modalities. Thus, creativity sessions mobilize new materialization tools for the employees: rapid prototyping, drawing (Air Liquide and SEB) or usage scenarios (Air Liquide).

We have no other place [than the SEBLab] to materialize ideas through rapid prototyping or to dare to use drawing as a key element in working together. When SEBLab facilitators lead a creative session with Design Thinking, these dimensions are essential [...] and it profoundly changes our habits and the way we approach projects. [SEB BU Marketer]

For EDF and Carrefour, DT contributes more broadly to a global policy of corporate transformation, with the ambition of impacting all business lines and functions. In this context, convincing people of the interest of DT entails concrete practice rather than methodological training.

The engineer doesn't forget the user or customer, but by professional deformation, he tends to consider this is not his problem. To change you have to educate. This involves changing exploration methods, and also depends on the expectations of engineers... When they consider that they are missing something, then it is easy to get them to change. [EDF R&D Engineer]

Design Thinking was first and foremost an attitude, which was formalized to be understandable by managers. [The objective to achieve is] to recognize it as a bundle of skills fused into all trades. [EDF Collective Innovation Catalyst]

Carrefour uses DT not only to design innovative products (such as a shopping cart imagined after an observation of the uses and unspoken desires of its customers), but also to rethink core activities such as the construction of internal brands' identity. In this perspective of global acculturation to Design, Carrefour even participates in the creation of a joint research laboratory in 2017 dedicated to the value of Design for organizations, alongside other academic and industrial actors.

Changes linked to the adoption of Design Thinking as Management Innovation

On the practices within the organization

Whatever the objective assigned to DT, its associated principles and practices overturn the technical, cultural and political dimensions of each company. Its adoption as a management innovation thus transforms the modes of knowledge production and relationships, but on various scales. The rupture is first of all of a technical nature, through the integration of tools from Social and Human Sciences or imagination.

For example, we invited novelists [...]. It's essential but complicated [...] because in this case, we bring something that really didn't exist before in the company and yet that is essential to innovate [...]. We don't use Design Thinking to present ideas on Power Point, otherwise it's useless! [Air Liquide I-Lab Manager]

The practice of multidisciplinarity also has an impact on the relationships between functions, on a local scale when DT is used in new innovation laboratories (Air Liquide and SEB). Thus, the composition of exploration teams changes from the traditional pair of strategic marketing and R&D engineering, interacting with other functions at specific phases of the innovation process. Within the SEBLab, 5 to 6 representatives of different functions (strategic and operational marketers, R&D and production engineers, designers, and even external users) are involved in all phases of the project over very short periods of time. At Air Liquide's I-Lab, the changes are reflected in the degree of autonomy of project leaders, who do upstream work with marketing, engineering and production functions as well as start-ups, for example to test prototypes with users. They behave like intrapreneurs, enjoying a freedom of organization that allows them to propose new ways of working and relationships in the activities for which they are responsible.

While the most visible changes are local, the adoption of DT can also have impacts on the rest of the organization, reflecting a broader cultural transformation:

I have observed that the practices developed in the I-Lab are gradually spreading beyond [...]. I see more and more employees who use DT at least partially to carry out their project on a daily basis [...] For example, they are looking to change the composition of the teams, including more systematically employees from other functions to find a solution. [Air Liquide I-Lab Manager]

In the cases where DT is considered as a step towards Design, this cultural impact is sought on a global scale. Nevertheless, the transformation has not been completed within EDF. While DT's methods for project management are systematized in the Innovation Hub laboratories, the approaches are not clearly claimed and the associated mindset struggled to be spread. Three cross-functional experts called "Innovation Catalysts" work as facilitators to bridge the gap between the traditional functioning of the organisation and promote DT, which has so far been seen in a rather negative way.

Organizations underestimate the ability of Design Thinking to formalize collaborative processes and organizational forms. Yet it is the discipline best suited to managing complexity. I use it to set dynamics in motion, with a maieutic objective. [Collective Innovation Catalyst EDF]

The obstacles to the adoption of new practices are mainly cultural. DT clashes with the dominant evaluation criteria in an engineering-focused company.

How to enhance other types of innovation in this company where patents remain the standard? This is an on-going discussion... [EDF Project Manager Designer]

If DT represents for EDF a step towards the integration of Design, it is therefore incrementally, without breaking or questioning the preponderance of engineering in the innovation processes.

For Carrefour, on the other hand, the cultural transformation has been faster and more marked since the creation of a Design Centre to meet the strategic ambition of developing innovation centred on uses (Marketing being initially not very legitimate on these subjects). The arrival of a tutelary figure, former head of Design Decathlon, as Design Director has facilitated the process of disseminating DT practices and tools to all branches of the company. Today, the impact of projects carried out according to these Design approaches can be measured by "increased sales or press coverage". This tangible evidence ensures an interest in DT methods on a global scale, although some "silos and power struggles" [Brand Designer Carrefour] remain.

On the Design function

In each case, the adoption of DT also impacts designers and the institutionalization of their role in the organization. For SEB, the designers can be involved from the early stages of exploration projects within the SEBLab, unlike their daily work, where they are limited to product design on prototypes validated by engineers. For them, DT is a rather familiar approach, even if they are *"not used to [mobilizing it] in their daily work"* [Designer SEB]. On the other hand, they were able to bring their technical skills into the SEBLab:

They are the ones who most easily use drawings and graphic representations to reason and share some thoughts.... They are often more active in rapid prototyping or use scenario building. [SEB marketer who participated in a project within the SEBLab]

The experience of designers within the SEBLab has gradually convinced SEB's Design Director that their role could evolve in the innovation processes, gradually including other forms of contribution in the company.

At Air Liquide, where no Design function existed, DT is not associated with any specific business. However, the need to rely on professional skills quickly became apparent, and the I-Lab recruited a designer. This one has a double skill: as a product designer, he masters the methods and tools of field observation and solution Design; as a "design maker", he masters the methods and tools of prototyping. He is a professional who allows *"to move from a traditional logic to a really professional logic"* [I-Lab Manager]. This designer is thus mobilized in all phases of the I-Lab projects. Upstream, he takes part in the study of consumer behaviour, explorations and helps to propose approaches to shift points of view. Downstream, he intervenes in the phases of prototyping and integration of user feedback, up to solution Design.

Within EDF Group, the adoption of DT has made little contribution to the institutionalization of the Design function. The reclassification of the "Transversal Design Manager" function to "Collective Innovation Catalyst" illustrates the low prevalence of the profession. Similarly, no career paths are planned for in-house designers. Today, only one project manager comes from a Design background. Nevertheless, the skills associated with her

original expertise as a designer seem to contribute usefully to managing innovation projects involving DT. *"The ability to materialize, to give shape"* helps her to include and articulate the visions of different stakeholders: *"I seek to give others what I have sometimes lacked [when I was involved in projects]: i.e. meaning"* [EDF Project Manager Designer].

> *Like a cat which kicks his paws and sees how it reacts, you have to develop the ability to judge quickly and accurately, to listen, to detect, to assume responsibility for listening to an intuition. These are not qualities specific to designers, but unlike other professional cultures, they have not at least learned to repress them. [Collective Innovation Catalyst EDF]*

At Carrefour, the Design function has been considerably strengthened over the past ten years. Thirty designers gathered in the Design Centre play an educational role in the group's departments. This can be done through the organisation of training courses, conferences or multi-trade workshops, the production of brochures or videos, as well as the organisation of exhibitions. Many consider themselves as *"Design Ambassadors"* even if their recognition as actors of innovation at the company level is not systematic. While the services are largely convinced of the value of the methods and tools advocated by designers, they use them on an ad hoc basis, sometimes using external competition to reduce lead times. The Design function today aims for a broader political recognition: *"We need [...] to obtain a critical mass of designers in the company [...] and to organize internal governance to avoid bypassing."* [Carrefour Design Director]

Although DT is linked to a global strategic approach for Carrefour, led by the Design function, the political impact remains limited as long as the Design Centre is not fully recognised as a pilot.

Profile and role of the change agent

In the cases studied, two types of profiles carry DT's initiatives: engineers and designers. Their internal legitimacy depends on the organizational context. In the three companies where the culture is mainly based on engineering, engineers with seniority promote DT. For Air Liquide and SEB, the fact that the use of DT is limited to a clearly identified physical location, and that the pilots are familiar with the organization, facilitated the adoption of practices that are at odds with organizational culture. Open and curious, these engineers have initiated themselves into DT by collaborating on projects with start-ups or experienced consultants.

> *It is all the more credible to talk to them about an approach [Design Thinking] that is very different from theirs because we are one of them [...]. It is also reassuring […]. If we have succeeded, then they too can do it. [SEBLab Manager]*

> *It is easier to convince employees to adopt 360° practices in their daily lives when you are at home, when you have managed to do it yourself and when you communicate with the right words to reassure. [Manager I-Lab]*

This internal legitimacy of the change agent has smoothed the political stakes associated with the adoption of DT is key in order to avoid considering the adoption of this management innovation as a questioning of the power held by certain key functions of the organization in the innovation process. For example, as an experienced R&D engineer in the company, the SEBLab manager was able to convince the engineers and marketers responsible for innovation projects to change the way they involve designers, without this being perceived as an infringement of their prerogatives.

Similarly, the main pilot for the adoption of DT within EDF is an engineer. Nevertheless, he defines himself as a *"frustrated designer, pushed towards technology"* [Collective Innovation Catalyst EDF], who discovered DT during his studies at the University of Technology of Compiègne. Convinced of the relevance of dual profiles in a culture of change, he now uses his engineering background as well as his knowledge of Design to formulate approaches and assign the most appropriate designers on a case-by-case basis.

Carrefour is the only case where a designer occupies a hierarchical position that allows him to be an advocate of DT, because his function is sufficiently institutionalized to ensure legitimacy in the company. He acts as a mentor for designers, defending them so that they can do their job as well as possible. *"He tries to open the hierarchical door for us to act."* [Carrefour Brand Designer]

Table 3 synthesizes the results of the compared study.

Table 3 – Synthesis of the results

Company	*Relationship DT / Design in the initiative phase*	*DT change agent*	*Application of DT key practices*	*Trajectory of adoption of key DT practices and degree of novelty*	*Impact on the designers and the Design function*
Air Liquide	DT as management tool	Engineer with seniority	Strictly within the I-Lab, more flexibly beyond	Local disruption in a new Lab, with progressive diffusion of the user-centred approach in other entities of the group	Emergence of the Design function: recruitment of a specialist designer
Carrefour	DT as theoretical basis of Design	Designer at high hierarchical level	Flexibly, considered legitimate on a global scale	Global disruption at the technical and cultural level but partial at the political level (orchestration by the poorly acknowledged Design function)	Design became legitimate to represent the Innovation function because there was a gap to fill
EDF	DT as theoretical basis of Design	Engineer with a strong design culture	Flexibly, considered legitimate on a global scale	Progressive and punctual adoption on which entities of the company: no technical / cultural / political breakthrough	Designers' role still limited, spread in the Innovation Lab laboratories
SEB	DT as management tool	Engineer with seniority	Strictly within the SEBLab	Local disruption in the newly created Lab	Progressive evolution of the role of designers at group level

Discussion

This research allows better qualifying DT as a management innovation impacting organizations on two aspects: the practices associated with exploration projects management, and the role of designers in their implementation.

The way in which DT is used, as a toolbox for managers or as a theoretical basis for Design, is a key element of the theoretical controversy over its degree of novelty. The case study shows that this conceptual debate is not neutral within companies: it strongly influences the strategic objectives assigned to DT, much more than it reveals concrete differences in practice between these two approaches.

Considered as a managerial tool, it is locally deployed in order to acquire new and complementary innovation capacities. When DT is regarded as the theoretical basis of Design, it is promoted as a means of transforming the company's culture and practices in all fields. It is then associated with a mixed management innovation as defined by Le Roy and al (2013), intended to change the production of knowledge and the relationships between actors.

The case study tends to show that these two different visions of DT are linked to different profiles of change agents: DT as a managerial tool is carried by non-designer managers, while DT as a theory of Design is carried by professional designers (Carrefour) or managers who have developed a global knowledge of Design in their career (EDF). These change agents contribute to building meaning around DT. This perspective allows us to rephrase initial proposals 1 and 2, and to propose a new outcome from the field analysis:

Proposal 1 reformulated: When DT is considered as a managerial tool detached from Design, it is based on a strategic objective of acquiring new practices to manage innovative projects. Its application is local.

Proposal 2 reformulated: When DT is considered as the basis of a general design theory, it is based on a strategic objective of global transformation of the organization, both in the way it produces knowledge and in the relationships between actors.

New Proposal: The change agents who use DT as a managerial tool are non designer managers, while DT as a basis for Design is carried by professional designers or managers accustomed to Design and influenced by its practices.

Indeed, the conceptual approaches of DT are linked to different visions of the degree of disruption that management innovation should bring to the organization. But they do not prefigure the actual level of disruption brought by its adoption. In all the cases studied, the practices attached to DT contradict the technical, cultural and political dimensions of large established companies. The strict or flexible application of new practices depends on the need to negotiate their content in regards to the company's cultural and political challenges. In line with Ansari and al (2010), the study showed that these two dimensions determine in which ways the management innovation is adapted. The local adoption of DT as a managerial tool in newly created innovation laboratories makes it possible to strictly apply practices, thus creating a break with existing practices. Using DT contributes to the gap with the rest of the organization by promoting multidisciplinary teams, a user-centered approach and new techniques to materialize ideas. As soon as practices diffuse beyond these laboratories (Air Liquide), they are adapted to fit the cultural and political context of the company. Their application is consequently more flexible, and the degree of rupture less important.

The case study shows that the introduction of DT as a managerial tool does not necessarily devalue professional designers, unlike the results of Rauth and al. (2014) or Carlgren and al. (2016b). Rather, it leads to the enhancement (SEB) or emergence (Air Liquide) of a Product Design function. Moreover, the contribution of designers to the innovation process can extend beyond aesthetics and solution Design (SEB). This positive impact on the Design profession is partly explained by the change agent who plays a key role as mediator, legitimizing the use of DT and reducing potential political tensions. These results lead us to invalidate the relevance of proposals 3 and 4, and to propose the following formulations:

Proposal 3 modified: When DT is understood as a managerial tool, key practices can be strictly applied and therefore a source of disruption as soon as they are adopted in a defined environment that functions differently from the rest of the company.

Proposal 4 modified: DT as a managerial tool introduces a new sensitivity to Design professions, if the change agent contributes to enhancing them through his or her legitimacy, in a way that is consistent with the company's political context.

When DT is considered as the theoretical basis of Design, the gap between the management innovation and the organization can lead to a strong adaptation of DT key practices. Thus, in the case of EDF, despite ambitious strategic objectives associated with DT, the new practices are applied in a flexible way, sometimes on an ad hoc basis, because the engineer's culture remains predominant. In this sense, even if designers' profiles are recognized as relevant in exploration projects, the profession remains poorly represented and valued in the company. The Design function has therefore not been strengthened by the adoption of DT, although change agents play the role of facilitators. This is due to a fragmented hierarchical positioning that does not allow them to act as a lever for global impact.

DT linked to a theory of Design may create a break in practices provided that internal power relations evolve. For instance at Carrefour, the Design Centre promotes DT methods and tools. The function is gradually being strengthened, until being recognized as key in innovation processes – even if not yet unanimously acknowledged. Only then will Design skills appear as a meta-competence at the service of innovation in the entire organization. In this perspective, our results lead us to reformulate proposals 5 and 6:

Proposal 5 reformulated: When DT is seen as a general theory of Design, it is at odds with the technical, cultural and political dimensions of the company, and can only be adopted globally when the political context of the company is favorable to designers.

Proposal 6 reformulated: When DT is seen as the theoretical basis of Design, it strengthens the Design function in the company's innovation processes provided that policy alignment has been achieved.

Table 4 summarizes the results obtained and the new framework for analyzing the impact of DT on organizations.

Table 4 – Analysis of the impacts brought about by DT as management innovation

DT as	*Type of Management Innovation*	*Strategic objectives associated with DT*	*Change agent*	*Degree of rupture depending on the context (technical, cultural, political)*	*Impact on the Design function*
Toolbox for managers	Local and mixed	Bring additional capacity for innovation	Manager non designer	DT practices adopted in a comprehensive and strict manner. They bring rupture in a dedicated space (break with the organization). Beyond the Labs, DT practices are deployed in a flexible way.	Enhancement of the designer as a specialist profession
Theory of Design	Global but little mixed	Support the organizational transformation towards a Design-centered approach	Designer	Tendency to adopt DT's key practices in a flexible way. The technical and cultural ruptures depend on the capacity to change the relationships of power in the organization.	Enhancement of designers' meta-competence. Institutionalization of the Design function, innovation pilot

Finally, an unexpected contribution of this research is to highlight the figure of the change agent to explain adoption trajectories, as suggested by Volberda and al (2014). Therefore, the fact that this manager is a designer or not influences the strategic objectives assigned to DT. In addition, the change agent's internal legitimacy (partly linked to the function embodied) is key in the diffusion of management innovation. Distinguishing between DT as a toolbox for managers and a theory of Design also highlights different skills and contributions of designers in the adoption of DT practices. While using DT does not always require a professional designer as a sponsor, including a variety of expertise and forms of idea materialization remains attached to professional Design skills. In line with Carlgren and al (2016b), these results suggest that the more the company seeks a significant break, the more specific skills are involved in the implementation of DT. Acquiring these skills takes time and can slow down the adoption of DT in organizations.

Conclusion

Until now, research on the degree of disruption associated with DT has mainly focused on its generic principles rather than on its adaptation while diffusing in organizations. This research proposed to consider DT as management innovation in two different ways: as a toolbox for managers or as a theory of Design. This allowed distinguishing between its generic principles and actual adoption trajectories depending on organizational contexts. The results contribute to informing the debate on the impact of DT in companies.

This research presents several perspectives for future work, and limitations. First of all, it does not analyze all the potential impacts of DT on the organization and is limited to impacts on practices and on the Design function. Further work on the decision-making process in innovative projects could thus be useful to complement our approach. Secondly, the generalization of the proposals made in this article is not possible at this stage. The abductive method made it possible to produce relevant hypotheses and a clearer analytical framework to define and evaluate the impact of DT as management innovation, based on the initial objectives attached to it and its adoption trajectory. However, these hypotheses must be tested on more numerous and varied cases. Finally, this study opens up new research perspectives on the role of designers and non-designer managers as change agents.

A Model of Positive Strategic Sensemaking for Meaningfulness

PÄÄKKÖNEN Tarja*; MIETTINEN Satu and SARANTOU Melanie

doi: 10.33114/adim.2019.03.217

This article proposes a design perspective on strategizing by presenting a Model of Positive Strategic Sensemaking for Meaningfulness. Theory elaboration is used drawing from three related disciplinary fields; strategizing, sensemaking and design. It is proposed that positive and human-centred design facilitation enhances strategizing as an ongoing embodied and material activity where meaning changes in strategy and vision may emerge. By viewing strategizing as a socially constructed evolving phenomenon the model adopts sensemaking and critical theory perspectives where the consequences of decisions for human beings and environment guide further activities. Designers as co-strategist may support or challenge an existing strategic direction resulting in incremental or more radical meaning changes among those affected by, and affecting, the emergence of strategies.

Keywords: Sensemaking, meaningfulness, HCD, strategizing, design research

Introduction

This article proposes a new design perspective on strategizing by presenting a model of Positive Strategic Sensemaking linked with broader considerations for strategy and changes of meanings that are facilitated by design professionals. It is proposed that positive strategic sensemaking that is facilitated by design contributes, firstly, to how new, even radical meanings, may emerge (Verganti, 2008; Verganti & Shani, 2016, pp. 104-105) and business opportunities can be explored. Secondly, the article creates links between design that is action oriented, strategy as practice and open strategy discussions. Thirdly, the article contributes to both sensemaking and strategizing as material and embodied phenomena. These three aspects will have an impact on the evolving role and requirements for future design professionals and their education. There is a paradigm shift in which designers gain increasing importance in addressing strategic questions (Åman, Andersson, & Hobday, 2017; Brown, 2009; de Mozota, 2017; Liedtka, 2015; Muratovski, 2015).

Dealing with uncertainty and discovering opportunities in multiple alternative futures are the domains where designers mostly feel at home. The aim of this article is to pay attention to the impact design professionals have in strategic sensemaking, which means exploring vision and interpreting its potential in organizations. This leads to new meaning discoveries for organizations and actors. The model presented in this article draws from design streams in human-centered design (HCD), (van der Bijl-Brouwer & Dorst, 2017), and positive design (Desmet & Pohlmeyer, 2013), and links them with streams of research that address sensemaking and strategy. Johansson and Woodilla (2017) encourage design researchers to expand from the prevailing functionalist view to other paradigms (pp. 461-465). It is in this vein that the article reflects upon what a change towards human-centered design-driven strategic processes may entail. Attention may shift towards the responsibility of broader consequences (Alvesson & Willmott, 2012, p. 30) of the decisions in organizations

concerning their meaning for users, employees, citizens and the environment. This article can be linked with Critical Theory (Burrell & Morgan, 1980, pp. 298-299).

Earlier research has pointed to creative actions that facilitate organizational learning (Beckman & Barry, 2007; Cousins, 2018; Ford & Ogilvie, 1996, p. 4), which in turn aims at, for example, enhanced adaptability (Argyris, 1999, p. 1) needed in uncertain conditions. Learning is believed to increase flexibility and enhance organizational knowledge creation (Nonaka, Toyama, & Konno, 2000, p. 6-7). This article proposes that new meanings for products and concepts emerge from learning through a broadening frame (Dorst, 2015; Paton & Dorst, 2011) through sensemaking that can be facilitated by design professionals.

Following the threads of strategy as practice (SAP), (Jarzabkowski, Spee, & Mets, 2013, pp. 41-44), and open strategy (Whittington, Cailluet, & Yakis-Douglas, 2011, p. 532), the paper yields insights in design professionals working in strategic sensemaking contexts. The framework presents a way of understanding how the impact of design may enable more inclusive and embodied strategic involvement in design-driven organizations. As a result, the design function itself may reach a higher impact at strategic-level decisions. Consequently, the values and practices of designers may transform the way organizations and people in organizations understand and modify their own core meanings and values that drive organizational life. The term strategizing refers generally to activities that lead to the creation of organizational vision and strategies (cf. Vaara & Whittington, 2012) including devising and thinking of strategic issues.

Meanings may change gradually, yet a radical rewiring of core values is not excluded. A parallel can be found from innovation management perspectives: Verganti (2008) has pointed to incremental and radical innovations in contexts in which playing with new materials and technologies is conducive (pp. 444 & 450). Designers are not the only meaning-makers; rather, this article depicts the designer as a co-strategist and facilitator embedded in social situations enabling and triggering meaning exploration. However, human beings who are ultimately the losers or winners of decisions taken within and amongst organizations lie close to the hearts of designers. Radical meaning change, or a change in vision, can have its origins in unknown circles (Verganti & Shani, 2016, p. 104-105). When the conventional management view on the rational consumer who seeks economic advantage is replaced by a broader view of the plural contexts of humans, the consequences of production (Alvesson & Willmott, 2012, p. 30) for the natural environment in which people live gains importance. People seek meaningfulness and seek to emphasize the positive. Vuori, San and Kira (2012) link sensemaking with the need to understand. For meaning-making to occur, the authors explain that people at work seek to create positive order. Thus, this article adopts the presupposition that meaningfulness is the driver of human action.

The article contributes to research discussions on 1) meaning and meaningfulness through design 2) positive design and human-centred design in strategizing and 3) strategizing as a material and embodied design supported activity. These lead to a) a reconsideration of the strategic role of a designer; b) design impact on more inclusive strategizing; and, c) design facilitation contributing to new meanings for products, services and society.

The article uses theory elaboration (Lee, Mitchell, & Sablynski, 1999) and aims at making sense of what is occuring, and what might occur in the future, when a design professional is embedded in organizational strategizing. It draws from the design expert´s perspective and combines it with theoretical insights towards a new cross-disciplinary theoretical model suggesting meaning changes that are influenced by design´s enactment in strategic sensemaking. The model suggests that the search for new meanings within company-level and profit-based views may not be the only factor producing positive meaning changes. Challenging current strategies may open up radical changes towards meaningfulness in all stakeholders. However, theory elaboration typically does not present hypotheses (Lee et al., 1999, p. 164).

Next, methodological considerations are presented, followed by the theoretical framework leading to the model of Positive Strategic Sensemaking (Figure 1).

Methodological considerations

This article utilizes pre-existing conceptual ideas derived from the fields of sensemaking, strategizing and design. It reviews some of this literature with the aim of theory elaboration. As Lee et al. (1999) explain theory elaboration occurs when pre-existing conceptual ideas or producing a preliminary model is the driving factor of the research. Fisher and Aguinis (2017) refer to horizontal theory borrowing as a form of theory elaboration (p. 455), in which an existing theory can be adapted in new contexts crossing disciplinary fields. The

elaboration of theory in this research results from a combination of a cross-disciplinary literature review and overarching themes forthcoming from a longitudinal research on the evolving role of the design profession in organizational settings. These aspects form the core of the proposed model of Positive Strategic Sensemaking.

This article takes largely a sensemaking perspective, yet with a critical perspective by being concerned with consequences (Alvesson & Willmott, 2012) of strategic decisions. Reflexivity is part of qualitative research (Lee et al., 1999, p. 163). The article makes a first elaboration on a theoretical model narrowing the gap concerning the partly overlapping fields of strategizing, sensemaking and designing. Hypotheses and theory testing, however, as Lee et al. (1999) confirm, are not the aim of theory elaboration. Typical for design research, however, is the exploration of what might be. This article has extended this prospective sensemaking aspect into its research approach.

The longitudinal research focuses on experienced professional designers in middle or senior management positions in companies ranging from large technology driven international manufacturers to some specialized renowned design consultancies. The participants represent a range of design disciplines closely linked to service design, such as interaction, industrial, graphic, HCI, UX and experience design. Initially, thematic analysis (Braun & Clarke, 2006) was utilized. It became evident that the overarching themes identified during the analysis required to continue research by employing theoretical elaboration, thus forming the following step across disciplinary borders as part of the ongoing longitudinal research. The research concentrates on exploring how the designers make sense of their professional approach and its contribution to the organizations they work for. The ongoing research considers interdisciplinary interactions as part of the context in which designers work.

Theoretical framework

This article proposes a Model of Positive Strategic Sensemaking. The focus of design is shifting from implementation of existing strategies towards increasingly exploring possibilities of new and fundamentally different meanings and opportunities. Designers are hence becoming co-strategists. In this approach, sensemaking and strategizing are intertwined, becoming one ongoing activity. The model forms the theoretical understanding of meaning change through positive and human-centred strategic sensemaking (Figure 1).

The proposed model draws from and combines three theoretical streams: strategizing, sensemaking and positive HCD. By viewing this triad as one core the model suggests a process in which design embedded in an organization co-acts in continuous sensemaking which is strategic and positive. Aiming at positive change and following the ethos of designers, it considers reflection on the consequences (Alvesson & Willmott, 2012) of future alternatives as a key element in developing and facilitating alternative views in co-creation with participants. Ultimately, any technology, product or system is translated into experiences that either have positive or negative consequences for humans and the environment we all share. The discussion on consequences should thus not be separated from any discussion on profits and innovations. Finally, meaning changes, incremental or radical, and steps towards meaningfulness may remodify the core of the organization towards a better future.

First, sensemaking, strategizing and positive design will be discussed, after which the proposed model will be introduced (Figure 1).

Sensemaking

Sensemaking is an interplay between action and interpretation (Weick, Sutcliff, & Obstfeld, 2005, p. 409). Designers are involved in positive sensemaking embedded in social and discursive, but also material and embodied contexts which can support strategic sensemaking. Designers guided by their ethos may challenge existing organizational values and suggest new meanings. For example, service designers´ specific values are holism, empathy, and co-creation (Fayard, Stigliani, & Bechky, 2017, p. 282). Consequences for humans and environment as guiding principles of design may yield surprising new meanings for participants and users.

Weick (2001/2011) proposes that people act in ways that create value and give meaning to their action, groups act their values to their identities and organizations to their mission (pp. 3-4). Sensemaking unfolds retrospectively during an actual event while uncertainty prevails. In retrospect, events seem to make sense for participants. Weick suggests that micro behavioral commitments can have macro consequences with a social basis (pp. 14-15). The language of goals implies collective justification (p.7). When designers participate in

strategic sensemaking, different perspectives are voiced and visualized. Designers mediate between the values of users, management, stakeholders and other participants. Environmental values and individual meaningfulness can be part of design facilitation. Normal rational routines are broken and allow more space for human sensemaking, beyond profits as the starting point.

Ravasi and Stigliani (2012) examined designers supporting conversational practices by exchanging, combining, and constructing interpretations collectively (p. 1232), and in prospective sensemaking in future oriented group processes (Gioia, Thomas, Clark, & Chittipeddi, 1994), such as strategy making or new product development. Change can be understood as a change in the strategic position or in the cognitive perspective (Mintzberg, 1981, p. 319-324). The participants made sense of their situation for themselves and others, while simultaneously acting both as influenced and influencing actors in uncertainty and ambiguity (Gioia et al., 1994, p. 376). Prospective sensemaking occurs when participants make attempts to see future consequences of their actions as a way of understanding their present situation (p. 378). Key symbols and metaphors were central to the construction of meaning. Symbols formed the means for participants to express their preferences and served as an impetus for influence and action.

Designers´ positive sensemaking utilizes material symbols supporting cognitive interactions (cf. Weick & Roberts, 1993) and knowing in practice (Orlikowski, 2002). Participants are engaged in sensemaking by joint action such as by prototyping items that are not judged on their aesthetic features. Rather, collective understandings and meaning-making are facilitated (D´ellera & Verganti, 2010, p. 125; Krippendorff, 1993a, p. 21; Krippendorff, 1993b, p. 35; Norman & Verganti, 2013, p. 89). Gioia and Chittipeddi (1991) in their study of a strategic change refer to sensemaking and sensegiving (p. 442). Sensemaking is connected with "meaning construction and reconstruction by the involved parties as they attempt to develop a meaningful framework for understanding the nature of the intended strategic change´´ (p. 444). Sensegiving occurs in attempts to influence the sensemaking and meaning construction of others toward a preferred organizational reality. These findings resemble design processes as they, following Gioia and Chittipeddi (1991), took place in an iterative, sequential, and reciprocal fashion. Meaning is socially constructed, while the creation of things is also about interpretation and meaning making. Meaning is always co-created (Ind & Coates, 2013, p. 87).

The current research supports the view that sensemaking processes are anchored in and engage with material settings (Bakke & Bean, 2006, p. 1). These authors transcend the cognitive, intersubjective or communicative approaches and propose materiality as the basis of sensemaking suggesting that both sensemaking and design have an influence on future actions through material elements. Sensemaking studies may hence gain insights from design studies. There is an emergent perspective of organizations as social, discursive, and material systems. Individual identities are formed as cognitive, emotive, and corporeal entities where organizations shape, and are shaped by, individuals, other organizations or societies. In the context of designers´ positive strategic sensemaking, materiality presents itself in specific design units and creative spaces or labs as is evident in the current research. Materiality of thoughts, however, is not limited to the spaces devoted to creative activities. For designers, the material and the cognitive are interlaced and form a design space, both physically and mentally. The material and the embodied are embedded in the social and the cognitive and vice versa.

Strategizing

Strategy as practice (Jarzablowski et al., 2013) uses the verb strategizing to place emphasis on the strategic practices by practitioners (p. 41). Designers often are involved in strategizing, although this is not always explicit. Strategy as practice extends beyond rational strategy analysis, but involves the social and the material (Vaara & Whittington, 2012). Spee and Jarzablowski (2011) reconceptualized strategic planning as a communication process (p. 1219). Referring to Ricoeur´s recontextualization (Thompson, 1981), they show the cyclical and evolving nature of strategic planning where the plan itself is the result of the process of reinterpretations. The relationship between text and talk forms the basis of their analysis. In the current paper, design influences such strategizing by more versatile elements than only text and talk (p. 1238). Additionally, the SAP approach (Jarzablowski et al., 2013) resonates well with the conception of socially constructed meaning in strategizing and the call for research on materials (pp. 41-43).

Strategy can be viewed as situated, socially accomplished activity through the actions and interactions of actors (Vaara & Whittington, 2012). Design experts act as co-strategists by embedding design knowledge into organizational and inter-organizational contexts. Designers are co-strategists who facilitate learning and learn themselves during the process, while helping others to simultaneously experience and learn (Orlikowski, 2002) from the experiences that designers facilitate. Collective positive sensemaking enabled by designers in

strategy-making involves the framing and re-framing of divergent views. Drawing from the present research, it is suggested that design experts facilitate sensemaking in strategic context by hands-on collaboration with multiple stakeholders and by altering between thoughts and material prototypes or other artifacts. Iterative cycles of positive sensemaking allow design experts to support and concretize collective future-oriented sensemaking as a mode of strategic way-finding (cf. Jacobs & Wintrob, 2016, p. 45). Strategic renewal can be viewed as continuous innovation (Ravasi & Lojacono, 2005, p. 54).

Strategizing as a verb and continuous activity enables learning by empowering organizational members to experiment and reinterpret unfolding events. However, the learning school of strategy underlines that strategies balance between deliberate planning and emergent more spontaneous forms of becoming. The emphasis between the two fluctuates over time, yet emergent strategies are connected with more flexibility and better suited to coping with complexity in environments. Important for organizations is the ability to learn and become self-aware of the effects of actions (Mintzberg & Waters, 1985; Mintzberg, 1987) when predictability of future events is difficult (p. 69). Sensemaking, like strategizing, can be viewed as an ongoing activity where strategies unfold. The two form a unity. Not the planning, but rather the joint action and reflection describes strategizing. Both Weick and Mintzberg are thus intrigued by the connection of action and thought in organizations (cf. Argyris, 1999, p. 9) and suggest that action itself *is* to make sense. This implies an ongoing flow of iterative interpretations amongst participating actors who learn from each event. Mintzberg (1987) implies that intentional strategies may remain unrealized (p. 68), and advises organizations to avoid rigidity by fostering a more creative approach.

By viewing sensemaking and strategizing as an ongoing unfolding activity aiming at a positive goal, the current research proposes that design may have an important role in extracting cues and facilitating the emergence of new positively charged meanings, leading even to organizational transformation. Design activities are fragmented, yet often embedded in events, creating opportunities for collective understandings and meaning-making (D´ellera & Verganti, 2010, p. 125; Krippendorff, 1993a, p. 21; Krippendorff, 1993b, p. 35; Norman & Verganti, 2013, p. 89). Mintzberg (1987) speaks of crafting a strategy by comparing a company strategy to the strategy of a pottery maker (p. 66-68). Crafting might better capture how strategies come to being. The potter as a craftsperson "must also resolve one of the great challenges the corporate strategist faces: knowing the organization's capabilities well enough to think deeply enough about its strategic direction" (Mintzberg, 1987, pp.66-68). What matters is learning continuously by experimenting. Elsbach and Stigliani (2018) suggest that experimental design thinking tools (cf. Liedtka, 2015; Tripp, 2016) and organizational cultures are tightly linked. They suggest design thinking tools support the development of the values, norms and assumptions that form an organizational culture. For example, organizations using design thinking tools were more open to experimentation and collaboration and had a culture that valued human-centeredness and collaboration.

The present article suggests that design professionals act as co-strategists in organizational contexts. Especially making as meaning negotiation (Groth, 2017, p.82) can be linked with strategic sensemaking. Design methods (cf. Fayard et al. 2017, pp.292-296) share some similar ideas by placing stakeholders into a situation where making and thinking merge. Experimentation guides further action, learning takes place in cycles. An obsession with control and planning may lead to risk aversion. In such a case, reluctancy emerges towards creative ideas or quantum changes. Both of them are unpredictable and beyond control. (Mintzberg, 1993, p. 33.) Balogun and Johnson (2005) suggest that strategy development should be seen as an emergent process instead of as a top-down model (p. 1573). Mintzberg proposes that organizations utilize more visionary approaches and learning through experimentation (Mintzberg, 1993, pp. 37-38). This line of thought brings design approaches close to the ideas of strategizing.

Open strategy trends have become of interest in strategy research (Whittington et al., 2011, p. 532). Openness is not only connected to innovations and external actors but is also a trend concerning the degree of participation by internal actors (p. 535). Large corporations face new pressures for both greater inclusion and transparency. Strategizing becomes less exclusive and elitist. From a sensemaking point of view, participants with less formal power are nevertheless able to construct meaning resonating with others. This meaning may turn out to be the one enacting an environment (Maitlis & Sonenshein, 2010, p. 572). However, even holding formal power does not automatically lead to a dominant position in constructing meaning as people interpret the given meanings individually. Action follows from collective justification (Weick, 2001/2011).

Many design-driven organizations utilize participatory approaches and co-creation (Degnegaard, 2014; Frow, Nenonen, Payne, & Storbacka, 2015) while designers shift from designing form and function towards participation in strategies concerning services and systems development in, for example, digitalizing

environments. The designer or design team is mostly embedded either in an organization, or guiding an organization from outside in a facilitating role, as a strategic design thinking unit, or as a consultant. However, the designer context, as earlier notions confirm (Verganti, 2008, p. 444), extends beyond the organizational borders.

Positive and human-centred design

The focus on human happiness is central to the world of design. Positive design aims at engagement in meaningful activities; some designers, for example, believe to be able to design happiness (Desmet & Pohlmeyer, 2013, p. 6). Supporting the emergence of new meanings, and meaningfulness is an asset that designers can utilize in their activities. Maitlis and Sonenshein (2010) point to optimistic sensemaking effects on organizations and their members where positive statements emphasize possibilities for actors to enact their futures in post-crisis change situations (pp. 555-556). Meaning is not given; rather, it is co-constructed among participants (cf.Mattelmäki, Brandt, & Vaajakallio,2011). Desmet and Pohlmeyer (2013) use "positive design" as ´´an umbrella term for all forms of design, design research and design intention in which explicit attention is paid to the effects of design on the subjective well-being of individuals and communities´´ (p.6). It is additionally concerned with the side-effects of consumption. Van der Bijl-Brouwer and Dorst (2017) explain how HCD can support exploring deeper insights of the human needs and assign this ability to design expertise built over long term practice. Verganti (2008) suggests that radical changes in meanings imply radical change in sociocultural regimes and can be understood by taking a broader view on long term phenomena (p. 442).

Positive strategic sensemaking has its foundation in the positive attitude often found amongst designers. (Michlewski, 2008, p. 386-387; Brown, 2009, pp. 76 & 242). Michlewski´s (2008) views support the idea that designers are well suited to strategizing; they focus on future and see reality as pliable. Assertion instead of evidence guides their work. Designers may combine the rational, emotional and aesthetic, prefer novel ideas and may stimulate change due to their generally positive attitude towards change (p. 386-387). Especially service design with participatory approaches and empathy (Fulton Suri, 2003) connects with “the human turn” in business and service development. This broadens the scope of service design well beyond services as its only application field and points towards strategic opportunities. Positive design aims at engagement in meaningful activities. The willingness and even enthusiasm to accept constrains is the very foundation of design thinking (Brown, 2009, p. 18). Finding a balance between organizational constrains such as feasibility, viability and desirability contributes to strategic sensemaking (p. 18-21).

Designers´ ethos may well guide an organization towards a future where climate change or other social challenges need broader understanding. With a firm belief in making positive change with good consequences for human lives and nature, designers suggest new strategic meanings and facilitate other people´s voice being heard. Sometimes they may be channeled through designers´ ethos. This research has some links with Sonenshein and Dholakia´s (2012) three meaning-making dimensions explaining employee engagement with strategic change (p. 16). These dimensions (strategy worldview, benefits finding and positive affective meaning) may resonate with positive design facilitation, thus supporting strategic change. Employees’ interpretations of strategic change play an essential role in determining how they ultimately implement such change (p.16). Yet, the model did not discuss radical bottom-up initiated meaning change. Importantly, the content of meaning-making proved essential in understanding employees’ responses to change. The research involved social psychological viewpoints in strategic change implementation.

A Model of Positive Strategic Sensemaking leading to meaning change

The model of Positive Strategic Sensemaking thus draws from the three theoretical streams presented, and combines them: strategizing, sensemaking and positive human-centered design. The intertwined ongoing interplay between the three elements yields a different perspective on strategizing and the role of designers supporting or initiating these activities. Instead of describing a strictly controlled managerial process, the model stresses joint action for meaning construction. The model suggests an ongoing activity with diverse participants and perspectives joined for finding a meaningful focus. This perspective stresses the core of the vision and meaning of organizational life rather than implementation of a distant strategic goal that is given top-down by an organization. Positive Strategic Sensemaking implies an ongoing search for cues that are meaningful enough for actors to change course and, at times, challenge an existing strategy or clarify its content. The strategy is in a constant state of becoming and evolving in an iterative fashion.

Figure 1: A model of Positive Strategic Sensemaking leading to meaning change and meaningfulness. Source: Pääkkönen & Sarantou, 2019.

Allowing even critical views on strategy to surface and be articulated and elaborated on, may yield insights and energize substantial change. This paper proposes that positive strategic sensemaking through the design perspective opens up opportunities for meaning change and increased meaningfulness for participating actors. Incremental meaning changes as Verganti (2008) suggests, follow the existing strategic route and modify it to some extent, yet maintaining the course of the existing strategic direction. In the case of radical meaning change, the direction and basic values of the organization are rewired towards genuinely striving to increase well-being of individuals and communities. It also positively challenges organizational actors to reconsider consequences of consumption and environmental effects on the long term. Ultimately, the support rendered by positive design may transform the organization into a radically new positive direction. Consequently, meanings cannot and should not be forced. Even when proposed, ultimately, the interpretation cannot be managed. What can be beneficial, is ongoing reflection following each move. Paradoxically, challenging the current strategy may thus not be directed to criticizing management, or is not a matter of power play; rather, it can be viewed as a joint positive force in a world that, according to many design perspectives, does require change towards meaningfulness.

The professional designers mentioned some examples of meaning changes. A manufacturing company changed the core of their strategy from a supplier of technology towards understanding their role in enhancing health and well-being at home. New visions around sharing economy have emerged, challenging the traditional conceptions of ownership. Early phase probing, earlier than any prototypes or testing, is an example of continuous extracting of cues that further builds design knowledge available for use in specific situations. Becoming a service company entails support for the crucial role of the employees who provide the promised service experience. A software company focuses on users who generally dislike the software they need to use. Many of these examples changed the strategic understanding of the organization where the designers worked. However, more research is needed to find out if radical changes extend to the less evident aspects such as genuine environmental protection, choice of materials that are sustainable and ethically sound production site conditions. Meaningfulness gains importance on the long run and has value for human beings who form the core of organizations. While these changes cannot be managed, their emergence, perhaps, can be cultivated.

Discussion and Limitations

As to radical innovations (Verganti, 2008; Norman & Verganti, 2014, p. 88-89; Verganti & Shani, 2016), the radical new meaning may become the core of the strategy and transformation inspired by design ethos and support. Designers work in multidisciplinary interactions. Strategizing is not only open to more participants,

but allows insights other than those given or chosen exclusively by conventional management. Radical new meanings need not take quantitative data as the first or only criteria. Other cues and opportunities may guide action such as health, well-being or equality concerns. Reducing cognitive load is a challenge that is not yet solved. One might ask if robots are needed in elderly care and if so, whether children in a few years will be taken to robotic daycare. Regarding the increase of Artificial Intelligence (AI) in service industries, the replacement of mechanical and analytical tasks is estimated to take place rapidly. Instead, intuitive and empathetic skills and creative thinking will offer sustainable and lasting advantages to human service employees. Ultimately, the AI revolution in the service economy is a realistic threat to all employment in the sector. (Huang & Rust, 2018.)

Strategizing is continuous sensemaking. With designers' values and ethos, there is scope for meaning changes with a broader impact. While design managers gain power, the research encourages them to give voice to those who will be impacted by their designs. Designers are both capable of supporting and challenging existing strategies. The latter can take place with designers supporting and triggering change by focusing on consequences for society and people. Material, embodied interactions by design facilitation support learning and create involvement. By finding meaningfulness strategizing makes sense.

Limitations

This preliminary theory elaboration is a first attempt to link sensemaking, strategizing and the positive enabling aspects of design into a theoretical model supporting meaning change. It is meant to serve as inspiration and insight for further exploration and elaboration both among designers and design, strategy and sensemaking scholars. However, Maitlis and Sonenshein (2010) found warning examples of too much optimism where routine actions cause blindness preceding crisis situations (pp. 555-556). Strong positive statements made the event look ordinary and participants neglect the signs of danger. Design-driven organizations and their sensemaking processes on individual and collective levels require further clarification.

One possible purpose of qualitative research is radical change. Following the Critical Theory path, the current paper makes a first elaboration on a theoretical model through which actors in organizations, through sensemaking and responsible reflection, may radically change the meanings of their actions. Such new meanings might guide organizational strategies towards change that benefits the environment and people. However, this research is limited to theory elaboration, instead of testing a hypothesis. Theory elaboration may lead to overly complex theories. Interdisciplinary theory elaboration risks being limited by the depth of scholarship in the field from which one borrows. The aim of theorizing in this article has been both to borrow yet also to contribute to the other fields of sensemaking and strategizing and bring design closer to these disciplines. As to the design field, the model is a step towards better capturing features of the design profession in the context of strategizing, in which the management perspective has been dominant. This research has limitations as to the interpretations made and it cannot exclude the assumptions held by the researchers with backgrounds in business and design fields. Perhaps the model proposed appears to be too optimistic in some cases. Further, the research takes the perspective of design experts' views; a design knowledge perspective that has not gained much attention. In addition, cultural differences have an effect on the intensity of design use. Organizational learning may not always be a beneficent phenomenon and even its desirability as axiomatic can be questioned (Argyris, 1999, pp. 9-14). Neither have Open Strategy developments, so far, led to transfer of decision rights (cf. Hautz, Seidl, & Whittington, 2017; Mantere & Vaara, 2008; Whittington et al., 2011), while the evolving role design experts play in organizational strategizing, requires further research.

Design as a discipline contains multiple streams. Many other design streams could have been included in the theoretical model supporting strategic impact on organizational questions of sensemaking. The model does not claim that designers are the only actors involved in positive change. Yet, reconsidering strategic direction is necessary in times of limited planetary resources and both design and other disciplines need to face this situation as a shared responsibility. Designers are there to support this change.

Conclusions

A Model of Positive Strategic Sensemaking was presented. It utilized the theoretical insights from sensemaking, strategizing and positive and human-centered design. Positive Strategic Sensemaking can be understood as an ongoing evolving sensemaking activity embedded in social and discursive, but also material

and embodied strategic contexts. Positive Strategic Sensemaking implies an ongoing search for cues that are meaningful enough for justification and joint action towards meaningfulness supported by design.

The article proposes that designers support positive strategic sensemaking as facilitators or co-strategists. Sometimes designers, interacting with others, support an existing strategy. At other times, they might challenge the strategy. In both cases meaning changes are made possible and new opportunities may be found. In the first case, meaning changes follow largely an existing strategy with minor changes in products and systems. In the latter case, radical meaning changes might emerge as a result of opening strategy to multiple interpretations among participants. Meaningfulness is a strong trigger for changes that may not be derived from managerial rationalism but from a sense of deeper meaning for human beings. Such genuine meaning changes reside in individuals and societies, waiting for a suitable moment to become active and visible. Radical meaning change, even a new vision leading to transformation, may emerge where designers' ethos guides action.

The research opens new avenues for design to be closely aligned to and associated with strategizing. The current research suggests that positive support by inclusiveness and empathy allows diverse interpretations to be articulated and a broader understanding of issues influencing a future event be constructed. Communication is supported by materials and embodied activities encouraging different perspectives to be heard. The research is of importance to designers showing their strategic importance as facilitators and supporters of meaning change. This has implications for education of designers and managers alike, stressing the search for meaningful consequences as a positive force supported by design facilitation. Future research could, for example, look deeper into meaningfulness by considering the many perspectives involved as well as the enabling and hindering factors behind such attempts on individual, collective or organizational levels.

Social and material embodied design involvement offers space for further research. Research could look deeper into the ethos of designers interacting with other organizational actors enacting their organizational values towards meaningful futures. The research may interest those involved in SAP or open strategy research from design impact point of view. It contributes to the emerging sensemaking literature as material and embodied in addition to cognitive and discursive interpretations. In addition, there seems to be scope for research on strategy emergence, the role of materiality, and critical interpretations of strategy as Vaara and Whittington (2012) point out. This article has provided new insights regarding the role of design experts and their approaches in this context by combining positive design streams with strategizing and sensemaking as an ongoing phenomenon.

Acknowledgements

We wish to express our gratitude to the research team members Ms. Essi Kuure, Junior Researcher, PhD. candidate and Ms. Jaana Jeminen, project manager. The data collection in Silicon Valley was enabled by long term service design research work in three research projects: MediPro (2012-2013), HumanSee (2015-2016) and N4S (2014-2017) funded by Business Finland, the Finnish funding agency for business and innovation. One of the research programs, N4S, was recognized as a SHOK program, the Strategic Centres for Science, Technology and Innovation in Finland.

Research Perspectives IN THE ERA OF Transformations

Envisioning a design approach towards increasing well-being at work

OONK Maite*; CALABRETTA Giulia; DE LILLE Christine and HULTINK Erik Jan

Delft University of Technology, The Netherlands
* corresponding author e-mail: m.m.e.m.oonk@tudelft.nl
doi: 10.33114/adim.2019.04.374

Organizational attention to increasing employee well-being (EWB) is a relatively recent phenomenon, which can be linked to the penetration of information technology, its connection to organizational performance, and millennials facing a lack of optimism about the future. Recent research in the field of management has indicated that design principles like human centeredness and holistic thinking should be applied to create better employee experiences. However, how the positive impact of design on EWB can be achieved, is underspecified in literature. In this conceptual paper, we explore complementarities and potential synergies of design principles and practices with the conditions for EWB, leading to a principle-practice-ingredient (PPI) portfolio. This portfolio can help designers of employee experiences succeed in increasing EWB through the process they apply. For instance when applying envisioning and inspiring activities that address virtue and personal significance to develop workplace tools (such as an app for teamwork around a specific task).

Keywords: Employee well-being, positive and strategic design

Introduction and background

Employee well-being (EWB) can be defined as the overall quality of an employee's experience and functioning at work (Warr, 1987). It has become a major topic of research across several scientific disciplines in recent years (Bartels, 2015). The concept has also been receiving growing attention in business (Heath, 2017). This growing attention is supported by changes in the nature and context of work due to the rise of information technology (Guest, 2017), by its connection to organizational performance (Christian, Garza & Slaughter, 2011), and by millennials facing a lack of optimism about the future (Elliott, 2016). As an example of this growing attention, Facebook surveys its workforce twice a year, asking what their employees value most (Goler, Gale, Harrington & Grant, 2018).

> *Firms spend money on happiness coaches, team-building exercises, gameplays, funsultants, and Chief Happiness Officers (yes, you'll find one of those at Google). (Spicer & Cederström, 2015).*

Yet, many workplace well-being programs seem to have limited effect, as reflected in the low engagement scores measuring the effects of these programs (Morgan, 2017). The limited effects are mainly linked to organizations that apply short-term fixes instead of redesigning the employee experience. The employee experience was defined by Morgan (2017) as a holistic concept; a combination of organizational culture, the technological, and physical environment. These short-term fixes, or static reactions in need for control, seem

to be a recent phenomenon in a world that has become more 'fluid'. This 'fluidity' in terms of more open, complex, dynamic, networked problems will only increase because we live in a nexus between technological revolutions, and momentous social and cultural changes. (Dorst, 2015). Dorst explained that it is crucial to understand the underlying structures of the specific situation.

As part of the initial stage of a PhD project, a preliminary study was conducted by the authors at an international airline company to better understand the reasons for the limited effect of well-being programs. The airline company operates in a highly competitive, regulated and complex business. The preliminary study included in-depth interviews, observations during training- and management sessions, a survey shared with participants in a masterclass (n = 65), and an analysis of recent engagement studies done by Ipsos (Employee Monitor 2013, 2014, 2015, 2017; n = 10564). One of the main conclusions from this study is that HR managers do not know how to actually increase EWB (what to do and where to start with and "how to get the most value for bucks"). Employees experienced substantial benefits from being involved in design processes, such as more freedom to think and act, and a better understanding of the impact of their work related to the company's purpose. The assumed positive impact of design on EWB is further explored in this paper.

Dorst (2015) explained that leading innovators have increasingly been turning to design for help. According to Liedtka (2018), design helps innovators to get around human biases or attachments to specific behavior norms that block innovation. She argues that employee engagement is both a condition for, as well as an outcome of successful innovation, as organizations are built upon people's perspectives and emotions and the experiences of the innovators are shaped by design. A design process or a design outcome can support pursuing well-being (Desmet & Pohlmeyer, 2013). Pohlmeyer (2017) explained that design for well-being can play a pivotal role in facilitating activities and enabling experiences. For instance, Parker (2014), explained that the design of the employee's work experience can be a powerful vehicle to positively impact EWB. Recent research has indicated that design principles like human centeredness and holistic thinking should be applied to employee experiences (Gruber, De Leon, George & Thompson, 2015). However, how the positive impact of design on EWB can exactly be achieved, seems to be underspecified in the literature. The question arises which design principles and practices should be used to increase EWB? The following research question is addressed with a conceptual approach:

> *RQ1: What are the potential design principles, strategic design practices and positive design ingredients that increase EWB?*

The main purpose of this paper is to advance the current understanding of how design can be integrated and leveraged for improving employee experiences. Or, as identified in management literature (i.e., Knight, Patterson & Dawson, 2017), to create an employee experience in which employees can thrive. In this paper, we draw from the literature covering management, psychology and design perspectives on well-being at work, design principles, practices, and positive design ingredients in order to explore solution directions for increasing EWB. We advance an argument that applying a design approach helps to succeed in increasing EWB. We first synthesize conditions for increasing EWB, as part of the first phase of the PhD-project in order to define an initial set of propositions. In this paper we subsequently link these conditions to design practices (i.e. empathizing, connecting, leveraging sensorial aspects, prototyping, inspiring, and applying a 'gestalt' view), underlying design principles (i.e. human and meaning centered, design co-creative and inclusive) and positive design ingredients (i.e. design for personal significance, design for human flourishing). Through this conceptual approach, we organize design principles, design practices and positive design ingredients for increasing EWB into a principle-practice-ingredient portfolio (PPI). This PPI portfolio shows how design practices can be applied to the field of EWB to keep supporting contemporary (employee) innovation activities in a designerly way. Moreover, these design practices can be used as guidelines in combination with experience goals based upon positive design ingredients. Through these guidelines, this paper contributes to the design literature by extending the field of application of strategic design, and by providing initial insights into how the positive design approach can be applied within organizations, for the purpose of increasing EWB. In the following sections the literature review and PPI portfolio are discussed, followed by elaborating on the applications of these guidelines in the final section.

Increasing well-being at work

EWB was described in the introduction of this paper as the overall quality of an employees' experience and functioning at work. This holistic definition is an integrated perspective of the literature domains of healthcare,

sociology, psychology and philosophy (Warr, 1987). The definition moves beyond well-being as a primary affective state (the hedonic view, also known as subjective well-being [SWB]), towards a multi-dimensional phenomenon (the eudemonic view) (Taris & Schaufeli, 2015). The concept has been defined and operationalized heterogeneously in academic literature (Bartels, 2015; Taris & Schaufeli, 2015), varying from affective judgment to a broader phenomenon involving other, non-affective, aspects as well. The broad, holistic perspective, allowing for contextualization (Warr, 1987), is used in this study to define EWB. This definition includes the dimensions affective well-being (organizational commitment), aspiration (personal growth), autonomy and competence (mastery), and integrated functioning as a secondary dimension. Personality factors seem to determine well-being to some degree (Hallberg, Johansson & Schaufeli, 2007; Taris, Van Beek & Schaufeli, 2014). For example, individuals who pursue goals to fulfill intrinsic values (goal self-concordance) experience higher levels of EWB (Bakker & Demerouti, 2008). Since personality factors are generally considered to be difficult to influence, they are left out.

EWB interventions

Improving EWB is seen as a complex task according to management literature. Drawing conclusions about the kind of Human Resources (HR) practices that affect EWB has been difficult (Grant, Christianson & Price, 2007; Guest, 2017). Focusing on EWB brings multiple challenges, as there may be trade-offs between different types of well-being. Synergistically increasing multiple dimensions of EWB instead of creating conflicting outcomes is one of these challenges (Legge 1995; Ramsay, Scholarios & Harley, 2000). For instance, high levels of job challenge and opportunities for growth may coincide with high levels of stress (Cohen & Colligan, 1997).

Few studies on well-being interventions have been conducted (Lyubomirsky, Sheldon & Schkade, 2005). These studies describe only a few examples of synergistically increasing multiple dimensions of EWB, such as involving employees in the design of safety practices, leading to an increase in social, physical, and psychological well-being (Grant, Christianson & Price, 2007). Most of these studies focus on positive psychology approaches (Bolier et al., 2013; Wright & Cropanzo, 2004). Positive psychology was defined as 'a scientific understanding and effective interventions to build thriving in individuals, families, and communities' (Seligman & Csikszentmihalyi, 2000, p.13). The positive psychology approach often takes a one-size fits all approach, even though personalization based on people's need could work better (Bolier et al., 2013). Experiencing positive emotions (Fredrickson & Joiner, 2002), and task significance and variety are positive influencers of EWB (Hackman & Oldham, 1976). Multiple positive interventions at once may be more effective than engaging in only one activity (Sin & Lyubomirsky, 2009). Yet, much well-being-related research focuses on studying the effectiveness of single interventions at a time.

Three main short-comings in literature were identified:

- Well-being can be understood and measured in many different ways and relates to a wide range of concepts. It should not be limited to affect (SWB) only;
- Synergistically increasing multiple dimensions of EWB is a challenge, with only limited evidence of approaches that have succeeded in this;
- Very few EWB intervention studies have been conducted, mostly in the field of positive psychology, using a one-size fits all approach, only studying a single intervention at a time.

Towards a principle-practice-ingredient portfolio

We identified seven conditions for increasing well-being at work. These conditions were derived based on an in-depth literature review that included human resource management, psychology and organization research streams. The conditions for increasing EWB at work are codified in Table 1. In this table, illustrative references are included, highlighting the cross-disciplinary agreement over time. These conditions can be summarized as ensuring interventions are tailored to individual needs (Condition No. 1), address a sense of mastery and competence (Condition No. 2), address a sense of self-determination (Condition No. 3), address organizational commitment and support (Condition No. 4), address the job's meaningfulness (Condition No. 5), address the need to explore and assert (Condition No. 6), and include the broader context of EWB (Condition No. 7). The conditions for increasing EWB as shown in Table 1 are illustrative rather than exhaustive and will be further explained in the next sections.

Table 1 Conditions to increase EWB and illustrative references

No	*Conditions to increase EWB*	*Illustrative references*
1	Importance of tailoring interventions to individual needs	"In addition to demonstrating that happiness-boosting interventions can work for at least some people, this […] provides further support for our proposition that the fit of the activity to the person makes a difference" (*Lyubomirsky, Sheldon & Schkade, 2005, p. 124)*
		"It goes without saying that a user-centred approach is pivotal to positive design, because the user will be the only expert truly able to assess her own subjective well-being" (*Desmet & Pohlmeyer, 2013, p. 14)*
2	Importance of having a sense of mastery and competence	"How happy workers feel; how motivated they are by an intrinsic interest in the work; how positively they view […] their work, and themselves—all these combine either to push them to higher levels of achievement or to drag them down" (*Amabile & Kramer, 2011)*
		"First of all, […] healthier people possess a stable sense of identity – they have a good sense of who they are" (*Kets de Vries, 2001, p. 104*)
		"Furthermore, organizational leadership has to create the conditions to foster a sense of competence, signifying that organizational participants have a feeling of personal growth and development" (*Kets de Vries, 2001, p. 108*)
		"[…] think of in terms of five main components of mental health in Western societies. Those may be labelled as […] competence […]" (*Warr, 1994, p. 84)*
		"[…] we have identified the needs for competence […] – that appear to be essential for facilitating […] personal well-being" (*Ryan & Deci, 2000, p. 68*)
3	Importance of having a sense of self-determination	"The combination of employing and expressing a person's preferred self yields behaviors that bring alive the relation of self to role" (*Kahn, 1990, p. 700*)
		"Closely tied to this need for exploration is self-assertion, the ability to choose what one likes to do" (*Kets de Vries, 2001, p. 106*).
		"[…] think of in terms of five main components of mental health in Western societies. Those may be labelled as […] autonomy […]" (*Warr, 1994, p. 84)*
		"[…] we have identified the needs for autonomy […] – that appear to be essential for facilitating […] personal well-being" (*Ryan & Deci, 2000, p. 68*)
		"Happiness mostly results from an individual's ability to make choices" (*Gavin & Mason, 2004, p. 388)*
4	Importance of organizational commitment and support	"By supporting people and their daily progress in meaningful work, managers improve not only the inner work lives of their employees but also the organization's long-term performance, which enhances inner work life even more" *(Amabile & Kramer, 2011)*
		"[…] positive relations and working climate*returns once again to the perception of well-being as a positive quality of interpersonal relationships, regardless of the rules and position held" (*Biggio & Cortese, 2013, p. 9, 10)*.
		"People vary their personal engagements according to […] the guarantees, or the safety, they perceive in situations" (*Kahn, 1990, p. 703*)
		"Clearly, work characteristics influence psychological work adjustment factors that ultimately affect employee health and well-being" (*Wilson, DeJoy, Vandenberg, Richardson & McGrath, 2004, p. 582)*
		"A healthy organization is one characterized by intentional, systematic, and collaborative efforts to maximize employee well-being and productivity by

		providing […] a supportive social–organizational environment […]" (*Wilson, DeJoy, Vandenberg, Richardson & McGrath, 2004, p. 567)* "The results of this study support Laschinger's research that workplace climates and engagement were positively associated, suggesting that organizational leaders, managers, and practitioners by improving workplace climate in their respective organizations could increase employee engagement and increase the likelihood of positive individual-level affective outcomes […]" (*Shuck & Reio, 2014, p. 54)*
5	Importance of meaningfulness of one's job	"Whether the goals are lofty or modest, as long as they are meaningful to the worker and it is clear how his or her efforts contribute to them, progress toward them can galvanize inner work life" (*Amabile & Kramer, 2011)* "[…] work engagement is more strongly related to job characteristics that are associated with the perception of meaningfulness of the work itself […]" (*Christian, et al., 2011, p. 122)* "[…] an individual experiences positive affect to the extent that […] he cares about (experienced meaningfulness)" *(Hackman & Oldham, 1976, p. 255, 256)* "[…] people were personally engaging in situations characterized by more psychological meaningfulness than those in which they were disengaging (*Kahn, 1990, p. 704)"* "When a workplace is designed and managed to create meaning for its workers they tend to be more healthy and happy" (*Gavin & Mason, 2004, p. 381*)
6	Need for exploration and assertion	"[…] everyday progress—even a small win—can make all the difference in how they feel and perform" (*Amabile & Kramer, 2011*) "Playful exploration and manipulation of the environment in response to exploratory-assertive motivation produces a sense of autonomy, initiative, and industry" (Kets de Vries, 2011, p. 106) "[…] think of in terms of five main components of mental health in Western societies. Those may be labelled as […] aspiration […]" (*Warr, 1994, p. 84)* "[… those record the degree to which a person seeks out challenging goals in his or her job, a process which can be viewed as a central aspect of job-related aspiration*"* (*Warr, 1994, p. 86))* "Optimal psychological functioning requires not only that one achieve the prior characteristics, but also that one continue to develop one's potential, to grow and expand as a person" *(Ryff, 1989, p. 1071)*
7	Importance of a broader (multi-dimensional) perspective of EWB context	"[…] the individual and situational perspectives on the relation between individual well-being and performance are interconnected" (*Taris & Schaufeli, 2005, p. 24*) "The final aspect of mental health, integrated functioning, concerns the person as a whole and the relationships between other components" (*Warr, 1994, p. 86*) "Happiness is a holistic ideal" (*Gavin & Mason, 2004, p. 388*)

Building on the understanding of conditions for employee engagement, the following sections introduce an illustrative PPI portfolio for establishing well-being at work by addressing the research question:

RQ1: What are the potential design principles, strategic design practices and positive design ingredients that increase EWB?

We follow a similar approach to Karpen, Gemser and Calabretta (2017) by synthesizing the conditions for well-being at work and subsequently linking them to design principles (Beverland, Wilner & Micheli, 2015; Buchanan, 1992; Karpen, Gemser & Calabretta, 2017; Luchs, 2015; Swan & Luchs, 2011), strategic design practices (Argyris & Schön, 1974; Calabretta, Gemser & Karpen, 2016) and positive design ingredients (Desmet & Pohlmeyer, 2013). The illustrative PPI portfolio in Table 2 lists those practices and ingredients relevant for increasing EWB. The portfolio consists of seven illustrative constellations of conditions for increasing EWB, design practices, combined with the tools and methods of positive design. Each constellation builds on foundational conditions for increasing EWB that are well established in the literature (e.g. *Christian, et al., 2011; Lyubomirsky, Sheldon & Schkade, 2005; Ryff, 1989*), as shown in Table 1. The examples are used to outline a preliminary employee experience view of design practices and to lay the foundation for an evolving research stream in strategic design. In the following sections, design principles, strategic design practices and positive design ingredients will be subsequently discussed, in relation to the seven constellations.

Design principles

Businesses increasingly use design as a way to innovate in today's digital environment (Calabretta & Kleinsmann, 2017). As Kolko (2015) states, "There is a shift underway in large organizations, one that puts design much closer to the center of the universe". This study adopts the definition of design from Buchanan (2001, p.9): "the human power of conceiving, planning, and making products that serve human beings in the accomplishments of their individual and collective purposes".

Improving EWB can be considered a strategic challenge, as redesigning the employee experience involves several stakeholders, implies a long-term approach and a certain degree of risk, and requires a variety of resources (Gruber et al., 2015). As a result, strategic design was used as a starting point for reviewing design literature, since this is the research domain where this kind of challenge is dealt with (Calabretta, Gemser & Karpen, 2016). Strategic design connects design principles to practices that can be applied for strategic purposes and can be defined as "[…] the use of design principles and practices to guide strategy development and implementation toward innovative outcomes that benefit people and organizations alike" (Calabretta, Gemser & Karpen, 2016). The design principles as coded by Karpen, Gemser and Calabretta (2017), served as the starting part for this review. The principles that were considered relevant in the context of this study and could be directly linked to the conditions for increasing EWB can be found in Table 2.

Table 2. The principle-practice-ingredient portfolio for increasing well-being at work

Constellation	*Design principles*	*Guidelines in the form of strategic design practices*	*Positive design ingredients*
First constellation: individual needs	Design is human- and meaning-centered in nature	Empathize: the ability to deeply listen and create a dialogue to reach hidden needs	Design for personal significance *(personal engagement)*
Second constellation: sense of mastery and competence	Design is human- and meaning-centered in nature	Empathize: applying a 'people-first' approach, addressing individual competences and capabilities	Design for virtue *(identity affirmation, self-esteem);* Design for personal significance (*identity affirmation*)
Third constellation: sense of self-determination	Design is co-creative and inclusive in nature	Collaborate: connecting with others to influence the results	Design for personal significance *(control/autonomy)*
Fourth constellation: organizational commitment and support	Design is co-creative and inclusive in nature	Collaborate: being involved in creating solutions	Design for personal significance *(interpersonal connectedness)*
Fifth constellation: meaningfulness of one's job	Design is transformative and betterment-oriented in nature	Envision: helping organizations incorporate a future oriented, long-term perspective into their objectives	Design for virtue *(being a morally good person, identity affirmation, self-esteem);* Design for personal significance (*perceived impact, significance of work*)
Sixth constellation: exploration and assertion	Design is emergent and experimental in nature	Prototype: visualizing and materializing processes and outcomes to make intangible insights, ideas and concepts tangible, sharable and understandable	Design for personal significance *(pursuing personal goals)*
Seventh constellation: broader context	Design is holistic and contextual in nature	Simplify, structure (applying a 'gestalt-view'): selecting, connecting, and leveraging the relevant resources and knowledge to manage the complexity of the project, therewith taking the full context into account	Design for human flourishing (*individuals who live their fullest potential*)

Firstly, design being human- and meaning-centeredness in nature can be of relevance for improving employees' experience. Several sources describe the importance of context and tailoring interventions to individual circumstances needs in order to increase EWB (i.e., Knight, Patterson & Dawson, 2017; Lyubomirsky, 2001). If there is a lack of fit between the individual needs and demands and those of the environment, work-related stress can be an outcome (Cooper & Cartwright, 2013). According to Buchanan (2015), the true value of design is its ability to focus the attention of organizations on all of the people served by the organization.

Secondly, the principle of collaborating, - explained as design being co-creative and inclusive in nature, or as designers that create innovative outcomes through co-creation with relevant stakeholders (Sanders & Stappers, 2008) - can be expected to have a positive impact on people's well-being. A reason for this is that

stakeholders are in this case involved in creating their own solution, and have the opportunity to influence the results that they are going to work with.

Thirdly, design as being transformative and betterment oriented in nature, can help to have a positive impact on society and enhance people's lives (Buchanan, 2015). This desire can be related back to designers' personality characteristics, such as empathy and optimism (Brown, 2008), and is ingrained in designers' way of working through co-creating the world with the people that will be affected by the design. Enhancing people's lives. This principle seems relevant to EWB since meaningfulness of one's job is described as one of its' main antecedents.

A fourth principle that is relevant in the context of this study is design being emergent and experimental in nature, which seems to fit with the recommendation to perform interventions to increase EWB to learn from them and put them into action (Hassenzahl et al., 2013). While psychology is crucial to understand well-being, designers' skills might be useful to put this understanding into action (Lyubomirsky, Sheldon & Schkade, 2005). Design being explicative and experiential in nature seems to fit with the needs for exploration and assertion, which is about having the ability to play and work (Kets de Vries, 2001). This motivational need is associated with experiencing a sense of competence, of personal growth and development (Warr, 1987).

Finally, the principle of design being holistic and contextual in nature fits with EWB, as there is emphasis on recognizing and understanding the systems an individual is part of, in order to be able to improve it (Ojasalo, Koskelo & Nousiainen, 2015; Swan & Luchs, 2011). Based upon this first analysis of the two worlds coming together, it seems like there is a natural fit between the principles underlying design and increasing EWB, as visualized in Table 2.

Strategic design practices

In order to advance the current understanding of how design can be integrated and leveraged for improving employee experiences, we explored the design practices that can be directly linked to the design principles explained in Table 2 and the paragraph above. Design practices are routinized ways of working based on design principles (Karpen, Gemser & Calabretta, 2017) – e.g. envisioning in a human-centeredness manner, using a collaborative approach. There seem to be quite a few practices that can easily be linked to the challenge of increasing EWB when exploring the parallels with design principles and strategic design practices. At first sight, these practices, as described by Calabretta, Gemser and Karpen (2016), naturally seem to fit with the intended outcome, with similar arguments as design principles, and are visualized in Table 2. For sake of the similar argumentation, we will share examples for a subset of strategic design practices.

It seems for instance that the strategic design practice that fits the need to explore and assert (Condition No. 6), can be naturally linked to prototyping. Prototyping refers to designers' practice of visualizing and materializing their processes and outcomes to make intangible insights, ideas and concepts tangible, sharable and understandable to different stakeholders (Brown, 2008; Karpen, Gemser & Calabretta, 2017; Luchs, 2015). Another example is that one can clearly see the parallel between empathizing and the effect this can have on people, when addressing individual needs (Condition No. 1) or a sense of mastery and competence (Condition No. 2). Empathizing enables designers to apply their ability to deeply listen and create a dialogue to reach hidden needs (Michlewski, 2008). Designers can take a 'people-first' approach through which they can imagine solutions that are inherently desirable and meet explicit or latent needs, by generating solutions that are meaningful for users (Brown, 2008, Buchanan, 2015). Envisioning (related to Condition No. 5) refers to designers helping organizations incorporate a future oriented, long-term perspective into their objectives. Simplifying, which can be linked to the need for understanding the broader context (Condition No. 7), can also be explained as structuring or applying a 'Gestalt' view ("the whole is something else than the sum of its parts", Koffka, 1935, p.176). This view refers to selecting, connecting, and leveraging the relevant resources and knowledge to manage the complexity of the project, therewith taking the full context into account.

Positive design ingredients

Positive design is used as an umbrella term for all forms of design, design research and design intention in which the effects of design on the well-being of individuals and communities are explicitly addressed and intended (Desmet & Pohlmeyer, 2013; Pohlmeyer, 2013). These effects can be achieved by evoking valuable experiences through design processes and design outcomes. Positive design processes and outcomes can enable well-being by directing one's intentions towards desirable goals, and by inspiring and empowering

human engagement activities that are meaningful for the individual and the community (Desmet & Pohlmeyer, 2013). The process of designing for well-being is different from a traditional design process since it focuses on opportunities instead of problems (Desmet & Pohlmeyer, 2013). Design should be seen as medium that can address different components of well-being in multiple ways (Pohlmeyer, 2013). The Positive Design Framework (PDF), developed by Desmet & Pohlmeyer (2013), presents three universal ingredients that stimulate well-being: 'design for virtue', 'design for personal significance', and 'design for pleasure'. Design for personal significance for instance, can encourage people to live in accordance with their personal values, and commit to ideally self-concordant goals, in order to foster feelings of purpose (Sheldon & Elliot, 1999). This ingredient of personal significance can be linked to the need for addressing individual needs (Condition No. 1). The PDF framework was applied by Lu and Roto (2015) to set experience goals for meaningful work tool design, leading to a PDF for work tools. This PDF for work tools aims to guide designers of work tools to define meaningful experience goals at the starting point of their design. Design appears to have a pronounced potential to contribute to well-being in an indirect, facilitating manner: as enablement, or as support, as highlighted in the Design Well-being Matrix. This matrix illustrates the diversity of possibilities to design for EWB by connecting design roles to well-being components. In order to establish (enduring) success, positive design can only have an impact if the user is actively involved. A profound comprehension of the user context and translation to daily interactions is needed (Desmet & Pohlmeyer, 2013; Pohlmeyer, 2017). Following these conditions, the focus of this paper is on positive design's role as enablement and support. The portfolio that is developed is intended to be used in an active work-setting. Enablement is the result of an activity, and support can for instance take place in the form of a game. The positive design ingredients that are expected to be naturally connected to the different constellations - with similar arguments - are visualized in Table 2. In this table, we follow the approach of Lu and Roto (2015) to set employee experience goals in order to create an environment in which employees can thrive.

Results, conclusion and discussion

As discussed in the introduction, how the positive impact of design on EWB can be achieved, is underspecified in literature. In this paper, we provide a principle-practice-ingredient (PPI) portfolio from which six guidelines, in the form of design practices, for improving the employee experience can be distilled. The primary EWB dimensions (i.e., organizational commitment, personal growth, autonomy, and mastery) can for instance be linked to the design practices; empathizing, collaborating, prototyping and leveraging sensorial aspects, which seem most relevant to apply to increase well-being at work. Combining these guidelines with experience goals based upon positive design ingredients (Lu & Roto, 2015) (i.e. empathize with personal engagement or identity affirmation) can guide the early phases of a design process, to spark inspiration and empower concept generation. As described by Liedtka (2018), the role of design in workplace innovation provides a social technology. It not only contributes better outcomes for employees in the form of their experiences, it also provides significant value by nature. Adopting a design approach for improving employee experiences that puts people first sheds new light on contemporary processes and ways of working. Structurally listening to the voice of employees for instance, as part of design user research, brings along a ripple-effect in the form of a change in culture and mindset. Focusing on employee experiences instead of employee products breaks down physical, digital and service walls, as it touches many parts of a business.

From this portfolio we can conclude that the role of design in addressing employee innovation challenges is of great potential. Barrett, Davidson, Prabhu & Vargo, 2015 also pointed out that design practices are becoming progressively more essential. We demonstrated the natural fit between the intended outcomes, conditions for increasing EWB, and applying a design process. Design practices therefore seem to have the ability to address employee experience challenges, offering designers a structured method to analyze and transform the complexity of EWB's holistic concept.

As mentioned in the introduction, contemporary workplace well-being programs seem to have limited effect. In addition to organizations applying short-term fixes, another reason could be the lack of organizational knowledge on how to increase EWB in their daily practice. According to McKinsey "there is not a lot of good, independently validated science around what works" ('Wellness at work', 2017). Next to a missing academic discourse on how design can enable a thriving employee experience, the limited interventions that have been done in this field lack empirical evidence. Or, as Micheli, Wilner, Hussain Bhatti, Mura, and Beverland (2018) explained, empirical evidence of the impact of design is still lacking. Thus, applying the proposed guidelines in real-life settings, and measuring the impact of doing this, provide an interesting research outlook.

Next stages in the PhD-project are to prototype and apply design interventions, and validate the impact of these interventions in order to develop initial guidelines to increase EWB. We are currently experimenting with prototyping interventions in a workplace tool design project. One of the challenges in this project is to gain a better understanding of applying positive and strategic design methodologies in practice. How can these methodologies be made relevant for increasing EWB in a meaningful way? We have done a small pre-test on how applying the practices could work when designing the workplace tools. In the first creative sessions with future users, the collaborating practice was leading the process. The aim of these sessions was to envision how teamwork could be stimulated in the workplace tools of the future, by generating ideas. The collaborating approach that was used to build further on each other's' ideas, was positively evaluated amongst participants. A design researcher that was leading the session reflects;

> *Employees that participated in the session really appreciated to work like this. I noticed, and they also said it, that they liked having their say and sharing their feelings.*

In order to further specify the design practices guidelines for this specific research context, it seems that building upon the learnings of Participatory Design is a potential interesting approach. Participatory design assumes that workers are in the best position to determine how to improve their work and their work life and views computer-based applications not in isolation, but rather in the context of a workplace (Schuler & Namioka, 1993). Participatory design is described in the literature as beneficial for redesigning work methods regarding well-being (Vink, Imada & Zink, 2008). It demands active participation and people who are affected by the design should have an opportunity to influence it. The user is seen as partner (Sanders & Stappers, 2008). One of its characteristics is that the quality can be improved with strong and effective participation of the people involved, as is the purpose of the workplace tools design project. Therefore, trying to integrate the participatory design learnings in search for the right design practices to increase EWB is recommended for future research.

When exploring the specific design practices in detail one could argue that the need for integrated functioning, for human flourishing, and the need for tailoring to individual needs, seem to be conflicting. Design for human flourishing intends to encompass the entire life of people and communities. The need for tailoring experiences to individual needs however, could also apply in specific situations. Positive design research, that addresses design for human flourishing, has been inspired by positive psychology (Desmet & Pohlmeyer, 2013), a stream in literature that is not accepted by the research community unequivocally. In fact, one of the biggest critiques on positive psychology is the 'one size fits all' approach, even though personalization based on people's need could work better (Bolier et al., 2013). Positive psychology is defined as "a scientific understanding and effective interventions to build thriving in individuals, families, and communities" (Seligman & Csikszentmihalyi, 2000, p.13). Thus, exploring the use and effect of simultaneously applying the proposed design practices that are related to these needs, is one of the recommendations for future research.

Another potential critique on the principle-practice portfolio is that a few antecedents of work-related well-being were left out of scope. We intentionally excluded externally generated goals, availability of money, and physical security, as we did not find a clear link between these antecedents and design practices.

In line with Dorst's (2015) finding that innovators have increasingly been turning to design for help, the field of Human Resource (HR) management acknowledges the need for a shift in mindset (Cappelli & Tavis, 2018). The traditional HR practice is changing, and employees are more and more brought into the design process for co-creation and iteration to meet people's needs, instead of predominantly relying on 'experts' to build HR programs. Bersin (2016) explained this shift as changing the approach from instructional to experience design. As an example Bersin mentioned a telecommunications company using design thinking to come up with a solution for the high staff turnover in its retail stores. Based upon our research findings, designers could complement (HR) managers in developing employee experience strategies for well-being, using their practices to analyse and transform the complexity of EWB's holistic context.

Design and especially design thinking are becoming a strategic source of competitive advantage. From its business theorization in early 2000s the adoption and awareness in both academics and practitioners' world is unmeasurable. Todays the attention of academics is no more only on the process and its phases, inspiration, ideation and implementation but more and more attentions are positioned on the team dynamics and the more hidden aspects of such methodology. As a matter of fact, literature shows that design thinking is not unique but it can be framed in at least four different kinds creative problem solving, sprint execution, creative confidence and innovation of meaning. The investigation aims at discovering which are the different capabilities characterizing the different kinds of design thinking. Through a survey on the Italian market of service providers of design thinking services the paper shows the different skills, competences and attitudes that are more relevant for each of the four kinds of design thinking. This is valuable for both practitioner and academics because it enriches the knowledge on the team composition in terms of capabilities, a still blurred element of the design thinking literature.

Keywords: Design Thinking, Design Capabilities, Design Attitudes, Design Skills

Introduction

Design is increasingly becoming a strategic source of competitive advantage, to the point that scholars and practitioners investigate the managerial practices that firms employ to seize opportunities resulting from the adoption of design principles in companies (Capaldo, 2007; Dell'Era and Verganti, 2010; Verganti, 2017). The emergence of new paradigms such as human-centered design (Buchanan, 2001), participatory design (Sanders and Stappers, 2008) and especially design thinking (Brown, 2008; Martin, 2009), highlight the transforming role that design can play in the field of innovation. The growing number of publications in academic journals (Brown and Wyatt, 2010; Kolko, 2015) and the emergence of new approaches such as Circular Design or Design Sprint (Knapp et al., 2016) shows how the debate around this topic is still evolving and sometimes controversial. On the practitioner side the recent acquisition of Lunar by McKinsey or Fjord by Accenture represent just two examples of a broader phenomenon.

The attention toward the booming of Design Thinking is not only of interest for practitioners but also for scholars. As a matter of fact, since its framing back in 1991 by Rowe it evolved and changed a lot. Researchers pointed out many different processes to perform and realize a Design Thinking process but still an ongoing debate is present in both practitioners and academics word about the ideal structure and framing of such a process (Liedtka, 2015). Both in the literature and in the practitioner field huge resonance is given to the IDEO view on it, to the point that the several researchers recognize in Tim Brown the father of the Design Thinking first embodiment (Brown, 2009). In particular, at that time design thinking has been defined as a formal

method for practical, creative resolution of problems and creation of solutions (Brown, 2009). This definition clearly shows the fact that this paradigm allows to address wicked problems (Camillus, 2008) by adopting a creative problem solving approach. This is not the only aim for adopting a design thinking approach. As a matter of fact, it is evident nowadays in the practitioners' world how this approach is relevant for several different aims. When the goal is to learn in a fast way if the idea is valuable or not several approaches are relevant such as the Lean Startup approach (Ries, 2011), the Agile Stage Gate (Cooper and Sommer, 2016) or the Design Sprint (Knaap et al., 2016). These are united by the fact that they all look at a fast, sprint execution of the process in order to speed the time to market of the ideas. This in order to reduce the uncertainty and be sure that the idea is valuable. As it is event the sprint execution that join the above paradigms is strongly linked to the design thinking by the fact that nowadays the process is a subsequence of divergent and convergent phases as well as the activities are somehow similar. Moreover, lately Design Thinking has been adopted by companies in order to foster innovation and better aligned the vision of companies. In this strategic usage of Design case such as PepsiCo or 3M are pioneers with the formalization of the figure of Chief Design Officer. This figure is the promotor of the design thinking paradigm not only for solving wicked problems or in sprint executing an idea but to create the confidence inside people that will join the projects. This further evolution of the design thinking is ladled by researchers Creative Confidence (Kelley, D. and Kelley, T., 2013). Finally, what is emerging is that another aim for embracing design thinking as a paradigm for innovation is the identification of a new direction (Verganti, 2017). In this later approach the mindset and the practices of design thinking are steered toward a higher goal that is the envisioning of the new strategy for the organization. This envisioning process can leverage the strategy (Verganti, 2008) or the technology (Dell'Era et al., 2017).

What is clear in today's market is the plethora of these paradigms of design thinking that differ not only for the aims and the underpinning principles but also for the skills, competences and attitudes that are required for adopting them.

So, the main aim of the paper is to address this topic by exploring the different capabilities that are needed in order to offer different design thinking services. As a matter of fact, this avenue of research is interesting for both practitioners and scholars do to the fact that shift the attention from the process to the people and so enriches the knowledge of both in terms of skills, competences and attitudes that connote the different paradigms.

In order to address such a complex topic, we design a survey in order to gather such information and we decided to focus on the Italian market due to is crucial role in the design environment thanks to the mediatic attention toward several global initiatives such as the Milan Design Week and the Compasso d'Oro award.

The evidences gathered refer to the different skills, competences and attitudes that are relevant in order to deliver different design thinking services. So, after pointing out the four main paradigms, creative problem solving, sprint execution, creative confidence and innovation of meaning the investigations highlighted which set of capabilities were relevant across the different approach. As a result, the paper summarizes in a comparative perspective the most relevant skill, competence and attitude for each of the four approaches. This enriches the knowledge around the design thinking evolution for both practitioners and scholars due to its focus on the people characteristic more than on the process one.

The Paper is structured as follow. After a brief overview of the four paradigms of design thinking a literature review regarding the main skills, competences and attitudes will be reported. Then a dedicated section details the methodology adopted for both the data gathering and the data collection. Thus, the empirical results will be reported before the comparative discussion. Finally, the conclusion with the main contributions and the future avenues of research will be specified.

Theoretical Background

Given the aim of the paper the theoretical background has a twofold objective. First it aims at showing how design thinking has evolved over years from an academic perspective and how four main paradigms can be identified inside the emerging literature. The second is the identification of the relevant set of skills, competences and attitudes that are relevant for better exploring the four paradigms identified.

The origin of design thinking goes back to Rowe, that in his studies in 1987 defined this label. From then on, several researches have been published and the academic attention has grown exponentially to the point that today's in the academic world can be identified different paradigm of the same approach. In particular in this

study we will refer to four kinds of design thinking called creative problem solving, sprint execution, creative confidence and innovation of meanings. These four paradigms are defined in the academic world as approaches toward innovation that leverages on different principles and practices but that are united by the fact that they leverage on a "designerly" way of thinking at innovation (Cross, 2001).

In particular the first kind defined as creative problem solving takes its origin from the idea of facing wicked problems (Buchanan, 1992; Coyne, 2005) with creativity and naïve mind. In particular this approach was framed by Tim Brown that in 2009 framed this approach by pointing out the main underpinning elements. These are: the central role of the human, the iteration and the extensive usage of methods to foster creativity in the ideation phase. Thereafter further researches on design thinking as creative problem solving were performed in order to point out different aspects by adopting different perspectives the processes (Çetinkaya et al, 2013; Johansson-Sköldberg et al., 2013) or the people (Liedtka, 2015).

The second is the one that takes roots from the agile way of manage innovation (Cooper and Sommers, 2016). It is defined as sprint execution and leveraging on the idea that as far as the process is managed internally by the Research and Development team the uncertainty is relay high force the company in looking outside the boundaries by interacting in a fast and sprint way with the market (Knapp et al. 2016). As it is evident by deepening the approach sprint execution is the umbrella under which all the methodologies that focused a lot on Minimum Viable Products and iteration are inserted. This is the reason why this is the second approach of design thinking chronologically speaking. As a matter of fact, even if the lean startup approach (Ries, 2011) is aimed at supporting startups in developing solutions there are profound similarities in the two approaches that allow to generalize this kind of design thinking as sprint execution do to the focus on the fast experimentation and test of ideas in the market (Zeratsky, 2016).

Design Thinking can aim not only at solve wicked problems or execute in a fast way solution it could also support people in feeling more confident in proposing innovation. This usage of design thinking is the one that goes under the umbrella of creative confidence (Kelley, D. and Kelley, T., 2013) and it aims at fostering the individual creativity of the components of the team. So, the design thinking paradigm in this case it is not used to propose new ideas or test them in a fast way but in this case the idea is to use this methodology to incentivise people to be more confident in proposing ideas (Kelly, T and Kelly, D., 2012).

Finally, what comes out from the analysis of both the literature and the market is that the design thinking paradigm can be used also for identifying the new direction for companies (Verganti, 2017). In this case the principles and the aim of the approach is completely different from the previous one even if the "designerly" approach is still present. In particular this last paradigm of design thinking is the one that allow companies to identify new more meaningful direction for their business and so steer their strategy toward a more valuable vision (Verganti, 2009; Dell'Era and Magistretti, 2018).

What emerges from the brief overview previously reported is that in the literature and in the market, there are four kinds of design thinking that despite different aims they all leverages on the central role of the human, the idea of challenge the ideas and to have a defined process to reach the final solution. In particular the four paradigms refer to four different questions. Indeed, the creative problem solving aims at answer to the what question, sprint execution at the how, creative confidence at who and the innovation of meaning at why. These because the first is more oriented on the generation of wild ideas the second to the understanding of the functions of the idea challenged, the third is oriented at empowering the people and the last one at identifying the reason why people should love the new solution.

After having identified and defined the four kinds of design thinking that were the entry point of our investigation we now focus our attention on the capabilities that each of it will require. In order to do that we will review the literature related to three categories of capabilities labeled as skills, competences and attitudes. The reason of this classification is related to the fact that the first are more related to the background of the person and so are more tangible elements while the latter are more close to the soft skills and are inherent to people.

In particular when talking about design thinking the most important set of skills are user analysis, cultural insights, visualization, prototyping, testing and business modeling. These are the one that are recognized as relevant by scholars and practitioners. In more detail, the first, user analysis, is the capacity to gather and cluster insights obtained from users or clients (Veryzer et al., 2005). The second, cultural insights, is the capacity to spot and sense emerging cultural trends (Kolko, 2010). The third, visualization, is the capacity of communicating ideas and thoughts through sketches, images and drawings (Goldschmidt, 1994). The fourth,

prototyping, is defined as the capacity to transform ideas, even not fully developed ones, in tangible and working artefacts (Seidel and Fixson, 2013). The fifth, testing is the skills that allows one to organize the learning extracted from market tests (Ward et al., 2009). The last one, business modeling is the capacity to identify customers, partners and suppliers so that value creation and appropriation are both maximized (Chesbrough, 2010).

The second sets of capabilities considered are the competences. As a matter of fact, in order to properly manage the different kinds of design thinking in the literature it is reported how the competences of the people involved are fundamental in order to reach a valuable result (Danneels, 2002). In particular in this case the set of capabilities considered are framing/reframing, collective leadership, creativity, criticism, brokering and storytelling. The first one refers to the competence in iteratively define and redefine the problem in order to deeply understand the faced challenge and identify new solutions (Schön, 1984). The second is collective leadership defined as the competence in mobilizing human, cultural, and technological resources in order to pursue a shared vision (Denis, et al., 2001). The third competence regards creativity and it is the capability to thinking outside of the box and proposing original ideas (Dorst and Cross, 2001). The literature than shows how criticism is also a crucial competence in design thinking as far as asking questions and providing effective feedback in order to dig deeper in the reasoning is relevant to address different problems (Verganti, 2016). In addition to these considering that design thinking is primarily a designer methodology the competence of brokering: defined as the capability to bridging solutions adopted in different settings and in gaining inspiration from different fields is relevant (Hargadon, and Sutton, 1997). Finally, the competence of sharing ideas trough storytelling is considered by scholars as a relevant competence to be considered in creating the team for delivering design thinking services (Liedtka, 2015).

In addition to the two previous set of capabilities by reviewing the literature and interacting with real companies become evident how the attitudes are also relevant in delivering design thinking projects (Rowe, 1991). So the attitudes that emerged as relevant are optimistic mindset, tolerating failure, embracing ambiguity, troublemaking, pragmatism, empathy. By optimistic mindset scholars refers to the attitude to think optimistically toward innovation results (Carlgren, et al., 2016). The second attitude considered is tolerating failure which stands for the acceptance of failures and willingness to learn from them (Holloway, 2009). In addition to those also embracing ambiguity as the attitude to accept to work on solutions that are not completely defined up to the end of the process is considered relevant by academics in design thinking projects (Sgourev, 2013). Moreover, troublemaking is an attitude that is believed as relevant as the embracing of ambiguity. As a matter of fact, the attitude to challenge continuously the solutions proposed by others is crucial to deepen in the reasoning (Knapp, et al., 2016). The fifth relevant attitude is pragmatism defined as the capability to concretely face problems through the quick identification of feasible, even if simplified, solutions (Romme, 2003). Finally, the empathy (Gruber et al., 2015) so the attitude to look at problems from the standpoint of other people (usually the end user) is the last but most important attitudes of all the four kinds of design thinking due to its centrality in the paradigm of human centered design.

The above overview of skills, competences and attitudes shows the fact that in the literature the capabilities that are recognized as relevant in order to offer design thinking services are present. What is missing is the link between these sets of capabilities and the different four kinds of design thinking previously highlighted. So, the aim of the paper is to enrich the knowledge of both practitioner and academics on which are the different capabilities characterizing the different kinds of design thinking?

Research Methodology

In order to answer to the previous mentioned research question, the paper adopted a survey methodology (Forza, 2002). This seemed, to be the best way to manage the investigation due to the fact that the skills, competences and attitudes emerged from the literature on design thinking and also the 4 kinds of design thinking are present in the academic literature. In particular the survey was framed by the authors leveraging the insights coming from the literature and 47 in depth cases studies analysed in the Italian market. Even if the cases were aimed at a different scope and the evidences are going to be insert in a different paper it is worth to mention that the fruitful discussion between the authors and the companies that offer design thinking services in the Italian market facilitated us in defining the structure of the survey. In particular the first draft of the survey was defined by the authors and then submitted to an international panel of academic experts in order to validate the construct. As a matter of fact, the initial numerosity of the sets was bigger than the 6 constructs that at the end were inserted in the survey. So, after the trial and the validation the survey the final

structure was as follow. The first part was more related to gather information about the respondents than the focus was shifted to the different sets of capabilities that the service providers of design thinking believe are relevant to properly offer the different kinds of design thinking. In particular the structure adopted to perform this second half of the investigation is the most articulated one. As a matter of fact, in order to answer to the above-mentioned research question, we asked informants to allocate 100 points over a set of 6 skills, 6 capabilities and 6 attitudes when the four different kind of design thinking where faced. In order to be more robust in the data gathering we decided, accordingly to the suggest received during the trial, to ask indirectly this aspect. So, we submitted to the managers 4 different briefs that were differently for the actions required and we asked to the informants to point out first the most important skill for that brief than the competences and finally the attitudes. So, at the end each informant allocated 100 points for 4 briefs three times (skills, competences and attitudes). The next section details both the data collection and the data analysis.

Data collection and data analysis

Due to the aim of the investigation and the focus on understanding the relevance of the different design thinking capabilities the survey was performed on the Italian market. In particular only service providers of design thinking services were addressed. This is justified by the fact that the aim of the investigation is to understand the skills competences and attitudes that are relevant in the four different kinds of design thinking previously reported, creative problem solving, sprint execution, creative confidence and innovation of meanings. Accordingly, the survey was submitted February 2018 to more than 500 managers of strategic consultants, design studios, technology developers and digital agencies operating in the Italian market. After a first round 80 replies were gathered and so two rounds of reminder in the period March and April were performed. This brought 100 more replies that after the cleaning of the database from incomplete or incorrect replies caused a reduction to the final number of 130 useful data points that means that 26% percent of the population addressed was reached.

After the collection of the data the process of data analysis started and in particular we divided the analysis into two subsequent phases. First, we considered the three sets of capabilities respectively skills competences and attitudes individually. Second, we compared and contrast the different capabilities among the four kinds of design thinking in order to better compare the capabilities more relevant for each approach. In order to do that the average points allocated by each respondent to the particular brief was considered. So, the mean was used in order to enrich the knowledge of both practitioners and researchers on the most relevant capabilities to offer different design thinking capabilities.

The next sections will report this evidence first by detailing skills by skills than by comparing and contrasting them.

Empirical Results

The empirical results report the evidences coming from the analysis of the 130 answers gathered from the survey. In particular we will follow the structure of the survey itself in reporting the results. So, starting from the skills, we will advance with the competences and finally we report the attitudes. In particular in each section we report the insights for each kind of design thinking pointing out the most relevant one.

Skills

Starting from the skills the set considered in the analysis are the one reported above in the literature and in particular are user analysis, cultural insights, visualization, prototyping, testing and business modeling. These were selected among the large number available because they are crucial and relevant when design thinking is offered. Figure 1 reports the average number of points allocated by the respondents on the four kinds of design thinking in particular in red is reported the allocation on the creative problem solving, in blue the sprint execution in yellow the creative confidence allocation and finally in green the innovation of meanings.

What emerges from the analysis is that in the creative problems solving managers that offers design thinking services believe that user analysis is fundamental to manage such approach. This is coherent with the theory reported above that stress the fact that this kind of paradigm focuses entirely on the central role of human and his needs. For what concern the sprint execution on the contrary the most important skill is the prototyping. Managers averagely allocated 23 points on this stressing how this skill is fundamental to fast comprehend if the idea is valuable in the market. Also, in this case the answers gathered are aligned with the

theory previously exposed. Managers offering design thinking services suggest that when the aim is to support innovators in creating ideas the skill of cultural insights is crucial. This is relevant because people in this approach should be motivated in looking at external trends and gather them in order to better understand the motivation of the people. Finally, when the focus is in offering design thinking services with an innovation of meaning approach the business modelling is the most important skill. This because the reason why people should love the new direction and consequently the solutions proposed should be deeply explored in terms of pain, gains and value proposition.

Figure 1: Skills relevant in each of the four kinds of design thinking

Competences

When the attention is moved from skills to competences and so to capabilities that are more personal and less related to personal background the set explored are framing/reframing, collective leadership, creativity, criticism, brokering and storytelling.

In particular, in the creative problem solving approach the informants pointed out as the most important competence the creativity. This is aligned with the idea that in this kind of design thinking the number of idea generated is quintessential. In the sprint execution the capabilities of framing and reframing and brokering existing solution are equally mentioned as relevant by service providers in the Italian market. These two competences are in line with the idea that in a very short period of time service providers should support companies in solving complex problem by framing and re framing it very quickly. Moreover, the ability to bring existing solution in the ideation phase is something crucial for sprint execution this because otherwise there is not time to properly develop the prototype and testing it. In addition to that Figure 2 highlighted how collective leadership is the crucial competence for creative confidence and how this competence is the most important for service providers that want to offer this kind of design thinking services. As a matter of fact, creative confidence aims at facilitate the creation of innovation by working on the people so the competence of inspiring a collective leadership is crucial. Finally, in innovation of meanings the managers reached by the survey shows how the creativity is important also in this paradigm of design thinking. This is aligned with the idea that this approach is inside out and so without creativity is difficult to generate a new direction that people would love.

Figure 2: Competences relevant in each of the four kinds of design thinking

Attitudes

The last section of the empirical results reports the attitudes that were indicated on average as relevant by the service providers that replied to the survey. In particular the item considered in this analysis were the optimistic mindset, tolerating failure, embracing ambiguity, troublemaking, pragmatism, empathy.

In particular for wat concern the creative problem solving approach the respondents pointed out as the most important attitudes the optimistic mindset and the empathy. These two are due to the fact that this approach more than anyone else requires a deep ability in entering into empathy with the final users and moreover requires an optimistic mindset in order to design the set of possible solutions to the wicked problem identified. Figure 3 then reports how in sprint execution the most important one is pragmatisms and this attitude is linked to this kind of approach by the fact that consultants involved in such approach must be oriented on delivering tangible solutions and practically test the hypothesis. Finally, in innovation of meanings the respondents to the survey spotlight as the most important attitude the optimistic mindset. This is in line with the idea that people could not love a product that you do not love which is one of the pillars of such kind of design thinking.

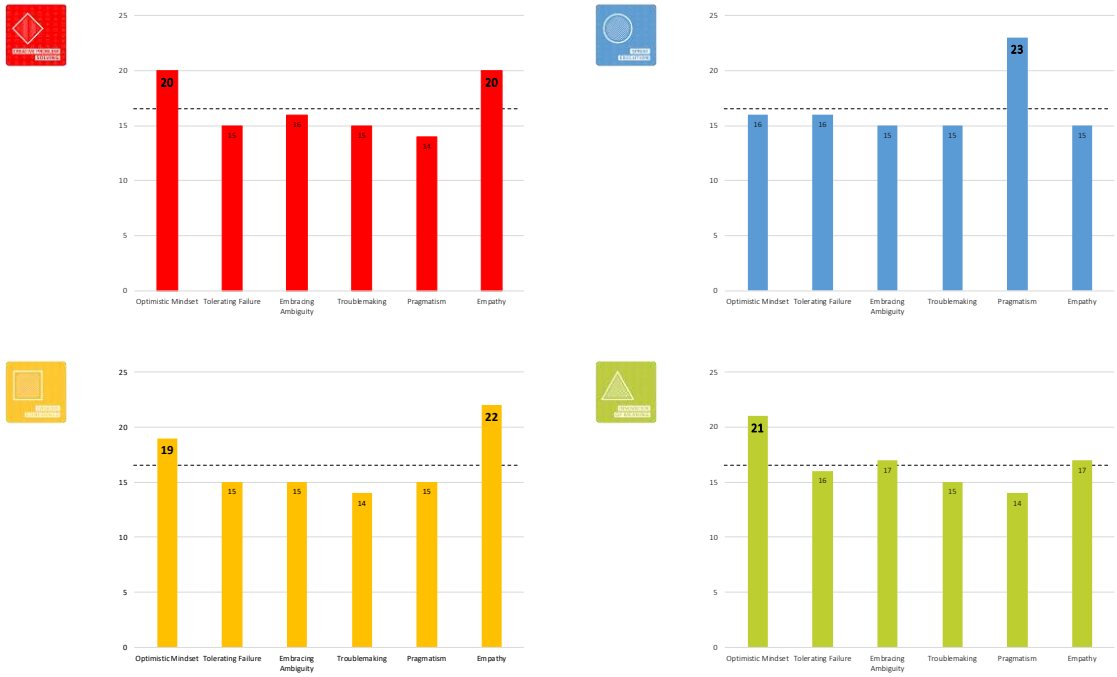

Figure 3: Attitudes relevant in each of the four kinds of design thinking

After having reported briefly the results gathered from the analysis of the 130 responses next section will better compare and contrast the different responses and points out the main contribution both on practices and theories.

Discussion

The following section aims at comparing and contrasting the different skills, competences and attitudes among the different paradigms. This will enrich the knowledge of both academics and practitioners on the relevant capabilities in offering design thinking services.

Starting from the skills the comparative analysis in the creative problem solving is interesting how the skills supporting the divergent phase (user analysis and cultural insights) are almost equal in relevance to the one supporting the convergent phase (prototyping, testing and visualization) the sum is almost 80 points and are 40 for diverging and 40 for converging. This is extremely interesting because on one side support the idea of the double diamond of the Design Council that implicitly says that the traditional creative problem solving is equally distributed on convergence and divergent phases (Brown, 2008), on the other side shed lights on the skills that companies should cultivate in order to effectively promote such paradigms. On the contrary in sprint execution the most relevant are the one related to the converging phase 53 points compared to the 28 of diverging. This is aligned with the idea of the agile approaches (Ries, 2011; Cooper Sommers, 2016) but it stresses the role of the prototyping and test skills. As a matter of fact, the evidences reported in figure 4 shows how this skill are crucial for a sprint execution. If the team is not trained and does not manage properly the creation and testing of hypothesis the success of such approach is a hard to follow. This evidence enriches the literature on experimentation (Thomke, 2003) by stressing is relevance also in the design and innovation field. As a matter of fact, 130 managers of companies offering design thinking services believe that the prototyping and test skills are crucial nowadays. When it comes to creative confidence is evident how the user analysis and cultural insights are more relevant than the remaining ones that are more oriented toward the solution. This insight corroborates the growing attention of design thinking in leadership and organizational behaviour (Martin, 2010; Liedtka, 2015). Indeed, not only researchers are trying to better comprehend how this kind of approach can create a better engagement of people in innovation but also practitioners are really interested in it. What is really interesting is the centrality of the cultural insights. This shows how managers perceive the skill of grasping trends and understanding where people want to go in order to facilitate the creative confidence, this is important because enriches the consideration of the Kelly brothers of just considering the primary role of tools and motivation (Kelly, T and Kelly, D., 2012). Finally, the innovation of meaning is the paradigm that shows, despite for the testing which is undoubtedly irrelevant, a more balanced relevance for

the skills. This insight is for sure relevant because it enlarged the evidence of such a kind of design thinking shifting the focus from the process (Verganti, 2016; Verganti, 2017) to the people participating in it.

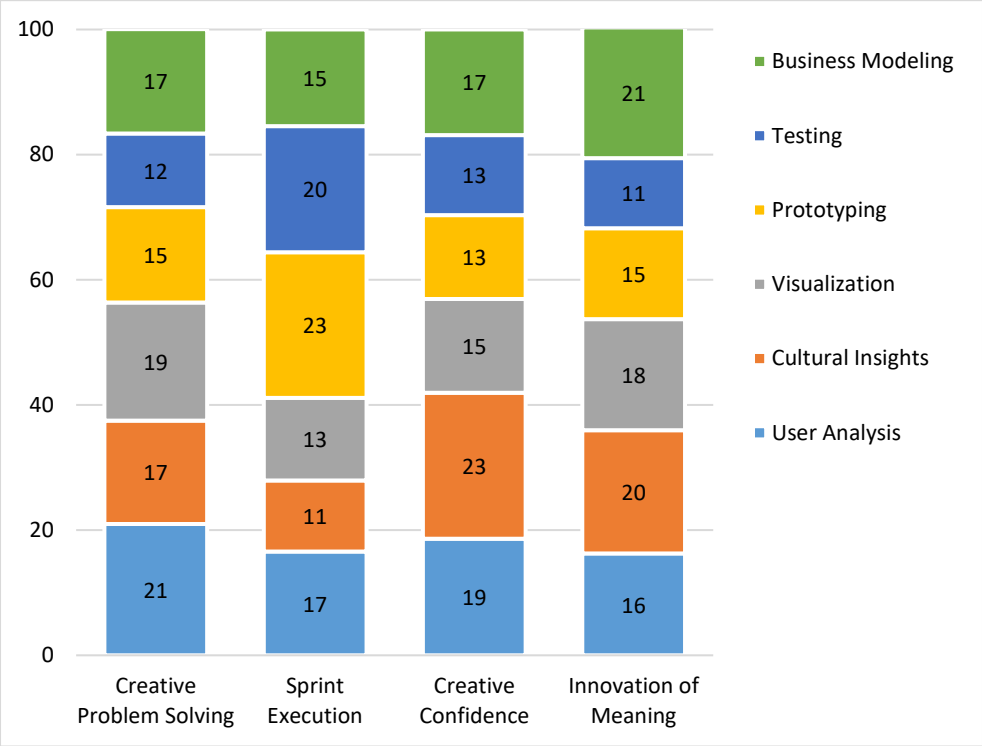

Figure 4: Comparative analysis of the key skills

Advancing the analysis from skills to competences and so from the background of the people to a less sizable capability the competences and the contributions of the investigation evolved.

The most relevant insight emerging from figure 5 is the fact that when it comes to competences, differently from skills, the distribution is more equal among the different 4 kinds of design thinking. As a matter of fact, the only paradigm that requires a different distribution is the creative confidence that differently from the other three shows a peak in the collective leadership. Another interesting evidence is the fact that both creative problem solving and innovation of meanings are requiring a higher creative competence compared to the other approaches. This is due to the fact that creativity is both required in the initial phase of the creative problem solving and innovation of meaning even if the aim of the two approaches is different. Indeed, in creative problem solving the creativity is a competence required for generate a high number of new solutions (Jonson, 2005) while in innovation of meaning creativity is crucial to envision a new direction and considering that it is an inside out approach (Verganti, 2017) is fundamental that the people involved in the project master this competence very well otherwise the first envision of the new direction will be less meaningful than expected. The comparative analysis shows how the competences varies over the four kinds of design thinking and this enriches the knowledge on the capabilities that are more relevant in order to offer design thinking services with different aims.

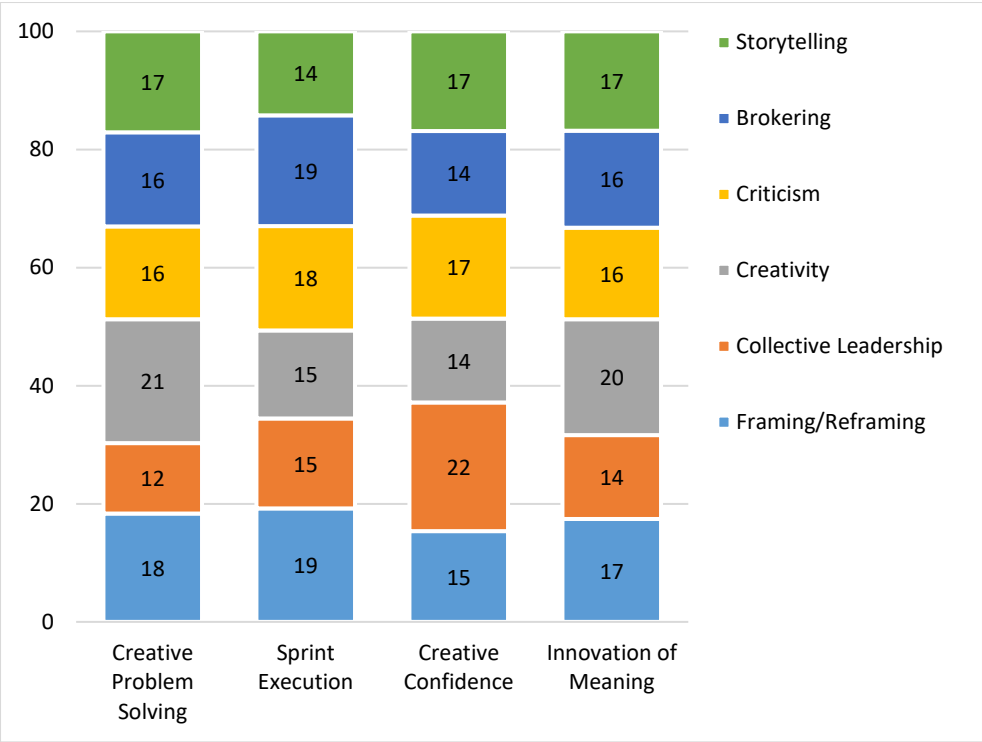

Figure 5: Comparative analysis of the key competences

Finally, the comparative analysis on the key attitudes reports how optimistic mindset is relevant in all the 4 kind of design thinking. The only one in which is just close to the average is in sprint execution while in the other 3 is way above the average. This is in line with the literature of design thinking that reports how this approach should embrace a positive perspective on wicked problems (Carlgren et al., 2016; Calabretta and Kleinsmann, 2017). Moreover, this investigation shows how this competence is cross approach and it is not just relevant in the creative problem solving but it reinforces the value of such soft skill across the different paradigms. The other interesting elements coming from the cross comparison is the fact that pragmatism is a key attitude for sprint execution while is less relevant in the other paradigm. this evidence is coherent with the idea of the agile and scrum methodologies (Sommer et al., 2015) as well as with the design sprint where the orientation toward the resolution of difficult challenges in a practical way is the core goal of these approaches. What is the added value of this research being the fact that in the sprint execution all the other attitudes are equally distributed while the 130 respondents believe that pragmatism attitude is of primary importance as attitude of the team. Finally, empathy shows a significant relevance in creative confidence and creative problem solving while it is less relevant in sprint execution and innovation of meanings. This aspect is interesting because entails a link between the focus of the approach and the role of people. This is for sure interesting because it stresses the relevance in the attitude of the people that should be involved. As a matter of fact, if the focus of the project is on the what (creative problem solving) dimensions or on the who (creative confidence) user needs both inside and outside the team are really important while if the focus is on the how (sprint execution) or on the why (innovation of meanings) the empathy is less relevant. This is counterintuitive because traditional view of design thinking (Buchanan, 1992; Brown, 2009, Martin, 2009) stress the centrality of the human and the crucial role played by the empathize phase while this investigation shows how the empathy is differently relevant in different kinds of design thinking.

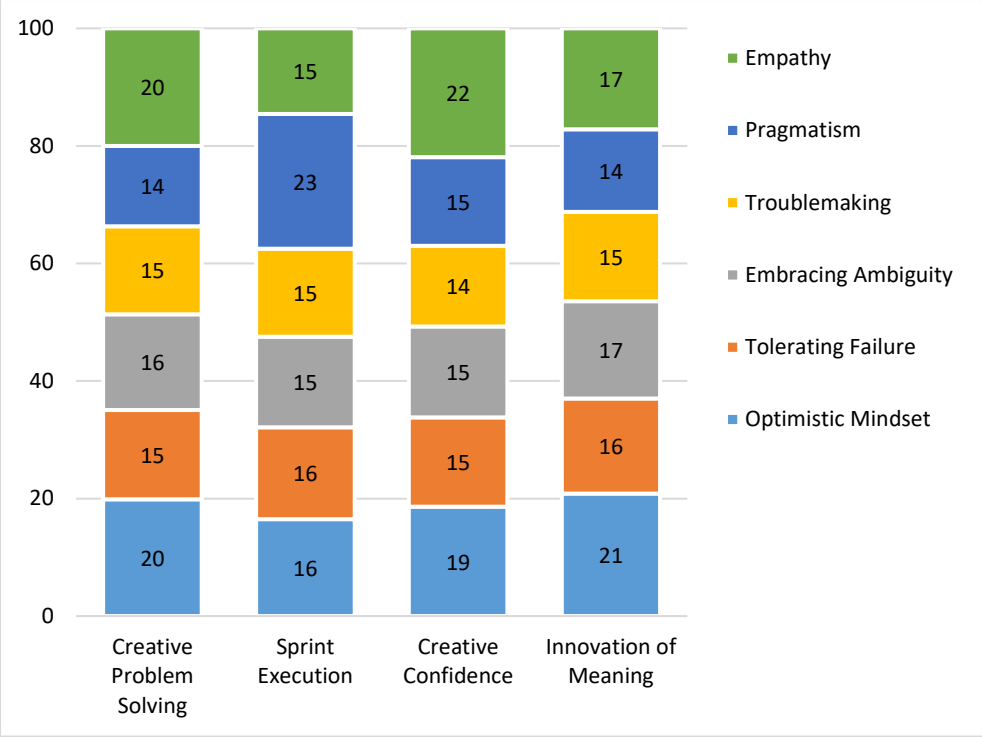

Figure 6: Comparative analysis of the key attitudes

Conclusion

As previously mentioned, the investigation aims at enriching the knowledge of both academics and practitioners on the different capabilities that are relevant and significant in order to offer different design thinking services. In particular by leveraging the results emerging from a survey performed in the Italian market the paper shed lights on the skills, competences and attitudes that are relevant in four different kinds of design thinking. As shared in the discussion part depending on the fact that the innovation project aims at answering to different questions the sets of capabilities that are more relevant are different. Indeed, if the question is what the possible ideas are to address a user need, how can we execute rapidly an explorative test of a solution, who are the people inside the organization that can be better engaged in the innovation process or why people should love the new direction the mix of capabilities required are different. So, by shedding lights on the capabilities the investigation enriches the theoretical knowledge of academics on the fact that the design thinking is evolving from a process to ideate and generate new ideas to a structured methodology to execute, engage and envision. This are the main elements behind the four kinds in order: creative problem solving, sprint execution, creative confidence and innovation of meaning. This is the first contribution of the study. In other words, supporting the fact that the four kinds are not only differentiated by the related aims, questions or process but are also different for the kind of skills, competences and attitudes required in order to be offered to companies. This is an important contribution to the growing streams of design thinking due to the fact that it contributes to a under researched perspective of it that is the capabilities of the teams involved.

Concerning the managerial implication of the study the investigation is important for the practitioners for two main reasons. First because it guides the managers that want to offer design thinking services in better comprehend which set of capabilities are relevant for the team. Second because it could suggest the facilitator of design thinking services on selecting the tools that are more aligned with the skills, competences, attitudes that are required by each approach. This both in term of increasing the probability that people would adopt them due to the alignment with their capabilities and for increasing their capabilities in that direction and so increasing the likelihood of a meaningful results.

Finally, similarly to all the existing academic articles also in this case there are limitation of the research. First the fact that the survey was delivered only to the Italian market could limit the generalizability of the research. Second the study is performed on four kinds of design thinking due to the previous research performed by the

authors and to the fact that this are the most popular one but there are no limits to the possibility of adding others kinds in future investigations. Finally, the sample size, even if quite focused and reliable is for sure not extensive. From these limitations are generated the possible future avenues of research. Of course, a survey that covers more nations could bring more insights, maybe also considering the impact of the national culture. In addition to these researchers could explore a different distribution of the capabilities in order to understand if the degrees of skills, competences and attitudes is valuable. Finally, an extension of the sample also involving the team level and not only the managers of the project could enrich the knowledge on the whole team capabilities and not only on the one perceived as relevant from the service provider perspective.

The practice of 'managing as designing'

ÇIDIK Mustafa Selçuk[a]*; ZERJAV Vedran[b] and PAPAGIANNOPOULOU Vasiliki[c]

[a] London South Bank University, United Kingdom
[b] College London, United Kingdom
[c] Faithful + Gould, United Kingdom
* corresponding author e-mail: selcukcidik@gmail.com
doi: 10.33114/adim.2019.06.352

Recent studies of 'design thinking' for management have criticized the current focus on principles and tools of design thinking, for creating an over-simplified view of a complex process. As a response, this paper sets out to study the empirical details of 'doing designing' in order to explore what 'managing as designing' involves in practice. Adopting a practice-based theoretical orientation, the paper presents findings from the design meetings of three residential refurbishment projects in the UK. The findings suggest that the management of design practices was accomplished through everyday interactions during which the nature and level of uncertainty of various issues were established, and the corresponding adaptive and innovative courses of actions were developed. Based on these insights, it is concluded that 'managing as designing' is primarily about facilitation of everyday organizational interactions, and leadership for the reconciliation of various concerns of multiple stakeholders.

Keywords: management, managing as designing, design thinking, practice

Introduction

Over the last two decades, management scholarship and practice have had a continued interest in 'design' to find ways of dealing with the challenges of continuous adaptation and innovation under uncertainty (Glen, Suciu & Baughn 2014; Marc, 2015). As a result, the concept of 'design thinking' has become prominent in management literature. In management literature, 'design thinking' predominantly refers to methodologies for creative problem-solving which involve a set of principles and practical tools to be applied to complex, ill-defined managerial issues. However, the current emphasis on principles and tools has caused a lack of consideration of the empirical details of 'doing designing' (Luck, 2012), which limits the understanding of what 'managing as designing' (Boland, Collopy, Lyytinen & Yoo, 2008) involves in terms of mundane interactions and activities in an organization. The present paper takes an initial step forward to address that lack by presenting explanations about how mundane interactions in design practices enable adaptation and innovation under uncertainty.

Using the observational data collected from the design meetings of three residential refurbishment projects, the paper demonstrates that managerial activities, which enabled innovation and adaptation under uncertainty, were enacted in practice through mundane sayings and doings of design stakeholders during everyday design interactions. The discussion emphasizes the importance of recognizing the role of unfolding everyday interactions for 'managing as designing' and reflects upon the definition of 'managing as designing' as well as its key practical challenges. It is concluded that 'managing as designing' should be primarily and equally concerned about (i) facilitation of the interactions among stakeholders to support knowledge

representation and negotiations, and (ii) leadership to reconcile the different opinions and concerns of various stakeholders. It is also concluded that more practice-based studies of 'doing designing' are required to further establish what 'managing as designing' involves in practice and to develop strategies for leading and facilitating everyday organizational interactions from a design perspective.

Design thinking and management

In the last two decades, design thinking has gained popularity as an approach to deal with complex challenges of practice in a variety of fields including education, medicine, and business (Dorst, 2011). In the world of management, design thinking has attracted significant attention as a response to the increasing complexity of markets and technologies, within which present day organizations strive to achieve and maintain competitive advantage (Owen, 2007; Kolko, 2015). The main promise of design thinking for management has been identified as enabling innovative problem-solving (Liedtka, 2014) for 'wicked problems', which are characterized by high ambiguity, complexity, multi-facetedness, as well as involvement of multiple stakeholders with loosely defined goals and constraints (Liedtka & Ogilvie, 2011; Glen et al., 2014; Elsbach & Stagliani, 2018). Wicked problems are seen as distinct from so called 'tame' problems which can be defined in homogeneous and non-ambiguous ways, and thus lending themselves to straightforward, optimal and/or standardized solutions (Coyne, 2005). The challenge with wicked problems is that, as initially suggested by Rittel and Webber (1973), their resolution does not have a definitive formulation, and rather relies on intuition and creativity because "the information needed to understand the problem depends upon one's idea for solving it" (p. 161). As a result, design thinking has attracted growing attention in the management world by providing a perspective (Owen, 2007; Dorst, 2011) and an accompanying methodology (Tschimmel, 2012) for enabling and exploiting the intuition and creativity required for dealing with 'wicked' managerial challenges.

However, as recognized by Owen (2007), and Elsbach and Stagliani (2018), if the nature of managerial challenges were imagined on a spectrum with 'wicked' and 'tame' at its opposite ends, any managerial challenge would invariably fall between the two extremes. As a consequence, in practice, design thinking in a managerial context does not imply total exclusion of analytical (i.e. inductive/deductive) thinking but rather the need for skillfully combining both creative and analytical approaches in tandem, depending on the evolving circumstances of the challenge in hand. The need for iteration between these two distinct logics is also apparent in the studies that investigate design thinking methodologies (e.g. Tschimmel, 2012) and those that conduct design thinking experiments (e.g. Seidel & Fixson, 2013). Along those lines, previous work on design thinking in management has established that this process of iteration is highly erratic (Beverland, Wilner & Micheli, 2015; Elsbach & Stagliani, 2018) and fraught with social, cultural and political challenges (Bjögvinsson, Ehn & Hillgren, 2012; Beverland et al., 2015; Kupp, Anderson & Reckhenrich, 2017), which advises against the use of standardized prescribed management scripts.

Although there is a growing volume of research on design thinking in management, there is a paucity of guidance on how to navigate the unfolding situations in practice in order to effectively accomplish the needed iterations (Kimbell, 2011, 2012; Carlgren, Rauth & Elmquist, 2016). As a result, a concern is voiced that the current understanding of design thinking in the management context adopts relatively superficial (Johansson-Sköldberg, Woodilla & Çetinkaya, 2013) and step-wise (Howard, Senova & Melles, 2015) representations of a complex process (Kupp et al. 2017). An important critique is that more focus is needed on the circumstantial and empirical details of design thinking in the management context, because this would provide a better understanding of how meanings are created and decisions are made as situations unfold in practice (Johansson-Sköldberg et al., 2013; Marcus, 2013; Carlgren et al. 2016).

Methodology

The research presented here explores how design thinking enables the management of ill-defined situations in practice. To this end, the paper studies how management was enacted in the observed practices of three construction design projects using a practice-based theoretical approach (Feldman & Orliskowski, 2011). A practice-based theoretical approach suggests that social reality is produced by peoples' actions in situated organizational practices (Orlikowski, 2010). This means that 'management' is not seen as a punctual or distinct act, and neither as performed by distinct individuals called 'managers'. Rather, management, like any other practical undertaking, consists of a set of empirically observable everyday actions and interactions that unfold in certain ways, thus leading to certain outcomes. Key to the adopted theoretical orientation is the relational epistemology (Emirbayer, 1997), which suggests that in practice, entities do not belong to universal categories

with fixed properties but rather gain their meanings as a result of the unfolding organizational whole of which they are part. This suggests that the world is composed of events and experiences rather than distinct entities, and each event arises out of, and is constituted through, its relations to other events (Langley, Smallman, Tsoukas & Van de Ven, 2013).

To explore what 'managing as designing' involves in practice, the research studied the design meetings of three high-end residential refurbishment projects in the UK. The architect was the same firm in all three projects. The observed projects were delivered to private clients who were by and large inexperienced, which made the role of the architects key in the management of these design projects. Observations for this research started after the completion of a year-long internship as Architectural Assistant in the observed firm, which provided the required interactional expertise (Collins, 2004) to make sense of the observed practices. This previous hands-on experience was also essential for the purposive sampling that was used.

Data collection mainly took place through two types of observation during the regular weekly design meetings of the projects. The first type of observation is passive observation whereby the researcher only observes decision-making and does not interrupt the process, allowing the researcher to observe instances and interactions that others within the cultural system cannot (Dainty et al. 2010). The second type of observation is participant observation whereby the researcher becomes part of the decision-making process and has the opportunity to interrupt when necessary. Becoming a participant involves being part of the cultural system, which in turn translates into a better first-hand experience of the organization (Lloyd & Deasley, 1998) and better comprehension of the decisions being made (Millen 2000). Besides the two types of observations, the researcher extensively took notes, as a tool to evoke memories of the events later and as a means of interpreting the events after further consideration (Jackson, 1990; Pink, 2005). Alongside participating in meetings and analyzing the minutes and e-mail correspondence, the researcher was also engaged in reflective conversations with the relevant informants in the case study organization. Data collection was carried out over a one-month period. Within this month the researcher attended seven meetings, which lasted approximately three hours each, so a total of twenty hours was observed. Each meeting had subsequent minutes produced by the project architects and following emails which would question any decisions that were misunderstood or altered after the meeting. The data collection method for the research is represented in Table 1.

Table 1: Data collection method

Projects	*Data collected*
Project 1	- 2 Meetings, each approximately 2.5 hours long. 1st Meeting: (Architect, Client at the client's house) To discuss the design with the client - a combination of passive and participant observation techniques used. 2nd Meeting: (Architect, Client at the office) The purpose of the second meeting was to discuss progress – passive observation technique used. - 2 Subsequent meeting minutes - written by the architect (after each meeting). - 3 Emails, regarding follow up queries from the meetings.
Project 2	- 2 Meetings, each approximately 3 hours long. 1st Meeting: (Architect, Contractor, Basement Specialist at the office) To discuss about pipe problem – passive observation technique used. 2nd Meeting: (Architect, Contractor, Basement Specialist at the office) To cut costs – participant observation technique used. - 2 Subsequent meeting minutes - written by the architect (after each meeting). - 2 Emails, regarding follow up queries from the meetings.
Project 3	- 3 Meetings, each approximately 3 hours long. 1st Meeting: (Architect, Contractor, Engineer on site) To generally discuss design issues – passive observation technique used. 2nd Meeting: (Architect, Contractor, Engineer, Client on site) To discuss design with client - combination of passive and participant observation techniques used. 3rd Meeting: (Architect, Contractor, Engineer, Client on site) To discuss progress - a combination of passive and participant observation techniques used. - 2 Subsequent meeting minutes - written by the architect (after each meeting). - 1 Email, regarding follow up queries from the meetings.

The research uses qualitative content analysis to develop insights into the practice of 'managing as designing'. Drawing upon Schreier (2012), initially two themes of exploration are selected following a deductive strategy that draws upon the adopted practice-based theoretical orientation. These themes are 'establishing uncertainty in practice' and 'the practice of innovating and adapting under uncertainty'. After the selection of the themes, the themes are developed based on the sense that the researcher made of the collected data. Hence, in line with the analysis, as well as the practice-based theoretical orientation, in the following section, the two themes are presented through a set of events. The implications of the themes are then discussed to reflect upon the definition and challenges of 'managing as designing' in practice.

Findings

In this section, findings of the research are presented under two themes. The first theme is 'establishing uncertainty in practice' and the second theme is 'the practice of innovating and adapting under uncertainty'. Using practice-level interaction data, the first theme demonstrates how uncertainty was experienced, judged, and organized in everyday design practices. Building upon the first theme, the second theme then demonstrates how innovation and adaptation were accomplished in practice based on the previously established understanding of the uncertainty. Importantly, when considered together as an ongoing cyclical process, the two sets of interaction provide a practice-based view of 'managing as designing' showing how establishing the problem (i.e. establishing uncertainty) is part of developing a solution (i.e. innovating and adapting under uncertainty) and vice versa.

Establishing uncertainty in practice

Findings from the observed meetings suggested that, in design practices, practitioners established the nature and extent of the uncertainty of an issue through their interactions with others. For example, Event 1 below, which is from a design review meeting between an architect and a client, demonstrates that when the issue in hand was straightforward for all the interacting parties, decisions were made quickly without experiencing any uncertainty. Decisions like this did not even appear in the minutes of the meeting, as the minutes mainly captured pending decisions due to some sort of ongoing uncertainty.

Event 1 (Project 1 – Meeting 1, 100-103)

100	Client	Do we need a USB portal for the sockets?
101	Architect	Better to have the option, won't change size and the
102		cost will be minimum.
103	Client	Great. Let's do it.

On the other hand, uncertainty was experienced when one or more of the interacting parties did not know enough about the issue in hand to agree on a course of action as shown in the following event from the same meeting.

Event 2 (Project 1 – Meeting 1, 250-257)

250	Client	Budget is critical, maybe we shouldn't have under-floor
251		heating if it means that we have to remove all the
252		radiators. Also, if we keep the radiators where would
253		they go? How much is underfloor heating?
254	Architect	We will see the quotation at tender, not sure from the
255		top of my head. We could get rid of another costly
256		element. However, it is difficult to make the decision
257		now without having further information of the costs.

As Event 2 demonstrates, such interactions did not merely reveal the presence of an uncertainty which hampered decision-making, but also they were the means to establish the nature and extent of the uncertainty. By establishing the uncertainty of the issue in hand, these interactions also determined the possible (and acceptable) ways forward. In Event 2, the decision about the heating system could not be made due to the uncertainty about the cost of various heating-system options, and this diagnosis led the interacting parties to postpone the decision until they see the quotations in tender.

The events below (Events 3 and 4) present interactions from the same design review meeting (A1, 340-354) and from the follow-up email (E1, 10-19), and provide another example of establishing uncertainty through interactions which then suggests an agreeable way forward. Similar to the previous event, the uncertainty is established to be about the cost implications of alternative design solutions. However, in the events below, it becomes apparent that the architect had multiple considerations when judging the nature and extent of the uncertainty as opposed to the client having one major consideration, which was the cost.

Event 3 (Project 1 – Meeting 1, 340-354)

340	Client	See here, on this elevation, there is glass covering
341		the staircase. Would it be possible to expose the
342		staircase? Wouldn't this make it cheaper?
343	Architect	You need the fire glass so as to isolate the basement
344		from the ground floor, allowing the space to be fire
345		protected.
346	Client	Isn't fire glass more expensive? Could we have the
347		separation of the floors at another point?
348	Architect	No. But perhaps we could redesign the stairs so that
349		there isn't such a large area with glass. So we could
350		have glass in the basement and then only a glass
351		balustrade on ground floor. Any other option of boxing
352		the ground floor will be cheaper but won't look very
353		good. Let's put it in for tender and then decide.
354	Client	Ok, but the best option is the cost effective one.

Event 4 (Project 1 – Email following Meeting 1, 10-19)

10	Client	I thought that we were having (fire) glass only at the
11		basement level with the ground floor to be boxed in
12		rather than replaced with glazing to save costs?
13	Architect	We mentioned that at some point but I really think
14		putting a wall up will completely destroy the space. We
15		need to open up and make the descent to the
16		basement inviting.
17	Client	I am concerned that we are adding further to the cost
18		but I guess we will have to see what the tender prices
19		come out at and value engineer at that stage.

The events above (Events 3 and 4), suggest that the architect operated at multiple levels of analysis bringing richness in the process of establishing the uncertainty. This suggests that establishing uncertainty was not an isolated process of simply comparing the knowledge required with the knowledge available. Rather, it was a co-construction process where various concerns, which were based on practitioners' expertise and understandings of the situation, were expressed; and therefore, addressed.

Event 5 below is particularly interesting because it reveals that uncertainty did not always refer to a lack of knowledge, but it could also be a matter of knowledge representation and/or persuasion. Besides, similar to the previously presented events, this event once again demonstrates that the way in which the uncertainty was established, determined the way it was addressed.

Event 5 (Project 1 – Meeting 1, 50-63)

50	Architect	We need to get rid of the fixed island as the current
51		clearance is not enough. Also, the bench is reducing
52		the versatility of the space.
53	Client	Is it too much to have a table and a sofa?
54	Architect	A solution for you to have a flexible space which has
55		an island, table and sofa would be to re-create the
56		linear space into a U-shaped kitchen, with the table
57		acting as an island. This will enable the rest of the
58		space to allow for a sofa and more seating

59		arrangements [drawing to show ideas].
60	Client	To be further convinced I would like some 3D
61		drawings, as I cannot visualise the space as proposed
62		at the moment. Also good to have these options in 3D.
63	Architect	Ok sure. I have to persuade you; this is the best option.

Overall, these events suggest that, in practice, 'uncertainty' was not a generic issue about a general lack of knowledge about the developing design. Rather, it was enacted in practice in uniquely situated ways based on the unfolding interactions that were driven by the varying expertise, understandings, and so, concerns of, the interacting parties. As a result, establishing the unique nature and extent of the uncertainty provided the frame in which innovation and adaptation could be accomplished. Next, the focus of the analysis will shift to the details of the interactions through which such innovation and adaptation were enacted.

The practice of innovating and adapting under uncertainty

As implied by the findings presented in the previous section, once the uncertainty was established for an issue in hand, the way in which it was established had already created a frame in which innovation and adaptation would/could be achieved. This was because establishing the uncertainty involved establishing the concerns around a decision. Hence, according to this explanation, adaptation meant adapting to various concerns that were deemed important by the design team, and innovation meant finding the solution that adequately addressed such concerns.

The events presented in the previous section have already provided some examples of this dependency between the practical actions for adaptation and innovation, and the way in which uncertainty was established. For example, when the client raised his concerns about the cost in Events 2, 3, and 4, the decision was to wait until the tender to see the quotations. In these instances, pausing the decisions around the heating system and the type of the balustrade were the enactments of 'adaptation' in practice. Similarly, pausing the decision to address the cost uncertainty was what enabled the solution's relevance for the client's needs, which was key to enabling an 'innovative' solution.

However, the findings of the research suggested that the dependency between 'establishing uncertainty' and 'adapting and innovating under uncertainty' was not linear but cyclical. This meant that establishing uncertainty framed the potential ways forward for adapting and innovating, but the act of establishing uncertainty itself relied upon the previous decisions relating to adaptation and innovation because such decisions shaped practitioners understandings and concerns around a particular issue. Hence, the meanings of 'uncertainty' and 'adaptation and innovation' co-evolved in practice. This aspect of design practices is exposed in the event below through the references made to the shared past of the interacting parties (i.e. an architect, a basement construction specialist, and a representative of the main contractor). Here, the references made to the past decisions helped developing an actual understanding of the uncertainty around the issue in hand. Then, this updated understanding of the uncertainty paved the way forward for an adaptive and innovative decision that progressed the design acknowledging the lessons learnt from the past discussions and decisions.

Event 6 (Project 2 – Meeting 1, 110-143)

110	Contractor	Need to know the diameter of pipes to make a good
111		judgment call about the required depth and length the
112		excavation requires.
113	Architect	If we don't know the dimensions required we cannot
114		redesign need your expertise [points at basement
115		specialist (BS)].
116	BS	Perhaps we could have a diverter.
117	Architect	We had tried that previously, but it didn't work.
118	BS	So then we could drop the ceiling height to
119		accommodate the length of the pipe.
120	Architect	Can save cost doing this option. However, we need to
121		consider the depth issue with reaching the water level.
122	BS	In that case you can consider using piles instead, even
123		though the costs may increase.
124	Contractor	How about underpinning instead, it can be considered

125		as temporary works which is cheaper?
126	BS	The problem with underpinning is that you have to keep
127		it dry, so if we don't know the level of the water it might
128		not work as a viable option.
129	Architect	Also, underpinning will require further drawings, so it
130		will increase both the costs and the completion date.
131		As an alternative however, how about if we raised
132		everything by 300mm? There is room for the head
133		height in the basement to be reduced.
134	BS	You could drop the level of the main instead so the
135		level of the height will not be affected.
136	Contractor	Only a water company can tell you the level of the
137		water. If it's low then we could just drop the main.
138	Architect	The ideal scenario would be to get rid of the piles and
139		move the mains downwards.
140	BS	Yes, that is the most cost effective option. If the pipe
141		can be moved, great, if not we need to do the piling
142		option. We need to find out where the water is and then
143		we can meet again to make that decision.

The event above illustrates that, in practice, innovating and adapting were not punctual acts. Rather they were about continuously advancing the understanding of the uncertainty based on various perspectives that had a stake on that issue and taking a series of decisions based on this developing understanding.

However, the situated and path-dependent understanding of 'uncertainty', also meant that, with time, the previously made decisions reduced the number of alternative ways forward by knitting different parts of the design increasingly tighter. In such cases, adaptation and innovation were still derived by the interactions of practitioners with different expertise but in more constrained ways as shown in the following two events.

Event 7 (Project 3 – Meeting 1, 10-21)

10	Engineer	To have sufficient circulation ventilation you will require
11		a new unit and pipe to make it work.
12	Architect	How much will this cost?
13	Engineer	(sum) pounds.
14	Architect	That is quite a lot. How about we push the floor above
15		slightly back to allow for trickle ventilation?
16	Engineer	No, that won't be a cheaper solution as the wires have
17		already been built into the floor.
18	Contractor	How about we ensure that the windows on this floor can
19		be opened?
20	Engineer	I am afraid that the one I am suggesting is the cheapest
21		option. No other alternative I am afraid.

Event 8 (Project 3 – Meeting 1, 50-66)

50	Architect	Can we use this depth for the electrics meter and the
51		AC?
52	Contractor	Yes but the depth of the AC is more, so the space will
53		seem disproportional with both in the same room.
54	Architect	Ok. How about the distance between gas and
55		electricity?
56	Engineer	Not enough room, you need to leave a substantial gap
57		in the utility room.
58	Contractor	How about placing it here, on this side of the wall?
59	Engineer	Yes, we could slightly adjust the timbers so that it
60		would fit.
61	Architect	Could we move the timbers even more so that the AC
62		can fit in here as well?

63	Contractor	That is possible. How about the AV racks? We need
64		space for those as well.
65	Engineer	We could put the AV racks in the media room
66		horizontally instead of vertically, so they don't take up space.

Most of the times when issues were discovered with the previous decisions, these could be addressed within the constraints of the previously taken decisions as shown in Events 7 and 8. However, sometimes rewinding of the decisions was required to return to a previous state of uncertainty which would then release a wider set of options for adaptation and innovation as shown in the event below.

Event 9 (Project 3 – Meeting 2, 50-58)

50	Client	I need more storage in the utility space.
51	Contractor	We had a discussion two weeks ago about how much
52		wiring is required to go here and how this is the
53		optimum solution in terms of electrics and AC. That will
54		mean that you won't get as much storage as you
55		initially wanted.
56	Client	Storage is premium, anything you can do will be
57		appreciated.
58		[Contractor and architect look perplexed]

Overall, the findings suggest that the capability of design to adapt and innovate was a result of simultaneously working with different understandings and extents of uncertainty around different issues through multiple ongoing interactions between multiple stakeholders. In this context, adaptation and innovation were not punctual acts but ongoing accomplishments which relied on progressing the stakeholders' understandings of 'uncertainty'. Although this enabled the much-needed flexibility and experimental learning, this way of progressing also sometimes required rewinding of the decisions due to the changing concerns of stakeholders and/or discovery of previously unforeseen or miscommunicated issues.

Discussion

In management literature, 'design thinking' predominantly refers to methodologies that consist of a set of principles and tools that lever creative problem-solving for ill-defined challenges. A closer look at the practice of 'doing designing' reveals how managerial activities were accomplished as part and parcel of everyday design interactions, thus enabling insights into what 'managing as designing' involves beyond the use of design perspective merely as a problem-solving methodology for certain complex issues. This section will start by discussing the implications of the findings on the definition and practice of 'managing as designing'. The first part of the discussion builds upon the first theme presented in the findings section (i.e. 'establishing uncertainty in practice') and reflects on the definition of 'management' within the context of 'managing as designing'. Building upon the second theme presented in the findings section (i.e. 'the practice of innovating and adapting'), the second part of the discussion reflects on the key practical challenge of innovating and adapting while 'managing as designing'.

Managing as designing

Boland et al. (2008) claim that applications of a design perspective to management should consider design as a process rather than a noun. Adopting a practice-based view of 'doing designing', findings of this paper sheds some light on what this means. First of all, the findings of this research suggest that 'managing as designing' is not as much about maximizing exploration in all circumstances as implied by the majority of the previous studies on 'design thinking' for management. Rather, the findings suggest that, 'managing as designing' is first and foremost about the capability of establishing the uncertainty associated with an issue in order to come up with a decision-making process that suits the perceived nature and extent of the uncertainty. From Event 1, it is clear that some of the issues that were faced were perceived as straight-forward and did not require effortful exploration. Whereas in other events (e.g. Event 3, 6) the significant effort put into exploration of potential solutions was apparent, when there was an uncertainty which hampered decision-making. Therefore, it can be argued that application of design perspective to the management of an organization is essentially about establishing the environment and mechanisms that can filter and sort the issues depending

on the nature and extent of the uncertainty that is associated with them. By doing this, the observed design teams simultaneously worked at various levels of uncertainty, thus optimizing their use of time and effort, and only engaging in effortful negotiations when an uncertainty was noticed based on their professional and/or interactional expertise. This argument is in line with Kupp et al. (2017) who suggested that, in order to reach its full potential, design thinking in business must be more closely aligned with the realities and social dynamics of established businesses. Hence, in order to use design perspective as an organizational management approach, it is necessary to reflect upon the existing knowledge and interactional repertoires of the organization with the purpose of establishing the environment and mechanisms that can effectively notice, filter, and address issues based on their nature and extent of uncertainty.

The findings also emphasize that 'uncertainty' associated with issues was not something absolute; but rather uncertainty was established through the interactions of the practitioners who have a stake on that issue. Based on this, Event 5 demonstrated that uncertainty can be a matter of knowledge representation and/or persuasion among the interacting parties. Furthermore, Event 4 showed that experts with different backgrounds operated at multiple levels of analysis of uncertainty even if they did not explicitly bring these levels into their discussions with other practitioners. These findings highlight that 'managing as designing' should primarily be about enabling adequate means and processes of communication as opposed to setting abstract managerial goals and/or performance criteria based on long-term planning. Methodologies of 'design thinking' provide a sense of the variety of communication means and processes that can be used while establishing and addressing uncertainty. However, in line with the point made above, this paper suggests that organizations must develop their own communication means and processes based on their existing professional and interactional strengths and expertise. This implies that 'managing as designing' fundamentally requires a sound understanding of the multiple levels of analysis at which various organizational actors operate when judging uncertainty. Such an understanding would be the basis for the management to identify which existing interactional patterns are useful and needed for 'managing as designing', which ones can be abandoned, and what new patterns of interaction might be useful.

The key practical challenge of 'innovating and adapting'

The findings highlight the interplay between innovating and adapting while 'doing designing'. The events showed that adaptation and innovation were not punctual acts, but they were rather enacted through design interactions. This meant that they were not exclusive and separate from each other but rather they were implied by each other. When decisions are paused in Events 2, 3, and 4, this can be seen as an adaptation to the uncertain environment, but it can also be seen as the necessary course of action for enabling an innovative solution that consider the needs of the client. On the other hand, in Event 6, various design specialists negotiated the potential ways forward to fit various elements in a limited space and came up with an innovative solution. However, this discussion had a strong sense of 'adapting' to the existing design constraints that were due to the previously made design decisions. In both cases there were both adaptation and innovation, however, in the first instance a design decision was not made, and design exploration was left open, whereas in the second one a decision was made within the constraints of the previously made decisions. There is also some evidence in the findings that previously made decisions could be reversed occasionally when the benefit of doing such was judged to be higher than adapting to the previously made decisions. However, this meant rework and extra time, which could be frustrating for design practitioners, due to returning to a previous state of uncertainty.

Therefore, the key practical challenge of 'innovating and adapting' in design practices can be articulated as the judgement of whether adaptation to uncertainty or adaptation to constraints are required for various instances. As illustrated in Event 9, in such cases, various stakeholders may have different opinions regarding the course of action to follow due to their peculiar concerns. This does not only mean a challenge of knowledge representation and/or persuasion but also reveals that, while 'managing as designing', a higher-level prioritization of certain types of concerns can be useful to reconcile various individual concerns of different stakeholders. Nevertheless, such priorities must be set and articulated attentively in order to avoid the suppression of the richness of having various opinions. For example, in several of the presented events, it was apparent that lowering the cost was the top priority for the client, who was the project sponsor, and therefore, the most powerful actor in the presented settings. This higher-level prioritization helped reconciling various views, and so, had a strong influence on the ways in which practices unfolded. However, on the other hand, Event 4 explicitly showed that the architect had concerns about 'destroying the space' for the sake of

reducing the cost, which revealed the risk of suppressing the richness from various opinions through such higher-level priorities.

Conclusions

Over the last two decades 'design thinking' has attracted significant attention from the managerial world based on the promise that it provides methodologies to tackle complex, ill-defined business problems. The focus on principles and tools of 'design thinking' in management literature has recently started to attract criticism due to the instrumentalist view of design that it favors, which lacks an adequate consideration of the empirical details of the complex process of designing. As a response, this paper presented findings of a practice-based inquiry into the design meetings of three residential refurbishment projects in the UK. The analysis of rich empirical data on design interactions revealed insights into the practice of 'managing as designing' by exposing how uncertainty was experienced, judged and addressed as well as how innovation and adaptation were enacted, through everyday design interactions. The findings suggest that 'managing as designing' of an organization is essentially about establishing the environment and mechanisms that can filter and sort the issues depending on the nature and extent of the uncertainty that are associated with them. A fundamental requirement to enable this is to have the adequate means and processes of communication to support the interactions. However, the key practical challenge of 'managing as designing' is identified as the conflicting needs of addressing various concerns presented by multiple stakeholders and reconciling such concerns, while assuring that there is progress towards an adaptive and innovative solution.

Based on these arguments, it is concluded that management under a design perspective should be primarily and equally concerned about (i) facilitation of the interactions among stakeholders to support knowledge representation and negotiations, and (ii) leadership to reconcile varying opinions and concerns of various stakeholders. It is also concluded that more practice-based studies of 'doing designing' are required to further establish what 'managing as designing' involves in practice, and to develop strategies for the facilitation of, and leadership in, everyday organizational interactions from a design perspective.

Research Perspectives IN THE ERA OF Transformations

Exploring the Fourth Order: Designing Organisational Infrastructure

KLITSIE Barend[a]*; PRICE Rebecca[a] and DE LILLE Christine[ab]

[a] Delft University of Technology, The Netherlands

doi: 10.33114/adim.2019.07.227

Companies are organised to fulfil two distinctive functions: efficient and resilient exploitation of current business and parallel exploration of new possibilities. For the latter, companies require strong organisational infrastructure such as team compositions and functional structures to ensure exploration remains effective. This paper explores the potential for designing organisational infrastructure to be part of fourth order subject matter. In particular, it explores how organisational infrastructure could be designed in the context of an exploratory unit, operating in a large heritage airline. This paper leverages insights from a long-term action research project and finds that building trust and shared frames are crucial to designing infrastructure that affords the greater explorative agenda of an organisation.

Keywords: corporate infrastructure, fourth order design, action research, design process, innovation

Introduction

In recent periods, as companies aim to establish *organisationally fit* or *resilient* exploitive organisations (Martin, 2019; McGinn & Hacket, 2019), it has become increasingly attractive for organisations to create specific innovation labs (Blindenbach-Driessen & Van Den Ende, 2014). These labs perform the needed exploration of new strategic possibilities to lower the risk of disruptive innovation (O'Reilly & Tushman, 2013). Some companies' plan their explorative capacity by using the logic that they know from exploitative activities. An example is Unilever's R&D organisation, where R&D is split up in research streams that mirror the commercial organisation but are separated in a stage-gate manner. Alternatively, some organisations' experiment with other organisational designs such as corporate venturing units or cross-disciplinary teams with mixed results (Tushman, Smith, Wood, Westerman, & O'Reilly, 2010). The foreclosure of the Disney, Coca-Cola, Turner and Microsoft innovation centres over the past 3 years (Berengian, 2017), is testament to the challenges of creating organisations that afford the creativity and risk-taking associated with innovation while supporting the need for effective outcomes (Pisano, 2019).

In recent years, driven at least in part by *Design Issues* editor Richard Buchanan and catalysed by the special issue of *Design Issues* 'Design and Organisational Change', a number of (design) scholars have come to a common understanding. To:

> *Emphasize design as a professional practice that is consciously moving into the domain of organisational design and organisational change, drawing from areas of design practice that are more*

closely identified with design as it is commonly understood in the design community, including architecture, industrial design, information design, and interaction design. (Buchanan, 2008, p. 4)

These scholars posit that a design approach, taken to a strategic level, may result in both a different change process and different organisational structures (Gruber, De Leon, George, & Thompson, 2015) which can be better suited to support exploratorive activities.

Despite a number of publications that mention this movement of design (Buchanan, 2015; Dunbar & Starbuck, 2006; Gruber et al., 2015), few papers explicitly display how organisations could be 'designed' or what the expected benefits might be (Buchanan, 2008, p. 8). This research leverages the insights of an 18-month action research engagement to display such a process. Additionally, we introduce the concept of organisational *infrastructure* as design material. In this paper, we thus aim to explore: (1) what are the components of organisational infrastructure, and; (2) how can we design with these components? This paper thus contributes an initial methodology, a sequence of steps and an underlying philosophy (Kettinger, Teng, & Guha, 1997).

Literature Review

Organisations

According to Puranam, Alexy and Reitzig (2014) who have accumulated heavily cited definitions of an organisation, an organisation is "a multiagent system with identifiable boundaries and system-level goals (purpose) toward which the constituent agent's efforts are expected to make a contribution" (p. 163). Underlying this definition is the assumption that organisations are formed to allow a group of individuals to achieve more than they would alone (Junginger, 2008; Puranam, 2014) and that within large organisations, sub-organisations may be identified, with separate actors and goals.

For example, the airline that was studied in this project has a clear group of members (in-house and contracted employees), boundary (activities performed by the company) and purpose (to survive as company by raising capital through the business of transporting customers and goods). Additionally, within this airline, we could identify specific sub-organisations such as the department that is responsible for ground handling (which focusses on a minimum number of delays) and the department that is responsible for the operations inside the plane which focusses on customer- and-employee satisfaction.

In line with Tushman and O'Reilly (1996) an organisation can be described by looking at four aspects: the (1) culture, (2) structure, (3) strategy and (4) the processes used to create value for end-customers (Stoimenova & De Lille, 2017). All of these four aspects can be 'designed' in a way if design is viewed as the act of making plans (Dorst, 2017). For example, many tech-companies currently focus on realizing 'an engineering culture' of which the design is materialized through the definition of a number of values. Of these four, this paper focusses on solely infrastructure, as a variation on structure, as it has received the least attention from design scholars so far.

As Buchanan (2015) states: "most of the research and applications of design have focused on attitudes, skills, methods, and techniques" (p. 5). Whereas design scholars have published on how a design approach can improve an innovation culture or mind-set (also named *design attitude*) (Kochargaonkar & Boult, 2014; Michlewski, 2008; Yee, Jefferies, & Michlewski2017), innovation processes (or *design thinking*) (Lievesley et.al (2017), and strategy for innovation (also coined as *strategic design* (Calabretta, Gemser, & Karpen, 2016). Yet how one practically goes about the design of an organisation's infrastructure remains largely under-researched (Brown, Buchanan, Doordan, & Margolin, 2008)[1,2].

[1] Exceptions are the papers in the *Design Issues* special paper from 2018: Design and Organisational Change (Boland et al., 2008; Buchanan, 2008; Junginger, 2008) and scarce other papers (Brown & Martin, 2015; Junginger, 2005) in which the design process is presented as a complimentary activity to the design of more concrete products and a conference paper (Kronqvist & Salmi, 2011) in which infrastructure is designed in conjunction with a new innovation process.

[2] Organisation Design is a related but different topic as it aims to compare the effect of organisational structures and developmental processes, for organisational designers to then implement (Dunbar & Starbuck, 2006). We specifically focus on the process of creating new designs, explicitly leveraging local context. Nevertheless, we aim to build a bridge by leveraging knowledge from the organisation design field, for example by adopting Puranam's (2014) micro-structural approach to organisations.

Organisational Infrastructure

Similar to how product designers need knowledge of materials and experience designers need to understand the components available to them, so do we search for the materials of fourth-order design. It is to this end, that we aim to introduce organisational infrastructure as design material.

Much like structure, the word 'infrastructure' has been used on many occasions in a wide variety of media and has lost much of its meaning (Prud'homme, 2004, p. 3). Infrastructure, according to the Oxford living dictionary (n.d.) and the *business* and *academic content* Cambridge dictionary (n.d), describes the systems and services that are needed to operate or work effectively. In contrast, a description of structure focusses on the arrangement of- or relations between parts of a system (Oxford living dictionary, n.d.). Infrastructure thus provides more focus and detail on the elements themselves and the interaction between the system and the user is of crucial importance[3]. If we take the budgeting systems as example, we are more interested in how the budgeting system works and what 'the rules of the game' are, than how the budgeting system relates to the HR system.

Infrastructure is the "built networks that facilitate the flow of goods, people, or ideas and allow for their exchange over space" (Larkin, 2013, p. 328). Infrastructure is often approached functionally (Torrisi, 2009): we don't design roads, bridges or tunnels, we design *a highly effective transportation system for an engaged society.* Similarly, when considering the design of organisational infrastructure (infrastructuring in participatory design[4]), we aim to conceive a means for communication, rather than the meetings structure or hierarchical design. A budgeting system, again, provides an example: it is a means for employees to receive capital for their projects – which in turn provides a means for innovation outcomes. In sum, we engage with infrastructure not because of the elements themselves, but because (when coupled with labour) they are a means to support and maintain work to be done (Agid, 2018; Prud'homme, 2004).

Designing in the fourth-order

As Gabay (2018) illustrates after an extensive literature review (as indicated in Table 1), designers have a distinctive approach to problems if compared to a typical business approach. As a result, a design process is human-centred, future-oriented and visual (De Lille, Roscam Abbing and Kleinsmann, 2012), focussed on creating new opportunities over selecting from existing alternatives and it emphasizes co-creation (Aguirre, Agudelo, & Romm, 2017) and prototyping (Carlgren, Rauth, & Elmquist, 2016).

Table 1: Contrasting business and design, adopted from Gabay (2018)

Criteria	*Business approach*	*Design approach*
Value	Exchange-value: quantitative, objective (revenue, costs, profits)	Use-value: qualitative, subjective (experience, emotions, desires)
Focus	Customers, market (age, gender, size)	Humans, culture (personality types, backgrounds, traditions)
Tools	Analytical, numerical input, (ROI, BEP, NPV, CLV), 'Planning Oriented'. Support 'yes or no' decisions	Intuitive, observation, imagination, empathy (ethnographic research, journey mapping, prototyping), 'Action Oriented'. Reveal and connect new information
Attitude towards uncertainty & failure	Uncertainty: Fight (reduce, eliminate or control) Failure: avoid or eliminate	Uncertainty: Embrace (explore, experiment) Failure: accept

[3] Additionally, Prud'homme (2004, p. 4) and Star (1999) provide a number of specific qualities of infrastructure such as embeddedness.

[4] The verb *Infrastructuring* has also received increasing attention within participatory design literature (Hillgren, Seravalli, & Emilson, 2011). Although these authors' do refer to some similar qualities such as a long-term focus and embeddedness, our conceptualization is organisation-based.

Logic	Deductive, inductive	Abductive
Activities	Exploitive	Explorative
Work Processes	Linear, clean, short	Iterative (circular), messy, long
Thinking	Convergent	Divergent, convergent
Bias	Reliability (inability to include new relevant information)	Validity (no consistency in processes and measurements)

As designers' have been tasked with increasingly complex and wicked problems (Muratovski, 2015), scholars have realized the suitability of the approach due to how it reframes problems and solutions (Dorst, 2017) and its human-centeredness (Norman & Stappers, 2015). However, designers will also need to develop new methods to use their skills in this new context (Björgvinsson, Ehn, & Hillgren, 2012; Norman & Stappers, 2015).

In *Wicked Problems in Design Thinking*, Buchanan (1992) distinguishes between four (4) areas in "which design is explored throughout the world by professional designers and by many others who may not regard themselves as designers" (p.9). These areas (as visualized in figure 1), have no hierarchy and may be seen as working domains in practice (Golsby-Smith, 1996). In recent years, a number of authors have suggested that an increasing number of designers act on the *Systems, Organisations and Environments* level (Boland, Collopy, Lyytinen, & Yoo, 2008; Cooper & Junginger, 2009; Gruber, De Leon, George, & Thompson, 2015; Kronqvist & Salmi, 2011; Muratovski, 2015). In this level, organisations are seen as products which can be designed (Buchanan, 2008). Designing at this level focusses on systemic integration and the performed activities, which may be spurred by design on other levels, are geared towards finding a new 'organizing thought' and the resulting organisational changes (Buchanan, 1998, 2001; Junginger, 2005).

According to Golsby-Smith (1996), fourth order designers need to deal with three unique features in their approach: purpose, integration and systems (or community). First, the fourth order designer needs to understand and influence the *field* which revolves around processes and tasks, consisting of system level values and a purpose. Second, design in this order seeks integration with connected systems and activities. Third and last, is a focus on people or communities, in which discussion is not only fostered but the direction and facilitation of the conversation is key.

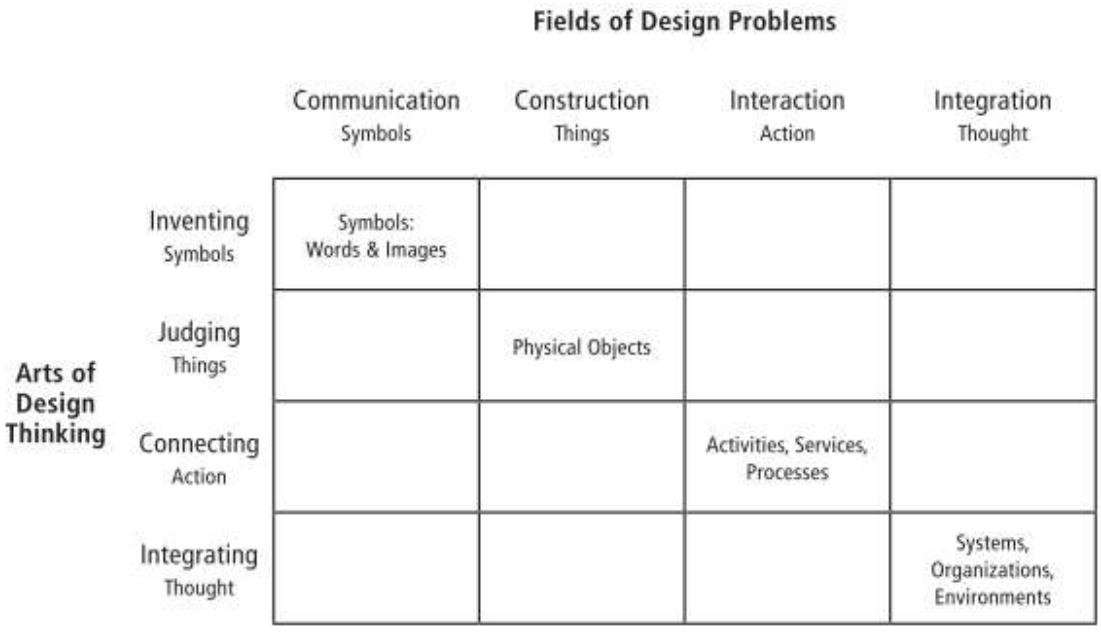

Figure 1: Four orders of design (Buchanan, 2015)

Research Design & Methodology

To explore what organisational infrastructure consists of and how it can be designed, an action research approach was applied (Reason & Bradbury, 2008). This approach fits the explorative nature of the study and the importance of the contextual (social) embedding of the phenomenon to be studied (Coghlan, 2011). The overall research design is similar to that used by a 'Design Innovation Catalysts' as described in detail by Price (2016). Crucially, a long-term engagement was set-up between the first author, a designer by education, and a large airline (from hereon: FlyCo). Over an eighteen (18) month period, the researcher conducted three individual *Action Research Cycles* (Lewin, 1946).

This paper reports on the insights gained in the third and final cycle, where the action researcher was asked to act as manager of an innovation team and use his knowledge and experience of design to come up with a new organisational infrastructure. During this cycle, the first author became 'an insider' (Brannick & Coghlan, 2007; Ottosson & Björk, 2004) and spent four days of every week as line manager of a small team, responsible for creating and prototyping operational innovation. The researcher joined meetings with directors and executive vice presidents, but also spent a significant amount of time with project level and operational employees. He thereby gained access to a vast amount of internal data sources, including strategic documents and was able to record rich insights into the dynamics of the organisation (Brannick & Coghlan, 2007).

Qualitative Data Generation and Collection

During this period, the design researcher author carried a digital diary in which he took field notes of observations from one-on-one meetings and group participatory observations. This primary mode of data collection is used to gather:

> *In-depth descriptive details of people (including oneself), places, things, and events, as well as reflections on data, patterns, and the process of research. These details form the context and quality control that shape multiple qualitative data points into articulated, meaningful, and integrated research findings.* (Brodsky, 2008, p. 324)

The observations were captured in plain text, drawings, schemes, pictures and film. The author thus aimed to record not only observable facts, but also his own experience of the process of designing infrastructure and theory building (Herr & Anderson, 2005). The observations were captured on a password protected digital device and standard company in-house measures could be followed to ensure data security. Additionally, semi-structured interviews with fellow managers were done to canvas the organisational infrastructure and how innovation was realized (Sarpong & Maclean, 2012). Finally, a second researcher interviewed (and performed a focus group with) the team-members regarding their experiences as innovators within the company and as participants in the infrastructure design process.

A number of measures were taken to increase validity and reliability of the research design, which focused in this case on minimizing reactivity, 'going native' and alignment (Langley & Klag, 2017). To improve construct validity, both data and methodological triangulation were performed (Blandford, 2013). Additionally, by member checking our findings with the participants of the study, possible interpretations were evaluated from multiple perspectives to increase rigor (Baxter & Jack, 2008). Finally, to avoid a distorting subjectivity effect, on the fifth day of the week a 'critical friend' (in this case colleague) was used to discuss findings and conclusions (Herr & Anderson, 2005).

Foci: Components of Organisational Infrastructure

To be able to collect data in the field regarding organisational infrastructure and in line with this papers' aim to contribute to a practical understanding, the concept of organisational infrastructure is further broken down into a limited set of observable components. As this research explored the concept of organisational infrastructure as design material, the specific materializations of the components were not completely predetermined by literature. Rather, throughout the first two cycles of this action research project, the four (4) tasks of organisation (Puranam et. al, 2014) and the qualities of infrastructure (Prud'homme, 2004; Star, 1999) were used as guidelines to identify organisational infrastructure components at the studied company. Table 2 provides an overview of the identified components of organisational infrastructure.

Table 2: Identified components of organisational infrastructure – building on Puranam et al. 2014.

Component title	Example questions
The division of tasks	
Team composition	What different functions work together in a team or on daily basis?
Team responsibilities	What is a team held responsible for? What do they need to complete?
Hierarchical structure	Who reports to whom? Who evaluates whom?
Location	Where do people work on a daily basis? How do people communicate?
The allocation of tasks	
Project selection criteria	How are projects selected? Which projects are prioritized and why?
Formal roles	What are official internal titles, what terms are used in job vacancies?
The provision of rewards	
Budget systems	How are budgets allocated? When and through which systems do teams request budget?
Team Key Performance Indicators (KPI's)	How are teams evaluated? On which aspects or by which measurements?
Professional development paths	How and on what basis are employees promoted or (financially) rewarded?
The provision of information	
Hierarchical structure	(see above)
Meeting structure	Who is invited to which meeting? When do these take place?

Qualitative Data Analysis

As this paper focusses specifically on the infrastructure design process, only data from evens that were explicitly related to this process were included in the analysis. An overview of which data was in- and excluded for the analysis for this paper can be found in the appendix. In total 26 pages of field notes from one-on-one meetings, 29 pages of field notes from group activities (such as meetings) and 40 reflective notes were analysed. Together, this adds up to just under 100 *temporal observations* of the design process (Langley, Smallman, Tsoukas, & Van De Ven, 2013). Additionally, seven (7) one-hour interviews were included in the data-set.

A qualitative data analysis process was performed over a two-step process as proposed by Braun and Clarke (2006). First, the authors spend an extensive amount of time to get familiar with the data on a high, process level. This was done by mapping key events of the process and the related insights of these moments as prescribed by Poole, Van de Ven and Holmes (2000) (and exhibited in Figure 2). Secondly, a thematic analysis was performed, which involved searching for themes in the data based on reoccurring patterns and testing these themes on the entire data set.

Figure 2: Data familiarization through process mapping

Findings

A key characteristic of action research is an element of change which is introduced by the researcher. As a result, and as exemplified by Lüscher and Lewis (2008), action research is often reported in a narrative form where events and reflection are combined (Reason & Bradbury, 2008). In this manner, the following sections describe how organisational infrastructure was designed.

The Context and Design Challenge

As a traditional, network carrier, FlyCo faces constant competitive pressure from low-cost airlines. Specifically, FlyCo is challenged to continually improve its operational performance, both in quality (i.e. avoiding delays and cancellations) and in quantity (i.e. optimizing the amount of flights per aircraft per day). To this end, an innovation team was established. This team (team Y) uses (co-creative) design and lean start-up methodologies to find and quickly prototype new operational tactics to be implemented in live operation. Table 3, at the end of the end of the findings section displays the organisational infrastructure of the team before the redesign process.

At its initiation, Y focused on realizing results quickly, by utilizing a lean governance structure, close ties with top management and by holding to a credo of 'learning by doing'. The team and especially their managing director noticed over time that an increasing number of innovations that were prototyped weren't further developed and implemented whilst there was no apparent reason or decision to kill development. After initial prototyping, these projects would end in *the Valley of Death* (Markham, Ward, Aiman-Smith, & Kingon, 2010). As the director would later recount: "…the former manager of the team, he would use his network and willpower to get stuff done. He would just keep nagging at every table until it was realized. That doesn't work anymore" (field note, 17/08). The *Valley of Death* was becoming an increasingly important problem, one field-note of another meeting with this director shows "We need to make bottom-line impact. Otherwise, others will do it" (field note, 24/04). Crucially, the lack of implemented innovation started to influence the credibility of the team (field note, 20/05 & 29/5).

Additionally, an increasing number of departments within FlyCo became interested in the way of working that team Y developed and wanted to apply those same methodologies. However, articulating, translating and transmitting a way of working required new capabilities and the team found it challenging to organise this activity within their current infrastructure (field note, 04/06).

After a personnel change, the managing director was left searching for a (temporary) manager. After inquiry by the author into replacement, the director asked him to consider the job (field note, 16/05). The author would be tasked with determining a strategy for Y to go "into a new S-Curve" and together with the team and the director, design a suitable organisational infrastructure.

Process overview

Over period of six months, a number of sessions were organized by the first-author to support the infrastructure design process, as exhibited by figure 3. These sessions were structured and presented as a co-creative design innovation process. By this framing, the author hoped to invoke the same open-minded, creative and critical mind-set that the team was known for and thought themselves to be (internal communication, 09/09). Additionally, by doing this, the author explicitly framed the process of infrastructure design as similar to the process of product innovation design. These sessions were preceded by a number of meetings in which the assignment was presented by the managing director and the challenges were further elaborated by the parting manager of the team. After the strategic sessions, three one-on-one meetings were held between the author and the manager to finalize the design. Finally, the results were presented to the team.

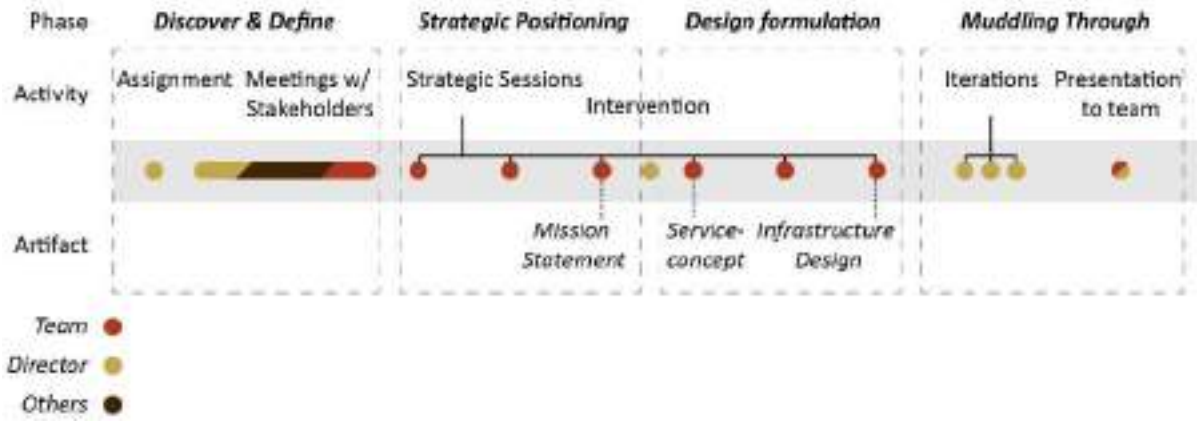

Figure 3: Infrastructure design process

Four phases of the design process

The design process can be divided into four phases which differ in the type of activities that were performed, and the stakeholders involved. The first phase included the analysis of the status quo and the problems to be solved by the new infrastructure. Following this, a higher abstraction level was assumed in which a new strategic direction was created for the team. This direction was embodied in the formulation of a new mission statement. After this phase, this strategy was gradually given body by defining the *service concepts* needed to attain the strategy and constructing the necessary infrastructure. Finally, this plan or infrastructure design, was presented to the managing director. At this point, a final process of iteration and negotiation began as a final design emerged. In the next paragraphs, each of these four phases will be examined in more detail.

1) Discover and Define

Initially, the author met with the departing manager, former and current employees of the team and again with the director. During these unstructured interviews the challenge to be tackled was explored. Through open-ended questions, starting from the current challenges of the team, asking about the historic development of the organisation and collectively looking forward towards possible solutions, the author aimed to uncover both explicit and implicit dynamics (Sanders & Stappers, 2012). Additionally, the author participated in regular team meetings and observed during meetings and informal discussions. This allowed the author to see the described organisational dynamics and uncover additional information that may have seemed irrelevant for the interviewees.

Over this period, the challenge to be solved was explicated from different angles. Some indicated team culture as an important factor: "scaling-up prototypes is just not in the mind-set of the team" (field notes, 07/05).

Others pointed towards “unclear targets” which “weren’t defined” (07/05) or according to some “didn’t focus on implementation… If they would, the process would change” (field note, 15/05). Still others mentioned that work pressure interfered with actions to ensure implementation (15/05). Finally, additional challenges surfaced during this period, such as internal team struggles (field note, 16/05). In sum, the design brief expanded considerably over this period as the context became clear. This process may be best compared to what in design process descriptions are often called the *Discover* and *Define* phases (Liedtka, 2015).

Two observations during this period are particularly recurring and thus worth noting. First, there seemed to be many different ‘frames’ (Dorst, 2017) through which to look at the Y team and their challenge (within and outside of the team). According to some, Y was a team that had unique research capabilities and therefore could educate the business on their needs. It was referred to as the team that came up with the concepts that people didn’t know they wanted, or the team that co-created solutions with employees. As described by Dorst (2017), these different frames influenced the perceptions of the challenges to be solved and the ‘criteria’ with which the new design would be judged.

A second observation was a disrupted bond between the members of the Y team and the director, due to a decreased level of (field note, 12/06). This also appeared to be related to a figurative ‘distance’ between the Y team and the rest of the department (field note, 25/05). This situation complicated the entry of the author into the team (as he was hired by the director) but also complicated the process in general, as for example, team members weren’t forthcoming about their concerns and viewpoint on the problem to be tackled (field note, 12/06).

2) Strategic Positioning

After the author spent his first months on the job, the director posed a question to the entire team: “Do you accept my assignment? Will you design a strategy and think of an organisation which shows how to design innovations…takes these innovations from concept to implementation and… brings your way of working to the rest of the organisation?” (field note, 19/06). This was the trigger for the first-author to organize a series of strategic sessions in which the team co-created a new strategy and organisation.

In total, six (6) sessions were organized by the author, of which three (3) focused on crafting a strategy and three (3) on designing the organisational infrastructure. Participants in these sessions were the PO’s, the author and an employee from the larger department who represented an outside view. During these sessions (which lasted on average 3 hours), (silent) brainstorms were held and a constructive and critical discussion was fostered to come to agreed-upon statements.

In the first session the author presented his findings of the first months as context. These were presented in the form of statements. For each statement, the team debated on whether they agreed and/or whether changes were needed. These statements generally focussed on the merits and dangers of designing a strategy in general and what would make a good strategy. Statements included were for example: “without a clear strategy, we will have prioritization issues” or “a strategy will help us to communicate better with Business Owners” (internal correspondence, 26/6). The team also initiated a brainstorm on what would be the downsides of determining a strategy, and thus what the strategy should not result in. These included statements such as: “a strategy might result in tunnel-vision.” (field note, 18/07). Finally, the team felt the need to determine what ‘a strategy’ would include. A decision was made to adopt a strategy design tool which defines four linked elements:

1. Where are we now?
2. What is our vision of this team and department?
3. What projects will get us there?
4. What are our guiding principles in getting there?

The second meeting focused on getting ‘on the same page’ (internal communication, 19/07). Beside exploring the strategies that were made in previous sessions and exploring the current business context, the author touched upon a number of examples from other companies. Also, the team agreed upon a number of major themes to focus the strategic efforts on: (1) mindset, (2) tools, (3) methodology and (4) organisation.

The third and final meeting focused on defining a new vision and mission for the team. Out of a silent brainstorm, a clustering exercise and a thorough discussion, the team came up with a statement which described why the team existed and what it intended to achieve.

With the formulation of this statement, the team effectively decided on which frame to pursue during the next phase. This was important as team members mentioned earlier that they found it challenging to think about and propose decisions regarding their own infrastructure due to the uncertainty of their situation and the complexity of the problems they were facing (field notes 24/07). Without a specific frame to pursue, decisions regarding infrastructure seemed impossible to make (reflective journal, 26/07).

3) Infrastructure Design Formulation

The last three strategic sessions had the aim of translating the new mission to more concrete infrastructure. This phase was initiated with a one-on-one meeting with the director, in which he indicated an expectation to implement a piece of infrastructure. This element had been discussed in earlier sessions and seemed to compliment with the new mission. Following this intervention and a session in which the team defined a *service-concept*[5]*,* two (2) sessions were organized in which the concept was translated into elements of the organisational infrastructure.

This discussion was facilitated with the use of a template adopted from Van Assen (2019). Eventually, three 'products' were defined. In the final two sessions, an organisational infrastructure that would facilitate the 'production' of these products was proposed. Again, this infrastructure was eventually 'coloured-in' by answering a number of questions collectively and coming to a final answer through discussion. Questions that were likened those presented in table 2 (internal correspondence, 06/08).

A noteworthy observation is that in the *service-concept* session, fierce debates erupted in which team members realized that their frames on the team (and implicitly on the problem to be solved) did not match. Even though the team members had agreed on a mission statement, a chasm appeared between two groups of team members. Eventually, the author had to make a decision. When this was done, the rest of the infrastructure elements, such as team roles, responsibilities, resourcing and KPI's fell into place[6]. As one of the team-members mentioned: "It's weird…we are just talking from our toes, really from the inside…we're just writing down stuff that we already know implicitly" (Memo, 24/08). Finally, what is interesting to note about these sessions, is that the team uncovered that to be able to implement their solution, they needed to include the infrastructure design of another team into the scope. This conclusion essentially broadened the scope of the both the problem and solution space. This co-development of problem and solutions is typical for a design process.

4) Muddling Through

In the final phase of the infrastructure design process, the author presented the work that was done and the results to the director. The new mission statement, service-concept and infrastructure was presented with the aid of visualizations which acted as prototypes. Subsequently, the author and director performed another round of iterations to make the design fit with the progressed insight of the managing director and other developments that were taking place in the department (field notes 13/09). Finally, the new design was presented back to the team. At the time of writing, a selection of elements of the design have been implemented. Within the context of fourth order design, this final phase should be considered an integral part of the process. Currently, the managing director and newly appointed manager are muddling through: opportunistically and incrementally implementing elements of the design (Norman & Stappers, 2015).

In this final phase, the previously mentioned trust issue re-occurred. This especially surfaced when the final design was presented to the team. First, they mentioned that they missed the connection between what they had felt owner of through co-creation and what was presented back to them (field notes 05/10). Second, the team indicated that they found it challenging to work with and towards a design that wasn't completely detailed yet, as long as they couldn't trust that their vision was aligned with that of the director (field note, 22/10).

Another resurfacing issue was that the author and director appeared to have different frames. This became especially apparent in a discussion on team composition. Whereas the director preferred a composition which was more fit for the development of solutions (exploitation), the author proposed a team that would be

[5] To define a 'service concept', is to decide if the team were a miniature company, what would it offer, what would it need and how would it organize itself?

[6] According to Dorst (2017), this is common on design processes. Once a working frame has been identified, solution elements are easily identified.

equipped for research and ideation (exploration) (20/09). This was eventually resolved by adopting a new frame, in which teams develop over time to perform both functions subsequently (internal communication).

The Infrastructure Design

Table 3 illustrates the previous organisational infrastructure of team Y as well as the new infrastructure that resulted from the design process (infrastructure that was altered is bolded for emphasis). This table indicates the nature of the changes that were applied as well as the scale of the changes. As can be seen, the new design differs on many aspects from the original design.

Table 3: New Organisational Infrastructure of Y Teams – changes in **bold.**

Component title	*Infrastructure of Y teams*	
	The division of tasks	
Team composition	• Full-time former operational staff • Part-time operational staff (gate-agents, baggage staff, etc) • Access to an internal team of software developers	• Full-time former operational staff • **Full-time analytical staff** • Part-time operational staff **when needed** • Staffed with **in-team software developers when needed** Full-time former operational
Team responsibilities	• Analyse operations to define bottlenecks • Design & Prototype concepts to prove feasibility, viability and desirability • Spreading way of working to other departments	• Analyse operations to define bottlenecks • Design & Prototype concepts to prove feasibility, viability and desirability • **Support a new team which spreads way of working** • **Develop and implement solutions** • **Evaluate operational impact**
Hierarchical structure	• Reporting to a director, who reports to the COO in the operational organisation (as opposed to the support or sales organisation) • In a department with high-tech product teams that develop software tools for the optimization of the operation • Not formally connected to other innovation teams	• **Reporting to a product manager,** who reports to the director • In a department with high-tech product teams that develop software tools for the optimization of the operation • Not formally connected to other innovation teams • **Supported by a *capability lead***
Location	• At the airport, close to *the action*, far from other teams in the department	• **Co-located with other development teams** • **With a lab at the airport, close to '*the action*'**
	The allocation of tasks	
Formal roles	• Product Owners[7] (PO's), expected to set, manage and perform activities needed to develop concepts and	• **Challenge** Owners, expected to set, manage and perform activities needed to **tackle 1 challenge** and related stakeholder

[7] Adopted from the 'agile' methodology but adapted to a context of prototyping.

	stakeholder management. Also responsible for daily management of the builders • Builders, operational staff that design features and prototypes and perform tests.	management. Also responsible for daily management of the builders **in their team** • Builders, operational staff that design features and prototypes and perform tests
Project selection criteria	• Yearly objectives are set for the team in agreement with business owners[8] • Manager of team gathers challenges related to objectives from business owners • Team selects projects based on a number of factors[9] • Product Owners take-up challenges whenever they have time left with no distinction for the business in which the challenge lies	• Yearly objectives are set for the team in agreement with business owners • **Challenge owners** gather challenges related to objectives from business owners • **Challenge owner** selects projects **related to their challenge** based on a number of factors[10]
	The provision of rewards	
Budget systems	• Yearly budget set for staff and costs of prototyping • Separate budget 'envelope' to finance software support, based on high-level plans for half a year	• Yearly budget set for staff and costs of prototyping
Professional development paths	• Unclear	• Unclear
Team KPI's	• Number of prototypes tested at scale & implemented in the organisation • Number of departments that are engaged	• **Amount of progress made on objectives set by business**
	The provision of information	
Hierarchical structure	• (see division of tasks)	• (see division of tasks)
Formal meeting structure	• Bi-weekly update with small portion of operational innovation staff • Weekly team meetings with PO's and team manager • Bi-weekly update with other PO's from the department • Team manager meets weekly with management team of department	• Bi-weekly update with small portion of operational innovation staff • Weekly team meetings with **C**O's and team manager • **Product manager** meets weekly with management team of department

[8] This was as it was presented and designed, the data shows however that objectives were only set once at the start of the team and the team added objectives along the way.

[9] The expected operational impact, technology, priority as indicated by business owners and *wow*-factor.

[10] A new set of criteria was developed, including expected operational impact and cross-departmental engagement.

• (Bi)-monthly update meetings with business owners	• **Challenge owners meet regularly with business owners**

Conclusion & Practical Implications

This paper introduced the concept of organisational infrastructure and explored its potential as part of a widened view of fourth order subject matter. Four interlinked elements of organisational infrastructure are presented based on literature and observations. Also, we describe a methodology which uses these elements and includes four stages, consisting of interviews, co-creative sessions and a final 'muddling through' phase.

Even though this project has assumed a design process which likens to that of lower order design projects, some fourth-order elements are clearly distinguishable. First, throughout the process, the facilitated search for team and department *purpose* is recognizable as proposals for mission statements and infrastructure designs brought to light differences in what the purpose of the team should be. Second, there is a recognizable attempt to reach integration, which culminated in the 'muddling through' sessions, but which is also recognizable in the fact that the scope of the project was enlarged with another department. In this case, the search for integration also allowed for an organisational design to emerge which explicitly recognizes and facilitates an ambidextrous operation.

Two notes of caution for the application of the presented approach to organisational infrastructure design should be mentioned. First, it is important to have established a bond of trust between those that are part of the organisation that is being redesigned and the designer. Overcoming ambiguity and uncertainty, which are typical elements of design processes, is challenging when the object to be designed is the infrastructure of an organisation. In this context, we do not design a tool to work with, *but what to work on, how to work and who to work with*. This personal level of involvement seems to magnify moments of uncertainty and a lack of trust in either the process or the designer thus introduces considerable challenges. Involvement of all stakeholders on a more regular basis, the authors' feel, may mitigate this challenge.

A second implication from the discussion of the results is the perceived effect of not explicitly agreeing on a reframed problem statement. During the described process, the author, director and team did not openly agree on *what problem* the infrastructure design should solve and thus which frame to operate from. As a result, conflicting frames re-appeared a number of times, confusing and frustrating stakeholders when viable solutions to problems were ignored or undervalued because of diverging frames.

This research also indicated towards two (2) possible benefits of designing organisational infrastructure. First, similar to Junginger's findings (2005), the co-creative approach to organisational infrastructure design resulted in engaged employees who felt ownership of change. With this sense of ownership came an openness from employees to quickly adopt the designed change. Second, the explorative and iterative approach allowed for the problem and solution to co-evolve. By allowing this, a more holistic and coherent design could be developed. However, despite the noteworthiness of these observations, future research is needed to establish these more firmly.

Finally, this paper presented the results of an ongoing analysis and as such includes only a sample of the available data. Future research will involve further qualitative data analysis of all three action research cycles and write-up regarding the journey of FlyCo as a company undergoing transformation via design. Further research will be performed to explore, amongst others, the interplay between the Y team and the rest of the organisation as a result of these organisational changes.

Included	**Excluded**
Field notes	
- Only third research cycle - Meetings and strategic sessions with director - Y team meetings surrounding major strategic events - Introduction meetings with former team manager and related business owners - Strategic sessions with Y - Trainings sessions with larger department (on implementing innovations)	- First and second research cycles - Introduction with management of other departments/units - One-on-one meetings on daily business - Leadership coaching meetings - Y team meetings in general
Interviews	
- Y team members and managing directors on organisational infrastructure	- Y team members and other FlyCo employees on general processes and innovation management
Reflective Memo's	
- All audio and visual reflective memos from the third research cycle	- All audio and visual reflective memos from earlier research cycles
Archival data	
- Working document strategic sessions - Presentation to director on organisational infrastructure - Mails, presentations and memo's related to major events in ARC 3	- Archival data, such as documents and presentations from earlier research cycles - Mails & memo's unrelated to organisational infrastructure or the assignment

Digital Britannia – Secret Histories and Hidden Practices

KNIGHT John

Aalto University, Finland
john.knight@aalto.fi
doi: 10.33114/adim.2019.08.360

Digital design practice is distinctive in its relationship to material and focus on fabricating that into interactive products and services. It's a discipline that has evolved from significantly different disciplines: Product Design and Human-computer Interaction (HCI). The foundational role that HCI played in the growth of digital design is largely hidden, as is the secret world of design practice. These two shrouded phenomena have evolved from early user interface research, through user experience, to today's post-agile world and tomorrow's open design. We report ten years of first-hand accounts to create a grounded, contextualised and evidence-based account of design in the real-world from the 1980s to today. This condensed history of digital design in the UK forms the basis of the concluding sections. The first traces the evolution of design practice over the last ten years. The concluding section presents a first-hand account of practice. This case study shows how design is now deeply permeated by business and development ideas and practices. The paper concludes with some ideas of how digital design practice might progress beyond this presently constrained condition.

Introduction

1980s Invention – from controls to interfaces

Human–computer interaction emerged in in the UK in the late 1950s. In 1959, Brian Shackel, published the first article in the area entitled 'Ergonomics for a Computer'. This was based on his experience designing what was effectively the 'user interface' of the EMIAC II, albeit one that consisted largely of knobs and lights. Shackel's influence in HCI continued to be felt in later years both in the industry-facing HUSAT research centre at Loughborough, and his role in establishing IFIP TC 13 and the INTERACT conference series in the early 1980s.

However, academic HCI in the UK owes perhaps its greatest debt to the Alvey programme. In 1983, and in response to the Japanese 5th generation computer programme, the UK launched its own half–billion-pound funding programme. This covered five core research areas including the 'Man–Machine Interface'. The choice of these areas was determined by a commercially savvy, industrial committee. The group foresaw the essential role of the human in future computing, something that computing academics at the time regarded as marginal.

This programme was largely responsible for the creation of major cross-disciplinary HCI research groups, including those at York and QMUL, as well as strengthening existing work in the area such as Loughborough, John Long's Ergonomics Unit at UCL (now UCLIC) and usability standards work under Nigel Bevan at National Physics Laboratory. Early work on accessibility can also be traced back to this time in the UK (Edwards, 1987) catalysed by Alan Newell's work at Dundee University. To this day, the 'children of Alvey', PhDs and researchers first employed in the programme, are widespread in the professoriate across the UK and contributed to growing early commercial adoption.

Another initiative of that period was the British HCI Group, (now a specialist group (Interaction) of the British Computer Society (BCS)), and the British HCI Conference. The latter was one of the core international venues at the time as well as nurturing the growing UK HCI community, both in academia, but also the initially small group of practitioners employed in agencies and companies such as IBM in the midlands and NCR in Dundee.

The close connection between research and practice continued into the 1990s with the UK joint industrial–academic CSCW programme. Whereas Alvey had fostered research connections between psychology and computing, the CSCW programme brought sociologists and management science into the interdisciplinary milieu, which was unusual if not unique in the world. This rich community attracted both Lucy Suchman, who brought ethnography into HCI, and Xerox Europarc to the UK. During this time, early courses in interaction design emerged coinciding with Bill Moggridge's tenure at the RCA.

By the dot-com years at the end of the 1990s, the British HCI community, in both academia and industry, was mature, and had a unique character of its own that often connected theory with more practical methods and design. The small but growing number of interactive agencies were filled with graduates of the UCLIC's MSc programme. Indeed, some of the children of Alvey, themselves became the hi-tech entrepreneurs of the dot.com boom.

1990s Refinement – from text books to standards

The rapid emergence of multimedia for both business and consumers in the early 1990s, extended HCI from the ergonomics of the workplace into the mainstream. Dix *et al* (1993) was a prevalent HCI textbook for the early masters' degrees in multimedia. Until this point the consumer had little access to technology, but as early handheld devices (e.g. Palm Pilot) appeared, and mobile phones became not just a tool for young professionals but a fashion accessory, ergonomics for consumer electronics converged with IT design.

The first edition of Dix, et al (ibid) is often thought to be engineering-driven, and iterative waterfall methodologies are not unusual for its time of publishing. Part I, Foundations, spends a hundred pages on "the science bit" and part III a similar amount on futuristic and emergent issues, but part II, Design Issues, spends three hundred pages on the process. Therein are multiple references to standards and guidelines (pp 161-168) for that which is produced, but also for the processes (pp168-188) for producing it, leading with Usability Engineering. This focus on design rules and guidelines is extended further in later editions of this book and also in Preece et al (1994), Benyon et al (2005), Sharp et al (2007), other definitive textbooks that followed.

Nowadays, the engineering focus is almost a curiosity. At the time, however, constraints of processor, memory and connectivity were considerable, and, in our experience, the risks of any failure were high and expensive. Personal computers booted from floppy disks, CD-R was an expensive (£20 per disk) and fragile technology. In 1991, a SCSI hard drive with the capacity of a CD cost over a thousand dollars. It cost $25,000 (and a flight to LA) to digitise an hour's MPEG-1 video to fill a CD-i in 1994. Any failure or unnoticed error in the digitisation, the authoring, the mastering, or the pressing, erased profit margins and drove many early multimedia companies out of business in the latter 1990s.

Nevertheless, it became clearer that good usability is a fundamental objective of digital design and that this should be achieved by conforming to standards both for content *and* for process. By INTERACT'99, the conversation had progressed to how to make usability, itself, usable. The gathered academics viewed usability as mature, the attendees from government felt that "Usability Now!", a decade earlier, had "transferred the technology" to industry, and local TV captured industrial exhibitors using "ease of use" to differentiate their innovations. Yet employers complained about graduate skill sets, and major product investments were still leading to marketplace failure due to poor usability or accessibility.

In the meantime, dedicated individuals such as Charles Brennan, Nigel Bevan, Jonathan Earthy, Martin Maguire and Catriona Campbell had succeeded in codifying, first into British and then ISO Standards (e.g. ISO13407 (1999) - *see below*), and then into government policy, definitions of process and content.

> *[…] an approach to interactive system development that focuses specifically on making systems usable. Whatever the design process, the allocation of responsibilities and roles adopted, the incorporation of a human-centred approach is characterised by the following:*
>
> - *the active involvement of users and a clear understanding of user and task requirements;*
> - *an appropriate allocation of function between users and technology;*

- *the iteration of design solutions; and*
- *multidisciplinary design.*

(ISO 13407, 1999)

At this time, the British HCI Group saw two opportunities - one, to create a website that would provide a global hub for usability knowledge and debate, and two, to update the standards used by business to define job roles and employment contracts. UsabilityNews.com went live in 2001, employing an editor/author part-time to create and collate content. Over the next few years it achieved a global following and was the conduit by which tales of practice fed back into the group. Initially these were detailed accounts of practice and increasingly via a steady and growing stream of detailed job vacancy descriptions. This information fed into the efforts led by Jonathan Earthy to have HCI more adequately reflected in the primary definition of skills in this sector, SFIA - The Skills Framework for the Information Age.

SFIA had grown out the BCS's Industry Structure Matrix (or Model) ISM (1986) and is used in many countries as the basis for employment contracts, identifying training needs, and demarcation of labour. In the UK, Sector Skills Councils (SSC) coordinate this effort, and most work domains have a relevant SSC. The challenge in design practice is that there are (at least) three relevant ones which sometimes overlap (SFIA, Skillset, CCSkills). SFIA, by 2009 defined 86 "skills" each at several levels of competency, with each of these based on underlying items of knowledge or other attributes. Bodies such as e-Skills or BCS then build more detailed definitions, with BCS's SFIAplus running to several thousand pages of detail. Employers then might define a job role as, say, requiring level 3 of skill X and level 4 of skill Y. While this may sound reductive, equality legislation has required human resource professionals to use objective ways of measuring the demands of, and capabilities needed for, a specific job. This enables equal pay, removes possible areas of ethnic discrimination, and provides the individual with a clear career ladder.

An HCI2009 Educators Workshop paper (McEwan, 2009) records that joint efforts from 2002, by BCS and the Usability Professional Association, to develop accreditation of competency in usability had foundered, both in terms of the legal implications of administering 'licence to practice', and the dearth of competency definitions in the upper (Professional) levels of SFIA. This effort subsequently led, however, to five rather than two HCI-related skills (and 20 separate role-levels) in version 3 of SFIA (2005), including at the most senior professional level. This success was not unqualified, as SFIA continued to use outmoded terminology, such as 'non-functional needs', and HCI and Usability were still excluded from relevant skill sets such as 'requirements engineering', and 'content creation'.

2000s – Augmentation – from labs to agencies

A handful of digital 'labs' emerged in the late 1980s, that provided HCI style offerings, such as usability testing. Some way distant from marketing, these evolved into the 1990s as highly specialised industrial and product design organisations (e.g. IDEO) or emerging technology service providers (e.g. Sapient). As Interactive CD-ROM production company's success peaked, their staff found a new niche as 'multimedia' web developers. The growth of a new kind of agency was sustained by the New Economy (Tapscott, 1997). Here the emergence of email, the internet, mobile communications and ever maturing software platforms created demand for 'digital' design and improved usability.

The commercial application of HCI had two effects. Firstly, it shifted and extended research agendas into commercial product and service contexts, thus opening up hitherto unaccounted for issues and domains such as use. Secondly, it spurred growth in what would now be called 'start-up' organisations, seeking to provide commercial variants of classically developed tools and methods. In 2001, the UK market for such services was limited to approximately 50 organisations, with the biggest concentration in London (Jefsioutine and Knight, 2003) including Oyster, FramFab and Wheel. These early pioneers were a mix of the traditional advertising agency, with some of the strategic mettle of their global counterparts (e.g. Frog and IDEO) and a close connection to academic HCI founded through the Alvey programme. Nowadays, that figure has grown tenfold.

In this climate, some students started their own commercial agencies (e.g. Amberlight) or gained employment in niche design oriented ergonomic and usability labs including User Focus and System Concepts. This diverse milieu found common cause in developing a small but influential community of practice through discussion lists (e.g. London Usability Group that first met in 2000) and catalysed the growth of the BCS HCI Group, UPA (now UXPA) and IXDA (now SDA).

A further significant shakeout of advertising-oriented agencies occurred during the dot.com bubble. Frenzied capitalisation in new, internet-oriented business led to a bonanza in web design. The resulting downturn and reaction against 'creative' fostered commercial interest in usability and process. 'Web 2.0' (O'Reilly, 2005) heralded venture capital's love affair with the tech start-up scene. Lessons learnt in the dot com bubble had a significant economic impact too. Behemoths such as Amazon and Apple were deeply scarred and shaped by that experience, including their embrace of design. The particular type of design that these companies, and the many agencies that serviced them employed was a hybrid. This HCI based fusion encompassed 'User-centred Design' (UCD), that drew on the distinctively British socio-technical tradition of Trist (1951), Scandinavian Participatory Design (Ehn, 1988), instrumentally oriented engineering approaches (e.g. Usability Engineering, Gould and Lewis, 1985) and experience oriented product design (e.g. Jordan, 2000).

2010s – Traction – beyond usability to service experience

Nascent agencies, internal teams and researchers adopted a loosely defined User-centred Design (UCD) process at this time. This methodology evolved across traditional disciplinary boundaries of computer science, design and even political activism. A common factor in these seemingly disparate elements was in front-ending audience research and testing with low-cost prototypes before undertaking any development work. This preliminary work reduced production risks and costs and was a good fit to the prevailing waterfall development methodologies of the time.

Participatory Design's emphasis on a common language using "low-fidelity" prototypes (Ehn and Kyng, 1991) not only fitted engineering methodologies and focus on risk mitigation (albeit downplaying the social democratic political agenda) but were also valuable in a commercial context. Cheaply made, early prototypes bought marketing 'ideas to life' and were thus useful in pitching for work, let alone aiding workplace democratisation. Low-fidelity prototyping also provided a bridge between traditional design disciplines and software development. Yet over time prototyping widened a gulf between design and development, that had been absent in HCI. Focusing on prototypes rather than working software gradually shifted the focus of design, firstly from collaboration with engineers at a philosophical and practice level and secondly from "making stuff in the here and now" to a future (idealised) state as is the orthodoxy in much academic design research.

UCD's future was now assured, albeit with a final important shift toward the experience economy (Pine and Gilmour, 1988). The result was a loose amalgamation of what were by now relatively robust design practices (e.g. wireframing) applied to a holistic definition of quality (e.g. Service Design and User Experience, respectively). The core set of practices extended into voguish notions of 'Design Thinking' that provided an innovation focused counterbalance to the discipline's risk mitigation strategies. UCD's future was also secured with the launch of highly successful consumer devices such as the iPad and the exponential growth of the tech giants of today. The speed and magnitude of this growth as well as further disciplinary accumulation of Lean and Agile has further obscured the critical role that HCI played in developing a global digital economy.

2015s – Reinvention – from abstraction to agile working software

This potted history would be incomplete without noting the critical role that agile development (Beck, et al, 2001) has had on digital design. While agility traces back to the previous century, its impact has accumulated over nearly fifteen years sparking a seismic change to practice and even the very nature of design outcomes. In a similar way to the Alvey programme, The Government Digital Service (GDS) incubated the latest incarnation of digital design that adds agility and a service orientation to UCD. From humble beginnings this organisation has established itself as a highly visible design-led organisation enabled to make strategic change in how citizens interacting with public services. GDS has also been critically important in growing the wider industry. As direct employer, it has sustained many seasoned practitioners, a mass of early career designers and developers, as well as a legion of mid-level contractors. GDS' close coupling of interaction design and software development reflects a broader turn against the kind of surface abstraction (making blueprints rather than services) characterised by service design orthodoxy. In other words, fusing agile development with experience design marked a return to HCI's core values of building working usable digital products and digitally enabled services. Lastly, outside of academia the number of commercial courses and accreditation initiatives grew significantly including the BCS UX Foundation Certificate, initiated by David Travis at User Vision.

Account of Practice

The role of HCI in digital design is a hidden history that can be retraced through rediscovering the rich materials found in various the conferences, publications and initiatives described in this section. Obscurity is compounded by a lack of first-hand accounts of digital design doing. These are stories of those involved in the doing of digital design as much as the pioneers who forged this potent blend of technology, creativity and a sense of social democracy. Indeed, few researchers have shed light on the everyday world of the digital designer and when they have done their conclusions lack a feel for the craft – a practitioners perspective. There is also a dearth of substantive data on practice. This means findings are hard to generalise out into broader insights and trends in the economy.

A number of studies were prepared to address this gap. These combined empirical exploration into practice as well as a case study type of account. Experimental work included secondary research data analysis, primary research (surveys, questionnaires and data-gathering workshops), practice-based research (practitioner workshops) and immersive research in an industrial setting. Together the resulting data, combined the breadth and veracity of society level trends (e.g. changes in working patterns such as the 'gig economy'), the narrow focus of targeted hypothesis driven studies (e.g. what methods do practitioners use most) and insights derived directly from practitioners and indeed elicited in the field of practice through immersive research.

As a longitudinal piece of work over a decade, it's has uncovered fluctuations in how design is practised from a number of perspectives that span recruitment to tools, methods and deliverables. The findings suggest that digital design has a core set of competencies that have remained relatively stable for nearly ten years. This foundational set of practices span research to development and has, through time, included relatively specialised roles in data analysis, research and interface development.

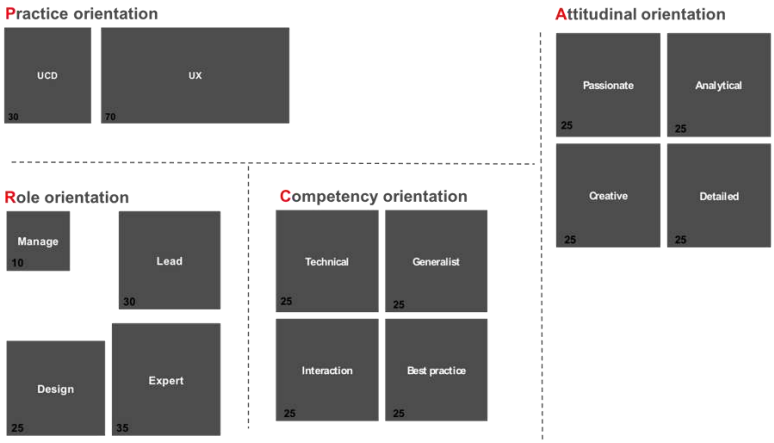
However, a fundamental shift has taken place during the period of study and that is the relationship between design and development. The HCI-oriented ways of working that influenced practice during the early studies in this work tightly coupled these two disciplines. For a while, the disciplines diverged, and design focused on abstraction, using futuristic blueprints to map out idealised future experiences.

This moving apart has begun to reverse now. Instead a focus on delivering working software (rather than descriptions of how it might be) has become a strong influence with the advance of agile. Now and looking to the future, this ebb and flow between the two ways of working is maturing into a truly hybridised discipline that manifests, arguably the best practices of both fields and where pace, innovation and deep collaboration are combined within a broad set of common tools and methods within a strongly holistic vision of the future and desired state.

JOB DESCRIPTION ANALYSIS (S1)

The first study (S1) addressed the lack of standard role definitions in digital design in 2010. This ambiguity caused problems for potential employers and employees alike. The research involved analysing a sample of job descriptions (n=48) from a number of organisations, selected from four regions (UK, Europe, US and Asia). The sample included a broad spread of role types ranging from research to development and were almost entirely drawn from the public sector as adoption outside of agencies and technology companies was extremely limited at the time. These were then categorised, and common role attributes identified. This was done 'ground up' from the data and supported the development of design role framework. This was operationalised through a job description matrix which was used to standardise job definitions.

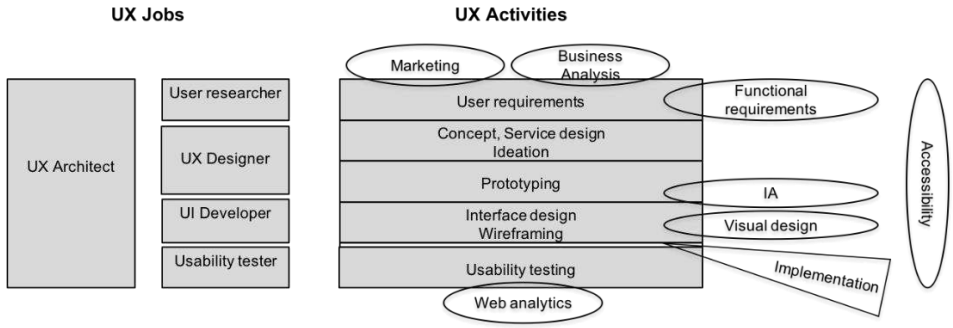
The framework consists of four dimensions including practice, competency, role and attitudinal facets (see below). The surveyed roles showed a broad spread of employment needs from research through to strategy. The demand for research was surprisingly low (6%) especially when compared to consultancy with the biggest proportion of roles relating to interface design and development. While senior positions were few (3%) these required the relatively short tenure of three to four years' experience. Many roles reflected the contemporary engineering paradigm noted in the history, with few mentions of design methods and practices. Instead a focus on HCI style methods including expert reviews and waterfall development was evident, as well as design to development workflows based on wireframing (see below).



COMPETENCY WORKSHOP (WS1)

An initial workshop (WS1) was facilitated to extend the analysis and validate the competency framework with attendees from academia, industry and recruitment firms. The outputs of the workshop (2010) provide a useful snapshot of perceived in-demand competencies and also prevalent methods and methodologies used in industry at that time. Perhaps unsurprisingly the outputs of the workshop aligned to traditional engineering paradigms for design and development. This was reflected in the prevalence of software development roles and terminology (see below) and a focus on functional requirements and business analysis. Design was tightly constrained as only relating to 'visual design', with a lack of facilitation skills or mention of 'design thinking' practices. Interestingly, however, was the explicit integration of design activities within development and relative lack of prototyping. This tight coupling between definition and working software would emerge much stronger with the widespread adoption of agile. There was also a strong focus on process that reflected contemporary work on developing standards at the time. Given the relative infancy of the discipline, it is also perhaps to be expected that that there was a strong emphasis on growing awareness, education and leadership and for strong communication skills (see below).

Core UX/UCD activities and associated professions



JOB ANALYSIS (S2)

The data from the workshop was used to refine the framework and operationalise it as a set of role definition criteria. These were used to standardise job adverts on Usability News. At the time, this website was one of the most reputable and visited sites for gaining information on the growing topic of user experience and finding jobs in this emergent industry. The high traffic into the site generated much data on the type and characteristics of design employment at the time. In just two years the site, had accumulated hundreds of standardised job descriptions from many potential employees and a sample of these (407) were analysed in 2013. In retrospect, it is interesting to note the prevalence of senior and middle management roles in the sample (71%) at this time with a (relatively short) expected tenure of five years. The high number of permanent to freelance roles (83 to 17%) is also surprising and counter to the largely freelance constituency of current employment patterns.

PRACTITIONER SURVEYS (S1,2 and 3 and) AND IMMERSIVE RESEARCH

While this study uncovered valuable insights into broad employment patterns it lacked detail on the specifics of design work in industry. To address this gap, an online questionnaire was (S1) used to survey practitioners' method use and also one to explore common design practices involving a range of senior practitioners (n = 28) with a range of skills and employment experience in 2015. The study found a shift from engineering practices toward a growing hybrid combination of agility, 'design thinking' and UCD methods. Interesting to note is the strong separation with development and the trend for more "designerly" methods such as workshop facilitation. Diminishing influence of engineering methods and software development practices is also noteworthy, with the requirements focus of the competency workshop five years earlier reducing. The growth in agile (scrum) goes some way to explain this as these would have replaced many of the more traditional waterfall activities such as requirement management. This might also explain the relative decline in blueprinting. Research was also strong, and the number of methods used expanded from the previous studies. Together these findings suggest practitioners were using an ever-diversifying set of methods, with a continued focus on design outcomes and also structurally managing collaboration with other disciplines and stakeholders. These broad trends can be traced in Table 1 and 2 that summarise the key data taken from the various studies that is also elaborated in the section below:

Table 1

Responsibilities	*(S1) %*	*(S2) %*	*(IR) %*	*(WS2) %*
Analytics	2	4	5	5
Research	6	9	12	39
Requirements	16	12	9	5
Development	24	16	12	11
Management	26	7	8	4
Design	26	52	32	36
Project Management	0	0	6	0
Facilitation	0	0	16	0
Total	100%	100%	100%	100%

Table 2

Deliverables	*(S1) %*	*(S3) %*
Persona/Scenarios	4	0
Reports	14	13
Prototype Development	12	9
Conceptual Models	12	8
Design Thinking	14	15
Blueprints	18	8
Wireframes	26	23
Scrum	0	18
Co-design	0	6
	100%	100%

IMMERSIVE RESEARCH (S3)

A full immersive 'account of practice' was undertaken as a case study to validate the survey and workshop findings. This was also grounded in a full literature review of six other practice-based studies (Knight, 2017). This work found a lack of similar research on the confluence of design and development. Combining practice-based data with insights from the literature review led to creating a set of practice-based constructs within an overarching descriptive theory. Together this describes digital design activity as a collaborative, goal directed activity; (Mission) that creates knowledge, capability and value (Agency) for clients' and users' needs (Vision) at pace (Velocity).

In agile, design activity often starts in a 'Discovery' phase or 'sprint 0' which delivers 'Little Design Up Front' and where designers originate enough assets to start development. Working in teams, variously known as 'pods', 'trios' 'cells' or the 'three amigos' designers are usually paired with a developer and product owner. Pods work in situ (or are 'co-located' to maximise communication), often using 'The Wall' to 'crit' work and run 'Show and Tells'. Designers' multifaceted role can be challenging; as they need to 'feed' developers' assets, maintain vision, and conduct research. Often, their contribution is limited to low-value 'production' activities. A lack of user research, marginalization of designers and dearth of design thinking is also a common challenge.

ACCOUNT OF PRACTICE (Case study)

While these general observations are applicable to many agile design practice, this study provides a valuable in-house perspective on it. This is especially important given the strong adoption of digital design outside of the traditional bounds of agencies and consulting practices. Exploring the experiences of a small team working in a largely agile software development context is also important given this is a common situation and structure in which designers work. Practice-based research was carried out in order to explore and understand the impact of agile on design. Immersive fieldwork (S3) was conducted over a one-year period in a digital design team within a large private company. The researcher was a fully participating member of this team during the period of immersion. Research activities included semi-structured observation, recording via coded notes, informal interviews, workshops and collecting relevant artefacts.

The team was involved running one of the most visited websites and apps in the UK. The team was responsible for research, design and delivery of these public facing touchpoints as well as some internal tools and systems including an intranet. The team was also supported by a number of third-party organisations. These included a human-centred design agency, an accessibility consultancy and a number of contractors. This external support helped on a number of larger projects, including contributing to the conceptual development of a new app. For research, a university usability lab was hired on occasions, as well as an online user testing platform. The team fluctuated in size during this time, ranging from its smallest incarnation of four designers to its largest size with the team augmented by an interaction designer, user researcher and consultant. The team worked on a variety of work, spanning operations, tactical projects and strategic programmes. In all cases, they worked in a larger multidisciplinary group of developers and business stakeholders within an agile framework. The tight integration with development and a strong project management culture strongly influenced how the team operated, the methods used, and the work delivered. Their relatively small number required building advocacy, continuously showcasing the work they produced and, most importantly, being willing and able to tackle anything that the business required with a minimum of resources and often with little previous experience to draw on.

The various data outputs from the immersive research was explored and validated in a summative workshop. This revisited key activities and events during the research period and explored themes (e.g. collaboration), specific topics and issues (gaining stakeholder buy-in) with the design team itself. Different projects were analysed in detail, and the group categorised these into project types. This helped to produce a high-level practice framework consisting of Strategic, Tactical and Operational design work. The first project type related to scrum being applied to large scale strategic projects, usually with sprint-based development following a period of 'up-front design', roadmap and strategy definition. In the case, this (Strategic Scrum) variant was applied to developing a complete and new mobile application. In this context the focus of design work was in defining and visualising a near-future oriented and innovative solution. Considering how project outcomes might fit within existing customer experiences was deemed less important than creating a futuristic vision for the company.

At the same time, the outcomes needed to be viable within a given technology stack and commercially sensitive timescale and also to the level of detail where accurate estimates for development and follow-on interaction design work could continue from. Practically, this involved design research including co-design sessions, experience blueprinting, the development of concepts, navigation models, screen templates and some prototyping with high-fidelity visuals. The mix of functional design work with brand was an important consideration as the project was dependent on senior management buy-in and financing of future work. This also meant that this work was relatively separate from development. While agile methods were applied in a design context, the result was not 'working software' but abstractions of the future built experience. The disconnection between design and development was less problematic here, however, as the focus was to scope out future work and develop a business case from estimated costs and customer feedback.

The second category related to more tactical work that involved redesigning component parts of an end-to-end journey. In the research, this kind of agile project (Tactical Scrum) was most often applied to single product lines on the company's website. Instead of the broad and strategic focus of the mobile app work, this activity was more focused on short-term gain and alignment to the existing experience, in some ways because it was delivered on a single technology platform. Taking one journey, this involved identifying 'pain-points' in the experience and then purposefully removing barriers to the user's flow from a 'landing page' through to task completion. Improvements were a combination of better designed pages and flows, but also through improved technical solutions as well as new product features. This distributed decision-making among different teams meant that design (and technical) solutions had to be regularly reviewed with other teams. The result was a less than perfect solution, but one that could be readily implemented, and which had broad support across the organisation because of the many stakeholders (not just the design team) directly involved in the work. This way of solutioning is widespread in agile projects and frames design as one of many strands within a collaborative activity. At some junctures, this necessitates design activities, thinking and solutions taking a lead and at other points allowing and, in some cases, facilitating other disciplines to do the same. Commonly applied techniques in this type of project typically align to 'Design Thinking' methods where there is a need to diverge, converge and reach consensus. Of all the different contexts for design, this is in some ways the most challenging as successful outcomes rely as much on social skills, communication and persuasion than traditional design competencies. At the same time, practitioners are also part of the delivery team and so cannot just help team's reach consensus, but need to be cognisant of how collaborative interactions impact their own deliverables.

The last type of agile project is perhaps the most commonly applied variant. This aligns to the common practice of 'small change' or 'Business as Usual', where a shared backlog combines purely technical, operational and design-led improvements together. In the case, this kind of agility was used to make small, incremental changes to easily adapted assets such as content and wording. Even then, modifications often involved substantial resources, but provided imperceptible improvements. Where this operational design activity (AKA Design Ops) provided value was when it was coupled to a broader and more strategic programme of change. In the case, this was exemplified by a workstream dedicated to solving common issues that the organisations call centre dealt with. Connecting small change to such measurable issues, not only provided evidence to prioritise tasks, but also helped create a focus on customer needs throughout the company.

This 'low-level' design activity is perhaps the most unfamiliar to the broader design community. Not only is the focus on micro-level aspects of the product or service, but the nature of the work means that design is a fractional part of the work. In some cases, (e.g. adding a register mark to a logo) it is hard to categorise as design, but in most cases is almost always carried out by people or teams who align to that practice. Agile is often considered as merely a development methodology that focuses on delivering at pace. In reality, this study not only shows a diversity in context for scrum-based working but also highlights how these different ways of working frame design activity. Traditional design is most closely associated to the first case, where the outcome is an abstract vision of the future. The second, sets design as a facilitator and the third as micro-level tweaking. The range of design activity is at odds with the design orthodoxy where it is primarily future oriented and focused on abstraction rather than tangible change. While these conclusions need further validation, the study provides an example of an account of practice too. Such research is needed to extend our understanding of the design economy at the level of practice.

PRACTITIONER WORKSHOP (W2)

While the case and supporting studies and literature review, provided deep insights into the fabric of contemporary design practice, especially in the context of agile development, it lacked validation to a wider

sample. The results of this activity were validated during a final workshop (WS2). This was run with participants with a broad range of experience who attended a professional networking event in November 2018 and mapped the different types of projects that practitioners are involved in. The findings reinforced both the case and other studies in that design is tightly integrated into software development and delivery of digital products and services. Furthermore, in line with the general trend of the research, practitioners' evidence greater diversity in method use, a strong tendency toward hybrid roles and ever widening employment, especially in the public sector. Other common contemporary patterns of practice include the need for small teams and individuals to be able to turn their hand to any business need (Team of one) and to be able to navigate and thrive in a diversity of organisational contexts, including where stakeholder knowledge of design is low.

Conclusion

This paper has attempted to bridge an important gap in design research and history. This account charts the important role that HCI has had on the growth of digital design between the 1980s and present day. Its influence extends beyond an instrumental focus on accounting for people in developing technology to one that promotes human values that are then practically operationalised through a set of robust tools and methods. These handed-down and evolved practices have shaped how designers work today. This paper has addressed the lack of 'accounts of practice' that show how designers work with these tools at the intersection between technology and people too. In describing the day-to-day work of today's designers, the research shows how agile and hybrid are challenging traditional disciplinary boundaries. Future research will validate and extend these findings out into the broader context of the design economy and inward to more deeply explore and map the field of practice.

Research Perspectives IN THE ERA OF Transformations

Using Corpus Linguistics to Analyse how Design Research Frames 'Design Thinking'

GHASSAN Aysar

Coventry University, United Kingdom
corresponding author e-mail: aysar.ghassan@coventry.ac.uk
doi: 10.33114/adim.2019.09.302

Academic research communities create knowledge which helps them to claim authority over their investigative domain. The knowledge is not necessary objectively true—often it is skewed to help communities to claim legitimacy. This paper investigates how the design research community frames 'Design Thinking', a key concept in design research. Existing literature identifies skewed methods which the community uses when framing Design Thinking. The literature suggests that creating an artificial separation between the ways that designers and scientists think helps the community to claim knowledge on Design Thinking. To further investigate how the community creates knowledge, this paper subjects abstracts from peer-reviewed journal papers which focus on Design Thinking to empirical analysis using Corpus Linguistics methods. The study suggests that use of 'nominals' and the creation of 'meta-knowledge' helps researchers to claim authority on Design Thinking. These practices appear however to perpetuate an artificial separation between Design Thinking and other design domains.

Keywords: Design Thinking, Corpus Linguistics, Discourse, Discourse Communities, Ways of Speaking

Introduction

The linguist John Flowerdew (2013) argues that knowledge claimed by given groups or institutions is never objectively true. Rather it is produced in a subjective manner. The knowledge is always skewed to suit the aims and objectives of the group (Swales, 1990; Rabinow, 1991). The term *discourse* is used to describe the skewed knowledge disseminated by a given social group (Flowerdew, 2013). The term *discourse community* denotes the collection of individuals making up such a group (Flowerdew, 2013; Swales, 1990). A discourse community creates discourse with the aim of occupying a particular intellectual territory termed a *domain* (Rabinow 1991). Members of discourse communities use written or spoken language to disseminate discourse (Flowerdew, 2013). Theorists use the term *ways of speaking* to characterise the language used by discourse communities when they are creating their discourse (Finken, 2003).

A discourse community is only sustainable if it can maintain its perception of truth and its hold over the production of knowledge (Rabinow, 1991). To do this, it must reject knowledge which threatens to undermine its position. In practice this means rejecting knowledge produced by other discourse communities which may compete for ownership of a given domain (Finken, 2003; Foucault, 1980). If successful, the process of knowledge creation undertaken by a given discourse community undermines the validity of knowledge

created by other discourse communities (Foucault, 1971). The process of knowledge formation enables a community to claim legitimacy and wield power (Rabinow 1991; Foucault, 1971). The importance of ways of speaking is such that theorists tend to define discourse communities by the ways in which they speak on issues which are key to the community (Flowerdew 2013). Researchers may, for example refer to, the *discourse of managerialism*, the *discourse of advertising* or *Christian discourse* (Flowerdew, 2013). It does not necessarily follow that members of a discourse community disseminate ways of speaking with the intent of being intentionally deceitful. Members tend to be immersed in the community's discourse and may not recognise that their claims may not be objectively true (Rabinow, 1991).

Academic Discourse Communities

The concept of discourse communities applies in academic fields. The sociologists Becher and Trowler (2001) have investigated the way in which academic disciplines construct discipline-specific discourse. Becher and Trowler (2001) argue that academic disciplines function as—in their terms—*tribes*[1]. In the main, tribe-members cement their identity through their ways of speaking: "the professional language of a disciplinary group plays a key role in establishing its cultural identity" (Becher and Trowler, 2001, p.46). This is not to say that academic disciplines are entirely homogeneous. The way that principles within a discipline are taught can differ from institution to institution (Becher and Trowler, 2001). There are also regional differences within academic tribes. Academics in certain nations may focus on creating knowledge on certain aspects of a discipline over others. Indeed, Becher and Trowler (2001, p.44, original emphasis) argue that "national stereotypes of a conventional (and relatively crude) kind" can influence some perceived differences in ways of working. However, despite regional differences, "strong resemblances persist between different branches of the same [academic discipline]" (Becher and Trowler, 2001, p.44). In this respect, disciplines have specific ways of speaking on knowledge associated with their domain. Historians tend to use the term "masterly" to commend a piece of research, whereas sociologists often term good research "thought-provoking" (Becher and Trowler, 2001, p.46). Ways of speaking allow members of academic discourse communities to cement the knowledge claimed by the tribe and to differentiate their field from other domains. Analysis conducted by Thompson and Hunston (2003) illustrate this process in action. Thompson and Hunston reflect on how a researcher in the field of *applied* linguistics cements the value of research conducted in his tribe whilst differentiating it from the field of *theoretical* linguistics. The researcher of the applied linguist (John Swales) is published in a journal which specialises in disseminating research on applied linguistics. In differentiating between his area and that of theoretical linguistics, Swales infers that "Both types of research are valid but applied [linguistics] research is more significant" (Thompson and Hunston, 2003, p7). This helps the applied linguist underscore the legitimacy and importance of his field whilst differentiating it from theoretical linguistics. His ways of speaking also invoke a sense of camaraderie with other members of the community, "precisely [because members of the applied linguistic community] write and read papers like this" (Thompson and Hunston, 2003, p7). Thompson and Hunston's (2003) research illustrates how members of academic discourse communities create skewed ways of speaking which reflect the aims of the tribe.

This paper examines ways of speaking the design research discourse community use when claiming knowledge on Design Thinking. To begin with, the author identifies existing literature which suggests the presence of skewed ways of speaking. The paper then uses a method termed *corpus linguistics* to uncover skewed ways of speaking in a data set of design research papers.

Existing Signs of Skewed Ways of Speaking in Design Thinking Research

The design research community commonly uses the term Design Thinking to describe the cognitive process used by designers when they are engaged in solving design problems. Design researchers often claim that Design Thinking differs from problem-solving processes used by natural scientists (Cross, 2004, 2011; Dorst, 2011, 2010). The work of Nigel Cross (2004; 2011) illustrates the position commonly taken in the design research community. Cross (2004) claims that scientists attempt to identify a problem fully and then work to solve it. Indeed, the focus on identifying a problem leads Cross to term scientific thinking a *problem-focussed* process. Cross argues that once scientists have identified the problem, they engage in trying to solve it. For

[1] Indeed, the title of Becher and Trowler's (2001) book is *Academic Tribes and Territories*

Cross (2004, 2011) the movement from identifying a problem to attempting to solve it implies that scientific problem-solving is *linear* in nature.

A host of design researchers claim that the linear, problem-focussed way of thinking used by scientists limits both exploration of problems and idea generation and can therefore produce unsatisfactory solutions (e.g. Cross, 2004. 2011; Dorst, 2011, 2010; Oxman, 2002; Stempfle and Badke-Schaub, 2002). Design Thinking researchers argue that designers do not attempt to identify a problem prior to beginning to solve it. Instead, designers work to understand a problem as they attempt to solve it (Cross, 2004). Therefore, rather than focusing on a problem, designers focus on finding the solution. This trait leads Cross (2004) to term Design Thinking a *solution-focussed* process. Dorst (2010, 2011) claims that designers work to identify the problem through undertaking a series of cyclic steps in which they iteratively return to the problem in order understand different elements of it. The presence of cyclic steps indicates that Design Thinking is *non-linear* in nature. Dorst claims that this non-linear, solution-focussed way of thinking enables design solutions to evolve progressively, allowing opportunity for reflective practice:

> *"[Designers] know that bringing the full force of evaluation to bear upon a fledgling idea is a very effective way of killing it, blocking any further exploration and stifling any progress in the project". (Dorst, 2010, p.133)*

The discussion within the design research community on *problem-focussed* and *solution-focussed* problem-solvers and *linear* and *non-linear* methods suggests that design research commonly constructs a dichotomy between scientific thinking and Design Thinking. Maciver et al. (2016) illustrate this dichotomy in the form of a table (Figure 1). In expanding on the dichotomy, Maciver et al. (2016) suggest that designers focus on using the *left* hemisphere of the brain whilst scientists predominantly use the *right* side; scientists employ *logic* to solve problems, whilst designers use their *intuition*.

Sciences	***Arts***
Mathematics, physics, engineering	Creativity, language
Logic	Intuition, subjectivity
Left brain	Right brain
Linear, sequential	Holistic, chaotic, divergent
Reductionist enquiry	Naturalistic enquiry
Facts, figures, formulae	Interpretive forms, subjective expression
One correct answer	Many solutions
Technologists - computer scientists, software engineers, information science experts, coders...	***Designers*** - product designers, interface designers, design researchers, graphic designers...

Figure 1: The Dichotomy between Scientific Thinking and Design Thinking. Taken from Maciver et al. (2016, p.3)

A small body of research questions the validity of the dichotomy between Design Thinking and scientific thinking. Research on *wicked problems* provides an example of this critique. The idea of wicked problems was famously developed by Rittel and Webber (1973). Rittel and Webber describe problems as being wicked when they involve many stakeholders. Rittel and Webber claim that the presence of many stakeholders makes problems very difficult to solve using scientific ways of thinking. Originally, Rittel and Webber applied the concept of wicked problems to town planning issue. More latterly, design researchers have tended to argue that a range of design problems can be thought of as being wicked (Downton, 1993; Cross, 2011). Design researchers often claim that designers' ability to use Design Thinking enables them to tackle wicked problems (Buchanan, 1992). Farrell and Hooker (2013) challenge the idea that designers can tackle wicked problems more effectively than scientists. Indeed, Farrell and Hooker argue that scientists commonly tackle wicked problems. They claim that negotiation between stakeholders was key in allowing natural scientists to diagnose the illness termed *chronic fatigue syndrome*:

> *It was [...] initially unclear whether chronic fatigue syndrome was caused by a bacterium or virus, a fungus or mould, in each case perhaps deeply embedded in tissue, or was due to a psycho-somatic condition, with any of these options difficult and resource demanding to pursue. Then, just as with design, the issue becomes which few of these possibilities is currently most worth pursuing and in which specific forms. Various options will be developed in more detail, their resource demands and risks analysed and their merits spelled out for consideration. During that process more specific versions of the initial general problem will be developed, some of them (e.g. the psycho-somatic option) perhaps requiring a significant reformulation of both what the problem is and what criteria a solution would need to meet. A critical debate will develop about these options, the upshot being that one or two of them will be selected to pursue, perhaps by individual laboratories, perhaps as cooperative ventures. (Farrell and Hooker, 2013, pp. 688-689)*

Farrell and Hooker (2013, p.701) suggest there exists an intrinsic relationship between the way designers and scientists think, for both are the "product of a common core cognitive process". In critiquing the dichotomy between Design Thinking and scientific thinking which is such a prominent feature of design research, Farrell and Hooker (2013, p.683) argue that influential work on Design Thinking is "fundamentally flawed".

New and Kimbell (2013) contribute a further criticism of the dichotomy which design researchers construct between between Design Thinking and scientific ways of thinking. New and Kimbell (2013) reject the oft-stated argument that Design Thinking is unlike scientific thinking. In evidencing their position, New and Kimbell argue that, commonly, Design Thinking research does not present a true representation of scientific approaches to problem-solving. Rather, design research commonly presents a skewed interpretation. New and Kimbell claim that in Design Thinking research, the ways that designers think is mistakenly "repeatedly characterized in opposition to a caricature of rationalist, analytical 'orthodox' approaches" (New and Kimbell, 2013, p.139; original emphases). To illustrate their argument, New and Kimbell (2013) criticise the position taken in design research on the issue of *empathy*. New and Kimbell illustrate how design research commonly frames the way in which designers generate empathy. New and Kimbell use the example of a hypothetical study in which designers try to create empathy with wheelchair users:

> *…design practice would perhaps involve the designer themselves using a wheelchair, or collecting data on the overall travel experience, and look [sic] for interactions with the wider process. (New and Kimbell, 2013, p.144; original emphases)*

New and Kimbell argue that this form of empathy is not unique to designers. Rather they suggest it has parallels with the form of empathy developed through a scientific, analytical approach to problem solving:

> *This type of empathy, however, might still only be 'cognitive'. For 'affective' empathy to be involved the process of seeing through others' eyes requires a deeper engagement: this requires sharing the emotional response of the other. In the wheelchair example, it would require the designer to share, perhaps, the level of anxiety that a user might experience in the situation, or anger […] It is not that one can rationally appreciate the fact of another's emotions, but that one has the emotions oneself. (New and Kimbell, 2013, p.145; original emphases)*

New and Kimbell (2013) therefore argue that when it comes to generating empathy, the way designers think is similar to the way scientists think.

Both New and Kimbell (2013) and Farrell and Hooker (2013) provide some insight into skewed ways of speaking in the Design Thinking research community. However, neither New and Kimbell's (2013) nor Farrell and Hooker's (2013) research makes use of empirical, analytical methods which are specifically designed to investigate ways of speaking in texts. This limits the potential value of their insights. This paper contributes to filling this gap in knowledge by subjecting a data set of abstracts from peer-reviewed journal papers which focus on Design Thinking to critical analysis with *Corpus Linguistics* methods. Corpus linguistics tools are specifically designed to investigate ways of speaking in texts and are commonly used in the social sciences to facilitate critical analysis of claims made by a range of discourse communities (e.g. Baker, 2006; Mautner, 2009; Hoey and O'Donnell, 2008). So far, the use of corpus linguistics in design research has been limited to only 2 small studies (Blythe, 2014; AUTHOR, 2016). Therefore, in addition to unpicking ways of speaking on Design Thinking, this paper further embeds the use of corpus linguistics in design research.

An Introduction to Corpus Linguistics

The field of corpus linguistics is a branch of linguistics. Corpus linguists analyse data sets consisting of spoken or written language. Corpus linguists argue that people "express[] an ideological position" (Stubbs, 1996, p.107) when choosing words or terms to use. Researchers therefore look for patterns in word use in the data set. Evidence of patterns can create cohesive insights into ways of speaking on the research domain (Hoey and O'Donnell, 2008).

Corpus Linguistics research began in the late 1960s. The British linguist John Sinclair (1933 – 2007) is credited as being a pioneer in this field (Hoey and O'Donnell, 2008). Sinclair's work came in reaction to an idea which was dominant during the era in which he worked, namely that investigation into patterns of word use could not provide insight into ways of speaking. Instead, in the 1960s, it was commonly thought that cognitive development dictated which words a person chooses to use (Carter, 2004). To illustrate, Chomsky (1969) argued that people prefer to use words which are easier to remember than those which are more difficult to recall. This, thought researchers in the 1960s, is why people tend to favour using shorter words over longer words. It was therefore commonly assumed that analysis of spoken or written language can only create knowledge on the physiological structure of the human brain (Carter, 2004). In the latter half of the 1960s, this dominant school of thought was challenged by Sinclair and a handful of other academics (Hoey and O'Donnell, 2008). Sinclair argued that humans choose to use words which reflect their affiliation with discourse communities (Sinclair interview cited in Teubert, 2004). Sinclair's research into ways of speaking overturned the prominent view and as a result there are centres for corpus linguistics in universities worldwide.

Corpus linguistics research often provides insights into how discourse communities exercise their power and the ramifications of these ways of speaking. Rule and Levine (2011) analyse ways of speaking in the world of high-end modern art. To do this, they research a corpus consisting of artists' statements. Artists' statements consist of texts which often accompany artwork displayed in galleries. Written by artists or their representatives, these statements summarise the artist's influences and the aims and objectives of the artwork. Analysis reveals that high-profile modern artists tend to be concerned with what they believe to be important human and environmental issues. The artists do not aim to solve these issues, instead, they aim to raise awareness of them. Artists use terms such as "interrogate", "problematize" and "blur boundaries" in the context of raising awareness (Rule and Levine, 2011, unpaged). Rule and Levine argue that use of these terms helps artists to consistently frame the political ruling classes as failing to confront pressing human and environmental issues. In this way, artists' statements tend to "convey[] the sense of political tragedy" (Rule and Levine, 2011, unpaged). Interestingly, artists' statements often contain noun-forms of words. To illustrate:

> *visual becomes visuality, global becomes globality, potential becomes potentiality, experience becomes experiencability. (Rule and Levine, 2011, unpaged)*

Rule and Levine (2011, unpaged) argue the use of these noun-forms mimics a form of "highbrow written French" used by French poststructuralist philosophers such as Jacques Derrida. According to Rule and Levine, their use represents attempts to elevate elite fine art gallery practice and to imbue it with a sense of intellectual authority and legitimacy. These ways of speaking enable modern artists to discuss global political issues with an assumed air of authority (Rule and Levine, 2011).

Concordancers

Corpus linguistics analysis is facilitated by specialised software termed *concordancers*. Examples include *AntConc* (Gries, 2009), *WordSmith* (Scott, 2014) and *Sketch Engine* (Brezina and Gablasova, 2015). Texts which are to be analysed are uploaded into the concordancer. Concordancers can only process text which has been converted to a Unicode format termed UTF-8 (McEnery and Xiao, 2005). UTF-8 files contain a homogenised form of text: UTF-8 supports only one font, one text size and a single font colour. In addition, it cannot support images—converting data to UTF-8 causes loss of images. Conversion also deactivates any embedded web-links. The resulting file is termed the *research corpus*. The format of the research corpus can make it more difficult for a researcher to identify the origins of text. This may help researchers to analyse texts in a more neutral manner, contributing to less biased analyses (Baker 2012).

Corpus Linguistics Tools

The field of Corpus Linguistics contains a large toolkit of quantitative and qualitative methods which facilitate critical analysis. (See, e.g. McEnry and Wilson (2001) for an excellent overview of the range of available tools.) Because of limited space, this paper only discusses tools which are used in the forthcoming empirical study. The tools are *Keyword Analysis* and *Concordance Analysis*. Both are used extensively—and in combination—in Corpus Linguistics research (McEnry and Wilson, 2001).

- Keyword Analysis

When creating discourse, communities tend to focus on using terms which are important in allowing them to construct skewed knowledge. The terms vary from discourse community to discourse community. (In the aforementioned example of modern art discourse, terms like *visuality*, *globality*, and *potentiality* help artists create their discourse). Such terms are therefore *key* in helping the community to form its discourse. The process termed *keyword analysis* aims to identify these terms.

To measure keyness, it is necessary to compare the frequency of appearance of terms in the research corpus with their occurrence in another corpus. This 'other' corpus acts as a 'norm' by which to judge word frequency in the research corpus. The norm is termed the *reference corpus* (Baker, 2004). Concordancers contain examples of reference corpora which facilitate the comparative analysis. One example is the *British National Corpus* (University of Oxford, 2010), a reference corpus containing 100 million words taken from a broad range of sources. Keyword analysis involves statistical measurement. Sketch Engine uses the following formula[2] (Figure 2) to calculate the keyness of a term in the research corpus:

$$\frac{fpm_{focus} + n}{fpm_{ref} + n}$$

Figure 2: The Formula used by the concordancer Sketch Engine to calculate keyness.
Taken from Lexical Computing, (2005, unpaged).

Concordancers represent the keyness of words as a numerical figure in keyword lists in descending order of keyness. Figure 3 provides an example of a keyword list. The list shows keywords associated with an article on the subject of 'software' found on Wikipedia. The reference corpus is a large corpus of standard English. The term *microsoft* is a highly-ranked keyword, indicating that the company 'Microsoft' is strongly associated with the domain of software.

[2] The author is not a statistician. Because of this, the author asked a statistician to re-write the formula in a way that a non-statistician could better understand. The formula can be written more clearly, as follows:

$$\frac{(\text{Frequency of word in research corpus, if it were comprised of 1 million words}) + 1}{(\text{Frequency of word in reference corpus, if it were comprised of 1 million words}) + 1}$$

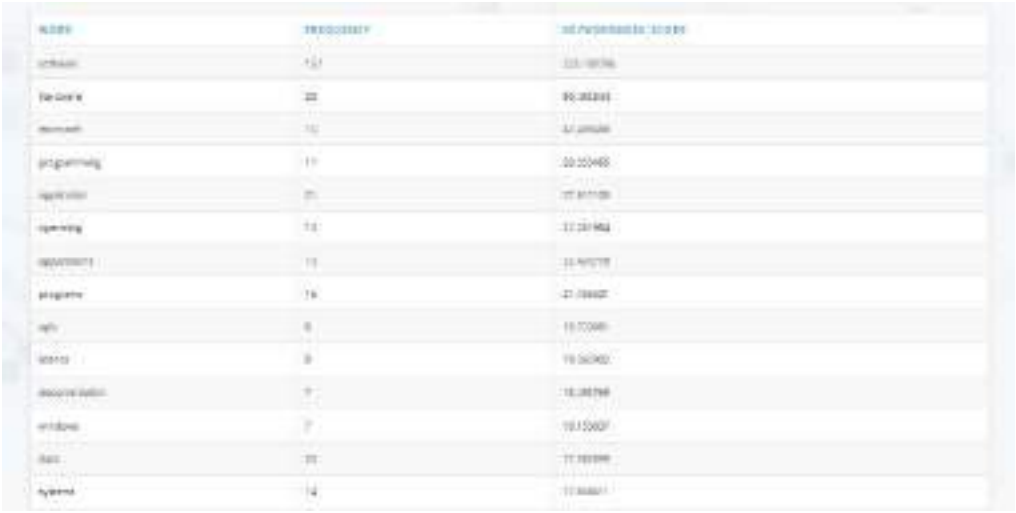

Figure 3: Example of a Keyword List, taken from Sketch Engine (n.d., unpaged)

When evaluating keyness scores, it is necessary to choose a tolerance to work to. The tolerance represents the likelihood that a particular word is actually key to the data set. Words with keyness scores above the level of tolerance are considered to be keywords (Baker, 2004). Often researchers work to a 95% likelihood of keyness (Gries, 2009). In statistical annotation, level of likelihood is described with a p-value (where 'p' stands for probability (Lancaster University, n.d.)). 95% likelihood is written as $p < 0.05$. $P < 0.05$ is associated with a minimum keyword score of 3.84 (Lancaster University, n.d.). Therefore, commonly, researchers will disregard keywords with a keyness score below 3.84.

Though keyword analysis helps researchers to identify terms which are important in enabling communities to create discourse, this tool does not provide insight into the context in which these terms are used. *Concordance analysis* provides contextual insights.

- Concordance Analysis

Qualitative analysis into the terms which accompany keywords in a given data set provides contextual insight into how keywords help to form discourse. In corpus linguistics terminology, qualitative investigation is termed *concordance analysis*. Concordance software facilitate concordance analysis by showing how keywords reside within sentences. Figure 4 illustrates an example from Hunston (2007). Figure 4 provides contextual insight into how the term *persistent* is used in a research corpus.

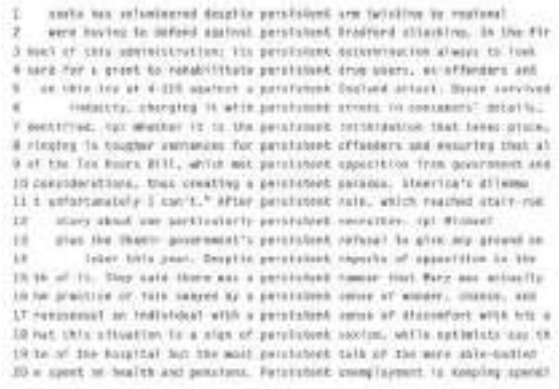

Figure 4: An example of concordances, adapted from Hunston (2007, p.254-255).

In addition to providing insight into how keywords reside in sentences (as in Figure 4), concordancers allow researchers to view more expanded sections of text which contain keywords. This facilitates more in-depth qualitative analysis. The combination of quantitative and qualitative analysis associated with corpus linguistics provides a logical approach to analysing ways of speaking in discourse communities (Baker, 2004).

The Data Set and Method

Conceivably, as the concept of Design Thinking has been important in design research for over 2 decades, it would be possible to analyse ways of speaking found in virtually any design paper, book or book chapter from the last few years. There is however comparatively little value in analysing texts which may mention 'Design Thinking' in passing. This practice would produce a diluted study with very limited insights. To increase the likelihood of creating valuable insights, it is more valuable to analyse a more homogenous sample which focusses on the research domain (Guest et al., 2006). In this study, this meant analysing papers which *focus* on Design Thinking. To do this, this study analysed papers which include the term 'Design Thinking' in the title of the paper. This strategy was used as researchers tend to rely on article title as the "main source of information" for judging article relevance (Jamali and Nikzad, 2011, p.653). Technology also supports searches conducted by article title. When using an online search engine to hunt for articles it is necessary to input terms which are relevant to the research domain. Search engines tend to prioritise searching for articles which contain these terms in the article title (Nagano, 2015; Beel et al, 2009). Users are more likely to access these results than results further down the results list (Nagano, 2015). These results are therefore more likely to contribute to the discourse of an academic community than articles which are found further down the list.

The widespread interest in Design Thinking means that articles which focus on this process are found in areas as diverse as *children's spirituality* (see, Tan and Wong, 2012), *medicine* (see, Patel et al, 2014) and *food science* (see, Olsen, 2015). Analysing papers which are published in a range of fields would however not provide insight into ways of speaking produced by the design research discourse community. One distinguishing feature of academic discourse communities is the specific avenues where members publish their work (Thompson and Hunston, 2003). This study analyses papers published in journals which include the term *design* in their remit. Design is characteristically a multidisciplinary area of research. Reflecting this, many design journals have multidisciplinary remits. This study analyses papers published in journals whose remits include *design, design and art* or *design and architecture.* The study does not include papers published in journals whose remit combines *design* with *engineering*. This decision results from the aforementioned idea that design researchers attempt to create a distinction between Design Thinking and scientific thinking. The author reasoned that including articles published in design engineering journals may reduce the likelihood of gaining focused insight into the design research discourse. The decision to exclude papers published in design engineering journals underscores the difficulty associated with creating a data set whose purpose is to uncover ways of speaking in a multidisciplinary discipline like design research.

The study does not include papers published in design conferences. Design researchers often publish in conferences with a view to extending the contribution to a journal article. Analysing journal papers may provide more of a definitive insight into ways of speaking than the process of investigating conference papers. In addition, the study only analyses papers which are published in peer-reviewed journals. The process of peer-review provides a definitive quality-check of research in an academic discourse community (Cope and Kalantzis, 2009). Because of this, analysis of peer-reviewed papers provides a more valuable insight into ways of speaking on Design Thinking than does investigation of non-peer-reviewed texts.

o optimise the search for data, the study makes use of 2 search engines: 'Google Scholar' and 'Locate'. The latter is available only at the author's workplace. Use of 2 search engines helped the author to find articles that either one of the search engines may have missed. The search for peer-reviewed journal articles was undertaken between 30th June and 7th July 2016. It identified 45 suitable papers.

Analysis of Abstracts

This study analyses only the abstracts of the papers in the data set. The purpose of the abstract in academic articles is to "reflect fully and accurately the work reported" in the paper (Pitkin et al., 1999, p.1110). Academic discourse is condensed in abstracts, because of this they can provide a rich source of data for researchers aiming to analysing ways of speaking (Thompson and Hunston, 2003). Indeed, analysis of abstracts have been used to investigate discourse in academic fields (e.g. Hyland and Tse, 2005; Blythe, 2014; Nagano, 2014; Ghassan, 2016).

Method

38 of the 45 papers contained abstracts. The individual abstracts were saved as UTF-8 files and uploaded into the concordancer *Sketch Engine*. Henceforth, the resulting data set is termed the *Design Thinking Data Set*. This corpus contains 5800 words. Keyword analysis and subsequent concordance analysis of keywords was conducted on the Design Thinking Data Set. The keyword analysis made use of a sub-corpus of the aforementioned British National Corpus as the reference corpus. The sub-corpus (termed *'Written Academic'*) contains a range of texts found in the "the 'Short Loan' collections of seven University libraries" (Burnard, 2007, unpaged; original emphasis). Short loan collections consist of academic texts which are core in their respective fields (Burnard, 2007). They therefore contain ways of speaking which are core to specific academic tribes. Specifically, the Written Academic sub-corpus consists of text from the following areas: humanities; medicine; natural sciences; politics; law; education; social and behavioural sciences; technology; computing; engineering. The corpus does not include text from art or design-based subjects. Therefore, using the Written Academic sub-corpus the reference corpus provides a good opportunity to uncover keywords used by the design research discourse community. The keywords analysis uses a tolerance of $p < 0.05$.

Results and Discussion

Figure 5 shows terms with a keyword score which is associated with a 95th percentile certainty of significance. To display the list effectively it is divided it into 2 columns.

Figure 5: Keywords for the Design Thinking Data Set

The keyword analysis uncovered 89 keywords, however space limitations prevent discussion on all these. The following discussion focusses on themes which relate to the aims of this paper. These themes are 'Creating meta-knowledge' and 'Speaking on Design'.

Creating Metaknowledge

The keywords ***reasoning***, ***framework***, ***criteria***, ***process***, ***processes*** and ***practices*** are used by researchers when putting forward broadly applicable descriptions of Design Thinking or Design Thinking steps. To illustrate, one researcher *"recognize[s] multifaceted **criteria** in the design process"*; another views *"design thinking as a **process** comprised of both linear and non-linear aspects"*. A further researcher notes a *"contingent set of **practices** carried out by professional designers"*. The tendency for researchers across academic disciplines to construct broadly applicable descriptions has been well documented (Kalfoglou et al, 2000). The pattern for researchers in the Design Thinking Data Set to create broadly applicable descriptions echoes this theme. When claiming broadly applicable descriptions, researchers across academic disciplines create what is termed *meta-knowledge* (Kalfoglou et al, 2000). To understand the importance of meta-knowledge in research fields, it is important to reflect on how academic discourse communities build an impression of legitimacy. Research communities attempt to describe and classify an intellectual territory which is associated with their domain (Betcher and Trowler, 2001). Creating broadly applicable descriptions of elements contained within the domain helps communities to claim more concrete ownership of the domain than do descriptions with a very limited application (Betcher and Trowler, 2001; Kalfoglou et al, 2000). In the Design Thinking Data Set, use of the keywords *reasoning*, *framework*, *criteria*, *process*, *processes* and *practices* helps researchers to make broadly applicable claims over the intellectual territory of 'Design Thinking'. Researchers in the data set are therefore creating meta-knowledge on their domain.

To recall, these keywords emerge from comparing the Design Thinking data set with a reference corpus comprised of texts from a range of academic disciplines. The presence of a host of keywords which enable researchers to claim meta-knowledge suggests that the Design Thinking research community may be particularly focussed on creating broadly applicable descriptions to engender a sense of legitimacy.

Speaking on 'Design'

The term 'design' can be used to refer to a verb (e.g. designing an object or service) or a noun (e.g. an undergraduate design course). The keyword ***design*** is used once as a verb in data set: *"graphic designers are increasingly asked to **design** innovative solutions"*. When professional designers or design students tackle a design brief, they tend to create a specific 2D or 3D artefact or service. Interestingly, in the data set, the verb-form of the term *design* does not refer to a specific object or service. Rather is refers to more abstract ideas—*"innovative solutions"*. This pattern is also seen when researchers use other forms of the verb *to design*. The highly ranked keyword *designing* (present tense) consistently refers to general and abstract ideas. Separate researchers refer to *"a model of **designing**"* and *"the different forms of thinking which can be observed in **designing**"*. Focussing on general or abstract ideas allows researchers in the data set to make broadly applicable claims when using the verb-form of the term *design*. Use of the verb-form of *design* therefore appears to help these researchers construct meta-knowledge on Design Thinking, further cementing their claims to ownership over the domain.

The process of speaking in abstract—rather than specific—terms may provide another function. It may allow researchers to separate the 'act of designing' associated with Design Thinking from the 'act of designing' associated with day-to-day design practice in professional studios and in classrooms. Put in a more distilled manner, the way of speaking on design 'as a doing word' may allow researchers to separate the domain of Design Thinking from those of design practice or design education. Framing the 'act of designing' as being associated with Design Thinking may further amplify researchers' claims to authority over their investigative domain.

Overwhelmingly, the pattern in the data set is for researchers to use the term ***design*** as a noun. Researchers use the term to signal a range of aspects as 'belonging to design'. It is possible to subdivide the issue of 'belonging to design' into 3 sub-categories: conceptual and intellectual ideas; practice-related classifications; people. Conceptual and intellectual ideas include *"the design process"*, *"design ideas"* and *"conceptions of*

design"; practice-related classifications include *"design disciplines"*, *"design professions"*, *"design tools"*; people with design-oriented affiliations include *"design teams"*, *"design experts"* and *"design professors"*. Betcher and Trowler (2001) argue that academic research communities use the strategy of sub-classification to deepen their claim to ownership over their domain. In keeping with Betcher and Trowler's (2001) theory, the use of the noun-form of the term *design* to create 3 sub-classifications may help researchers to deepen their claim to intellectual territory which they associate with the domain of Design Thinking. The process appears to allow researchers to overwhelmingly frame design as an intellectual domain (a 'thing') rather than as a practice (something that people do). This further underscores the idea that researchers may create a distinction between Design Thinking and design practice.

The overwhelming pattern for researchers to use the noun form of the term *design* echoes observations made by critical theorists who study how research communities claim authority over their domain. Billig (2008) reports a strong tendency for researchers across academia to focus on using the noun-form of words. This strategy (termed *nominalisation*) instils classifications or descriptions put forward by researchers with a sense of authority:

> *By turning verbs into nouns, speakers/writers can convey that the entities, denoted by nominalization, have a real and necessary existence (Billig, 2008, unpaged; original emphasis)*

The idea that nominalised descriptions come with a perceived sense of authority helps academics to frame an idea which is subjective as an objectively valid phenomenon: "speakers/writers turn processes into entities and typically assume the existence of such entities." (Billig, 2008, unpaged, original emphasis). This in turn affects how readers understand texts—readers can fall into the habit of assuming that nominalised descriptions are objectively correct (Billig, 2008). The term *market forces* is an example of a nominal in the field of economics. The term is used to denote fluctuations in finances without taking into account the actions of individual actors in financial systems. In this way, market forces have a life of their own, distinct from the actions of people who buy and sell commodities, products and services (Billig, 2008). Use of the term *market forces* has enabled economists to claim authoritative knowledge on financial systems without needing to defend the fact that they may not take into account the full range of transactions between people which create monetary systems. Use of the term *market forces* therefore enables economists to write this financial process into existence. Returning to the findings in the Design Thinking study, it is important to note that different design disciplines do not necessarily share "design ideas", "conceptions of design" or "design tools". To illustrate, fashion designers have different conceptions of design practice and use different design tools to automotive designers or interface designers. Furthermore, concepts like "design ideas" and "design tools" vary within a particular design discipline. Differences in design processes in the field which I teach—Automotive Design—illustrate this. Typically, in a vehicle design studio owned by a large, international manufacturer, the complete design of a vehicle is not carried out by any one particular professional. Instead, several different professionals with different specialist skills sets each work on different aspects of the overall design of a vehicle. The initial design phase is carried out by specialists who use sketching to undertake a 2D design process. Other specialists then use 3D CAD tools at a high level to create accurate 3D versions of the 2D designs. Therefore, there exists a *range* of design processes—the characterisation of each is dependent on where the specialist fits in within the overall workflow cycle and which tools he or she uses. Focussing on the noun-form of design enables researchers in the data set to frame these subjective concepts as objectively valid nominals which apply broadly across 'design' when they do not.

The results suggest that the use of nominals and the creation of meta-knowledge may enable researchers in the Design Thinking Data Set to claim authority over their investigative domain. However, the practice of claiming authority appears to require researchers to artificially separate Design Thinking and design practices when, logically, they must be intrinsically linked. The findings make it possible to speculate that use of skewed ways of speaking may help the design research discourse community to write 'Design Thinking' into existence.

Conclusion

Existing research suggests that creating a skewed separation between the way that designers think and the way that scientists think helps the design research discourse community to claim knowledge and intellectual territory on Design Thinking. This paper has used corpus linguistics tools to further investigate ways of

speaking that the design research discourse community use when claiming knowledge on Design Thinking. The findings in this paper suggest that use of nominals and the creation of meta-knowledge helps researchers to construct the domain of Design Thinking and claim authority over it. These strategies appear to have helped to create an artificial separation between Design Thinking and the domains of design practice and education. The findings raise the possibility that the community is writing 'Design Thinking' into existence.

Kimbell (2011) has argued that critical analysis of Design Thinking research is in its infancy. This is worrying given the influence of Design Thinking both within design research and in a range of wider fields. A lack of empirical enquiry using methods which are specifically designed to investigate ways of speaking may have contributed to the lack of critical analysis. This study has demonstrated the value of using one such method (corpus linguistics) in unpicking ways of speaking used in Design Thinking research. The author hopes that the findings help to enable design researchers to reflect further on how they may contribute to creating knowledge on Design Thinking in the future. The findings may also provide a valuable avenue for readers to reflect on existing Design Thinking research. The findings indicate the need for more empirical analysis of ways of speaking which are associated with Design Thinking research.

A limited amount of insight can be gleaned from analysing abstracts using corpus linguistics. Though condensed, abstracts represent only a proportion of the overall paper. In addition, corpus linguistics tools can ignore some extent contexts which do not relate to keywords and do not involve qualitative analysis of whole sets of data. The research in this paper represents part of a wider study which the author has conducted as part of their PhD. The wider study overcomes these issues.

Track 4.f Introduction: Strategic Design of Sustainable Business Models

BALDASSARRE Brian[a]; BOCKEN Nancy[ab]; CALABRETTA Giulia[a]; DIEHL Jan-Carel[a] and KESKIN Duygu[c]

[a] Delft University of Technology, The Netherlands
[b] Lund University, Sweden
[c] Eindhoven University of Technology, The Netherlands
doi: 10.33114/adim.2019.4f

Introduction

Concerns about the societal and environmental impact of how companies operate have generated increasing interest in more sustainable ways of doing business (Porter & Kramer, 2011). Research and practice from the past decade show that a Sustainable Business Model Innovation lens is suitable to embed sustainability into firms' objectives and operations (Bocken et al., 2014; Schaltegger, Lüdeke-Freund, & Hansen, 2012). Consequently, Sustainable Business Model Innovation has been emerging rapidly as a research field (Lüdeke-Freund & Dembek, 2017). Recent developments in this field build upon seminal work on Design for Sustainability from the past two decades to establish a connection with Strategic Design (Baldassarre et al., 2019; Geissdoerfer et al., 2016; Manzini, 1999; Tukker, 2004). Strategic Design is a research stream that studies how to leverage the discipline of Design in the context of Strategy and Innovation Management (Calabretta et al., 2016; Karpen, Gemser, & Calabretta, 2017). More specifically, it focuses on the application of design practices, principles and methods to the formulation and implementation of innovation strategies that benefit people and organizations alike (Calabretta et al., 2016). The connection between Sustainable Business Model Innovation and Strategic Design is mainly supported by the argument that the strategic and experimental nature of design enables the integration of stakeholders' objectives including sustainability concerns, while also providing the process dimension needed to move away from theory towards concrete practice and tangible impact (Baldassarre et al., 2017; Bocken, Schuit, & Kraaijenhagen, 2018). However, research on the role and contribution of Strategic Design to Sustainable Business Modeling is still in its infancy. Consequently, within this track of the 2019 edition of the Academy for Design Innovation Management Conference, we collected four research contributions at the intersection between Strategic Design and Sustainable Business Model Innovation. These contributions are summarized in the paragraphs below, followed by a reflection on all of them and potential directions for future research.

The first contribution from Baldassarre, Calabretta, Bocken, Diehl and Keskin reviews how the concept of Design for Sustainable Development has been evolving since its origins in the 1960s, gradually broadening its scope from the design of products to the design of product-service systems (PSS), business models and wider ecosystems. By taking a business perspective on this evolution, the review shows how designers have shifted their focus from designing products to designing solutions for business problems, thus assuming an increasingly strategic role within the organizations they operate in. This review is summarized into a visual framework, which is used as an input for a discussion with eight international academic experts on how the role of sustainable designers has evolved over time across these four nested levels of design. The findings point out that the role of Designers for Sustainable Development can be framed around five topics: strategic objective and its related perspective, language, key activities and main challenge. The strategic objective refers to the focus of designers in steering strategic decisions in organizations, the perspective they adopt in

approaching business problems and developing solutions, the language they use in communicating with different stakeholders, the key activities they engage during the design process, and the main challenges they face within this process. On a product design level, the strategic objective of design is to push organizations to think beyond the “form and function” of their products, and steer decisions towards changing their life cycle. This entails, for instance, adopting a technical language aligned with the R&D department, analyzing the life cycle of products and redesigning them accordingly. The main challenge is related to the reduction of material and energy flows associated with products. On a PSS-level, the strategic objective is to push organizations to think beyond the life cycle of products, and steer decisions towards changing tangible and intangible stakeholder exchanges such as knowledge, materials, energy and money. This entails bridging the perspectives and languages of different departments in order to analyze the stakeholders involved in the innovation process and design not only new sustainable products but also new services around them. The main challenge at this level is the implementing of sustainable product-service innovations. On a business model level, the strategic objective is to push organizations to think beyond products and services, and steer decisions towards (re)defining their purpose, how they function from an economic and operational standpoint, in order to pursue sustainability goals while making profit. This entails adopting a firm centric perspective and a strategy language in order to experiment with new business models. The main challenge is to ensure the financial viability of business models and scaling them up. On an ecosystem level, the strategic objective is to push organizations to think beyond their individual business, and partner with others in order to (re)define (un)sustainable market practices. This entails adopting a cross organizational perspective and speaking a policy language in order to analyze entire industries end ensuring cross sector alignments. The main challenge of this level is turning these initiatives and joint projects into new business entities.

The second contribution from Pinheiro and Jugend explores a knowledge gap on how to design new sustainable business models by linking Strategic Design with Circular Economy principles and a Product Portfolio Management logic. In the context of this study, the circular economy is referred to as a system aimed at minimising waste and making the most of resources through intentional design by reusing and refurbishing products, as well as through material recycling. Product portfolio management is referred to as the structured decision making process through which organizations choose to focus on and bringing to market specific projects, products and services. This study links these notions with Strategic Design and integrates them into a conceptual framework. Consequently, the framework is used as a conceptual lens to analyze the case of Brazilian company with one hundred employees operating in the wood industry. The product portfolio of the company is based on several products derived from wood and vegetable fibres, including gymnastics apparel, indoor and outdoor furniture. Some of the products within the portfolio are derived from recycled and reforestation wood. Using the lens of the framework, the study analyzes the drivers and barriers related to the Strategic Design of a Sustainable Business Models around such products with a specific focus on circular economy aspects. A first identified driver is the commitment of top management to prioritize circular products within the portfolio. A second identified driver is the dissemination of circular principles and sustainability goals across the company. A third driver relates to the compliance of the company with local legislation, which has recently started to promote the reuse of raw materials in the wood sector in order to preserve biodiversity in the country. Conversely, a main barrier for the design of a sustainable business model around circular wooden products is the lack of a wide range of technological possibilities to recycle the raw material in different ways that are functional to further diversify them and expand the product in this direction. Another barrier relates to difficulty in selecting suitable partners and suppliers across the supply chain to foster a business model that is fully Circular.

The third contribution from Ballie is a feasibility study focusing on how Strategic Design may support the development of circular / sustainable business model strategies. Specifically, the study looks at how Makerspaces might be used as educational hubs to experiment with new tools, skills, techniques and technology to develop circular design strategies for micro-manufacturing within the Scottish textile sector. The assumption is that Makerspaces might support the repurposing of textile waste within a redistributed manufacturing system (RDM). The research argues that design can play a strategic role in supporting the adoption of new mindsets, methods and models to enhance awareness and understanding of the need to design for a circular economy. The research activities comprised of field research and factory visits to engage with large Manufacturers to deeper understand systemic issues around textile waste. This was followed by hosting two Make-a-thon workshops within Makerspaces in both rural and urban environments – this provided an opportunity to connect with different stakeholders from across the supply chain and to invite them to input to make recommendations for conceptualizing Circular Fashion and Textile Archetypes. The insights drawn from this research act as a starting point for future work, reflecting on the implications of the

methods applied, concluding the circular economy is the same imperative whether people are focusing on ecology, economy or just their own business. In this research, she further demonstrates that connecting different stakeholders from across the supply chain is instrumental in supporting circular practices. However, the research unearths many contradictions in the current narrative about circularity in Makerspaces. For instance, the business focus of the CE, and the required Sustainable design strategies will require intensive resource management to implement a RDM system for local textile economies. Last but not least, the Makerspace as facilitator in this process has several advantages like a neutral place for stakeholders to meet and to prototype directly generated ideas. The other side of the coin is the business model of the Makerspaces as well as the sustainability (in the sense of long lasting) of the Makerspaces themselves: during the research, one of the two Makerspaces had to close down.

The fourth contribution from Cheung and Kuzimina focuses on the sustainability impact of service-based sustainable business models. In recent years, service-based sustainable business model innovations have been gaining increasing attention in design research. A prominent example of this research is the mobility services based on collaborative consumption. However, it is unclear how the implementation of such service-based business models, and related activities and practices, impact the sustainability and experience of the proposed service offering. In this study, Cheung and Kuzimina draw on the literature on service design, product-service system and sustainable innovation, and propose a design-driven framework to evaluate the sustainability impact of service-based business model innovations. This framework, referred to as 'sustainability evaluation service blueprint', provides visibility to the complex multi-actor service operations, creates an understanding of the existing structure of stakeholder interactions during service operation, and gathers insights into the captured and uncaptured triple bottom line values within the existing product-service lifecycle. The authors test and validate this framework through six expert interviews, and conduct a desk research to generate two case studies in the mobility sector. The results of this study reveal that sustainable value creation is a collaborative effort and require the knowledge and expertise of various interdependent actors. Moreover, the results show that public and private actors hold diverse perspectives and viewpoints on the collaboration process; as such, the development of shared guidelines for the design and development of service-based innovations is crucial for the emergence of trust and prevention of collusive dynamics. Finally, this study show that engaging stakeholders in sustainable value creation requires a simple language. Accordingly, the authors suggest to use the word 'benefits' instead of 'values' in communicating sustainability impact of service-based innovations. This paper offers a springboard for practitioners and researchers to uncover compelling insights, discuss latest service design developments, and envision future directions for integrating sustainability into service-based business model innovations.

In conclusion, the contributions summarized within this editorial provide a step forward in advancing emerging theory and practice at the intersection between Strategic Design and Sustainable Business Model Innovation. Specifically, the Sustainable Business Model lens may help Strategic Designers embed sustainability associated with newly designed products and services into wider firms' objectives and operations. First, the sustainable business model lens provides a holistic perspective on the way in which business is done, by highlighting the value proposition (what value is provided to whom?), value creation and delivery mechanisms (how is value provided?), and value capture mechanisms (how money and other forms of value are captured) associated with products and services (Bocken et al., 2014). Second, a business model perspective allows sustainable design (e.g. long-lasting design, modular design) to be more impactful and commercially viable. For example, 'Philips Light as a Service' allows longer-lasting LED lights to be sold as part of a service-contract, allows for longer term financial value from a longer lasting product, while reducing environmental impact by including maintenance, repair, and replacement services into the business model (Kramer et al., 2019). The Strategic Design lens allows business model researchers to develop and employ valuable tools and methods to put sustainable business models into practice. For example, the creative approach of design thinking can be used to stimulate new ideas and allow researchers and designers to focus on implementation (Guldman et al., 2019). Second, the action-oriented, stakeholder focus of strategic design is highly compatible with the needs of sustainable business model innovation, especially as it provides the necessary tools and approaches for enacting the related transformation (Baldassarre et al., 2017). Finally, experimentation as a concept emerging in design and business model research is a way to support internal transitions towards sustainability as well as starting to test which new business models in practice (Bocken et al., 2018). The research argues that design can play a strategic role in supporting the adoption of new mindsets, methods and models to enhance awareness and understanding of the need to design for a circular economy. Ultimately, we encourage future research along four main trajectories. In line with the first contribution of this editorial, we suggest to investigate deeper into the connections between sustainable design and sustainable business through a

systematic literature review across these two domains. In line with the second and third contributions, we propose to further explore how Strategic Design practices can be leveraged to bridge the knowledge gap on how to conceptualize and implement Sustainable Business Models and to support the transition towards a circular economy with a major focus on feasibility and viability aspects. Additionally, we encourage researchers to explore the role that designers can play in this transition, as suggested by the first contribution. Finally, as stressed by the fourth and last contribution of this editorial, evaluating the sustainability impact of new business model innovations is an aspect of crucial importance, and we accordingly encourage future research to focus on it.

Design for Sustainable Development refers to the application of a design process to solve a problem related to sustainability, such as creating a pair of shoes that can be recycled or managing waste collection in a large city. Since the origins of this concept in the 1960s, Design for Sustainable Development has been evolving, gradually broadening its scope over time from the design of products to the design of services, business models and wider ecosystems. In this evolution, designers have come closer and closer to business problems, thus becoming more strategic. In this paper, we explore this evolution from a business perspective. We visualize it into a framework and interview eight academic experts about the *Strategic role of Designers for Sustainable Development*. We find that the evolution can be framed around five topics: the strategic goal of designers, and their related perspective, language, key activities and main challenge. After discussing how the evolution took place around each topic, we draw implications for designers and managers who are willing to play an active role in the transition towards sustainable development.

Keywords: Strategic Design, Sustainability, Product Service System, Business Model, Ecosystem

Introduction

The research fields of sustainability and design have grown significantly in the last decades and increasingly crossed their paths in addressing contemporary societal challenges (Bhamra & Lofthouse, 2016; Ceschin & Gaziulusoy, 2016).

Sustainability is a concept that can be traced back to the 1960s, when increasing concerns about the impact of human activities on the planet started to arise around issues such as the pollution of natural ecosystems and the depletion of critical resources (Carson, 1962; Fuller, 1969; Hardin, 1968). In 1972, an academic report called “The Limits to Growth” argued that our planet is a finite system and human development must not exceed its limits if collapse is to be avoided (Meadows, Meadows, Randers, & Behrens, 1972). Sustainability is therefore defined as a dynamic state of development in which a complex system can thrive without collapsing (Meadows, Meadows, Randers, & Behrens, 1972). Afterwards, the United Nations defined sustainable development as “development that meets the needs of the present without compromising the ability of future generations to meet their own needs” (Brundtland, 1987). More recently, the transition towards sustainable development has been framed through a set of specific goals: the Millennium Goals (United Nations, 2009), later turned into the Sustainable Development Goals (United Nations, 2015), for countries and organizations to jointly pursue.

Design is a discipline with human centricity and the meaningful fulfillment of individual and societal needs as core principles. Therefore, its applicability to sustainable development challenges is straightforward. Particularly, design has a twofold nature: "design-as-an-outcome" and "design-as-a-process" (Kimbell, 2012). "Design-as-an-outcome" refers to an artifact, a physical object created by someone who is the designer. "Design-as-a-process" refers to a creative, yet rational process, to develop the solution to a complex problem (Buchanan, 1992; Simon, 1973). In this paper, we focus on how design-as-a-process can contribute to Sustainable Development.

We define *Design for Sustainable Development (DfSD)* as the application of a design process to solve a complex problem related to sustainability, such as waste management in a large city (Bhamra & Lofthouse, 2016; Manzini, 1999, 2009). Over time, academic research and industry practice picked up this concept in different ways, resulting in an evolution of *DfSD* (Ceschin & Gaziulusoy, 2016; Konietzko, Bocken, & Hultink, 2018). Our goal is to provide a comprehensive and up-to-date mapping of this evolution, by integrating the business perspective as one of its current and future drivers. Specifically, the scope of *DfSD* has become broader over time, moving from leveraging design principles and practices for addressing exclusively technical challenges to using such principles and practices for looking at sustainable development from the perspective of people behaviors and socio-economic systems (Ceschin & Gaziulusoy, 2016). In recent years, a new focus at the intersection between design and sustainable development research has emerged, which looks at design as a way of bringing business considerations at the core of sustainable development. This is the consequence of two occurrences: first a progressive realization in research and practice that the implementation of the sustainability transition requires its integration with business objectives (Maas & Boons, 2009; Whiteman, Walker, & Perego, 2013); second, the increasing role that design plays in driving the strategic decision making of organizations that strive for meaningful innovation (Brown, 2008; Calabretta, Gemser & Karpen, 2016).

In this paper, we want to integrate these recent developments and incorporate the business perspective as a driver of the evolution of *DfSD*. As a result, we propose and validate a four-level framework of how the role of designers in sustainable development has evolved by becoming more strategic in integrating business goals. We start from a comprehensive literature review to identify four nested levels of *DfSD*: Product Design, Product Service System Design, Business Model Design and Ecosystem Design. We subsequently use eight in-depth expert interviews to validate the framework and to further characterize the strategic role of designers in sustainable development from a business perspective. We conclude with some implications for designers and managers, and with some directions for future research.

Literature review

Product Design

The first level of *Design for Sustainable Development* is Product Design.

The global ecological and social concerns that had been brewing through the 1960s reached a crisis point in the 1970s, and affected design as well. Papanek's book, *Design for the Real World,* urged designers to introspect deeply about how they could contribute meaningfully to global social and ecological issues (Papanek, 1971). Papanek called on designers to be accountable for - and driven by - global ecological and social needs, rather than the consumer-led economy. As a consequence, the concept of "Green Design" for responsible consumers started to emerge. John Elkington formulated "*Ten questions for the Green Designer",* for a 1986 UK Design Council booklet, inviting reflection on the fact that each product has an impact associated to its life cycle, namely the way in which it is produced, distributed, used by people and ultimately dismissed. In the 1990s, the concept of "Green Design" evolved into the concept of "Eco-Design" (Brezet & van Hemel, 1997). Eco-design aimed to create a win-win situation by addressing both the ecology and the economy; it sought to minimize the negative ecological impacts of the product life cycle, while simultaneously offering financial benefits (so-called win-win situations) (Ceschin & Gaziulusoy, 2016). In Eco-design, the environment was given the same status as more traditional industrial values such as profit, functionality, aesthetics, ergonomics, image and overall quality (Brezet & van Hemel, 1997). It is just since 1995 that the term "*Design for Sustainability*" has received greater acceptance (Bragd, Baumann, & Boons, 2002). Many scholars, in describing *Design for Sustainability* draw heavily on a more broader and holistic scope than Eco-design by incorporating social, ethical and equity issues (such as wealth disparities and developing world factors) into design (Crul & Diehl, 2006; Crul, Diehl, & Ryan, 2009; Dewberry & Goggin, 1996; van Weenen, 1995). Initially, the strategic aspects of *DfSD* were minor and mostly related to identifying internal and external

drivers that could result in win-win situations in which the ecological benefit would result as well in economic benefits.

Summarizing the previous paragraph, we conclude that at the Product level of *DfSD,* the outcome of the design process is typically a "green" product with a life cycle that results in a lower environmental impact. An example of this is the Aeron Chair by Hermann Miller, which can be fully disassembled and recycled in all its parts.

Product Service System Design

The second level of *Design for Sustainable Development* is Product Service System Design.

In the late 1990s, several scholars and practitioners realized that a focus only on products would not be sufficient to achieve sustainability goals. Leveraging this and former Eco-design ideas, Manzini stated that *DfSD* should take into account not just products but also services (Manzini, 1999). As firms become responsible not only for production and delivery of products but also for other phases in the life cycle of products (e.g. offering maintenance services in the use phase and designing take-back systems for the end-of-life of products), they have more incentives to adopt life-cycle thinking during the design and development phase of products (Manzini & Vezzoli, 2003). Consequently, the concept of Product Service System (PSS) emerged. PSSs are defined as "a mix of tangible products and intangible services designed and combined so that they are jointly capable of fulfilling final customer needs" (Tukker & Tischner, 2006). PSSs Design for Sustainability then became a research field of its own (Tukker, 2004; Tukker & Tischner, 2006). This new perspective positioned design as a strategic competence for creating new business opportunities and new ways of fulfilling product functions through the design and combination of novel sustainable products and services (Manzini, 1999; Manzini & Vezzoli, 2003). In a PSS strategy, the starting point is not a product or service, but the final functionality or satisfaction of customer needs (Tukker & Tischner, 2006). In that respect, PSS are also referred to as 'function-oriented business models' (Tukker, 2004). Such a business model has implications for the ownership structure of products since the main activity of firms moves and/or extends from selling products to giving access to the use of products via, for example, leasing schemes or pay-per-service models (Tukker, 2004). Finally, the changes in the ownership structures replace material intensive products with intangible services. Thus, this potentially leads to the 'dematerialization' of the economy, which is associated with the reduction of material flows in production and consumption (Mont, 2002).

Summarizing the previous paragraph, we conclude that at the Product Service System level of *DfSD,* the outcome of the design process is a product - service combination that reduces the impact of the product while providing something better to people. An example of this is the "OV bikes", a bike sharing service from the Dutch Railways that reduces the use of cars by helping people who take public transport to reach their final destination.

Business Model Design

The third level of *Design for Sustainable Development* is Business Model Design.

After the emergence of the Internet in the business field as well as the steep rise of technology-heavy companies on the stock exchange, academic research on business models rapidly increased in the first decade of the 2000s (Osterwalder & Tucci, 2005; Wirtz, Pistoia, Ullrich, & Göttel, 2015; Zott, Amit, & Massa, 2011). The business model is a conceptual construct that describes how organizations propose, create, deliver and capture value (Richardson, 2008; Teece, 2010). In parallel, business model innovation was positioned as a way to tap into and even create new markets rather than a 'trade-off'(Porter & Kramer, 2011; Yunus, Moingeon, & Lehmann-Ortega, 2010). It was recognized that the construct provides an effective and systemic lens to investigate sustainable innovation and to discuss with organizations about the integration of sustainability into their objectives and operations (Bocken, Short, Rana, & Evans, 2014; Boons & Lüdeke-Freund, 2013; Stubbs & Cocklin, 2008). With increasing evidence on pressing sustainability challenges, sustainable business model innovation rapidly emerged as a research field (Bocken et al., 2014; Boons & Lüdeke-Freund, 2013; Dentchev et al., 2018; Geissdoerfer, Vladimirova, & Evans, 2018; Lüdeke-Freund & Dembek, 2017; Stefan Schaltegger, Hansen, & Lüdeke-Freund, 2016). This field places a prominent focus on design, which is mentioned repeatedly in some key publications as a strategic process for the creation of sustainable business models (Bocken, Short, Rana, & Evans, 2013; Boons & Lüdeke-Freund, 2013). Boons & Lüdeke-Freund recognized that the design of sustainable business models is a key challenge of the field (Boons & Lüdeke-Freund, 2013). Bocken and

colleagues explained that there are several archetypes of sustainable business models and that PSS is one of them, thus reinforcing the connection with earlier design literature on *DfSD* (Bocken et al., 2014; Tukker, 2004). Later work explicitly included design approaches in sustainable business modeling (Baldassarre, Calabretta, Bocken, & Jaskiewicz, 2017; Geissdoerfer, Bocken, & Hultink, 2016; Keskin, Diehl, & Molenaar, 2013). An analysis of this work shows that through the sustainable business model innovation field, *DfSD* research and practice has evolved beyond the Product Service System level, becoming even more closely connected with the business domain.

Summarizing the previous paragraph, we conclude that at the Business Model level of *DfSD,* the outcome of the design process is a (new) organization or a corporate venture driven by a social and environmental purpose. An example of this is Peerby, a company whose core mission is reducing the amount of products that are consumed while connecting people in the same neighborhood.

Ecosystem Design

The fourth level of *Design for Sustainable Development* is Ecosystem Design.

Across the first and second decade of the 2000s, the discussion on Sustainable Development has been increasingly leveraging a new paradigm defined as Circular Economy, which has gained momentum in business, policy and academy, not the least catalyzed by the Ellen MacArthur Foundation (Geissdoerfer, Savaget, Bocken, & Hultink, 2017; MacArthur, 2013). The origins of this concept can be traced back to the 1960s (Carson, 1962; Fuller, 1969; Hardin, 1968) and it refers to an economic system in which resource input and waste, emission, and energy leakage are eliminated or minimized (i.e. closing their loops) in order to achieve a positive environmental and economic impact simultaneously (Geissdoerfer et al., 2017; Lüdeke-freund, Gold, & Bocken, 2018). The transition to a Circular Economy requires the intentional design of new products and services, and experimentation with new business models to deliver them (Antikainen, Aminoff, Paloheimo, & Kettunen, 2017; Bocken, de Pauw, Bakker, & van der Grinten, 2016; Bocken, Schuit, & Kraaijenhagen, 2018). However, in order for these new business models to work in practice, it is essential to establish a collaborative capacity across organizations in the form of ecosystems (P. Brown, Bocken, & Balkenende, 2019; Kraaijenhagen, van Oppen, & Bocken, 2016). The term ecosystem comes from the fields of environmental sciences and industrial ecology, where it is used to depict relationships across businesses and their impact on the environment, exemplified by the concept of industrial symbiosis (Chertow, 2000; Frosch & Gallopoulos, 1989). The term has also been used in business and management literature to establish a connection with strategic innovation and business models (Adner, 2017; Talmar, Walrave, Podoynitsyna, Holmström, & Romme, 2018). In this context, ecosystems can be seen as “macro” business models in which multiple organizations create a value network and achieve together competitive advantage by jointly delivering a value proposition (Adner, 2017; Bocken et al., 2013; Clarysse, Wright, Bruneel, & Mahajan, 2014; Short, Bocken, Barlow, & Chertow, 2014; Talmar et al., 2018). More recently, these ideas on ecosystems have been leveraged by design literature as well, and reframed from the related perspective. Specifically, it has been pointed out that the discipline of design, the design process, design practices and capabilities, can be used beyond the definition of firm-centric business models, for the definition of ecosystems, or in other words coalitions, of organizations collaborating towards sustainable development and / or a Circular Economy (Baldassarre et al., 2019; Bocken, Boons, & Baldassarre, 2019; Den Ouden, 2012; Konietzko et al., 2018).

Summarizing the previous paragraph, we conclude that at the Ecosystem level of *DfSD,* the outcome of the design process is a coalition of organizations collaborating to drive the sustainable transformation of the economic system. An example of this is the “Adaptive City Mobility”, a national consortium of 13 organizations collaborating to implement an Electric Mobility System for cities in Germany.

Research question

We have explained that *DfSD* refers to the application of a design process to solve complex sustainability problems (Manzini, 1999, 2009). By looking at different streams of literature from different domains, we have explained that over time this idea has been picked up by academic research and business practice in different ways resulting in an evolution of *Design for Sustainable Development* into four nested levels of design (Ceschin & Gaziulusoy, 2016; Konietzko et al., 2018). This evolution is visualized in figure 1.

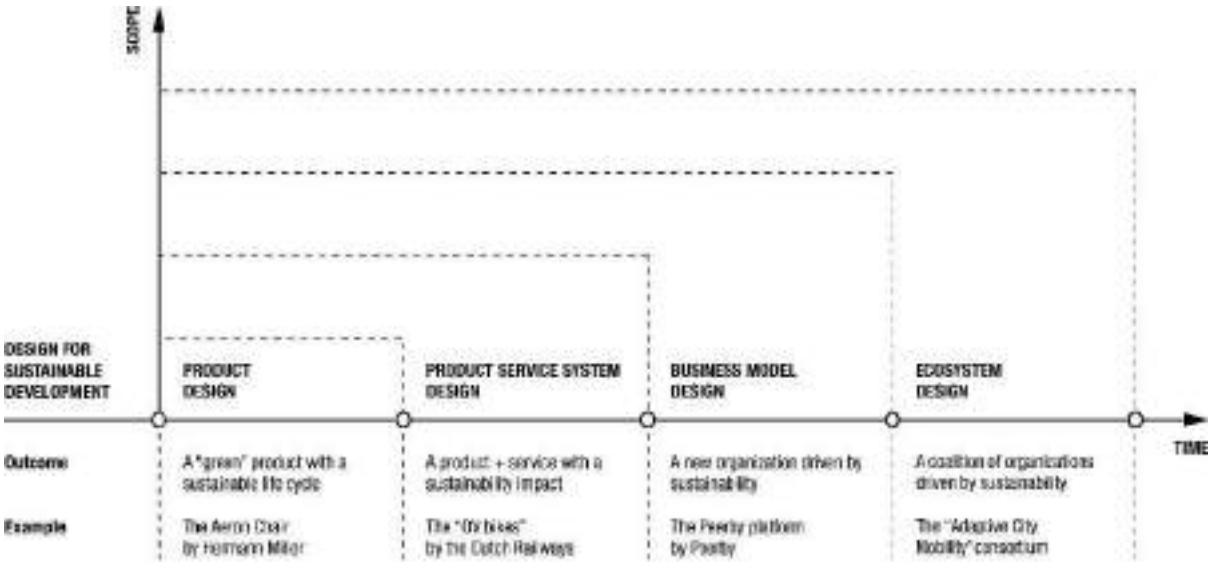

Figure 1: Framework of the evolution of Design for Sustainable Development. Based and adapted from: (Ceschin & Gaziulusoy, 2016; Konietzko et al., 2018)

Throughout this evolution, *DfSD* becomes increasingly strategic, establishing a connection with literature and practice from the domain of sustainable business (Baldassarre et al., 2017; Bocken et al., 2014; Manzini, 1999). Better understanding and leveraging these connections is of utmost importance if design researchers and practitioners want to play an active role as agent of change in the transition towards sustainable development (Manzini, 2009). Consequently, the goal of this paper is to explore the evolution *of Design for Sustainable Development* more in depth and from a business perspective.

Taking a business perspective on *DfSD* means looking at how designers can help in creating value for organizations while addressing sustainability challenges. Research has already studied how design practices and principles can play a strategic role in business domains like innovation (Calabretta, Gemser, & Wijnberg, 2017), branding (Beverland, Wilner, & Micheli, 2015), and shaping the organizational culture (Elsbach & Stigliani, 2018). However, how this might be the case in the context of *DfSD* and its evolution has not been analyzed yet. Consequently, we pose the following research question:

How has the Strategic role of Designers for Sustainable Development evolved over time?

In this paper, we leverage on a decision-making logic on the strategic role of design (Calabretta et al., 2017) and define the role of designers as 'strategic' when designers are able to get involved and influence strategic decisions on sustainable development. Strategic decisions are decisions implying high uncertainty in the final outcome, prolonged course of actions, significant resource commitment, and involvement of several decision makers (Eisenhardt & Zbaracki, 2019)

Method

In order to address the research questions, we used the framework of the evolution of *Design for Sustainable Development* derived from the literature (see Figure 1) as the starting point for a discussion with eight international academic experts working in six different European countries. In order to gain richer insights into the strategic role of designers for sustainable development, we selected experts with different research focuses. Furthermore, four of the experts that we selected have been working in the industry on related topics. The research focus, academic experience, and industry experience of the eight experts are summarized below in Table 1.

Table 1: Research focus, academic experience and industry experience of the experts selected for the interviews

	Research focus	*Academic experience*	*Industry experience*
Expert 1	Sustainable Design, Sustainable Business Strategy	3 years	5 years
Expert 2	Sustainable Design	27 years	-
Expert 3	Corporate Sustainability	12 years	-
Expert 4	Sustainable Business Strategy	8 years	5 years
Expert 5	Sustainable Design, Sustainability Policy	38 years	-
Expert 6	Sustainable Design	13 years	3 years
Expert 7	Corporate Sustainability	15 years	-
Expert 8	Sustainable Business Strategy	5 years	12 years

Data collection

Data has been collected using semi-structured qualitative interviews (Patton, 2002). Two researchers conducted the interviews. While one researcher showed the framework to the experts and probed them with the research question, the other researcher noted all the answers and comments on a printed copy of the framework. Some interviews were conducted face-to-face and some over Skype. All interviews were digitally recorded and consequently transcribed.

Data analysis

Data has been analyzed using a qualitative approach (Corbin & Strauss, 2008; Miles, Huberman, & Saldaña, 2013). The transcripts of the interviews and the experts' comments noted upon the printed models, have been scanned by the lead researcher and consequently condensed into written highlights and visual diagrams (Corbin & Strauss, 2008). After this first level of analysis, the written highlights and visual diagrams have been further analyzed through a set of face-to-face discussions involving the authors of this paper (who have relevant academic and industry experience on the *Strategic role of Designers for Development*). This second level of analysis allowed defining key topics (Miles et al., 2013). Written notes were taken during this process. Consequently, these notes have been used to map key developments onto the framework, to understand how the *Strategic role of Designers for Sustainable Development* has evolved around each key topic.

Results and discussion

The eight interviews, the follow up brainstorming and visual analysis allowed defining five topics related to the *Strategic role of Designers for Sustainable Development*. The topics are: strategic objective, perspective, language, key activities, and main challenge. They are presented and discussed in the following paragraphs. A visualization of how the *Strategic role of Designers for Sustainable Development* has evolved over time around these topics is presented in figure 2.

Strategic objective

Throughout the evolution of their role across the four levels of our framework (figure 1), the strategic objective of designers - namely what they need to focus on to steer the strategic decisions of organizations - has changed.

Designers traditionally focus on the "form and function" of products. Eco-designers are different because they do not only focus on how products look like but also on how they are produced, distributed and dismissed (Expert 2, Expert 5). Eco-design places a major focus on reducing the life cycle impact of products (Ramani et al., 2010). Consequently, at the Product level the strategic objective of designers is pushing an organization to think beyond the "form and function" of their product, and steer decisions towards changing its life cycle

(production, distribution, use, end of life), in order to reduce its environmental footprint while making profit. When the scope is broadened to services, suddenly the focus is placed on the exchanges with other stakeholders, and on how these affect the environmental and social impact of the supply chain (Expert 4, Expert 6). The design of sustainable services and business models places in fact a major focus on stakeholder interactions (Ceschin, 2012). Consequently, at the Product Service System level, the strategic objective of designers is pushing an organization to think beyond the life cycle of its product, and steer decisions towards changing tangible and intangible stakeholder exchanges (e.g. knowledge, materials, energy, money, etc.), in order to foster a positive social and environmental impact while making profit. Designers of sustainable business models place their focus on the entire organization (Expert 3, Expert 6). In fact, Sustainable Business Model Innovation entails redefining the core goals and underlying processes of organizations (Bocken et al., 2013). Consequently, at the Business Model, level the strategic objective of designers is pushing an organization to think beyond products and services, and steer decisions towards (re)defining its purpose, how it functions from an economic and operational standpoint, in order to pursue sustainability goals while making profit. When broadening the scope further, the focus of designers is fostering a sustainability transition (Gaziulusoy & Ryan, 2017). In other words, this can be described as a focus on the transformation of an entire market sector or industry through a collective conversation of all the parties involved (Expert 3, Expert 6). Consequently, at the Ecosystem level, the strategic objective of designers is pushing multiple organizations to think beyond their individual business, and steer decisions towards collectively (re)defining (un)sustainable market practices, in order to facilitate the transformation of existing sectors while making profit together.

Perspective

Throughout the evolution of their role across the four levels of our framework (figure 1), the perspective of designers - namely the point of view from which they approach a problem and develop a solution - has changed.

Most designers do not know what strategy is and how sustainability relates to it from an organizational perspective (Expert 7). Strategy is a core function of an organization that binds together all the other ones (e.g. R&D, Operations, HR, etc.) and as such, business sustainability can only be achieved if strategy demands it (van Tulder, van Tilburg, Francken, & Da Rosa, 2013). By training, designers have a technical background and are therefore able to change the way products are developed to reduce their impact (Expert 2). Consequently, at the Product level the perspective is department centric. The designer works from the perspective of the R&D department, aiming to change how products are made. However, when innovating with a broader focus, designers are forced to understand what is more relevant for business and how different people in their organization look at sustainability issues (Expert 6). Consequently, at the Product Service System level, the perspective is cross-functional. The designer works from the perspective of the R&D and the commercial departments, aiming to change how products are made and delivered to customers. Eventually, the business model framework can be used to take the perspective of the entire organization on a design change for sustainability (Expert 4). In fact, the business model can be used to define company strategy (Richardson, 2008; Teece, 2010). Consequently, at the Business Model level the perspective is firm-centric. The designer works from the perspective of the entire organization, aiming to change how it operates and makes money. When the focus becomes the sustainable transformation of an entire industry there are many perspectives because all the companies operating in that industry have different priorities and issues to deal with (Expert 1, Expert 5). In this case, the designer must be like a “spider-in-the-web” and be able to take all perspectives into account (Expert 5). Consequently, at the Ecosystem level, the perspective is cross organizational. The designer works from the perspective of multiple organizations, aiming to change together existing market sectors.

Language

Throughout the evolution of their role across the four levels of our framework (figure 1), the language of designers - namely the way in which they communicate with different stakeholders - has changed.

Designers working with complex problems must be able to speak different languages (Calabretta, Gemser, & Karpen, 2016). Over time, designers working with sustainability have learned to speak different languages in order to communicate more effectively with different audiences and foster the adoption of their ideas (Expert 5). When they design products, they must be able to explain to engineers how such products can be developed more sustainably (Expert 5). Consequently, at the Product level they use an engineering language, suitable to communicate with the R&D department of an organization. When they design services, they must be able to

explain to the commercial departments how sustainability requirements will change how the current offering is delivered (Expert 5). Consequently, at the Product Service System level they use an operational language, suitable to communicate with the R&D and commercial departments of an organization. When the focus is the transformation of a business model, it is important to understand and use the same language of the upper management (Expert 7). This is essential to make sure that sustainability efforts are driven from the top of the organization (van Tulder et al., 2013). Consequently, at the Business Model level they use a strategy language, suitable to communicate with the upper management and CEO of an organization. If designers want to focus on the sustainable transformation of an entire industry and take the perspective of multiple organizations, it is important that they understand policy dynamics and language (Expert 5). Consequently, at the Ecosystem level they use a policy language, suitable to communicate with decision makers in the public sector.

Key activities

Throughout the evolution of their role across the four levels of our framework (figure 1), the key activities of designers - namely the most important actions they have to get done - have changed.

Designers who want to develop sustainable products must be able to understand what a life cycle is and how it can be assessed (Expert 2, Expert 5). A life cycle approach to the design of a product is based on first analyzing the current life cycle and then setting clear design objectives and criteria to lower its environmental impact (Vezzoli & Sciama, 2006). Consequently, at the Product level the key activities of designers consist of life cycle analysis supporting product design. When designing services, the interactions of stakeholders and social aspects around the product life cycle come into play (Ceschin, 2012; Tukker, 2004). Thus, it is important to analyze who these stakeholders are, what they exchange with each other and what do they want to achieve (Expert 1, Expert 6). Consequently, at the Product Service System level the key activities are stakeholder analysis supporting product and service design. When the focus is broadened to designing business models, it is essential to try out different options by making very concrete experiments to see which model can work, not only from a sustainability standpoint but also from a business standpoint (Expert 4). Transforming the entire business model of an organization requires experimentation capabilities (Keskin et al., 2013). Consequently, at the Business Model level, the key activities are design of experiments supporting business modeling. When wanting to transform wider industries it is important to consider the role of businesses as well as that of the public sector (Walls & Paquin, 2015). Designers must be able to understand who are the players involved in a certain market, what are the power plays taking place and how they can be disrupted (Expert 3). Consequently, at the Ecosystem level the key activities are industry analysis supporting alignment of private and public sector.

Main challenge

Throughout the evolution of their role across the four levels of our framework (figure 1), the main challenge of designers - namely the most difficult issue that they face - has changed.

The more designers move away from designing products towards solving complex sustainability problems, the more their challenge will change from a technical to a business one (Expert 1, Expert 3, Expert 8). Reducing the energy and material flows associated with a single product is a technical challenge (Ramani et al., 2010). Consequently, at the Product level the main challenge relates to technical issues. Designing a “green” product requires reducing material and energy flows but this has a limited impact if the wider context is unsustainable. In fact, if the material is not sourced responsibly and if the energy comes from fossil fuels a product cannot be sustainable (Expert 2). Beyond the product level, design can foster more radical sustainability changes (Manzini & Vezzoli, 2003). However, when working in industry practice with an organization, the implementation of more radical solutions is difficult (Expert 6, Expert 8). Product - service combinations are complex solutions involving multiple stakeholders, which makes them difficult to implement (Morelli, 2002; Vezzoli, Ceschin, Diehl, & Kohtala, 2015). Consequently, at the Product Service System level the main challenge relates to implementation. Designing a product - service combination requires a change in how stakeholders behave and this may result in a design - implementation gap. Sustainable business models allow pushing forward even more radical changes but they are also affected by a design - implementation gap (Bocken et al., 2013; Geissdoerfer et al., 2018). In addition, the designer needs to make sure that the solution is financially viable in the first place and then that it can be scaled up (Expert 4). Consequently, at the Business Model level the main challenge relates to financial and operational aspects. Designing a sustainable organization (or venture) requires financial viability and followed by scaling. When multiple organizations are involved at the

same time it becomes even more difficult (Expert 1, Expert 8). Operating at this level requires bringing multiple parties together in the form of coalitions (Manzini, 2017). Such joint projects pose several political and legal challenges (Expert 1, Expert 5). Consequently, at the Ecosystem level the main challenge relates to political and legal aspects. Designing a coalition of organizations requires turning a joint project into a legal entity and this entails defining and negotiating roles.

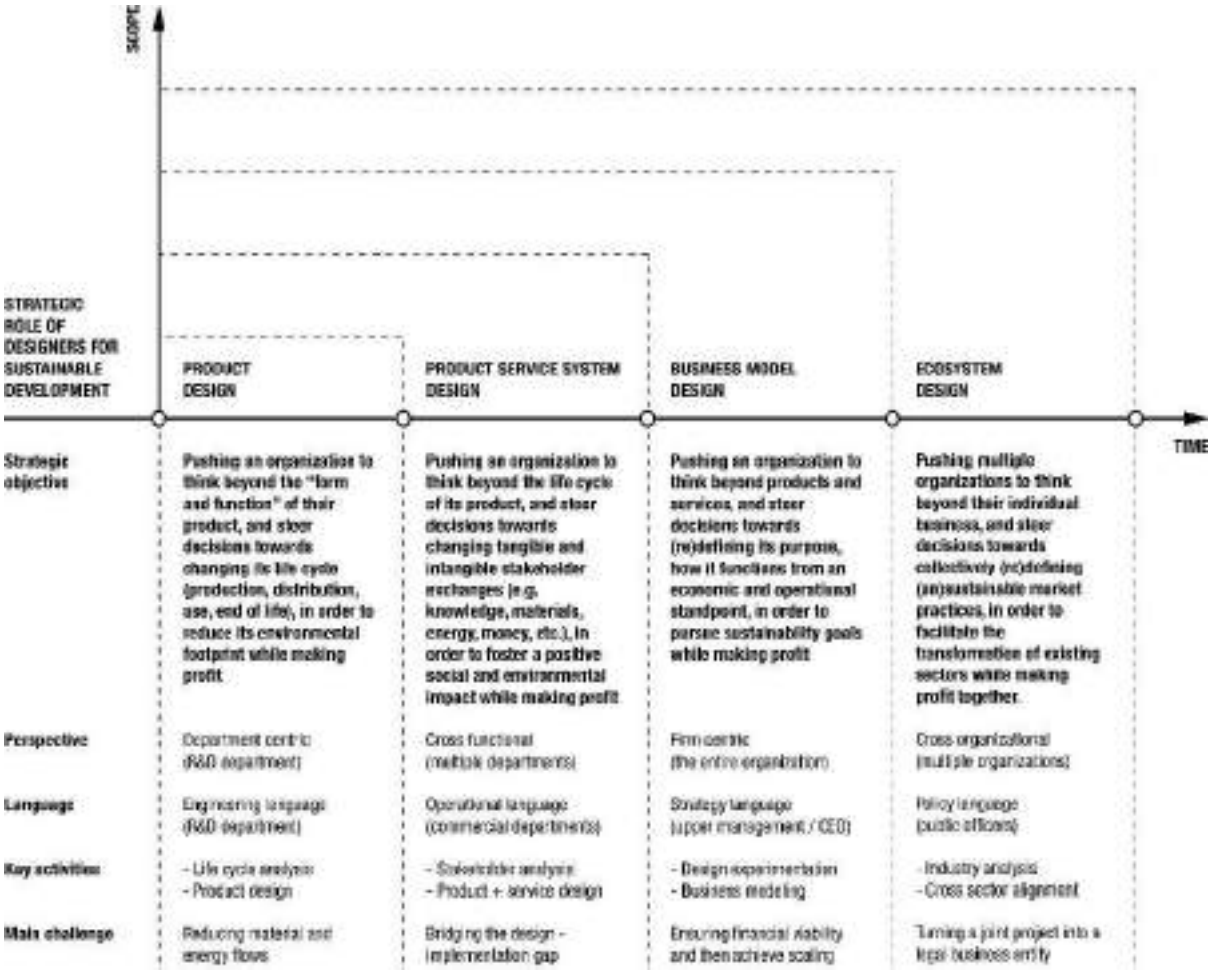

Figure 2: Evolution of the Strategic role of Designers for Sustainable Development. Based and adapted from (Ceschin & Gaziulusoy, 2016; Konietzko et al., 2018), and including the results of this research

Conclusions

In this paper, we explained that Design for Sustainable Development has been evolving over time, gradually broadening its scope from the design of Products to the design Product Service Systems, Business Models and Ecosystems. By combining sustainability literature from the fields of sustainable design and business, we visualized this idea into a framework, and further investigated this evolution from a business perspective, exploring how the strategic role of designers has evolved accordingly. To this end, we interviewed eight academic experts from six different countries, with mixed expertise in sustainable design and/or business, asking to provide their view on the framework and related subject. Their inputs have been analyzed qualitatively and condensed into five topics: strategic objective, perspective, language, key activities, and main challenge. Consequently, we connect interview data with literature to explain how the strategic role of designers for sustainable development has evolved through each one of these topics.

A final, overarching consideration relates to the fact that the four levels of design in our framework are nested. As explained by all the experts, and reinforced by literature, designers traditionally come from the inner level of Product Design and over time have been gradually involved into more strategic business decisions, which

are taken at higher levels (Micheli, Perks, & Beverland, 2018). In the light of this consideration, and of the findings of the research, we distill some implications for both designers and managers who aim to contribute to a transition towards sustainable development.

Implications for Designers

If designers want to become active agents of change for sustainability, they should go out of their comfort zone and continuously learn to do something new (Manzini, 2009). As explained, this implies not only having broader strategic objectives, but also being able to work from new perspectives, learning to speak new 'disciplinary languages' and crossing disciplines, to execute new key activities and to deal with new challenges. Working from new perspectives entails understanding how different departments and organizations see innovation related issues, and using design as a way of thinking to connect these multiple viewpoints (Calabretta & Gemser, 2015; Micheli et al., 2018). Learning 'disciplinary languages' and crossing these entails getting to know the terminologies that different professional profiles use when they talk about innovation related issues, and trying to translate those to facilitate communication across profiles (Calabretta et al., 2016; Calabretta, Gemser, & Wijnberg, 2017; Micheli et al., 2018). Executing new key activities and dealing with new challenges entails being comfortable to design in new situations of uncertainty, in a similar way that an entrepreneur would do, leading organizations through growth and transformation towards sustainability (Keskin, 2015; Romme & Reymen, 2018; Sarasvathy, 2008). These considerations underpin a crucial point: as designers acquire these new capabilities and their role becomes more strategic towards the right side of our framework, they should not become something else. They should remain designers and not forget all the capabilities that are described on the left side. Remembering that the path towards sustainable development is collaborative (Manzini, 2017; van Tulder, 2018), designers should use their skills of general specialists in order to bring together people on different levels by being able to move across all the four levels of the framework.

Implications for Managers

If managers want to truly use their influence to promote a sustainable transformation of their organization, they should in the first place acknowledge that designers are not just product makers (T. Brown & Martin, 2015; Liedtka & Ogilvie, 2012). As explained, they should embrace design as a mean of sustainable transformation and involve designers in the strategic decisions concerning corporate sustainability (Jay & Gerard, 2015; S Schaltegger, Lüdeke-Freund, & Hansen, 2012). Specifically, designers may be involved and play a role in balancing the desirability, feasibility and viability dimensions of innovation, with the dimension of sustainability, by performing a set of specific practices (Baldassarre et al., 2017; Bocken et al., 2019; Calabretta et al., 2016). These practices include, but are not limited to, conducting conversational interviews with key stakeholders of the innovation process, leading strategic brainstorming sessions, performing ethnographic observations with customers, conceiving and testing marketing campaigns through digital platforms and prototyping beyond focal products, entire value propositions, service exchanges and business models (Bocken et al., 2019; Schuit, Baldassarre, & Bocken, 2017). Going a step further, managers may consider learning to think more like designers themselves in order to breach corporate conventions and silos, an essential condition for operating sustainably (T. Brown & Martin, 2015; Porter & Kramer, 2011; Yunus et al., 2010).

Limitations and future research

This research has two main limitations. The first limitation relates to the small number of experts we interviewed. We only interviewed eight academic experts. The second limitation relates to our qualitative approach, which is not overly structured due to the exploratory nature of the investigation. We used semi-structured interviews to only start exploring the research question but did not have an interview protocol built on former research.

We encourage future research to address these limitations. A potential way to do that could be to build upon and improve the list of topics that we defined by interviewing more expert about the strategic role of designers for sustainable development by using a more structured data collection protocol. In addition, we see a fruitful avenue for future research in exploring more in-depth the connections between sustainable design and sustainable business. This might be done with a systematic literature review at the boundary of these two domains.

Minding the gap: The road to circular business models

PINHEIRO Marco* and JUGEND Daniel

Sao Paulo State University - UNESP, Brazil
* corresponding author e-mail: marco.pinheiro@unesp.br
doi: 10.33114/adim.2019.02.278

Despite strategic design (SD) and product portfolio management (PPM) play a pivotal role in driving companies toward a more sustainable economy, it is still not clear how SD and PPM can contribute to the advances of circular business models (CBM). In this context, the aim of this research was to analyse the main literature about SD, PPM and CBM proposing an integrative framework, as well as to reduce the gap on drivers and barriers in the development of CBM through a case study in a biodiversity company. As conclusions of this work, SD helps companies to define the strategic vision for innovation, integrating sustainable stakeholder objectives, meanwhile, PPM activities support the decision-making process, being responsible for the alignment of projects with firms' strategy when generating circular business. In addition, regulatory requirements and cost of production have shown the main drivers, whereas technological restriction is the main barrier to overcome.

Keywords: Circular economy, environmental sustainability, new product development, sustainable design

Introduction

The global sustainability has been hampered by the imbalance between demand and supply in the consumption of natural resources. The scarcity of the resources, environmental concerns and stricter regulations have forced researchers from academia and industries to develop new strategies dealing with the need for sustainability (Singhal, Tripathy & Jena, 2019). This has led to strategic decision of sustainability for many organizations (Goyal, Esposito & Kapoor, 2016). Hence, sustainability considerations in new product development as strategic processes has been gaining greater acceptance in organizations (Ali, Stewart, Boks & Bey, 2019), also regarding on sustainability issues to be institutionalized, visionary leaders are required to foster sustainable business models (Bonviu, 2014).

As products have historically been designed for convenience but with little consideration of the waste left behind and given the fact that natural resources are finite and global populations are steadily growing, traditional models that involve wasteful products for consumers to buy and own require reinvention (Mesa, Esparragoza & Maury, 2018). Therefore, in adopting more sustainable development pathways, companies should be open to new experiences, increase consciousness and agreement to share knowledge (Ceglia, de Abreu & Da Silva Filho, 2017). In order to slow consumption and close the resource ties in today's market, a regenerative economic model is needed. In this way, the circular economy has become an important school of thought in sustainable economics, receiving more and more attention worldwide as a way to overcome the current model of production and consumption based on continuous growth (Skene, 2018; Ghisellini, Cialani & Ulgiati, 2016).

For companies to contribute to sustainable development, they will need to rethink their business models (Bocken, Farracho, Bosworth & Kemp, 2014) because in the current processes, value creation is based on a material flow, where virgin material enters the upstream value chain and the entire product value is added up through manufacturing processes (Andrews, 2015). Further, expanding the innovative niche of circular economy business model, that aims to drive the sustainability of a business network through circular strategies (Baldassarre et al., 2019). Circular business model innovation is about capturing the value from what is considered waste in a linear business approach (Ghisellini, Ripa & Ulgiati, 2018), in this case, Strategic Design (SD) plays a pivotal role in driving the companies toward a more sustainable economy (Jadhav, Kalita & Das, 2019).

Since SD has been disseminated in sustainable business model innovation research and practice in order to support the process of collaborative innovation among stakeholders (Geissdoerfer, Bocken & Hultink, 2016; Manzini & Vezzoli, 2003). It may integrate design principles with a business, in order to reach both long term and short term performance goals (Calabretta, Gemser & Karpen, 2016). In this context, the term strategic design for sustainability means the ability to create new stakeholder configurations and develop an integrated product, service and communication system consistent with a medium- to long-term sustainability perspective while being economically viable and socially appreciable (Manzini & Vezzoli, 2003).

New areas of design activities have been drawn and new methods and tools are being integrated into the appropriate guidelines for sustainability (Joyce & Paquin, 2016; Manzini & Vezzoli, 2003; Meroni, 2008). SD integrating products and service could improve the performance of sustainable projects (Jadhav et al., 2019), also designers are more and more often called to use their principles, tools, and methods to influence the innovative strategy of the companies they work with (Calabretta et al., 2016; Joyce & Paquin, 2016). Regarding on this, Pinheiro, Jugend, Dematt̂ Filho and Armellini (2018), proposed a product portfolio management (PPM) framework, pointing out the early phase in the new product development process as relevant for integrating sustainable development and concerns about environmental issues. Thus, the integration of PPM and SD may represent an opportunity, from strategic direction to contribute to the development of CBM.

Some literature have pointed out a lack of knowledge on why and how to develop environmentally sustainable projects (Alblas, Peters & Wortmann, 2014; Brones, Carvalho & Zancul, 2014). The early phase of projects development can be useful to improve the environmental impact of new business models, since it is at this moment that more possibilities of choice can occur on the projects (Bocken et al., 2014), especially when companies present difficulty in integrating environmental aspects into product design innovations (Driessen, Hillebrand, Lok & Verhallen, 2013; Pinkse & Kolk, 2010). Nonetheless, PPM could unfold new circular strategies, since it regards on merging dimensions such as strategic, organizational, methods and tools (Pinheiro et al., 2018).

Despite the literature has presented the possibility of the SD approach to developing sustainable environmentally friendly innovation in the industry (Manzini & Vezzoli, 2003), few studies analyse its relationships with a circular economy and the development of CBM (Baldassarre et al., 2019). Their relationship remains unclear and an integrated framework has not been found in the literature. Moreover, since PPM has been playing a strategic role, supporting managers to better handle this process of selecting projects (De Castro & De Carvalho, 2010; Pinheiro et al., 2018); this article proposes to answer the following question that needs further investigation: how can strategic design and product portfolio management develop circular business models?

Hence, this research aims to answer this research question by posing two sequential research objectives. The first objective is to contribute to the literature by making an initial attempt to combine SD, PPM and CBM perspectives presenting an integrative framework on these themes. The second objective is to reduce the gap on drivers and barriers in the development of CBM in a biodiversity company, owing to bioeconomy implies a more efficient resource management of bio-based renewable resources and since these ideas have been well received at the industry level, fostering cost reductions, innovation, and competitiveness (D'Amato, Veijonaho & Toppinen, 2018).

Considering the lack of research on the subject, this exploratory study was carried out through a qualitative approach. A case study was applied in a Brazilian leading company in the timber industry, which develops and manufacture new products made of wood. As SD is inherent to the company's' products in fauna and flora due to its operation, it is understood that this case study provides an adequate environment for reflections on the subject. The study can also be justified because Brazil is known by having one of the largest biodiversity in the world (Mongbay, 2016; Sustainability for All, 2017).

After this introduction, literature reviews on the topics SD, PPM, and CBM will be present and summarised with a proposal of an integrative framework. Afterward, the sequence of activities carried out in the case study, with a focus on meeting the drivers, and barriers to developing CBM are approached, followed by the findings reported in the case study. Next, the results obtained are faced up with the reviewed literature in a discussion based on the findings. Finally, the conclusion chapter outlines the key contributions of this research.

Theoretical background

Strategic Design

Strategic Design is a line of research and applied discipline based on the use of design principles and practices for the formulation and implementation of innovation strategies for organizations (Calabretta et al., 2016). SD is an approach that is responsible for connecting and articulating different types of knowledge from the point of view of strategy. Furthermore, it refers to the use of design principles and practices for the co-creation of business strategies and processes (Calabretta et al., 2016). Strategic Design is about defining the strategic vision for innovation, designing a concept and the business around it and finally assessing results before moving into a new iteration (Baldassarre et al., 2019). The success of the SD depends greatly on the interaction of individuals from different areas and their ideas, understanding the market and the consumers that will be affected (Franzato & Campelo, 2017).

The strategic dimension of design is revealed by questioning, interpreting, experimenting and generating learning in dynamic contexts. SD prioritizes the contextualized reading of the competitive environment, technological and sociocultural of the companies; possesses ability of questioning strategies; and is oriented to innovation, building knowledge through experimentation (Bergmann & Magalhães, 2019). More specifically, it is about applying the practices, methods, and tools to help organizations gaining competitive advantage by balancing desirability, feasibility and viability (Baldassarre et al., 2019).

For Meroni (2008), the SD is an approach on making sense in the complexity of contexts that are changing; learn and build skills; as well as, establish a platform of tools and methods to develop investigations. Further, SD is about conferring to social and market bodies a system of rules, beliefs, values, and tools to deal with the external environment, thus being able to evolve and so to survive successfully, as well as influencing and changing the environment too. This is because the transformations in the context of the companies' actions are inevitable and SD offers resources so that they face the challenges of the future, valuing the potential visionary of design to respond to the changing values of contemporaneity.

It is expected that the design may help to develop the most adequate solution to compete sustainably in the future from the learning generated by sincere attempts at innovation, which generate new concepts to be developed by the industries (Bergmann & Magalhães, 2019). Unlike other strategy formulation methodologies, SD focuses on collaboration and orientation to innovation and sustainability as a process, collecting real-time information from sources within organizations as well as external sources, consumers and the market (Meroni, 2008). In this vein, traditional kinds of SD have their place within sustainable design; sustainability transitions also surface the potential for new types of SD in which the interested are the common environmental and social good (Mok & Hyysalo, 2018).

Realff, Ammons and Newton (2000) already stated the need to the utilization of resources become radically more efficient and the SD of reverse production systems would be one strategy for achieving greater material efficiency in the recycling of products back into useful raw materials. Manzini and Vezzoli (2003) argued that the design competencies should move towards the concept of SD for sustainability, shifting the business focus from designing and selling physical products to a system of products and services which are jointly capable of fulfilling specific client demands, while re-orienting unsustainable trends in production and consumption practices.

Product Portfolio Management

In the strategic product planning stage, a company's product portfolio of new opportunities to be launched is generated. The set of these parallel projects is called portfolio or product portfolio (Rozenfeld et al., 2006). The product portfolio designs start with a large number of ideas that become fewer projects, and these a smaller number of products launched (Cooper, 2008). Product portfolio management (PPM) deals with the structured decision process on which projects should be developed within the organization through processes and criteria

(De Castro & De Carvalho, 2010). It involves evaluation activities, identification of new ideas and opportunities, prioritization and the definition of approving or cancelling projects.

During PPM, available resources and their allocations in the projects, the planning horizon and the stakeholders are also observed (Cooper, 2008). In order to avoid issues on selection and decision making, the process and tools to be used for the organization and selection of projects should be clearly defined (De Castro & De Carvalho, 2010). De Carvalho, Lopes & Marzagão (2013) observed that the most cited methods and tools applied to PPM are financial, mathematical programming and statistical models.

Otherwise, with a focus on the choice of projects that meet sustainability criteria, environmental analyses should guide the choices of new product designs (Brones & Carvalho, 2015; Sihvonen & Partanen, 2016). The use of more efficient materials in their transformation, the adjustment of product portfolios and the selection of products, services and products-services systems (PSS) more sustainable are in line with meeting sustainability goals (Marcelino-Sádaba, González-Jaen & Pérez-Ezcurdia, 2015; Vezzoli, Ceschin, Diehl & Kohtala, 2012).

Given the need of environmental sustainability, Brook and Pagnanelli (2014) have suggested the environmental decision considering aspects such as: (i) strategic alignment: projects should be aligned with the sustainability of the company; (ii) brand: projects should strengthen the firm's position in relation to sustainability; (iii) market potential: the projects will allow an increase in market share; (iv) consumer orientation: projects should focus on meeting the needs of customers and market segments; (v) CO2 emission/biomaterials: projects should contribute to zero emission levels, and be based on biomaterials; (vi) leveraging technological capabilities: improving the company's technological capabilities in relation to sustainability.

In addition, to approvals and decisions at a strategic level, portfolio reviews are relevant to verify if projects meet environmental requirements, which may represent an opportunity to improve their environmental impact (Bocken et al., 2014). Just as the top management support, the involvement of the teams in portfolio review contributes to decision-making (Petala, Wever, Dutilh & Brezet, 2010). Besides the technical and economic aspects recommended by Cooper (2008), considering the development of environmental issues during portfolio review gates can be useful as it may contribute, for example, to the alignment of projects with the development of new circular products (Gouvinhas, Naveiro, Perry & Romeiro Filho, 2016).

Circular Business Models

A well-designed business model searches to create value for the company and its customers, as well as stakeholders such as suppliers and business partners. A sustainable business model describes a company's sustainable value proposition to its customers and all other stakeholders, how it creates and delivers this value proposition, and how it captures economic value while maintaining or regenerating natural, social, and economic capital (Lüdeke-Freund, Massa, Bocken, Brent & Musango, 2016). In circular business models (CBM), the economic, social and environmental value of the materials are preserved as long as possible, keeping them in the economic system, lengthening the lifecycle of products they formed or returning them to the system for reuse (Bocken et al., 2014; Joyce & Paquin, 2016; Lewandowski, 2016).

In this new perception, products are no longer something obtained at a cost from the environment in a linear way, but a component of the production process that is designed in a circular way, meaning that resources are initially obtained from the environment, afterward waste becomes itself a resource and it is indefinitely re-cycled in the economic process (Bonviu, 2014). Therefore, CBM attempts to explain how resources, capabilities, and activities are geared to providing a customer value proposition, which represents the benefits offered to customers through products and services to maximize resource efficiency (Bocken, Schuit & Kraaijenhagen, 2018; Joyce & Paquin, 2016). CBM represent an alternative to current economic models of extraction, use, and disposal (EMF, 2015). In circular business, most products that would have been disposed of in the linear model, are re-used e.g. as a raw material. Hence, the value of raw materials is kept within the system for the longest possible time (Bodova, 2017).

Research has shown that CBM and circular economy (CE) are mainly rooted in the environmental ecological economy and industrial ecology (Mendoza, Sharmina, Gallego-Schmid, Heyes & Azapagic, 2017). The concept of the circular economy (CE) has emerged in recent years in response to the need to decouple economic growth from the consumption of environmental resources and impacts (Ellen MacArthur Foundation [EMF], 2015). In order to maximize the efficiency of resources, circular business represents an alternative to the

current economic model with a focus on extraction and use. It may be necessary to build sustainable business models that are consistent with the principles of the circular economy (Bocken, de Pauw, Bakker & van der Grinten, 2016).

In this vein, Geissdoerfer et al. (2016) define circular as a regenerative system in which the inflow of resources and their residues, emissions, and energy are minimized by the slowing, closing and narrowing material and energy circuits, achieved through design, maintenance, repair, reuse, remanufacturing, restoration and recycling. Therefore, post-use design strategies like reuse, remanufacturing, and recycling becomes highly relevant for the circular business as they enable loop closure and influence cost and emissions of operational value recovery (EMF, 2015; Lewandowski, 2016).

In addition, the interdisciplinary structure of circular business offers good prospects for the gradual improvement of current models of production and consumption (Ghisellini et al., 2016). The shift to CBM can require radical changes in production and consumption so that producers, consumers and other stakeholders have important roles to play (Baldassarre, Calabretta, Bocken & Jaskiewicz, 2017). It may be necessary to build sustainable business models that are consistent with the principles of the circular economy (Bocken et al., 2016). These circumstances bring manufacturing companies to an uncertain position when it comes to circular approaches since the potentials of their product design in combination with new CBM are still under investigation (Lieder, Asif, Rashid, Mihelič & Kotnik, 2017).

Theoretical integrative framework

To summarise the theoretical findings, and in order to meet the first aim of this article, it is proposed a framework integrating SD, PPM and CBM perspectives. As it was shown in the literature, the relations between SD and PPM are mainly supported by the concern to the integration of stakeholder objectives, including sustainability issues, while creating new innovative products and business. Regarding on this, SD is an activity that must consider the collective interest and values, define its actions systematically after establishing an orientation through a set of scenarios (Calabretta et al., 2016; Meroni, 2008; Manzini & Vezzoli, 2003). Meanwhile, considering market dynamics and the complexity of decision-making, PPM activities verify the alignment of projects with the strategy of the firms (Jugend & Silva, 2014).

The model proposes that PPM may guide the decision-making process in the set of firms' business model (Kester, Hultink & Griffin, 2014; Kock, Heising & Gemünden, 2015), directing which one should be approved, prioritized, updated or cancelled (Cooper, Edgett & Kleinschmidt, 1999; Kock et al., 2015). As circular design requires a new model or at least a set of principles, strategies, and methods adapted (Den Hollander, Bakker & Hultink, 2017), this proposal may represent an opportunity to integrate sustainability into the business modelling process and to develop new circular business. Figure 1 presents an overview of the framework.

Figure 1 Framework integrating the main perspectives of SD, PPM, and CBM

The framework outlines the main activities inherent to the SD, PPM and CBM scope. Despite this context, there are limitations to the development of CBM due to barriers by both instruments and users, competence and experience in companies, information available of the tools, and the time and resources to select and apply them (Joyce & Paquin, 2016; Van Hemel & Cramer, 2002). The literature presents drivers and barriers to the implementation of environmental tools in business and operations (Luiz, Jugend, Jabbour, Luiz & de Souza, 2016).

Dangelico (2016) Van Hemel and Cramer (2002) and list as main drivers the improvement of the company's image, opportunities for innovation, benefits effectively generated to the environment, improvement of product quality, etc. Among the barriers are technological restrictions, possible commercial disadvantage, greater complexity associated with these projects - which tends to consume more development time, the need for information and the uncertainty of results (Collado-Ruiz & Ostad-Ahmad-Ghorabi, 2013; Van Hemel & Cramer, 2002). To deepen understand the development of CBM and in order to highlight in practice this scenario, a case study was carried out in a biodiversity company, which is detailed in the next section.

Case Study

Aiming to reduce the gap on barriers and drivers in the development of CBM, this research comprised a case study in a leading company in the development of products based on biodiversity, based in Sao Paulo state, Brazil. The research method was considered because besides being a useful approach to deepen the knowledge about certain topics, the case study allows an analysis of the researched situations, since for the accomplishment of the study; interviews, observations and document analysis allow a better evaluation of the context (Myers, 2013; Yin, 2015).

Since this topic has been recently studied (Andrews, 2015; Baldassarre et al., 2019; EMF, 2015; Ghisellini et al., 2018; Jadhav et al., 2019), the qualitative procedure was the most appropriate. According to Eisenhardt (1989) and Yin (2015), the method is adequate when seeking a better understanding of the facts. It was considered important the use of qualitative research with the presence of the researcher in the field, in order to capture and understand the perceptions of the professionals involved in the strategic design, product portfolio and circular practices in the company, and, thus, obtain greater familiarization with the object of study (Yin, 2015).

The company's choice to the case study was made intentionally by the following criteria: (i) to develop and manage a broad portfolio of products based on biodiversity; (ii) to be concerned with the preservation of biodiversity; and, (iv) to provide full access to the researchers. In addition to the criteria that have been met, the company is one of the leaders in the development and manufacture of products made of reforested wood. In order to guarantee the internal validity of this study and to minimize the subjectivity tendency of the interviewee, at first, a formal interview questionnaire was developed.

The guide was based on the literature and, especially, on the research by Brones et al. (2014), which from the case study had the interest to identify how the environmental dimension can be integrated to the management practices of new product development, as well as to identify the challenges of this integration. Before taking its final form, this questionnaire was evaluated and received suggestions for improvements by academics and specialists. The questionnaire was sent by e-mail to the managing director and to the production specialist, a forest engineer, for analysis and knowledge of the agenda. Then a meeting was scheduled in the company's headquarter to conduct an on-site interview with both leaders in which the questionnaire based the conversation and was throughout answered.

During the field research, the director of the company and the production specialist were interviewed, following the recommended procedures for a case study (Eisenhardt, 1989; Gibbert & Ruigrok, 2010). In addition, to enable additional information and the data collection, informal conversations through visits to the different departments and to the factory floor were conducted, besides reading of documents (Yin, 2015). These actions enabled the acquirement of new information and different perceptions regarding on the researched topic.

Company description

The company has been operating for twenty-seven years and currently has about one hundred full-time employees. Headquarter is located in Sao Paulo state, the wealthiest part of the country, and attends exclusively to the national market. It has a product portfolio derived from reforestation wood, being recently responsible for producing a major project of gymnastics equipment, with all basic apparel included, for

governments within more than 400 cities. Besides that, their product portfolio is composed mostly of showers, sinks, tables and peculiar furniture.

Designing circular business models: drivers and barriers

The company's strategy is to operate with environmentally sustainable products and since it is possible to prioritize the development of products that aggregate CBM. For this, the top management drives throughout the activities from the innovative process to the evaluation and selection of product portfolio. As part of the process, revision gates were pointed out as strategic, since they allow to evaluate the synergy degree of projects with the firm's mission, vision, and values. Hence, all decisions about which project will be selected are taken aiming environmental concerning the preservation of native forest, adopting eucalyptus as the main raw material used throughout its portfolio.

By choosing wood for its products, the company strategy is to do not use native wood as a raw material input in any new product design. According to the interviewees, the extraction of native wood significantly impairs biodiversity and, therefore, the company does not develop products that use materials that may generate harmful waste and pollute the environment. Hence, the decision of the top management, on which products to develop, occurs mainly with the possibility of using reforestation wood. Moreover, wood is the main way to apply circularity in business, since the waste is reused in new business models. During or at the end of the production process, the waste is collected and immediately relocated for reuse in new products that have been designed for this purpose. Some examples of these new products identified as new opportunities for CBM are landscaping, stakes for fence support, gravel, besides the own decomposition of the wood for the generation of a natural organic substance, which is also sold as a product.

The dissemination of the goals within the company and positioning in the market was identified as relevant to the firms' business, in addition, the presence of specialists with environmental bias, leading or supporting decisions during the PPM and about the current business models. These factors mitigate environmental risks in projects and can influence the decision-making considering the stakeholders' integration. Also, marketing demand and regulatory pressure were identified as positive to environmental sustainability decisions. The market stimuli refer to the image of the firm, whose vision is to be recognized by the market as a firm friend of biodiversity.

Compliance with legislation occurs because the company must follow standards related to the development and manufacturing of products derived from wood, especially the Brazilian Institute of Environment and Renewable Natural Resources (IBAMA). These factors were highlighted as responsible for generating new business models, since some of its customers seek products from logging companies that are recognized for not harming forest biodiversity. As good practices, it was identified the following steps as relevant: (i) Strategic design; (ii) Raw material definition; (iii) Decision-making processes; and (iv) Product planning. Furthermore, working with the internal and external disclosure of the has proved to be efficient in the process of achieving the company's business.

The company has faced challenges in generating new ideas for creating environmentally sustainable products. A substantial barrier highlighted refers to technological restrictions. Thus, according to the interviewees, since the timber sector is not very dynamic, there are few technological solutions available to aggregate on environmental products. In order to reduce some of these technological barriers, as well as to help in their creative process, the company has already established partnerships with local universities. For example, recently there was a joint effort between the company and professors of the Environmental Engineering at the University of Sao Paulo (USP). It was mentioned that the scenario is different in sectors considered more innovative, such as the electronics industry. However, as a successful case, recently the company approved the development of a new type of shower for swimming pools made of tree the stem, with an adaptation of the plumbing and replacing the common use of iron by wood in the structure of the product.

Discussion

Although the company demonstrates to be concerned about the products life cycle, strategic alignment and the strategic planning presented itself as the most commented items by the interviewees, what supports the literature either on SD (Baldassarre et al., 2019; Calabretta et al., 2016) or on PPM (Brook & Pagnanelli, 2014; Pinheiro et al., 2018) when integrating sustainability into innovation. Environmental aspects foreseen in the firm's strategic plan should promote the practice, being directly connected with the company's mission, vision,

and values (Bocken et al., 2018). That is, for the development of circular business the firm may have included environmental guidelines in its portfolio strategy.

Government pressure and legal issues are commonly recognized by the literature as one of the main barriers to the development of ecological products (Dalhammar, 2016; Van Hemel & Cramer, 2002). Otherwise, it was found that the adequacy of legislation and the adoption of systems could be a strength to the firms. As seen, the company takes advantage not only to enter in new markets but also to strength their image being in line with current legislation and best practices, in case IBAMA and certifications such as ISO 14001. That is, besides disseminating environmentally sustainable practices among companies, the legislation also represents, in this case, a stimulus for the adoption of environmental sustainability into the product portfolio.

On the one hand, confirming previous studies (Dangelico, 2016; Van Hemel and Cramer, 2002), it was observed the technological restriction as a barrier, since there are difficulties in the development and advancement of technologies for the timber sector. On the other hand, the company demonstrates initiatives for the development of these technologies through partnerships either with universities or by monitoring market demand as one of the sources for the process of generating ideas. It reinforces somewhat the literature (Franzato & Campelo, 2017; Marcelino-Sádab et al., 2015) suggesting a decision-making process based on more than one criteria, as well as that radical changes in production, requires the integration with stakeholders in order to develop CBM (Bocken et al., 2016).

In addition, there was a concern with the selection of suppliers due to the need for qualifications at various levels of the supply chain, is a relevant fact as pointed out in the literature (Marcelino-Sádab et al., 2015; Vezzoli et al., 2012). This process may help the company in their creative process and technological availability, since the integration with stakeholders is seen as a practice that contributes to the SD, also to the PPM, being one of the main perspective when developing CBM (Franzato & Campelo, 2017; Geissdoerfer et al., 2016; Lüdeke-Freund et al., 2016; Manzini & Vezzoli, 2003; Meroni, 2008). The reuse of waste as input to the development of new products, as well as the application of leftovers in the generation of natural organic substance presents a strong alignment with some characteristics of the circular economy (Bocken, et al., 2016; Bodova, 2017; EMF, 2015; Geissdoerfer et al., 2016).

In this case, there is no waste in its producton process, besides value being added through the lifecycle of products and even after the use when in decomposition state do not generate impacts to the environment (Bocken et al., 2018). This practice is also in line with the prevention of CO2 emission and use of biomaterials (Bonviu, 2014; Brook & Pagnanelli, 2014), as well as being a regenerative system in which the inflow of resources and their residues, emissions and energy are minimized, achieved through design (Bocken et al., 2014; Geissdoerfer et al., 2016). Table 1 presents the interviewees' comments about the scenario, highlighting some drivers and barriers when developing a circular business.

Table 1 Research variables and interviewees' comments

Variables	*Interviewees' comments*	*Literature*
Cost of production boosters the development of CBM	Mainly because of the total cost of production and the benefits of the entire lifecycle of our products, compared to market options for similar products, where part of them is composed of materials from non-renewable sources, such as polyethylene, concrete, etc. A finished treated eucalyptus product costs on average 50% less than a similar product, produced with wasteful raw materials.	Bonviu, (2014); De Carvalho et al. (2013); D'Amato et al. (2018); EMF (2015).
Stakeholders integration helps the development of CBM	Actions as dissemination of the goals within the company, brand positioning, presence of specialists with environmental bias, leading or supporting decisions, besides being attentive to marketing demand and to the regulatory requirements were identified as positive to environmental sustainability decisions.	Franzato & Campelo (2017); Geissdoerfer et al. (2016); Lüdeke-Freund et al. (2016); Manzini & Vezzoli (2003).

Reuse strategy prevent biodiversity when adopting CBM	When the strategy regards using reforested wood, the area of the forest has been already devastated for many years, so it is a way to preserve the native forest, avoid further deforestation. In addition, there is no waste in our process, besides value being added through the reuse techniques and even after use, the decomposition does not affect the environment.	Bocken et al. (2014); Bonviu (2014); Brook & Pagnanelli (2014); Geissdoerfer et al. (2016); Lewandowski (2016).
Lack of technology hinders the development of CBM	The technology available is stagnated when compared to other similar sectors of the economy. For example in agriculture: extraction, transportation, storage, and traceability equipment are most commonly applied and appear to be in more advanced stages than in the timber industry. Part of market thinks that the company's products have low quality due to the raw material.	Brook and Pagnanelli (2014); Collado-Ruiz & Ostad-Ahmad-Ghorabi (2013); Van Hemel and Cramer (2002).

As can be seen in table 1, another driver mentioned was the total cost of production, which facilitate the company operation. Besides the technological barrier, part of the consumer market sees the products as low quality when compared to traditional market products, due to the raw material used. Nevertheless, working only with eucalyptus from reforestation, is the greatest source of nature preservation, because the area of the forest has been already devastated. Company's' concern with the products lifecycle and the application of reuse techniques in the new products mapped in this study seems to be the main features of circular business model (Bocken et al., 2014; Brook & Pagnanelli, 2014; Geissdoerfer et al., 2016; Lewandowski, 2016).

Conclusions

This study has advanced the literature about SD, PPM, and CBM, contributing to academics by proposing an initial integrative framework on these themes. In addition, in order to reduce the gap on drivers and barriers in the development of CBM in a biodiversity company, a case study was applied in a Brazilian leading company in the timber industry, which develops and manufacture new products made of wood. Hence, this research also advances the practice of areas such as the development of environmental products and circular business since it outlines the results of a case study that shows how to manage more efficiently bio-based renewable resources at the industry level, fostering cost reductions, strengthen competitiveness and protecting the environment.

It is considered that the research problem was answered since it was presented that SD and PPM can develop CBM. At first, SD help managers and companies to define the strategic vision for innovation, designing a concept to transform their business model through a set of scenarios, applying practices, methods, and tools in order to gain a competitive advantage by balancing desirability, feasibility, and viability in its business. SD should integrate sustainable stakeholder objectives, considering the collective interest and values while creating new innovative products. PPM activities support the decision-making process, being responsible for verifying the alignment of projects with firms' strategy and generating new business models through it. In addition, by learning the practices of a leading company that operates with biodiversity, defining inputs that preserve or generate less impact biodiversity, and deciding to develop new products based on the waste of the production process itself, besides its main drivers and barriers when moving forward to CBM.

The case study has added to the literature that one of the relevant drivers for the development of CBM refers to the compliance with the legislation. By developing products derived from biodiversity, the firm adopts legal standards to choose the products that make up its portfolio, which guides decisions such as the selection of raw material to be incorporated in the production process and the concern with its lifecycle. This concern was evidenced by elements such as the possibility of keeping alive soils and forests and with the reuse of waste generated in new products, becoming a circular business model, typical characteristic of a circular economy. As the main barrier to the development of CBM, the technological restriction was mentioned as a characteristic of the timber sector, affecting mainly the front of innovation of the firm. However, partnerships with the professors of the USP has been shown as one of the strategies to deal with this lack.

This qualitative and exploratory research sought a familiarity with concepts of the research gap. However, it is recognized that the empirical results of this study should be viewed with methodological restriction, since, even considering that the case studied stands out in terms of product portfolio that respect biodiversity, due to the limitation of the research method employed the results presented here cannot be generalized. It is understood, therefore, that future research could be carried out in companies that operate in different sectors, environments, and present in developed countries with the purpose of identifying new strategies for the implementation of CBM. In addition, it would be interesting that future research, under quantitative approach verifies with larger lenses this relationship.

Circular Archetypes: a feasibility study exploring how Makerspaces might support circular innovation, within the Scottish textile sector

BALLIE Jen

University of Dundee and V&A Dundee, Scotland
jenjballie@vandadundee.org
doi: 10.33114/adim.2019.03.367

We live in a 'throwaway and replace' culture. Our growing population and demand for new products has placed huge pressures on our planet's resources. The research argues design can play a strategic role in supporting the adoption of new mindsets, methods and models to enhance awareness and understanding of the need to design for a circular economy. This paper provides a practical example. Drawing upon a feasibility study into Makerspaces, it will explore how they might be developed in the future to support circular innovation, within the context of textiles, to address complex issues around material waste. The insights drawn from this research act as a starting point for future work, reflecting on the implications of the methods applied, concluding the circular economy is the same imperative whether people are focusing on ecology, economy or just their own business. Furthermore, it will suggest that design-led approaches play a role in embedding collaborative ways of working to integrate sustainability into the business modelling process.

Keywords: Circular Economy, Design, Fashion, Textiles, Sustainability, Maker spaces

Introduction

This research is aligned to a design-led business support programme titled 'Design for Business' - positioned within the V&A Dundee – a Design Museum in Scotland. Design for Business aims to broaden the current remit and focus of design by using Design Thinking methods and approaches, to enable businesses, organisations and even citizens themselves to tackle complex problems, such as the Circular Economy (CE). "Design is key to circular economy" says Ken Webster (2017) through further quoting Cross (2001) and design thinking, "scientific problem solving is done by analysis, while designers problem solve through synthesis". This is connected to systems thinking and designers can play a role in helping to navigate through complex interactions, iterations and uncertainty (Webster, 2017).

This paper expands upon with insights drawn from a six-month feasibility study led by the author titled 'Re-Mantle and Make', funded by a larger project titled 'Future Makespaces in Redistributed Manufacturing', a two-year research project funded by the Engineering and Physical Sciences Research Council (EPSRC). The feasibility study explored how Makerspaces might be used to support circular innovation, within the context of fashion. To conceptualise a circular supply and demand model for the Scottish textile sector. This research was conducted in partnership with Kalopsia Collective, a micro-manufacturing unit based in Edinburgh, Scotland, with additional in-kind support from several Scottish based textile manufacturers; Johnstons of Elgin, Begg and

Company, MYB Textiles and the Scottish Leather Association, who participated within this research project and contributed further by gifting surplus textile waste from their factories.

Within the context of fashion, one of the most salient challenges facing the sector today is the global impact of the linear take, make, use and dispose model of production and consumption. An unsustainable model for a future that has disappearing material resources, energy scarcity and a society more aware of the human impact on our environments. Through this paper the author explores how the Circular Economy (CE) might offer a new outlook for textile design practice, building upon the work of Goldsworthy (2014) who claims designers need to learn how to adopt a more pro-active, systems-based approach that truly 'closes the loop'. Currently there are limited practical examples and it is unknown if it is truly possible to implement close loop innovation within the textile sector and if so, on what scale? This study aims to explore the barriers and opportunities to this closed loop scenario through piloting a circular model locally, in Scotland.

Through a design-led approach this paper intends to interrogate the concept of the CE and work in partnership across the supply chain to build new networks and connections between different stakeholders and to push the boundaries of linear practices. To explore opportunities for repurposing textile waste that attend to addressing gaps in knowledge and practice, by seeking to directly connect textile and fashion designers with other stakeholders across the supply chain. This will be explored through positing the research question 'How might Makerspaces be used as educational hubs to experiment with new tools, skills, techniques and technology to develop circular design strategies for micro-manufacturing within the Scottish textile sector?'

This paper presents an overview of the feasibility study to explore the concept of a circular supply and demand within the Scottish textile sector, drawing upon emerging insights drawn from key stakeholders across the supply chain. This study focused on the shifting role of the design practitioner by developing a conceptual framework for how Makerspaces might be used to share knowledge, practice and business support for circular innovation. This paper concludes by outlining next steps for this research, with recommendation for how the feasibility study might be replicated within other sectors or expanded upon through further research.

Context

Within the context of fashion, one of the most salient challenges facing the sector today is the global impact of the linear take, make, use and dispose model of production and consumption. Within the UK alone, we dispose of approximately 10,000 garments every ten minutes (Kerr & Foster, 2011), a level of waste that is unsustainable. Fletcher (2008) further estimates that up to 70% of our wardrobe content is inactive use. The linear economy results in an oversaturated and oversized fashion system with big environmental impact (Armstrong at al. 2016), it is imperative that we develop better use of resources and change the system. Garment life cycles have drastically shortened, for example in the UK WRAP (2012) has evidenced that the average time of lifetime of a owning a garment is 2.2 years (Gwilt, 2014). They also highlight that around 30% of clothing in wardrobes have not been worn for at least a year. The fashion industry is an engine for global growth and development. Generating £1.5 trillion in 2017, it employs around 60 million people along its value chain (Ellen MacArthur Foundation, 2017). At the same time the industry uses a large amount of resources and has a heavy environmental impact compounded by the industry's continuing growth.

Fashion consumption needs to transform, the commonly accepted role of design as a cheap resource of ideas, as a profession of beautification, and a powerful marketing 'tool' must therefore be questioned seriously and urgently (Mair, 2017). Today's linear 'take, make, dispose' economic model relies on large quantities of cheap, easily accessible materials and energy. With the world population expected to exceed 8.5 billion people and global garment production to increase by 63% by 2030, this model is reaching its physical limits (Webster, 2017). By acting now, the fashion industry can lead the transition to a circular system that reuses and recirculates products and materials, while offering new opportunities for innovative design, increased customer engagement and for capturing economic value.

Conventional methods of dealing with these issues have been cited as being symptoms based; they have not addressed continuous and rising consumption levels. However, there are garments that physically wear out and no longer function and those that are made obsolete by economics and it is here that it is cheaper to buy a new piece rather than mend an existing one (Fletcher, 2012). What actually happens in the lives of people who use garments should provide stimuli for fashion and textile design and production (Fletcher, 2015). These garments are currently designed in response to regularly changing trends that enable quick profit, rather than radically re-thinking new ways of designing (Niinimäki & Hassi, 2011). Value needs to be placed on consumer

use, attachment and stronger 'user-product', 'user-manufacturer' relationships (Chapman, 2006; Niinimäki & Hassi, 2011) and this research explores this further through 'user-designer' relationships.

Fast fashion only represents one very direct model of material interaction and it is clearly failing to fulfil consumer needs long term. How can we break the cycle of passive consumption to create a more sustainable, durable connection with our clothes? This project challenges the perpetual pursuit to obtain cheap, convenient, carefree clothing. Fashion helps shape our identities and what we wear signifies who we are and what we stand for. But there's something missing. There's a bigger story to be told about the conditions in which our clothes are made, the resources that have been used and the impact they've had on communities. Fashion is about change and about challenging the status quo, which, at present, is about 'more stuff.' In asking how much is enough and looking at elements of fashion that offer greatest delight, citizens and fashion professionals alike are questioning the quantitative approach to fashion and exploring ways in which its qualitative aspects can be brought to the fore (Chapman, 2003).

It is pertinent to challenge the existing paradigm by engaging with citizens themselves, as there is further disparity through disconnection between the designer, the process of manufacturing, and the consumer who is often left unsatisfied long term, which encourages the rapid replacement of products. In a genuinely circular fashion and textile system, design and use would comprise a single whole.

The Circular Economy (CE): Design-Led approaches for closing the loop on Textile waste

The Circular Economy (CE) concept envisions a reformed industrial system promoting resource efficiency by adding value through closed loop resource approaches (Ellen MacArthur Foundation, 2017). Some of these activities can already be observed in Makerspaces giving rise to a speculation on the potential role of makerspaces in a future distributed manufacturing system founded on CE principles. However, many authors argue that both sustainable strategies for product design and business model innovation are needed (Bakker, den Hollander et al. 2014; Brocken, Bakker and De Pauw 2016 and Prendeville et al 2017).

There is an increasing awareness of the requirement for new textile initiatives to be linked with the concept of the circular economy (Goldsworthy and Earley, 2016) However there is a requirement for more innovation tools, practical knowledge and accessible evidence available to provide support. Recently there has been a rise of projects that encourage and support textile and fashion designers in considering their responsibilities as creators of sustainable products and systems, but they have been struggling to comprehend the complexity of the challenges and to know how to go about tackling them in a scalable and economically viable way.

Within the UK, the RSA's Great Recovery programme has focused on the role of the design community in delivering a more circular economy. They highlight the importance of acknowledging that it is not the designer's responsibility alone to change whole supply chains and transition to a circular economy entails four fundamental building blocks – materials and product design, new business models, global reverse networks, and enabling conditions (Lewandowski, 2016). Businesses must also begin to develop design briefs around new business models that take account of provenance, longevity, impacts and end of life (RSA, 2012).

Existing business models for the circular economy have limited transferability and there is no comprehensive framework for supporting every kind of company in designing a circular business model (Lewandowski, 2016) There are very few studies covering how a circular business model framework should look. Most recently, the Ellen MacArthur Foundation has partnered with world leading design agency IDEO (2019) to explore how design might play a strategic role in supporting circular innovation to support systemic change focusing explicitly on the fashion industry. This research aims to learn from this ongoing work and expand upon it further to identify what sustainability strategies, innovation tools and business support is required to cultivate Circular Innovation and to re-think supply and demand on a local scale. This will require new knowledge to support and nurture new understanding of how fashion and textiles can be redesigned in the context of the circular economy (CE).

The Role of Makerspaces and Re-Distributed Manufacture (RDM) in Textiles

This feasibility study aimed to address the practicalities for repurposing textile waste within a redistributed manufacturing system (RDM) – supported by a Makerspace. This was achieved through partnerships with Kalopisa collective and MAKLab in Glasgow who provided access to their facilities, resources and staff. It was important to curate a space for previously disconnected stakeholders from across the textile supply chain to

come together, to interrogate the issue and to identify how they might work together in the future to explore a complex and systemic issues around textile waste.

Through working together these stakeholders engaged in a shared dialogue to consider a more holistic approach for designing and manufacturing on a local scale, and discuss the role Makerspaces might play in a future landscape of sustainable production. Redistributed manufacturing (RDM) involves rescaling global production by finding a multi-scalar (home, city, region, globe) and complementary fabrication ecosystem with a coherent distribution between domestic production, social fabrication, circular fabrication, supply-chains for batch production and global supply-chains (Diez, 2018). The potential of makerspaces in RDM and the Circular Economy was first identified by Prendeville *et al.* (2016). Based on Stewart and Tooze's definition (2018), we use '*makespace'* as *a catch-all term for an open access community fabrication workshop regrouping Fab Labs, Hackerspaces, (Re)Maker spaces and other facilities be described as spaces with a suite of fabrication tools and technologies openly accessible for use by a community.* Maker spaces are perceived as key spaces that actively interact with local (re)manufacturing businesses and public institutions, digital networks and more global institutions to develop a more sustainable redistributed manufacturing.

Makerspaces are commonplace design and fabrication laboratories, where people can access a range of equipment and machines for personal making (Smith et al. 2016). The Makerspace movement upholds the individual as a maker (Toombs, Bardzell, and Nasimento and Polvora, 2016) aligning itself with the values of localism, openness, sharing and collaboration, with the potential for citizen empowerment through making activities as a means to provoke the status quo.

An emergent network is feeding the discussion about the role and diversity of Makerspaces in the textile and clothing industry: the TCBL ecosystem (tcbl.eu) is gathering different stakeholders around seven principles (curiosity, viability, durability, multiplicity, openness, respect and responsibility) and create a network of interconnected labs that they defined as *"innovation spaces for exploration, creativity, entrepreneurship, small production, knowledge and innovation transfer to associate Enterprises and local citizens, where facilities, equipment, learning materials, case studies, business challenges, solutions, and exchange of know-how will be made available."* Analysing the landscape of craft makerspaces, Charny et al, (2017) claims that *"no makerspace has a single focus, rather they combine sympathetic activities to deliver their purpose"*. The activity can vary from activism for systemic or societal change, research and development, community and collaboration, learning for personal development, craft heritage, retail or tourist attraction, learning for professional skills or entrepreneurship, tools and technology.

Manufacturing and value creation are in the midst of a great transition, enabled by low-cost desktop digital technologies and the ability to share information easily and quickly over the Internet (Kostakis et al, 2015). Through new means to support product development costs and foster global communities around products, makerspaces are considered to play a prominent role in this transition. Distributed production is characterised by local production; cloud manufacturing services; flexible production environments capable of creating personalised and customised products; sustainable and resource efficient technologies; and flexibility and agility in production with shorter lead times (Srai et al 2016; EPRSC 2013; Moreno and Charnley 2016). This is because Makerspaces have the capacity to implement short and flexible production and consumption loops as well as reduce transportation (Birchness and Urry 2013) making it a potential enabler of a future CE. Sustainability may be benefitted by distributed production including product longevity e.g. product life extension through emotional attachment, intensification of use through product-service systems; local production with reduced transportation reduces environmental impacts; co-design by engaging users in the early stages of the design and innovation process for responsible decision making about what is produced; and technology affordances with the abilities and technologies to work towards sustainable practices (Kohtala, 2015).

So far, very little research has been undertaken that explores the relationship between makerspaces and circular practices. This is not unique to makerspaces – sustainable innovation requires intervening in what is designed, but also in the 'why': the values, beliefs, visions and objectives of organisations (Dewberry and Monteiro de Barros, 2009). Perhaps because designing with circular practices is challenging there is a lack of exemplars to draw inspiration from.

Understanding the Feasibility of CE for the Scottish Textile Sector

This research aimed to explore the feasibility of circular innovation within the Scottish textile sector by working with three of the largest global textile manufacturers who are based in Scotland; Begg and Company, Johnstones of Elgin, MYB Textiles and the Scottish Leather group. These manufactures played a pivotal role by providing on site access to their factories to conduct research to investigate emerging textile waste streams and to gain insights into how this was managed. They also provided their textile surplus as a resource for the feasibility study and an emerging RDM model evolved to re-think supply and demand within a circular framework.

The premise of the study was to identify new models to explore 'Future Makerspaces in Redistributed Manufacturing (RDM)'.

Developing a Design Brief

Through this research the author positions the Circular Fashion Archetype as a conduit to explore how designers might radically re-think how materials are sourced, designed, produced, supplied and distributed. To produce archetypes to share learning for others to replicate, expand and build upon.

This research endeavoured to learn more about the drivers for cultivating resourcefulness and cherish-ability within fashion and textiles – a term coined by Chapman (2006), but experimentation was required to identify creative methods through which these approaches could be implemented. A design brief was written (see Figure 1 below) to encourage those who participated within the workshops to challenge themselves as designers and citizens alike, to re-think new ways of designing. With a focus on developing concepts with 'designer-user' relationships to consider the cultivation of a new approach to consumption in which the user is provided with an opportunity to learn new skills, knowledge, and is motivated to extend the life or use of their clothing.

Through the design brief the workshop participants who engaged with this study were supported to conceptualise new ideas and the Makerspaces provided the facilities to prototype concepts are they emerged to support sampling and production using the textile waste gifted from the larger Manufacturers.

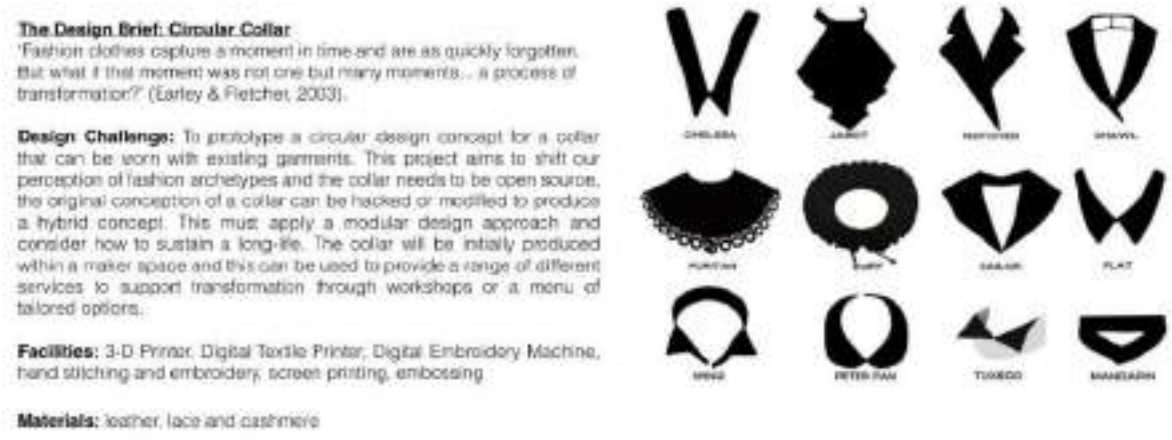

Figure 1 Circular Collar Brief

Methods and Approach

This research followed an Action Research methodology (Coghlan and Brannick, 2014) with methods integrated to support planning, action, observation and reflection. Figure 1 (below) depicts an on-going research process with three key stages: (1) scoping, (2) action (3) evaluation and analysis.

Figure 2 Project Phases

The research methodology is action-led, qualitative and exploratory. An action research approach was chosen as it is flexible and well suited to working within organisations and socio-technological concerns (Robson and McCartan 2015) and the emergent nature of action research (Koshy, Koshy, and Waterman 2010) is seen as well suited to the makerspace context. Bryman and Bell (2015) describe action research approaches as iterative, based on applied problems that require practical results and focus on changing thinking through collaboration. The research process was iterative insofar as the researchers carried out a series of activities in collaboration with a number of key stakeholders which were then reflected upon. In addition, through informal conversations, further insights were gleaned through on-site visits to makerspaces during the study.

Research Activities

The research activities comprised of; field research and factory visits to engage with large Manufacturers to deeper understand systemic issues around textile waste. This was followed by hosted two Make-a-thon workshops within Makerspaces in both rural and urban environments – this provided an opportunity to connect with different stakeholders from across the supply chain and to invite them to input to make recommendations for conceptualizing Circular Fashion and Textile Archetypes.

It was important to nurture lifecycle thinking and both workshops were facilitated to introduce the CE as a concept from the outset.

Stage 1: Assembling a Network of Key Stakeholders

The Scottish textile sector expressed a growing awareness and responsiveness to circular innovation. This could be credited to the work undertaken by Zero Waste Scotland, who had provided a range of training programs and master classes (Zero Waste Scotland, 2014-18) tailored to demonstrate a wealth of different strategies such as design for modularity, collaborative consumption, zero waste design and pattern cutting and material efficiency. The Scottish Textile and Leather Association (STLA) that provides national support for approximately ninety-five businesses of varying scale were also consulted. They made recommendations of manufacturers who might be responsive in donating textile waste and participating within the study.

Stage 2: Sourcing Textile Waste

This project aimed to identify RDM approaches for repurposing textile waste and this would not have been possible without the in kind support from several Scottish based textile manufacturers; Johnstons of Elgin who

donated wool products, Begg and Company who donated cashmere selvedge, MYB Textiles who donated lace and the Scottish Leather Association who donated leather offcuts.

Stage 3: Re-Make-a-Thons

Two Make-a-Thons were hosted within a Makerspaces in both rural and urban environments to explore how the facilities might be used to rework the textile surplus donated from the larger factories. The workshops were divided into three stages; conceptualisation, prototyping and presentation with a feedback loop between each stage to facilitate dialogue and capture insights.

While this paper focuses on the role of the designer, it is worth acknowledging that the workshop participants comprised of; textile and fashion designers, product designers, service and systems designers, consumer behaviors phycologists and Makerspace staff with technical expertise. Through interdisciplinary ways of working it was important to apply a holistic approach and consider the CE from multiple perspectives. Each participant contributed and collaborated to develop their own emerging ideas. This workshop structure supported collaboration and input from additional stakeholders across the supply chain from the manufacturers providing the textile waste, to other local businesses, design students, policy makers and citizens.

Figure 3 Prototyping Circular Archetypes

Figure 4 Discussing Circular Archetypes

The insights captured were clustered using thematic analysis and the following themes emerged:

- **Bringing Surplus Materials to Life:** the quality of the materials gathered were a real source of inspiration for designers but it took time for them to identify new processes to enhance reuse. E.g. This involved punching holes into leather to make it easier for sewing or laser cutting modular shapes with interlocking patterns.

- **Challenging Individual and Collective Mindsets:** due to unfamiliarity with the surplus materials, and the constraints of a designed brief for an open source collar archetype, they were forced to explore new ways of thinking and working. Practically, designers have the potential to unlock hidden potential within supply chains and materials.
- **Space to Make Together:** the Makerspace provided a place to experiment with new techniques and technologies, and to engage with people to focus on community building including public facing activity to broker relationships between different stakeholders.
- **Instilling Circularity**: throughout the project there was a clear concern to embed a circular ethos into the final designs, as well as ensuring quality. The shift towards a circular paradigm is inspired by motives such as new business opportunities, an urge of innovation, greater resilience against future risks and eliminating needless impacts.

Stage 4: Circular Archetypes

Concept Title	Circular Cape	Charm Collar
Brief Description	This cape can be layered together using different fabrics. It can be embellished, reprinted or modified over time. It can also be designed as an heirloom piece to gift across generations or to be shared within a family.	This collar aimed to engage the end user within the design process through co-design. It can be personalised digitally prior to production. With slots for adding bespoke embellishments that can be added, removed and reused overtime. The collar is also designed with fastenings to accompany any garment.
Materials: what materials or resources are required to produce this concept? How will they be sourced? Can the origin be traced? How can life cycles be optimised? What is the end of life strategy?	Open source pattern available via digital download or distribution.	Open source pattern available via digital download or distribution.
Methods: what sustainable design strategy/s have been applied? How is this concept made and what production methods are required?	▪ Design for Long life ▪ Design for modularity ▪ Design for Dissassembly	▪ Design for Customisation and Personalisation ▪ Co-Design ▪ Design for Dissassembly This cape is laser cut and assembled within a local maker space. There are slots for adding embellishments and they could be 3D printed using recycled plastic or other reclaimed materials.
Mindsets: how will you engage with the end user? What changes do you hope to see through the use of this concept? How will you mediate user-design relationships?	This concept explores cross generational skills – can it be used as a conduit to enable a grandmother, mother and child to share skills? The cape could be gifted and transformed aligned to family occasions and celebrations such as birthdays, weddings and anniversaries. A passport or guidebook could accompany the cape and be used to catalogue each lifecycle.	This concept explores personalisation and adaptability for the end user without the requirement of acquiring specialist skills and knowledge. The cape is produced within a Makerspace and accessories could be co-design and commissioned overtime. Therefore, a box of embellishments emerges through use and re-use. This might offer an approach for end users to connect to barter, swap or recreate the

		embellishments. Playing on the metaphor of a charm bracelet.
Model: how is this concept viable – what is the business case? Is micro-manufacture feasible? How is it designed, produced and distributed?	This cape is open source and can be produced using an heirloom fabric, a family tweed or tartan or a plain fabric with special lining. The business opportunity emerges through a bespoke production model. Expanding upon Savile Row and how a family archive is documents and revisited over time. The Makerspace could be used to explore a future tradition around craft and heritage within the context of the circular economy.	Design for Disassembly / Customisation. This cape requires a product service system with Makerspaces playing a pivotal role. The business opportunity emerges around the embellishments and there could be a subscription model.

Figure 5 Circular Archetypes

Stage 5: Showcasing Results and the Round Table

Through both Make-a-thons a broad range of ideas emerged to consider how Circular Archetypes might be produced locally using a CE model. The Makerspaces used to host each workshop also provided insights into what kinds of tools and equipment would be required to support RDM locally. Within this small study a lot was achieved by using a laser cutter, domestic sewing machine and heat press.

The larger Manufacturers did who provided the surplus were invited to preview the results and to offer their feedback on the feasibility of these concepts moving forward. With additional representation from Zero Waste Scotland – a government funded agency with a national remit of reducing waste and advocating circular practices within business, the public sector and to educate citizens.

The Circular Archetype Model (see figure X below) was presented to project partners to demonstrate how their surplus textile waste could be repurposed through RDM. This visual model expands upon the work of the Ellen Macarthur foundation (2017) and provided a visual framework to deconstruct the systemic issues concerning circular materials, products and services. While Makerspaces are situated within the third loop – they could be used to repurpose existing products within their second or third life, or simultaneously to produce new products using waste emerging from first life production. This session facilitated discussion and prompted debate and questions and provocations were used to invite stakeholders to position themselves in product ecologies, where they could have impact and what that impact might be.

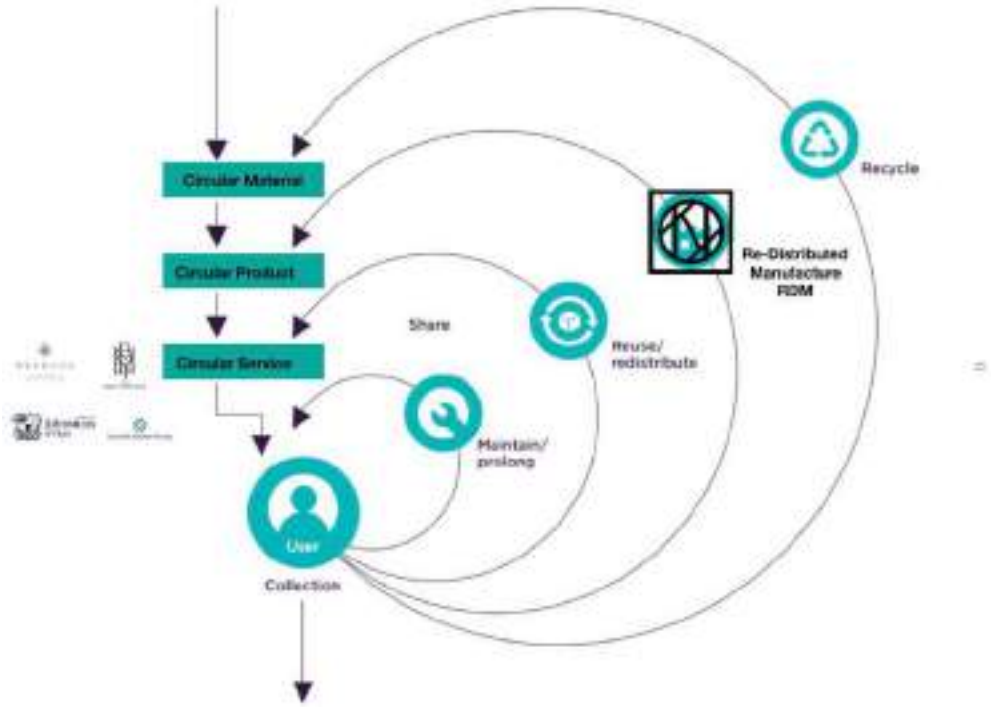

Figure 6 Circular Archetypes and Redistributed Manufacture RDM

Figure 7 Round Table

The insights captured were clustered using thematic analysis and the following themes emerged from the Round Table;

- **Tensions Between Volume and Niche:** The critical difference between opportunistic working with small amounts of surplus to make bespoke items versus operating at scale and the issues with supply, volume and quality of material.
- **Makerspaces Bringing Equality of Conversation:** As a neutral space for conversation, Makerspaces play a key role in democratic engagement with complex issues like the circular economy. They play a key technical role as places for experimenting and prototyping, they also play a key role as places were new ideas can take form and spread.
- **Material Making to Push the Conversation:** Tactile experiments and actually working through the process of designing and making with surplus material bring out systemic issues with implementing the circular economy in textiles.
- **The Questions of Scale:** Tensions between institutions, bringing that out in a democratic forum, evidence from our project, practice based, involved makers and policy and academia and Makerspaces and industry at different scales.
- **Peer Produced Knowledge:** The circular economy could be seen as a knowledge economy, education at all scales (human, industry, societal) is key to tackling the issue. Models and approaches are as important as technical innovation for implementing the circular economy. Will a more transparent distribution of knowledge contribute to a broader distribution of agency in the circular economy and develop new roles and responsibilities.
- **A Whole Ecology Approach:** For a circular economy to flourish and make meaningful change the whole system needs to be aligned to a particular way of working. The actions of individuals and small groups will face issues when colliding with the broader industrial landscape.
- **Roles and Responsibility:** Who is responsible for enacting the circular economy and how can agency be distributed through the system?

Results / Findings

This study provided a different lens through which to view RDM for the CE from a textile design perspective, with materials sourced from large scale industrial textile manufacturers who service a global fashion industry. While emergent, the Circular Fashion Archetypes provide stimuli to facilitate circular conversations to continue to discuss how we might expand upon the role, skills and capabilities of the designer in the future to equip them to operate within a circular economy.

Discussion

In this research, we see how connecting different stakeholders from across the supply chain is instrumental in supporting circular practices. However, the research unearths many contradictions in the current narrative about circularity in Makerspaces. For instance, the business focus of the CE, and the required Sustainable design strategies will require intensive resource management to implement a RDM system for local textile economies.

The feasibility study also raises further questions about the willingness of businesses to collaborate with both independent designers and makerspaces in the future. Many makerspaces are not financially self-sustainable. For this reason makerspace managers and founders themselves see a role for government intervention for issues related to sustainability and emphasise the important external factors that restrict their capacity to ‘act’ including consumer behaviour, market forces, policy and government legislation.

Sadly, since the initial study MAKlab a project partner and makerspace based in Glasgow has closed.This is illustrative of how circular makerspaces face many similar challenges (cultural, behavioral, organizational, technical, infrastructural) to sustainable innovation implemented in ‘mainstream’ design and manufacturing realms. The work of Zero Waste Scotland and similar public agencies will be essential in supporting joined-up approaches and the implementation of new practices.

Makerspaces are subject to rapid change and are not heterogeneous; therefore, the results may not be representative, but rather offer insights to a particular set of makerspaces at a given point in time. More research needs to be undertaken in this area and the following are recognised here:

- What processes, people and projects are synonymous with Circular Innovation – and how might new projects be identified to explore the decisions being made and the necessary guidance needed?
- What outputs are being produced, what facilities are required within the Makerspace and within its local and global ecosystem? This includes an audit of emerging waste streams.
- What tools and methods are required and how can they support designers, Manufacturers (Mirco and Macro) and SME's within the Circular Economy (induction manuals, signage packs, online resource, processes for mapping local resources)?
- What are the training needs of these individual and what is required to catalyse Circular Practices (guidance, know-how, leadership skills) to overcome challenges they face?
- Further clarification on what is meant by re-distributed production and how it can emerge from different types of Manufacturers needs to be better understood?
- Additional mechanisms and incentives to drive local re-distributed production need further exploration in terms of legislation, education and technology.

This paper highlights the importance of acknowledging that the circular economy goes beyond the capabilities of specific design disciplinesIt is a joint responsibility that cannot be undertaken in isolation (Goldsworthy, Earley, 2015). This will require the input of material scientists, business experts, waste managers and policy makers alongside other stakeholders and those undertaking roles that have not yet been identified. Practically, designers have the potential to unlock hidden potential within supply chains and materials (Whitty, 2018). Throughout this research, the author/s engaged with a large cohort of innovative Textile Designers based in Scotland who struggle to access new materials or RDM and business support due to the small scale of their business. However, while the research reveals immense opportunities to cultivate circular literacy from within Makerspaces, while emerging, this feasibility study provides a framework to facilitating circular conversations to continue to discuss how we might expand upon the role, skills and capabilities of the designer in the future to equip them to operate within a circular economy. Widespread unfamiliarity with the materials, and the constrained designed brief of an open source pattern collar, forced new ways of thinking and working for participants. With diverse stakeholders coming together in such circumstances enhanced skill sharing and a faster process of prototyping within a CE context. This also informed considered design outputs that weren't just designerly, but intended to inspire others tension in responsibilities from consumer to industry, makerspaces traversing audiences to change habits and mindsets around consumerism.

Conclusion

The CE is the same imperative whether people are focusing on ecology, economy or just their own business. Simply deciding that it must happen creates new spaces for ideas and action on a relevant scale of ambition. As policy and legislation influences businesses to re-evaluate how they manage, maintain and dispose of their waste streams, new business opportunities are beginning to emerge. But this will require knowledge exchange to support joined-up thinking to connect all stakeholders involved in the lifecycle of textile material journeys and new supply chain models. The RDM approach aimed to foster a joined-up approach to innovation to align emerging outputs to the principles of the CE and endeavoured to preserve and enhance natural capital, optimise the use of resources and foster system effectiveness by designing out wastefulness.

It is as important to know how to take things apart, as it is to design to design them. This is a new challenge for industry, business and designers, but also for consumers, who need to critically consider their own consumption practices. We have to create a new consciousness towards the use of clothing and introduce new practices for using our clothing longer, maintaining it well, but also investing in a smaller wardrobe with less content.

This study provides an opportunity for textile designers and students to experience the concept of the CE through participating within a practical intervention. Discussion was facilitated to challenge existing perceptions and prompt conversation around circular innovation to re-think design, production and use. The CE can provide a new lens to preview how we as designers would like to experience fashion. Research and development is beginning to help design and the textile industry to understand the value, viability, scalability and role of circular approaches in the future (DeCastro, 2014).

The adverse societal impacts caused by sharing mobility - a form of service-based sustainable business model innovations, showed that operation activities and managerial practices impact heavily on the sustainable value of a service offering. To identify how new service development (NSD) activities can better support the proposed service offering for sustainability, evaluating sustainability of service operations is needed. This study draws learnings from service design, product-service system and sustainable innovation research streams, to build sustainability evaluation framework into service blueprint. Six expert-interviews and two mobility case studies were developed, to illustrate service blueprint's capability in mapping sustainability input and benefits created during NSD and service operation activities. Results revealed a) the shift from using sustainable 'value' to 'benefits' concept in service operation evaluation, b) the public-private collaboration dilemma and c) the agile NSD and sustainable innovation incompatibility. This paper aims to offer a springboard for practitioners and researchers to uncover compelling insights, discuss latest service design developments, and envision future directions for integrating sustainability into service-based business model innovation.

Keywords: Service Innovation, Service Design, Sustainable Business Model Innovation, Sustainable Value Co-creation, Sustainability Evaluation Tool

Introduction

As environment and resource risk continue to challenge the world, a significant number of interests turn to how sustainable innovation (SI) drives economic growth while improving environmental and social performance (Boon et al., 2013; Charter and Clark, 2007). Recent years, rising service-based innovations have dominated the sustainable innovation in mobility activities, providing mobility services through collaborative consumption (Botsman and Roger, 2010; Morozov, 2013). Based on service-dominant logic, services are value networks (Vargo and Lusch, 2006) that presuppose social actors to be integral to the processes of service production as well as consumption. Thus, this brings to question how the implementation of collaborative organisational processes, activities and operations, impacts the proposed service offering and experience (den Hertog et al., 2010; Janssen et al., 2015). It is also unclear, how actors within a service operation co-create sustainable values in the delivery of service offering (Boon and Mendoza, 2010).

This gap is particularly visible in the mobility sector with the rise of sharing economy (e.g. peer-to-peer ridesharing and delivery). While the design of mobility service offering utilises assets through collaborative consumption, there is more and more attention drawn to rideshare services' unclear management policy of workers' rights and responsibilities, as well as the commoditization in aspect of life. With the blurry definition

of collaborator, the rise of rideshare became controversial and caused adverse societal impact in the service operation (Cohen and Kietzmann, 2014; Schofield, 2014; Morozov, 2013). Since sustainable innovation (SI) refers to product, processes or services that increase Triple Bottom Line (TBL) economic, social and environmental values in their production and consumption activities (Charter et al., 2008; Charter and Clark, 2007; Elkington, 1998), there is a need for evaluating the mobility service operation activities to identify how mobility service development process can be improved to better support its' proposed service offering for sustainability. This raises a question of how existing sustainability evaluation tools address and help service innovation and its' involved actors to integrate sustainability at every stage of the new service development (NSD) and service operation journey.

In the existing literature, sustainability, service and innovation have been the subject of much research and discussion (Calabrese et al., 2018; Chou, Chen and Conley, 2012; Vezzoli et al., 2015; Martin, 2016; Botsman and Roger, 2010; Cohen and Kietzmann, 2014; Yu and Sangiorgi., 2018), yet to the best of our knowledge no research has focused on how service design evaluates service actors' co-creation of sustainable values in NSD and service operation. Amongst the limited sustainability evaluation tools developed in the past literature, relevant literature scattered across three streams of research in service design, product-service system (PSS) and sustainable innovation (SI), focuses on different sustainability and innovation dimensions (Calabrese et al., 2018). The observed phenomenon within mobility sector points out an emerging field of service innovation for sustainability, which embraces multi-dimensional innovation across system, design, technology, organisation and customer in all three streams of research (den Hertog, 2000). Sustainability evaluation within service innovation in mobility needs to draw learnings from the three streams, develop practical tools that holistically address TBL sustainability and support the maturity of service innovation development for sustainability.

In this study, we investigate the potential of using service design's operational planning tool to evaluate service operation activities against proposed service offering for sustainability. We first review the service design and innovation literature, sustainable value creation and dynamic capabilities for sustainable business model innovation. Concept of uncaptured sustainable value within PSS stream (Yang et al., 2017) and the collaboration principles within SI stream (Curșeu and Schruijer, 2017) are reviewed, integrated into service operation planning tool - service blueprint and evaluated with industry experts for its' usability in practice. Then, the revised sustainability evaluation service blueprint is applied to two mobility case studies, to identify insights of what operation activities offer opportunities to innovate for sustainability. The results further conclude with implications in practice when using service design to facilitate sustainable values creation in service development process (Yu and Sangiorgi., 2018).

Service Design for Sustainable Innovation

In recent years, more and more sustainable business model innovations focus on providing services, in order to capture sustainable value through collaborative consumption (Cohen and Kietzmann, 2014). This view revealed that service is understood as a perspective on business, instead of simply a form of goods (Edvardsson, Gustafsson, and Roos 2005; Vargo and Lusch 2004).Therefore, a rising Service Design logic is being considered as SI's design and management strategy for its' suitability to deal with complex situation with multiple actors involved (Chou, Chen and Conley, 2012; Baldassarre et al., 2017; Prendeville and Bocken, 2017; Tukker, 2015). Service design is rooted in human-centred design, focus on problem solving with iterative design process (Stickdorn, Schneider and Andrews, 2011). Its' design process keeps customer journey at the heart and looks at end-to-end holistic service operation, as well as front and back service support at the same time (Sangiorgi et al., 2012). Through engaging actors with empathic design methods, service design discovers, identifies and addresses their concerns with service design and process reconfiguration (Segelström, 2013; Schmiedgen and Management, 2011)

Numbers of widely-used and effective tools have been developed to help service designers to sense make, discover and conceptualise new perspective on a particular service. In particular, service operation planning tool - service blueprint visualises a service user's experiences through different touchpoints, details their service interaction with front and back service support throughout the end-to-end journey (Stickdorn, Schneider and Andrews, 2011). It focuses on visualising user-interaction, relationship analysis and service experiences through multi-actors perspectives. Revealing the fundamental service design thinking to sense-make, organise and reimagine complicated relationships and interaction within a particular service, for an intended outcome (Dorst, 2015; Verganti, 2011, 2014). Through visualisation of service blueprint, it maps out how actors within a particular service interact. This means service blueprint key contribution is providing

visibility on complex service operations. Therefore, focusing service operation visualisation against sustainability evaluation requires a framework for evaluating service actors' sustainable value co-creation during operation. This draws the investigation of sustainability evaluation to product-service system and sustainable innovation literature, in order to discuss and integrate learnings into the development of sustainability evaluation for service operations.

Existing Sustainability Evaluation Tools

In the search of existing sustainability evaluation tools, we have found that many tools focus on evaluating the design of sustainable business model Innovation (BMI), its' value proposition and its' innovation process (Bocken et al., 2013; Evans, Rana, and Short 2014; Yang et al., 2017). Value mapping tool (Bocken et al., 2013; Evans, Rana, and Short 2014) evaluate BMI sustainability issues against internal and external stakeholders such as environment and society. Sustainable value analysis tool (Yang et al., 2017) focused on identifying the uncaptured sustainable values for stakeholders across the product life cycle, then translate them into opportunities for Innovation reconfiguration. These tools focus on analysing relationships and value exchange within a BMI, in order to improve value creation at the design and innovation process of BMI. Through the BMI perspective, these tools evaluate on the concept of how sustainable value can be delivered through a business, yet the perceived limitation of BMI perspective lies in its' capability to translate into practical business action (Prendeville and Bocken, 2017). This implies that these sustainability evaluation tools also have the limitation on evaluating the organisational and managerial sustainability impact in practice.

Amongst the two tools mentioned, sustainable value analysis tool (Yang et al., 2017) incorporates the perspective of product service systems (PSS) and establishes its' evaluation on product lifecycle, in order to bridge the evaluation gap between design concept of BMI and PSS development process. However, due to a number of factors, such as internal culture, organisational capabilities and the demand in multiple actors collaboration, PSS perspective still has its presupposed barrier to holistically evaluate the phenomenon of service innovation in the sharing economy (Tukker, 2015; Vezzoli et al., 2015). The comparison of these core concepts revealed the need to examine the practical organisational and managerial capabilities, in order to address the sustainability impact incurred in the service operation.

Organisational and Managerial Capabilities for Sustainable Value Creation

The importance of practical organisational and managerial capabilities is well defined in the literature of SI. According to Inigo et al. (2017), these are core-elements to co-creating social and environmental sustainable values in operations, as well as creating successful BMI (Mezger, 2014). In particular, the organisational capabilities needed for sustainable value creation involves understanding their own interaction with external set of activities in knowledge creation, stakeholder engagement and technological innovation, then utilising them with their own internal resources. This outlined two types of practical organisational and managerial capabilities, see table 1:

Table 1. Organisational and Managerial Capabilities for Sustainable Value Creation (Inigo et al., 2017)

Organisational and Managerial Capabilities for Sustainable Value Creation	
Capability in collaborating for sustainability	Close stakeholder dialogue and community participation leads to continuous learning and adaptation to the dynamics of TBL sustainable value creation
Capability in transforming operational activities for sustainability	Technological transformation of organisational structure and system activities creates TBL sustainability values for social actors involved

This draws the focus on investigating what's required for organisations to develop collaboration and transform operational activities for creating TBL sustainability values.

Capability in Collaborating for Sustainability

Achieving SI requires the collaboration between social actors involved in the particular innovation (Boons and Mendoza, 2010). Collaboration with multiparty enrich the knowledge pool and the comprehensiveness of sustainable value creation process. Through the collaborative process, actors explore their interdependencies, use their expertise and knowledge to integrate and influence the sustainability decision making outcome (Curșeu and Schruijer, 2017). It was discovered that the decision quality increases when social actors' diversity of interests is expressed through information sharing and exploration, while decision quality was compromised when social actors' diversity of interests was not acknowledged in the value creation process (Fadeeva, 2005, p173). Therefore, collaboration for sustainability considers the design of the internal structure with stakeholder interactions (Inogo el al., 2017). In which, scholars of stakeholder engagement in sustainability suggested three constructive collaboration principles that are crucial to capture actors' interest diversity and foster inclusive and sustainable value creation environment, see table 2 (Cox et al., 2010; Curșeu and Schruijer, 2017).

Table 2. Constructive Collaboration Principles for Sustainable Value Creation (Curșeu and Schruijer, 2017)

Constructive Collaboration Principles	*Example/Prompts*
Inclusive Stakeholder Selection	Are there tools in place to remove power disparity and assist peripheral stakeholders to voice their concern, in order to avoid biased selection of particular stakeholders and create sufficient representation of power dynamics between multi-stakeholders?
Normative System for Collaboration	Are there ground rules to build constructive task conflicts and engage in healthy debates, for enabling comprehensive problem formulation and cross-understanding of diverse viewpoints?
Process Consultation	Are there tasks consultation with multi-stakeholder during the process, to stimulate the emergence of trust, psychological safety and prevent collusive dynamics?

Capability of TBL Sustainable Value Creation in Operational Activities

On the other side, achieving technological sustainability transformation in organisational structure and system activities, consider how to harness the uncaptured TBL values within product lifecycle (Chou, Chen and Conley, 2012; Elkington,1994; Plepys et al., 2015). This implies that open and uncaptured perspective is crucial for sensemaking sustainability in product service lifecycle (Rauter, Vorbach and Baumgartner, 2017). Through focusing on the negative form of values, a reversal thinking was suggested, shaping focus for conducting complex sustainability research (van Veggel, 2005). It was suggested that the four forms of uncaptured values (Yang, 2016; Yang et al., 2017): value missed, value surplus, value destroyed and value absence can be utilised to discover, identify and articulate the comprehensive TBL values, which are not currently captured in the business model and its' product service lifecycle, see table 3:

Table 3. Adopted from Four Form of Value Uncaptured of Yang et al. (2016)

	Definition	Example/ Prompts
Value Missed	Something exists that is not exploited.	· Are there tangible or intangible resources that are underutilized? (e.g. capital assets or human resources?) · Is the business creating value in some form that it is failing to capture? (e.g. through the better use of data to enhance service?)
Value Surplus	Something exists that is not required.	· Are there excessive benefits? (e.g. overproduction, excessive service functionality?)
Value Destroyed	Something exists that undermines value.	· What are the negative outcomes of the business at each lifecycle stage?

		· Is there a potential or perceived risk of value being destroyed by continuing customary practices? (e.g. a risk of time to market?)
Value Absence	Something required that does not exist.	· What tangible and intangible needs of the company and its stakeholders have not been realized?

Through this identification process, organisation can transform the uncaptured TBL values and turn them into innovation opportunities. Yang et al. (2017) also used this uncaptured TBL values to develop Sustainability analysis tools (see figure 1), provided an effective step-by-step structure in analysing how captured and uncaptured TBL value incurred within the product life cycle. The step-by-step structure analyses value captured, then value uncaptured, for all stakeholders throughout the product life cycle. Through identifying the negative form of value, the analysis tool assists the discovery of new TBL value opportunities. It helps complex operations to take the initiative in understanding how their product life cycle can be optimised for sustainable value creation.

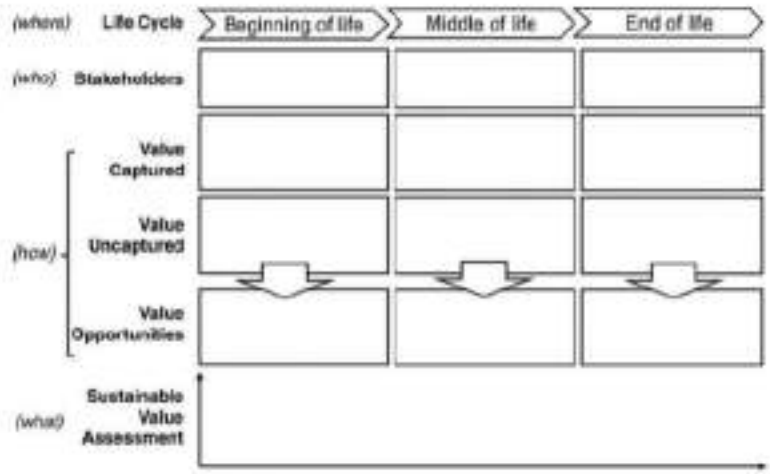

Figure 1. The Sustainable Value Analysis Tool (Yang et al., 2017)

Preliminary Sustainability Evaluation Service Blueprint

After the investigations above, we can see that achieving sustainable value creation in Service-Based Business Model Innovation requires not only the maturity in the operational and managerial capabilities. Most importantly, organisations need to understand the external environment of knowledge, stakeholder engagement, technologies and utilising them with internal resources for TBL sustainable value creation (Inigo et al., 2017). This points out the importance of sense making an organisation's design concept of BMI for sustainability, PSS development process and practical service operation. To do this, it is crucial to develop strategic and practical evaluative tool. A tool such as the service blueprint, which has capability in 1) providing visibility to the complex multi-actors service operations (Stickdorn, Schneider and Andrews, 2011); and the flexibility to sense make specific knowledge, such as 2) understanding the existing structure of stakeholder interaction during service operation, and 3) understanding the uncaptured and captured TBL values within existing product-service lifecycle (figure 2). Therefore, here we synthesise the literature findings and describe a preliminary sustainability evaluation service blueprint.

Identifying the New Service Development (NSD) and Service Operation process

Since the aim of the blueprint was to evaluate how the service was iterated and developed throughout the NSD and service operation process. Therefore, identifying the process to be blueprinted was the first priority (Shostack, 1984). The investigation would start from specifying physical evidence (service experience lifecycle), where the aim is to understand what iterations the service experience lifecycle has gone through (e.g. alpha, beta, launched version). Then, it goes deeper to look at what interactions are needed both digital and physical that support the customer interactions in each of these development phase. when are they aware of this

service? When do they join into test and feedback the product? And what are the relations between customers feedback and subsequent NSD activities?

Criteria 1: Evaluating Collaboration for Sustainability

As the blueprint develops, it revealed the different internal actors involved in the NSD activities. Therefore, it is also important to investigate who are the external actors that have been supporting the service development: How were they involved? What are the relations between external actors' feedback and subsequent NSD activities? The investigation of the above provided visibility to NSD activities, reveal silos and areas of opacity in existing service, as well as the complex and intricate relationships with different actors.

By evaluating how collaboration was conducted at each level and each step of the service operation, it allows us to analyse the comprehensiveness and the quality of the sustainable value creation process. It aims to identify whether there's a bias selection of stakeholders, there's a system for healthy debate and whether collaboration process was consulted with stakeholders to avoid collusive dynamics (Curșeu and Schruijer, 2017).

Criteria 2: Evaluating TBL Sustainable Value Creation in the Operational Activities

More importantly, this rich information enables the latter part of the blueprint to carry out sustainability evaluation against the exploited and unexploited TBL benefits. For example, one can specify how the service exploited TBL benefits in alpha version, which would be made comparable to the service's launched version. This then provide insights into whether NSD activities has been optimised for sustainable value creation.

By evaluating what uncaptured TBL values (value missed, value surplus, value destroyed and value absence) exist at each level and each step of the service operation, it allows us to determine whether there are activities underutilised in service operation; there are activities exist that do not align with TBL values; there are activities align with TBL values which was destroyed in the process of service operation; or there are activities that do not exist yet required, in order to align with TBL value creation in service operation (Yang et al., 2016).

With this thorough analysis, the blueprint then provide visibility towards what and how TBL values were created during NSD process and service operation. Enabling organisations to see the gap between design of service offering for sustainability and the delivery of sustainability during service operation, then reconfigure its' service operations' activities and managerial practice accordingly. This evaluation blueprint aims to function as the first step to sense making - internalising the environment of knowledge, stakeholder engagement, technologies of existing service for sustainable value creation (Inigo et al., 2017).

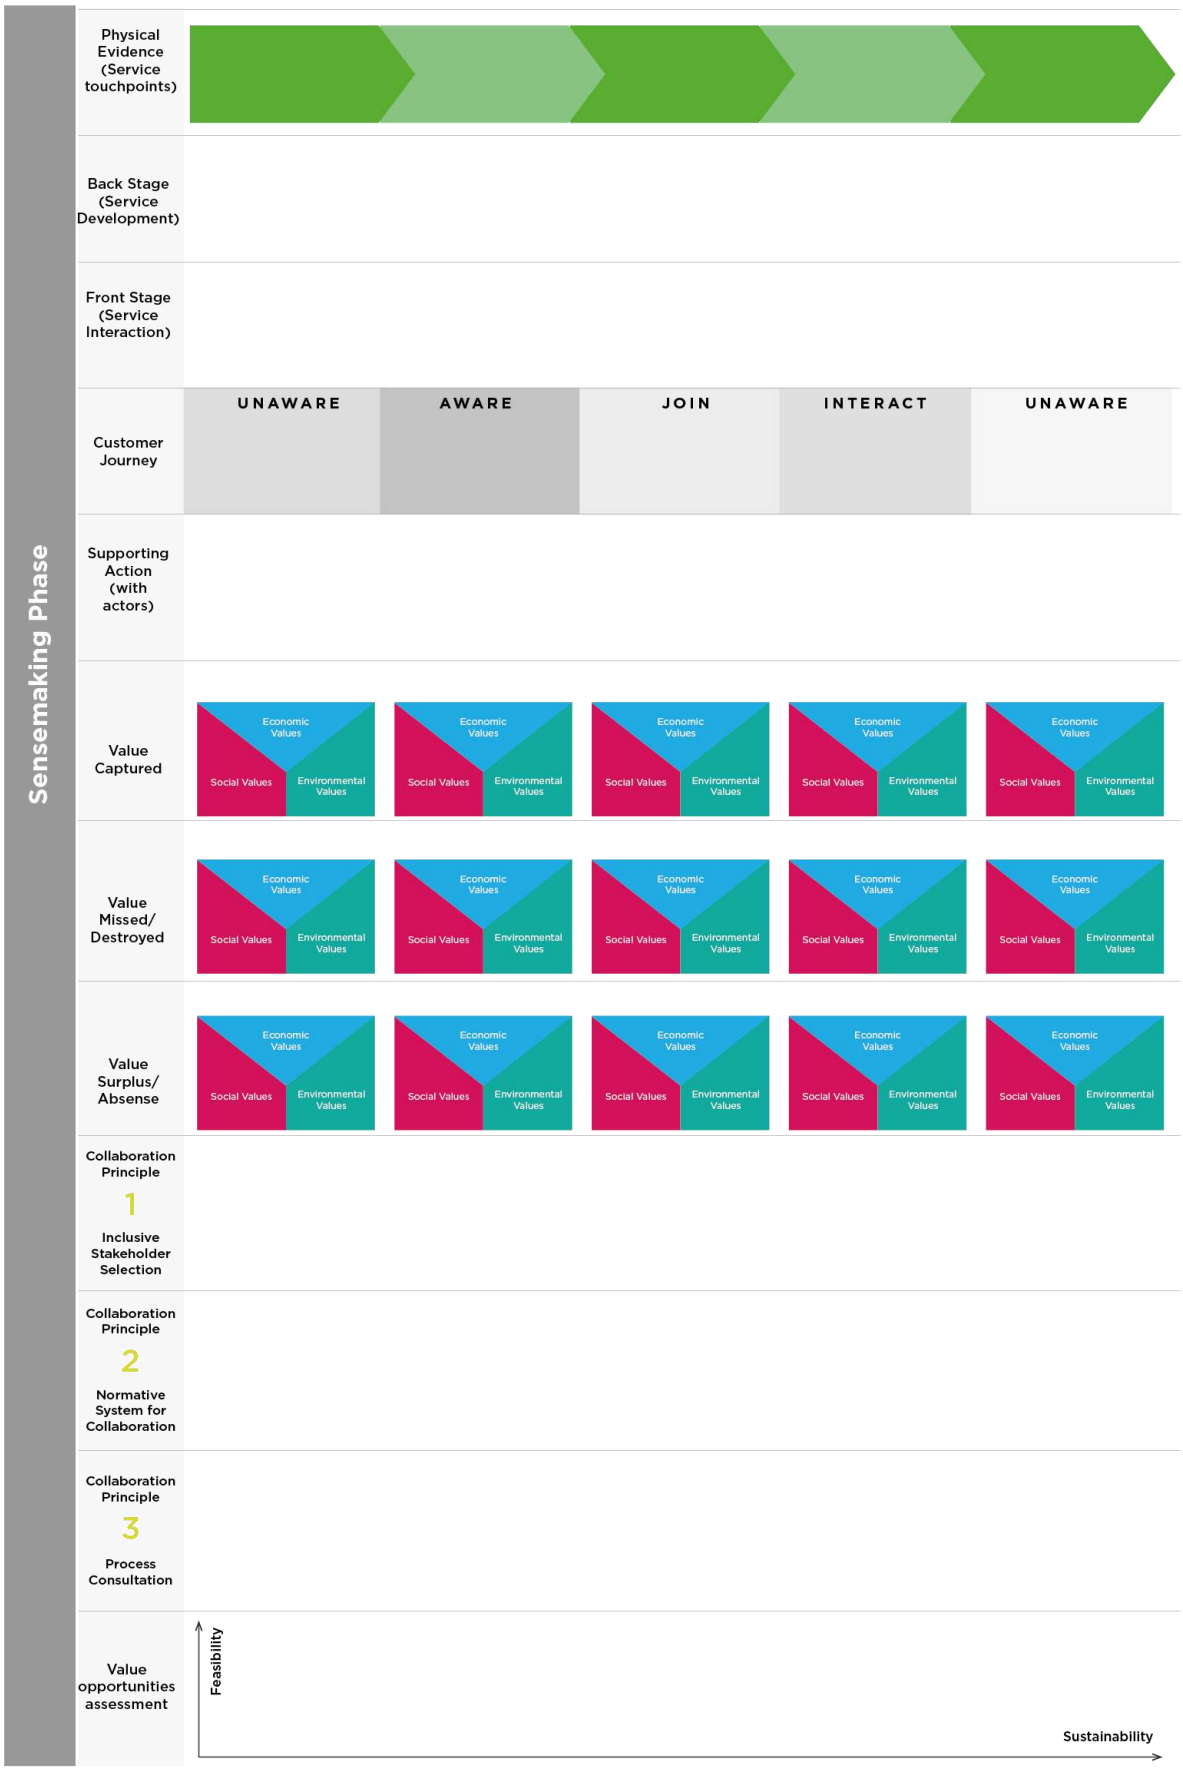

Figure 2. Preliminary Sustainability Evaluation Service Blueprint

Methods

This research is exploratory and uses the literature review to generate a preliminary blueprint. To provide insights into the service innovation as sustainable BMI phenomenon, our research design involved six expert-interviews for preliminary blueprint validation and desk research to generate two case studies in mobility sector (Bailey, 2010; Yin, 2003). Furthermore, it explores the actual practicalities in using the synthesised blueprint. See process diagram (figure 3.) below for methods used in each stage of research:

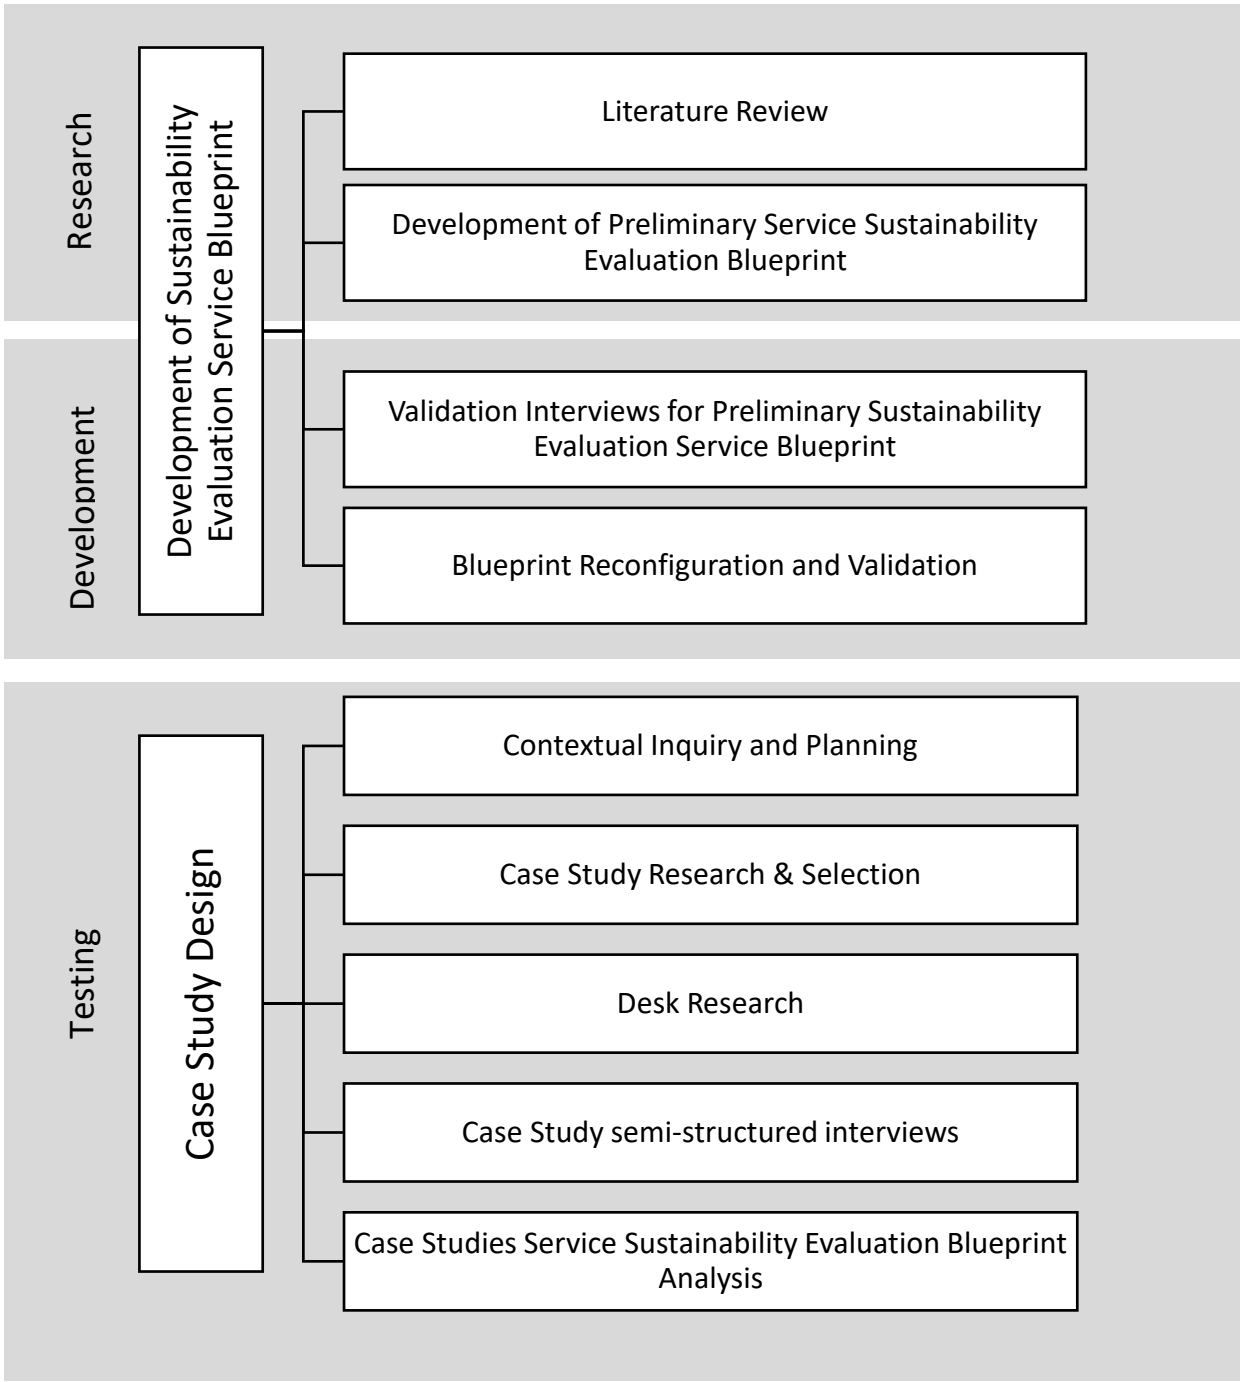

Figure 3. Research Methods Process Diagram

Development of Sustainability Evaluation Service Blueprint

A preliminary blueprint was synthesised from literature review of three research streams (service design, PSS and SI). As literature review and contextual inquiry pointed out that sharing mobility services is a newly emerged phenomenon, sustainability evaluation service blueprint can potentially be used by actors involved in all three streams of research. Therefore, semi-structured interviews were conducted with six actors involved in service design, PSS and SI. Upon completion of blueprint evaluation and validation, contextual research and interview insights were drawn. As information was vast, applicable information were sorted into clear categories using an Affinity Diagram, which allows key feedback to be addressed and summarized for revising the blueprint, see process diagram (figure 3). Iterated blueprint (see figure 5) was updated after discussion and feedback from expert interviewees. To test the iterated blueprint, case study method is determined to be an appropriate method for explorative research and observing phenomenon (Bailey, 2010; Yin, 2003).

Case Study Design

Figure 3 specified the process of using case study method to test and demonstrate the Sustainability Evaluation Service Blueprint. An initial desk research was conducted to highlight mobility services in sharing economy as sustainable innovation phenomenon (Botsman and Roger, 2010; Hyard, 2013; Cohen and Kietzmann, 2014). Citymapper Smart Ride and Ford Chariot were selected based on the criteria developed under desk research of Sustainable Mobility in the UK (See Table 4). Industry related documents and reports were reviewed and studied to establish an understanding of UK share mobility service industry practice, goals and strategies. To understand how multi-party actors contribute in sharing mobility service as sustainable innovation phenomenon, three experts interviews were conducted to provide insight for the investigation.

Table 4. Criteria for Case Studies Selection

Criteria	*Determined by:*
Clear intend to develop disruptive mobility innovation that meet TBL values:	Identifiable TBL values developed based on publications and recommendation by experts.
Social value	Satisfy the essential mobility needs of the people through promoting equality use of open data (Rose, 2017).
Economic value	Offers affordable, functional and efficient transport solutions that support economic development (Chariot, 2018; Citymapper, 2018a).
Environmental value	Limits carbon emissions and pollutants through utilising assets and resources (Chariot, 2018; Citymapper, 2018b).
Accessibility	Observable to researcher - operates in London, UK

Two selected mobility case studies were mapped using the Iterated Sustainability Evaluation Service Blueprint. Data about case studies was collected via desk research and expert interviews with share mobility service actors. While this analysis is not intended to be exhaustive, it aimed to illustrate how service operation's TBL values can be visualised using the conceptual Sustainability Evaluation Service Blueprint.

Limitations

The synthesised blueprint was evaluated by a small study sample of participants and experts, where it may be limited to its diversity and bias. Furthermore, the analysis examined the concept of the blueprint through exploratory case study approach, where wide range of public documents, research, articles and interviews were reviewed to address the phenomenon (Yin, 2003). Yet, the effectiveness and contribution of the synthesised blueprint has not been evaluated, which pointed out potential areas for future work in this topic.

Results

Blueprint Iteration and Validation

Thematic analysis was conducted using Affinity Diagram, where comments that are repeatedly mentioned by the experts during the interviews were written down on post-it notes, then sorted into different categories. Following this display of insights, key feedbacks could be identified:

1. **Varied collaboration principles comments depending on actor's commercial and non-commercial industry nature**
2. Time is a big concern for commercial actors to establish inclusive stakeholder selection and process consultation principles
3. **Confusing language of 'value' in sustainable values concept and uncaptured value concept**
4. **Facilitation is key to establish normative system for collaboration**
5. **The preliminary sustainability evaluation service blueprint lack facilitating guidance**
6. Contradictory comments in Inclusive stakeholder selection, where unexpected stakeholders delay timescale, but getting people involve is difficult
7. Tendency to select stakeholders based on running relationships and immediate network

The highlighted feedbacks above were particularly relevant in guiding the next stage of blueprint development. These feedbacks are categorised into the three themes below:

1. Facilitation is key to service blueprint swim lanes, yet there's a lack of facilitative question and prompts

The different terms of uncaptured values are difficult to understand and explain. As the 12 swim lanes investigations underlined the potential requirement of holding a series of stakeholder research workshops, to understand existing service, actors involved and how the collaboration was carried out. Therefore, interviewees suggested that plain English would be easier to understand. Also, facilitative questions linked to the swim lane would be preferable for facilitating workshops amongst actors (e.g. customers, front end staff, back end staff, external actors, etc). Interviewee commented:

> *'You only have that one opportunity in a workshop setting to get as much information as you need…you would want to plan for the entire facilitation, so you get what you want from them' (User Experience Designer, Commercial Design Consultancy).*

Therefore, prompted questions are created for the reconfigured blueprint based on Yang et al. (2017) facilitative question, see table 5.

2. From Values to Uncaptured Inputs and TBL benefits

Interviewees find the term value confusing between 'sustainable values' and 'uncaptured values'. Interviewee commented:

> *'I don't know whether this is personal aspiration values or organisational values?' (Consultancy Director, Commercial Sustainability Consultancy)*

Therefore, the usage of value concept is in need of further analysis in discussion session, which lead to the iteration of terminology used in the blueprint, where the term 'value' in 'sustainable value' was simplified as 'benefits', and the term 'uncaptured value' was simplified to 'unexploited input'. During the interviews, it was also identified that interviewees did not understand the different terms of values until an illustrative example was given. Consequently, the relevant value swim lanes on the blueprint were adjusted with the language suggested by the interviewees, along with the prompt questions based on Yang et al. (2017), see table 5:

Table 5. Iteration of Four Form of Value Uncaptured of Yang et al. (2017)

Terms	*Definition*	*Example/ Prompts*
Exploited input (Captured Value)	Something that has created and improved business economic benefits.	· How have they exploited benefits from the business operation process?
Insufficient Use of Input (Value Missed)	Something exists that is not exploited for sustainability benefits.	· Are there tangible or intangible resources that are underutilized? (e.g. capital assets or human resources?) · Is the business creating benefits in some form that it is failing to capture? (e.g. through the better use of data to enhance service?)
Excessive Input (Value Surplus)	Something exists that is not required for sustainability benefits.	· Are there excessive benefits? (e.g. overproduction, excessive service functionality?)
Undermined Input (Value Destroyed)	Something exists that undermines value for sustainability benefits.	· What are the negative outcomes of the business at each lifecycle stage? · Is there a potential or perceived risk of value being destroyed by continuing customary practices? (e.g. a risk of time to market?)
Required-but-Non-existent Input (Value Absence)	Something required that does not exist for sustainability benefits.	· What tangible and intangible needs of the company and its stakeholders have not been realized?
Identified Input opportunities (Value Opportunities)	Something that has been identified that can improve business sustainability benefits.	· How can insufficiently-use and needed input be introduced and exploited? · How can undermined and excessive input be eliminated? · What innovations could extend the exploited input in new and radical ways? · How can greater economic, societal and environmental benefits be captured from the existing business? · Where in the life cycle are there conflicts of interests between stakeholders? How can they be resolved?

3. Examination Needed for Collaboration Principles for Multi-Stakeholder

Interviewees generally agreed facilitating multi-stakeholder collaborations required two of the collaboration principles – Inclusive stakeholder selection and normative system for collaboration. Process consultation, however received the most diverse comments. Commercial actors pointing out that most of their commercial partners rely on them for process, interviewee also commented that:

> *'I don't quite agree on this one, if we consult them on process, it will take a very long time…I think it is more of an academic thing' (Consultancy Director, Commercial Sustainability Consultancy).*

However, public and independent actors are in favour of process consultation as a core principle and suggested that it is part of the best practice. Therefore, these diverse perspectives and viewpoints are in need for further examination, analysis and discussion through the case studies.

Iterated Sustainability Evaluation Service Blueprint

Based on the key feedback and desk research, the preliminary blueprint (see figure 2) was revised, to accurately present the information that was needed. The revised Sustainability Evaluation Service Blueprint (see figure 5) outlined facilitating questions to assist the investigation for the 12 swim-lanes: the existing process, physical evidence of artefacts, front-end service interaction, back-end service development, supporting actors involved, exploited input, insufficient use of input, excessive input, undermined input, required-but-non-existent input, identified input opportunities and input opportunities assessment.

By specifying the exploited TBL benefits in different NSD stage, the blueprint then goes deeper to evaluate (criteria 2) whether the NSD activities have evidence of insufficiently used input (or other types of inputs) at one specific stage that could enhance TBL benefits? Then, it goes deeper into evaluating whether (criteria 1) there is a quality sustainable value creation process. For example, do the NSD activities have evidence of embedding the 3 sustainable collaboration principles at each stage?

These evaluations then provide means to the next swim lane – identified input opportunities, where facilitative question, such as 'How can undermined input be eliminated?', is given to stimulate insight generation for service sustainability configuration. The blueprint ends on input opportunity assessment swim lane, where a sustainability-feasibility matrix is given to facilitate the evaluation of which input opportunities have higher sustainability impact and higher feasibility?

The sustainability evaluation service blueprint is designed to be modular and facilitative tool, for service designer and service developer to 1) understand an existing service, 2) understand the actors involved in the NSD and 3) to improve the service sustainability by identifying sustainable collaboration principles and eliminating unexploited TBL inputs in existing service.

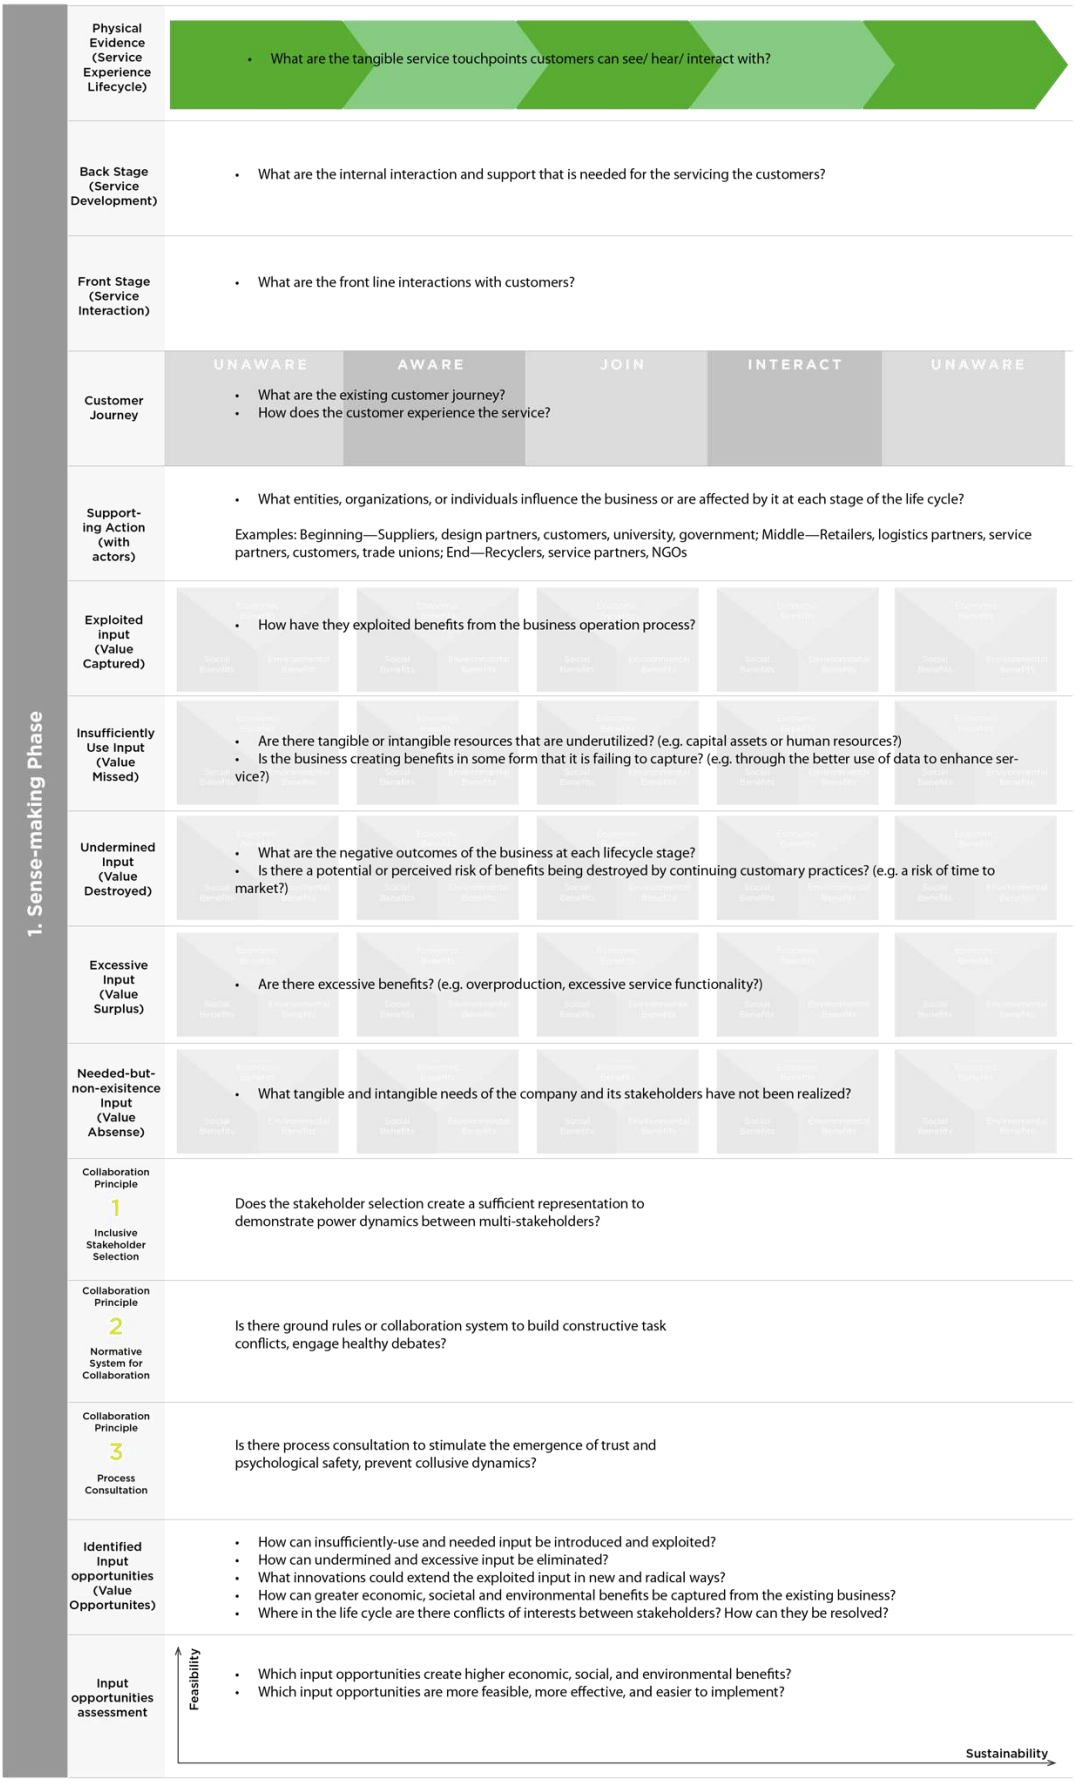

Figure 5. Iterated Sustainability Evaluation Service Blueprint

Testing Blueprint Through Case Studies

Combined the results from desk research and interviews, two case studies - Citymapper Smart Ride and Ford Chariot Commuter bus were mapped against the iterated blueprint, followed by a cross case study analysis.

Citymapper Smart Ride

Table 6. Citymapper Smart Ride Operation Profile

Background:	
Citymapper is an innovative transit and mapping service app that integrate open urban transport data and provide transit information to city users (Merlin and Eleni, 2018). This service provided Citymapper with insights on how public transport is supplied in an urban city like London. Therefore, Citymapper Smart Ride service was launched on the Citymapper app in 2017. It response to real-time transportation demand, utilised the open data capacity to identify underserved urban areas, then partnered with minibus/ taxi drivers to run commuter routes at those identified areas.	
Initial identification of service main sustainable benefits:	
Societal benefits	Operation prioritised underserved urban area to promote equality of commute options (Hern, 2018).
Economic benefits	Affordable fix rate £3 per journey that respond to real-time citizens' need of commute in underserved area (Hern, 2018).
Environmental benefits	Share transportation to ease congestion and pollution. (Ashtari, cited in Hern 2018)

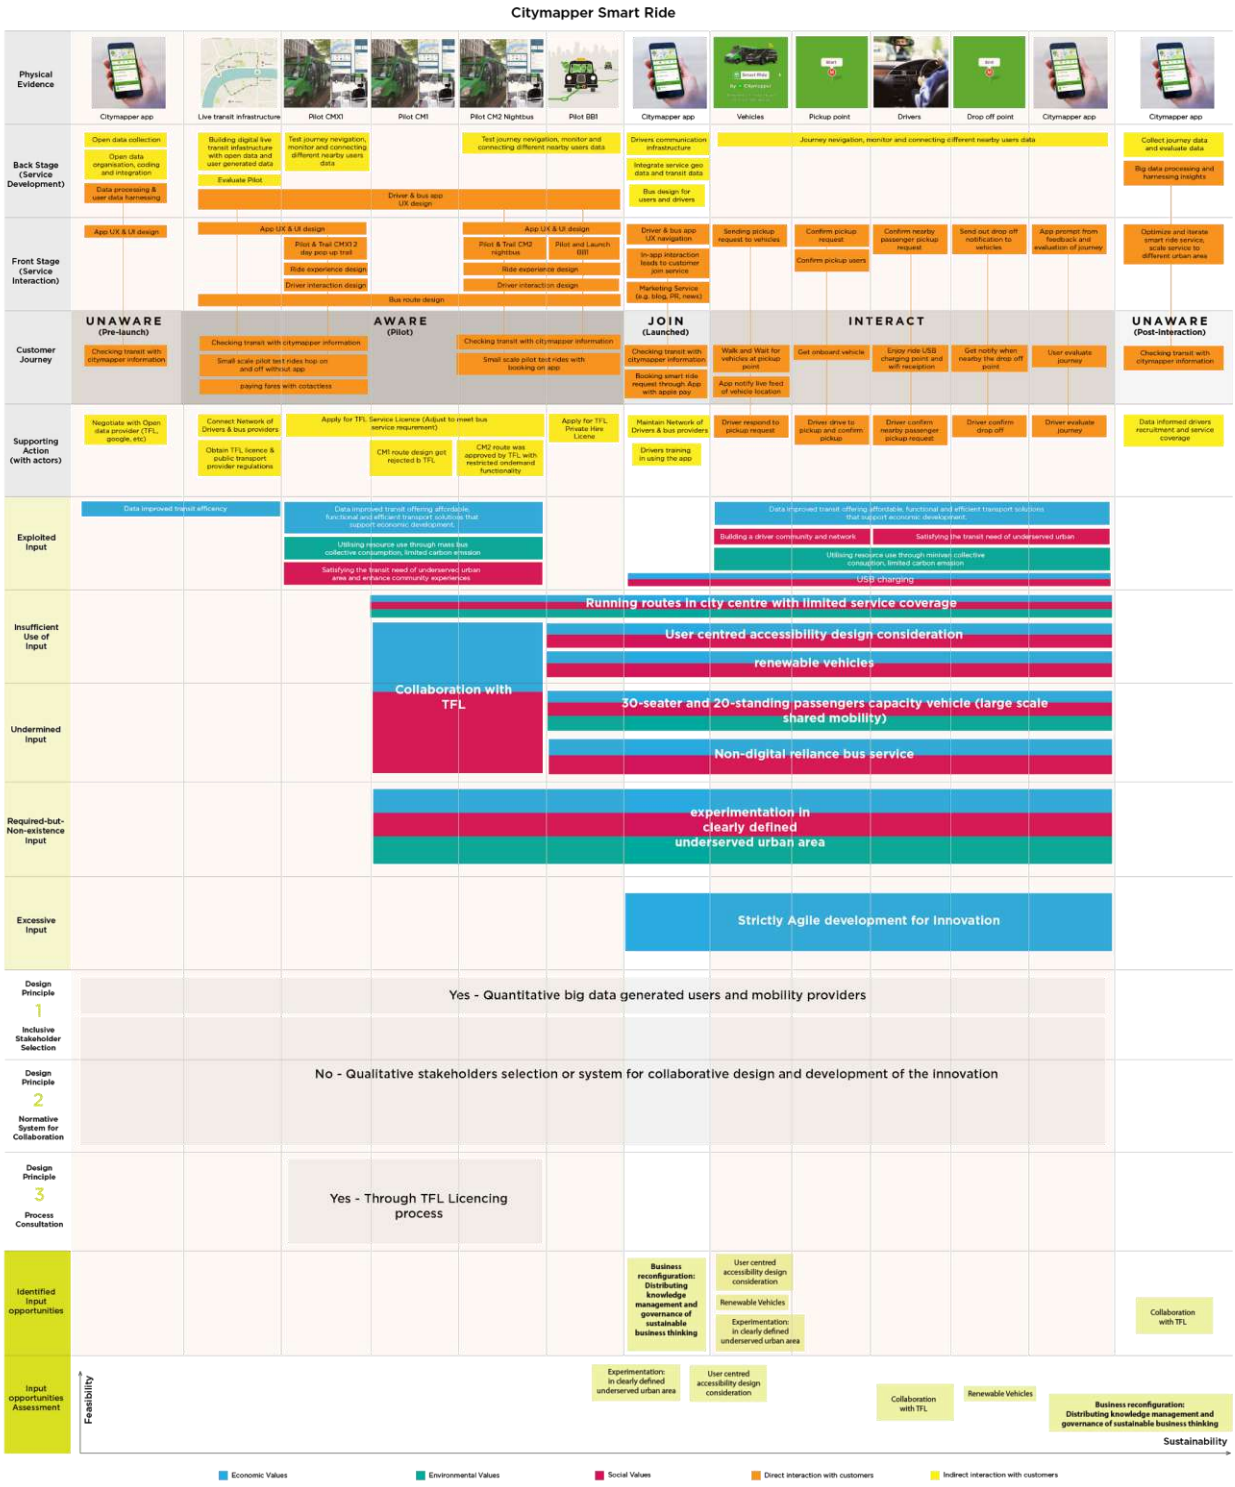

Figure 6. Citymapper Smart Ride Sustainability Evaluation Service Blueprint

Identified Collaborations Principles for Sustainability

The Sustainability Evaluation Service Blueprint (see figure 6) detailed that Citymapper Smart Ride has a unique business capacity of big data responsive network, generated from open transit database and Citymapper user-generated data (Kobie, 2018a). With the built digital infrastructure, Citymapper can respond flexibly to instant change in transit needs in different areas.

This concept was piloted with the testing 30-seater smartbus CMX1, designed with user-centred accessibility functions (Franklin-Wallis, 2017). The service applied for London Service Permission as CM1 and CM2 night

smart-bus (Price, 2017). Yet they were either rejected and restrained from its' flexibility advantage of responding to real-time transportation demands (Citymapper, 2018a), due to Transport for London (TFL) bus regulations 1981 for fleets carries 9+ passengers (e.g. fixed numbers of bus route per day, fixed distance between fleets). "*…It's not about a lack of desire, it's about changing the regulatory frameworks. At the moment it's a struggle to do this* (Bown of Citymapper, quote in ARUP 2018)." This quote and its supporting report drawn the attention to a main challenge of outdated policy overriding positive public feedback generated in the piloting phase. Regulatory difficulties with TFL and government body caused Citymapper to forfeit the pilot concept of London bus service and iterate their service design (Citymapper, 2018a). They scaled down their fleet size from minibus to minivan, carrying 6 passengers per fleet to obtain a private hire licence from TFL (Topham, 2018a), enter the share ride market of Uber (Barber, 2018).

In the end, Citymapper launched Smart Ride work with a network of 500 self-employed drivers (suppliers), provided them training in using the Citymapper driver app to connect with the users, similar to other ride hiring platforms (McMullan, 2018). This concept was born out from the agile approach of working, which forms an experimental closed innovation strategy that aims to solve immediate problem under a rapid timeframe (Citymapper, 2018c). These results show that the development of Smart Ride (see in Table 7) does not appear to have evidence of process consultation initiatives with multiple actors beyond TFL licencing requirements. Inclusive stakeholder selection and collaboration was also absent from documentation. As for normative system of collaboration, it can be argued that the open source transportation and user generated quantitative data were used for determining underserved area route creation, but no qualitative stakeholder collaboration was identified. Therefore, collaboration for sustainability remained largely unexplored in the design and development process.

Table 7. Identified Collaboration Principles in Citymapper Smart Ride

Design Principles	*Example*
1. Inclusive Stakeholder Selection	X
2. Normative System for Collaboration	Quantitative User generated underserved area route creation (Citymapper, 2018a)
3. Process Consultation	Process consultation done under TFL requirements (Price, 2017).

Identified Key Unexploited Input in Innovation

This section extracted some key results from the Citymapper Sustainability Service Blueprint exercise (see figure 6). The unexploited inputs (table 8) discussed below were identified in the reviewed documents, reports and news articles.

Table 8. Identified Key Unexploited Input in Innovation

Unexploited Input	
Undermined Input	*Downscaled Sustainable Impact through Bus to Minivan Iteration* The physical evidence of service operation journey (see figure 6) showed that the launch of smart-ride minivan has undermined the sustainability benefits of smart-ride minibus. The change in vehicle selection limited the user centred accessibility design of the ride experiences, including accessible exit for disabled users and large display for signposting bus stop arrivals (Tech Crunch, 2017). The down scale of the vehicles size also implies that more minivans are needed to satisfy a certain number of passengers, increasing the pollution and congestions on roads. This iteration also has turned the smart-ride into a digital exclusive service, which is only accessible to people with a smartphone that has installed Citymapper's app.

Insufficiently used Input	*i. TFL Collaboration* The iteration also lacks strategic input from collaboration with external stakeholders, which are the results of lacking collaboration principles (e.g. inclusive stakeholder selection and normative system of collaboration). As seen in figure 6, TFL is a major decision maker that impacted Citymapper's service iterations. Therefore, it can be determined that collaboration with TFL was one of the earliest undermined and insufficiently used input in Citymapper's Smart Ride service development. *ii. Run routes in City Centre with limited coverage (Citymapper, 2018a)*
Excessive Input	Short cycle, Speed focused User-Centred Agile App Development Process (caused by lack of business-government strategy)
Required-but-Non-Existent Input	*i. Lack of Business Government Strategy in User-Centred Agile App Development Process* On the other hand, the agile development approach is also suspected to block potential Smart Ride sustainable benefits. Agile development approach is commonly adopted in software development industry for its' speed of delivery and customer centric feedback method (Conboy et al., 2011). Although this iterative method has delivered speedy results for Citymapper in their public transit information service, creating smart ride service under agile development approach forced Citymapper to work in short cycles (Citymapper, 2018a, 2018b, 2018c). For example, the Smart Ride innovation team would then redevelop the service experience to problem solve the immediate regulatory feedback with technological solution, instead of strategically planning for business government shared objectives (Conboy et al.,2011). *ii. Experimentation in clearly defined underserved urban area* TFL denied the CM1 route based on the disturbing citizen in busy city centre (Price, 2017).

Ford Chariot Commuter Bus

Table 9. Ford Chariot Commuter Bus Operation Profile

Background:	
The Chariot Commuter Bus is a smart commute service app founded by Ali Vahabzadeh at San Francisco in 2014 (Brownstein, 2014), later on acquired by Ford in 2016 (Etherington, 2016). It is a first and last mile transport solution that supplement public transit trains and bus routes (Topham, 2018b). It connects users in the underserved urban area to their nearest public transport option (Smith, 2018a).	
Initial identification of service main sustainability benefits:	
Societal benefits	Operation prioritised underserved urban area to promote equality of commute options (Smith, 2018a).
Economic benefits	Affordable fix rate £2.4 per journey that has a guaranteed seat on the minibus (Topham, 2018b).
Environmental benefits	Share transportation to ease congestion and pollution. (Chariot, 2018b)

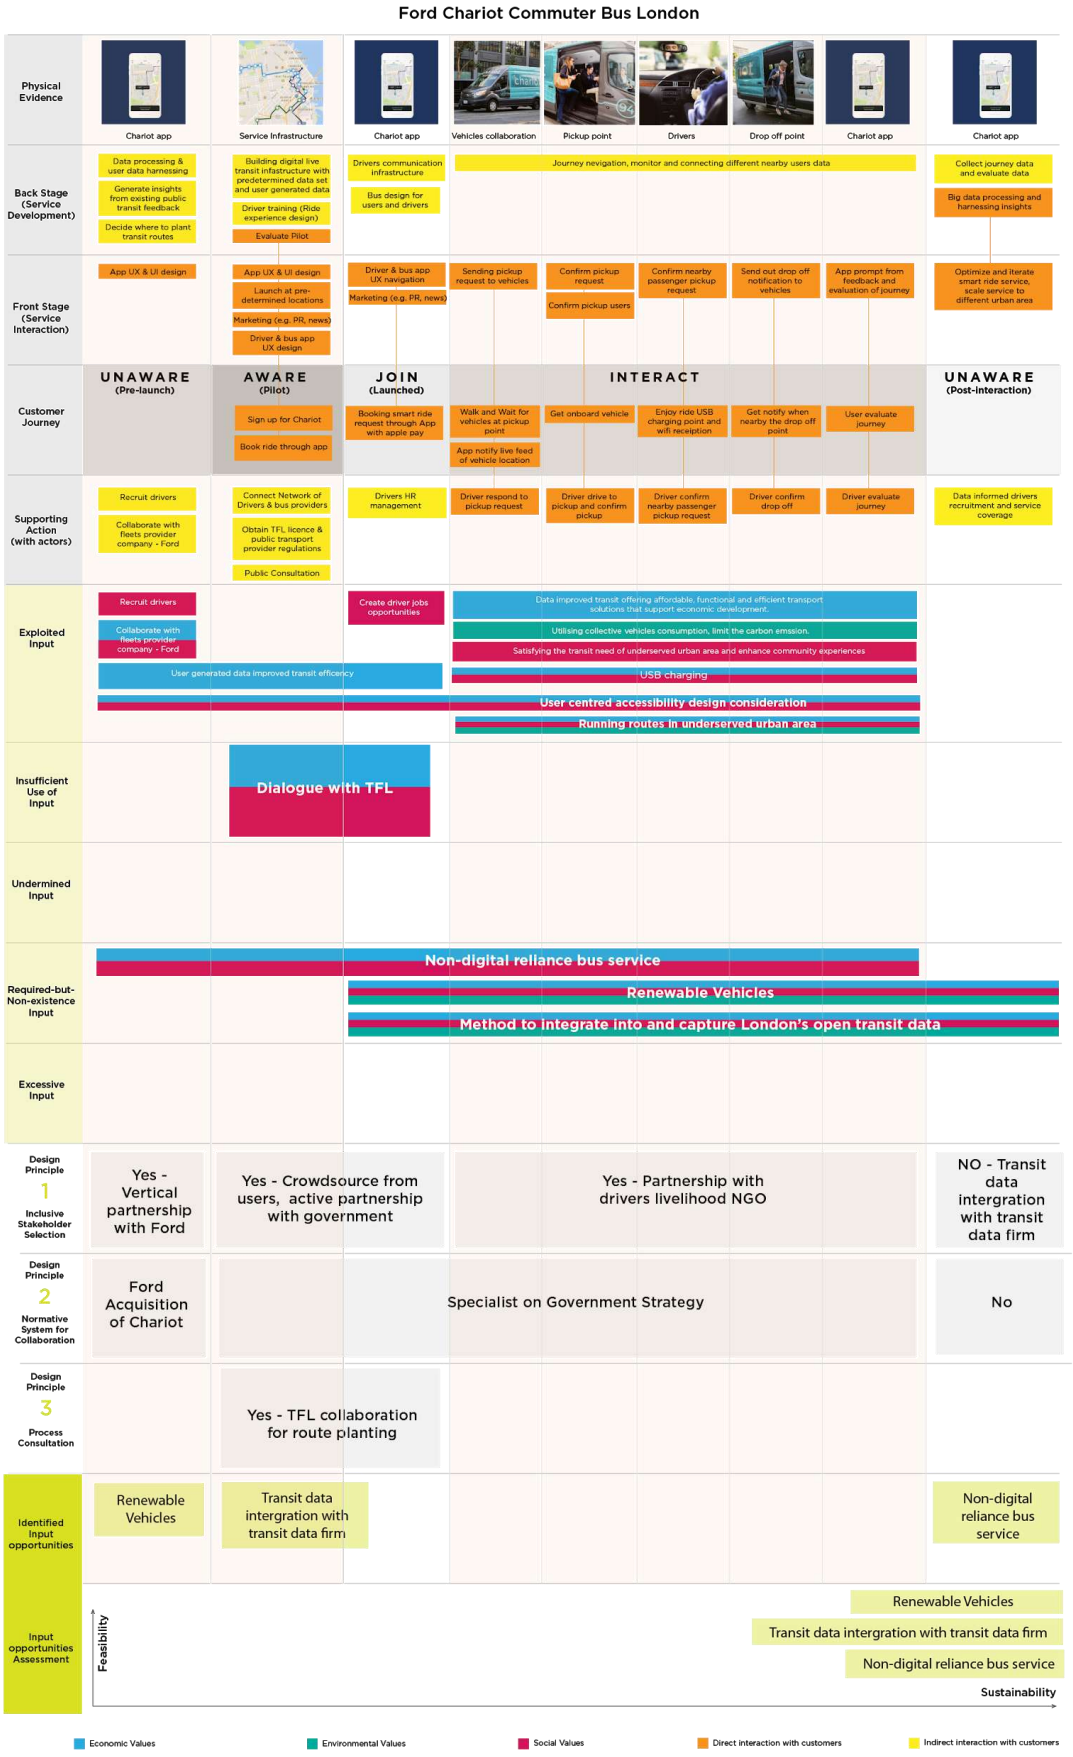

Figure 7. Ford Chariot Sustainability Evaluation Service Blueprint

Identified Collaborations Principles for Sustainability

The Service Sustainable Evaluation Blueprint (see figure 7) documented that Chariot, similar to Citymapper, also crowdsource for their route creation, desired-pickup and destination via the aggregated user interaction in Chariot's app (Etherington, 2018). However, without the advantages of having a public transit information app, like Google Maps or Citymapper, the process of aggregating user generated data was relatively difficult for Chariot.

Chariot was a proven successful in Bay area, San Francisco, which has led to the acquisition of Ford Smart Mobility. With Ford's help, the start-up expanded in different international cities (Etherington, 2018). Vahabzadeh, founder of Chariot stated in an interview that *"It became very clear very early on that Chariot would be able to leverage Ford's expertise in logistics and vehicle and operations to take Chariot and make this a global service, beyond just the Bay area"* (Etherington, 2018). This noticeable strategic corporate start-up collaboration taken early advantages of Ford's expertise. It also utilised its' business-governments relationships in multi-countries for operation expansion (Campbell, 2017), fast tracked Chariot's global development. While Ford's expertise secured the collaboration between TFL and Ford Chariot, collaboration difficulties with TFL continues to show. According to the Guardian, Chariot applied for six routes in underserved London areas, but only four were granted by TFL (Wilding, 2018). These events offer more insight into the cautious nature of public-private collaboration.

Researchers of mobility *(Lindsay, quoted in Wilding 2018)* explained that there are hidden concerns over investors increasingly investing in new and innovative digital transport solutions instead of public transport solutions, triggering possibility of '*ridesharing apps leading to a cycle of cataclysmic disinvestment '*. Greg Lindsay of the NeCities Foundation (cited in Wilding, 2018) also raised concern about private transport network: '*They will try to siphon off the most profitable customers and leave public transport a rump service*'. These quotes outlined the rivalry positions of public and private transit and the potential implication of social divide through transport options (Wilding, 2018; Topham, 2018c). Drawing the attention to an overall mobility challenge: How can private operators, like Chariot help to create a balance and synergistic system, instead of competitive relationship of private and public transit?

In this case study, Chariot has collaborated with its' vehicle supplier Ford, who's priorities are to develop partnerships with local government (see table 10). It utilised user generated data and strategic Ford partnerships in creating and expanding its' operation. However, similar to Citymapper, there was little evidence to show the process consultation beyond the TFL requirements. Therefore, collaboration principles were not fully revealed in the investigation.

Table 10. Identified Collaboration Principles in Ford Chariot

Design Principles	*Example*
1. Inclusive Stakeholder Selection	Ford strategic alliance lead to US local government partnership and UK expansion. (Etherington, 2018)
2. Normative System for Collaboration	User generated underserved area route creation (Etherington, 2018)
3. Process Consultation	Process consultation done under TFL requirements (Price, 2017).

Identified Unexploited Input in Innovation

This section extracted some key results from the Ford Chariot Sustainability Service Blueprint exercise (see figure 7). The key unexploited input (table 11) discussed below were identified in the reviewed documents, reports and news articles.

Table 11. Identified Key Unexploited Input in Innovation

Unexploited Input	
Undermined Input	X
Insufficiently used Input	*TFL Long-Term Collaboration* The Chariot service development journey (see figure 7) shown that the service has allocated resources for government strategy, keep on pursuing and developing relationship with local government, directly work with TFL to design routes that benefits both (Chariot, 2018b; Kobie, 2018b). Research also shows that Ford has contributed to a series of London mobility strategy, including TFL's 'Cleaner Air for London' initiatives, supplying TFL with hybrid vehicles that runs on zero emission electric power in city centre (Holley, 2018). Apart from government strategy, Chariot also voluntarily committed to The Living Wage Foundation's initiative, creating driver job opportunities that ensure minimum living wages of £10.20 per hour (West London Business, 2018). Although these contributions made Chariot business a desirable partner organisation for TFL, it is also worth to mention that the on-demand service idea was lately borrowed and operated by public authorities (Kobie, 2018b; Smith, 2018b), leaving Chariot service in a questionable operational future.
Excessive Input	X
Required-but-Non-Existent Input	*iii. Non-Digital Reliance Service* Although the operation principles of the service rely on digital and app to deliver its' service. It is suggested that digital only service may not be a sustainable solution for cities in the long run. Since app based on-demand service providers offer first and last mile solutions that targets commuters who are young professionals, it could create a symbol of social divide – segregating 'tech professionals and elites' from 'non-tech' ordinary public transport riders (Knowles, 2018). Consequently, distorting the intended societal benefits that the service supposed to deliver. *iv. Method to Capture and integrate into London Open Transit Data Information* Figure 7 also indicated an absence of public transit data integration. While rival Citymapper utilised its' own transit information app to integrate their service, Chariot has no means to integrate its' service with existing transit information provider, e.g. Google, TFL. Consequently, as information was not well received by London citizens, the service is less well known than its' rival. Besides, lacking capability to capture London's transit information has also put Chariot in a position that is dependent on TFL for routes creation and expansion.

Input Opportunity Assessments

The Citymapper Smart Ride and Ford Chariot case studies combined, offer learning points for sharing mobility services that aim to tackle sustainability challenges. While Citymapper Smart Ride uses agile experimentation approach to develop their service and highlighted the transport policy challenges in driving sustainable development with sharing mobility services, Ford Chariot revealed the macro challenge in private-public collaboration for developing holistic mobility ecosystem for sustainability. As the purpose was not to evaluate the effectiveness of both cases, the insights generated from the two case studies above are to provide means for discussing how innovation opportunities for sustainability can be explored under different service development and operation process. By doing so, the insights help to evaluate the implication of using service blueprint to sense-make sustainability related issues incurred in mobility service operation.

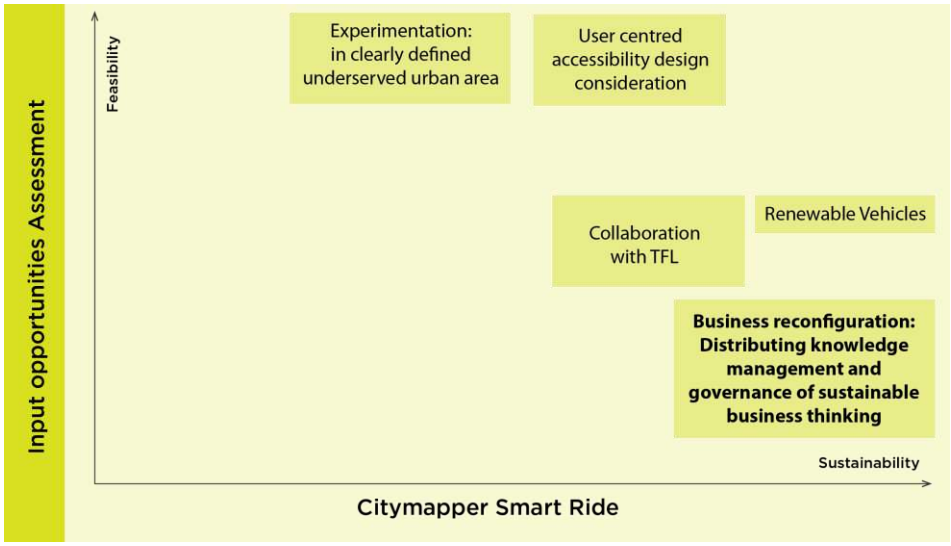

Figure 8. Citymapper Smart Ride Input Opportunities Assessment

According to the identified insights in the Citymapper smart ride case study (see table 7 & 8.), Citymapper has complex unexploited inputs related both on collaboration and TBL value. It showed that Smart Ride has made a lot of effort to meet the TFL licence criteria, including compromising their user-centred design, which led the business into an unsustainably demanding short-cycle development process. According to Inigo et al. (2017), radical innovation, like Smart Ride, would require reconfiguration (see figure 8) involving not only product service design, but business model reconfiguration, such as distribution of knowledge management (e.g. knowledge exchange and collaboration with TFL) and governance of sustainable business thinking (e.g. Smart Ride service operation managerial capability). These are all input opportunities worth considering for sharing mobility services models that aim to tackle sustainability challenges.

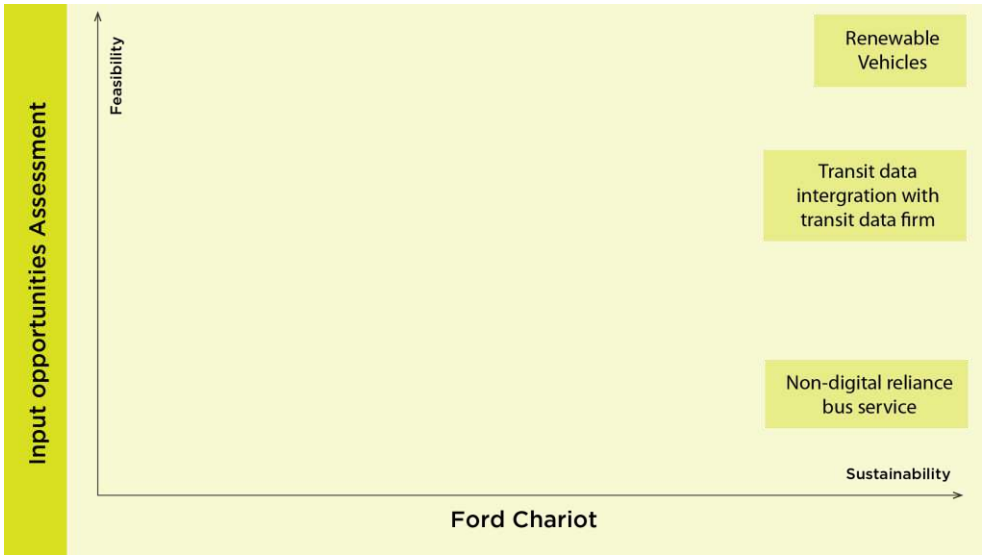

Figure 9. Citymapper Smart Ride Input Opportunities Assessment

According to the identified insights in the Ford Chariot case study (see table 10 & 11), Ford Chariot's unexploited inputs were all technical inputs that can be improved with Ford's capability to embrace new partnership. Therefore, the input opportunities assessment (see figure 9) determine that Ford's partnership capability increase the viability of transit data integration with transit data firm. While increased research and development capacity of Ford's renewable vehicles (Holley, 2018), could imply it is highly possible for Ford Chariot to operate their service on renewable fleets. Last but not least, non-digital reliance service may not be a feasible option for an app-based service company like Ford Chariot.

Discussion

This section analyses and discusses the findings according to the development of the blueprint and the two case studies, stating the contribution of the work to inform future research on sustainability evaluation, as well as the topic of sharing mobility service as sustainable innovation.

Sharing Mobility Service as Sustainable Innovation

Agile New Service Development (NSD) and Sustainable Innovation Incompatibility

The Smart Ride case study showcased a potential incompatibility in using Agile development process to iterate sustainable service, where regulatory feedback was answered with service technological solution, instead of strategically planning for business-government shared objectives (Conboy et al.,2011). While the agile development enabled the rapid progress of information technology (e.g. Citymapper's responsive transit data network), initiated the emergence of knowledge-based sustainable service concept - Citymapper Smart Ride. However, transforming mobility for sustainability builds on not only the result of the agile NSD and iteration with user feedback, but the sustainable value creation amongst the collaborative innovation networks (Elke den Ouden, 2012). This means the interdependent stakeholders ranging from TFL, Citymapper, drivers, users to local community members, needs to integrate their knowledge and expertise to create TBL values. This takes more than agile NSD and iteration on product and service feedback, but a shared working process, principles and tools to allow all the relevant stakeholders to work together constructively to test and build sustainable innovation that provide value at different levels - for the users, for the organisations and for society at large.

Private-Public Dilemma in Collaboration for Sustainability

Approaching sustainable innovation with service design and planning approach means considering how collaboration was conducted at each level and each stage of the service operation. From the first stage of validating service blueprint evaluation criteria to the examination of case studies, private and public actors hold diverse perspectives and viewpoints on collaboration process consultation in general. In the Mobility Innovation case study, the investigation reveals that while Chariot business is a desirable partner organisation for TFL, the on-demand service idea was lately borrowed and operated by public authorities (Kobie, 2018b; Smith, 2018b), leaving Chariot service in a questionable operational future. This event proven that while public process consultation allows public society and communities to feedback and improve the service innovation, it is unsustainable for business to do so without any protective measure on their rights to the service innovation. This further explained private actors' practice of setting process and ways of working as a self-protective measure, while public actors are in favour of process consultation as a core principle and suggested that it is part of the best practice.

Curșeu and Schruijer (2017) argued that these types of collaboration conflicts happened due to the distrust, unsafe and collusive dynamics of the collaboration. This further emphasis on building collaboration relationship on a normative system, where shared process and ways of working are established. These shared guidelines should aim to enable the emergence of trust and prevent collusive dynamics, building a constructive and safe multiparty collaborative system.

Sustainability Evaluation in Service-Based Sustainable Business Model Innovation

The Concept of Sustainability 'Value' in Evaluating Service Operations

Value is a term that was used throughout the literature and in the first iteration of the blueprint, yet feedback from actors indicated that the concept of value is difficult to use in practical operation evaluation. According to Yang et al. (2017), the concept of value was developed from Richardson (2008) and Amit & Zott (2012), which has established the academic theory building. Since this research aim to develop practical sustainability evaluation tools through service blueprint, requiring participatory research with non-academic actors who involved in the service operation. Therefore, using the term 'value' in a service blueprint would not be apprehensible for actors involved in the evaluation process.

Nonetheless, the concept of value defines things or activities exploited in the production process that have created and improved business economic benefits (e.g. profit margin), extended from Porter's concept of value chain (1985). However, this research focus on 'unexploited activities', which have not created, but have

potential to bring society and environment benefit - which is different from economic benefits as well. Through validation with industry experts, interviewees expressed that engaging stakeholders in sustainable value creations needs simple facilitative tools and language. Therefore, it was suggested to simplify sustainability 'values' to sustainability 'benefits', clarifies the purpose to create 'societal and environmental benefits', instead of simply 'economic benefits'. It was also suggested to simplify 'uncaptured values' to 'unexploited inputs', clarifies the consideration of 'unexploited activities', instead of 'exploited economic benefits - value'.

Role of Sustainability Evaluation Service Blueprint in Sustainable Innovation

Designing service blueprint with evaluation criteria of sustainable benefits and sustainable collaboration, allow us to identify insights for optimising the overall service offering for sustainability. It also informs the new service development (NSD) activities (Yu and Sangiorgi, 2017), especially relating to the organisational and managerial activities for sustainability. Together with service blueprint's capabilities to visualising user-interaction, relationship analysis and service experiences through multi-actors perspectives. The Service Sustainability Evaluation Tool stimulate comprehensive service operation evaluation against sustainability, to review the optic of sharing mobility as service-based sustainable innovation.

The two case studies above showcased how sustainability evaluation service blueprint can be used to contextualise the holistic service offer and operations development. For instance, the sustainability benefits criteria revealed that both services were driven by clear economic benefits, with either blurry and destroyed social and environmental benefits as the NSD activities progress into service operational and managerial activities. On the other hand, the sustainable collaboration criteria illustrated complex operational activities with multiple actors involved (Chou, Chen and Conley, 2012; Baldassarre et al., 2017; Prendeville and Bocken, 2017; Tukker, 2015), such as collaboration with TFL and community members, managing drivers, etc. Through mapping out stakeholders and their activities, service blueprint immediately exposed the unexploited input (e.g. electric fleet choice) and stakeholder impacts (e.g. social divide created through digital and non-digital commuters) in the rideshare service operation, opened up a clearer vision of the holistic service operation needs. The visibility enabled by this tool showcases its' value for practitioners to explore and employ service design thinking and practice for the advancement of sustainable innovation (Prendeville and Bockon, 2017).

Conclusion

This study contributes to the service design and innovation (including PSS research stream) and sustainability literatures. The synergies between sustainable values, collaborative principles for sustainability and service design tool construct a service operation sustainability evaluation blueprint. It draws on two explorative case studies and therefore there are some limitation to the conclusions drawn. By illustrating how service operation planning tool - service blueprint can facilitate the sustainability evaluation processes for sharing services, this research explored the potential of using service blueprint to improve the service sustainability by identifying sustainable collaboration principles and eliminating unexploited inputs in existing service. It repositions service design tool – service blueprint as a constructive facilitation tool for analysing sustainable service innovation. Most importantly, it enables service designers to map out all the interactions related with delivering a sustainable service and to determine feasibility of implementing those opportunities, leading to future possibilities for designing organisational interactions and policies for sustainable service innovations.

As the concepts of sustainable business model transform into concrete products and services, service designers and service developers need to learn how to evaluate and iterate for TBL benefits optimisation in the NSD activities, in order to build sustainable service operation journey. Further work is recommended to explore how to use the sustainability evaluation service blueprint to facilitate and improve TBL value creation in service operations of an organisation, which engage in a service-based innovation for sustainability. Learnings from an in-depth case study will further the use of service design practices, methods and tools, as strategy to build tangible Sustainable NSD process upon sustainability business model innovation theory.

Acknowledgment

We would like to thank British Standard Institute (BSI) and all the participants for their assistance, support and insights in this study.

In recent years, there has been a growing awareness of the human, social and economic benefits that experience design can bring to nations and organisations. Experience design is the process of enhancing users' trust, satisfaction and recognition of a product, service and system by improving the users' perception of the innovativeness, aesthetics and relevance of the experience provided in the interaction between the users and the product, service and system's design elements in a particular context. It takes the users' cognitive and emotional experience as its starting point and focuses on developing products, services and systems that could enable that experience. Experience design elements include information, navigation, engagement, entertainment and personalisation (adapted from Cheung 2016; Cheung 2020). Google Search, Google Maps and YouTube are illustrative of how intrinsic to our daily lives innovative experience designs have become. Tencent has its WeChat platform able to support location-based social plug-ins, allowing users to befriend and chat with nearby strangers through a simple shake of their smartphones. These types of experience systems did not exist in the pre-digital era and are now the focus of creative design. Alibaba's Tmall and Taobao implement technology-enabled forms of electronic payment security, product quality assurance and online dispute resolution to combat user distrust of online purchases. The success of these companies stems from the experience design strategies that they use, in which users are reached and connected through multiple touchpoints and interactions relevant to their sociocultural contexts. Experience design changes the nature and environments of physical artefacts by integrating digital systems and resources with the physical world. It can redefine the functionality, meaning and value of products, services and systems, strategically transforming them into highly integrated ecosystems capable of enhancing the sustainability and humaneness of our social and economic environments while offering industries a competitive edge. The sustainability of the experience ecosystems also relies on involving the users in exchanging value in ways that are mutually beneficial socially, economically and technologically over time. For example, Amazon, eBay and Taobao provide user-friendly interfaces that have enabled their users to create a new wave of small businesses and services on their platforms.

Yet as a relatively new area in the design field, experience design is in need for further research into developing a more sophisticated methodological framework for guiding its processes, and at the same time, creating evaluation criteria for measuring its outcomes in a more systematic and comprehensive manner. This track on "Experience Design – Method and Evaluation" aims to provide a platform for design researchers and practitioners interested in experience design to discuss its method and evaluation. The four papers accepted for this track propose a range of perspectives on the topic.

The first paper by Chen and Cheung, *Consumption experience on Tmall: a social semiotic multimodal analysis of interactive banner ads*, contributes to the methodology literature of experience design. It examines consumer-oriented advertising in e-commerce in China through analysing banner ads on Tmall with a synthesis of social semiotics, multimodal analysis, and interactivity. Departing from Tmall's annual Double 11 Carnival,

the analysis shows that the banner ads have been incorporated into a gamification design to encourage consumers to spend more and buy things they may not need even after the event has been completed. The authors' approach of analysing the ads on both the syntagmatic and paradigmatic dimensions is explicitly multimodal, taking the tri-fold convergence of linguistic, visual and interactive resources into consideration to study new phenomena in an e-selling environment. The approach could be helpful to scholars and practitioners in the field of experience design, where multimodality and textual analysis of visual information is of great importance.

The second paper by Alaali and Pitsaki, *Experience design at Starbucks: from global brand management to local spatial experiences*, explores how Starbucks achieves global consistency and meaningfully localised experiences within the context of global brands management and the need for integrating local identities. Through a review of literature and a series of interviews with store designers, design managers and brand concept experts at Starbucks, the authors compile the most commonly applied branding and design methods, with an emphasis on the locally relevant spatial experiences that the global brand would like to deliver. They also classify their findings in a way that could assist other brand and experience design teams in overcoming shared challenges. The findings focus on the management of the grounding brand concept, as well as operations and real estate teams. Through presenting some tools, manuals, guidelines and sample checklists, the authors suggest that store design teams in different locations can build strong, locally relevant spatial experiences that tie in successfully with the brand's global principles.

The third paper by Tellez and Gonzalez-Tobon, *Empathic design as a framework for creating meaningful experiences*, introduces empathic design as a framework and a strategy that can be adopted by the emerging field of experience design to create meaningful experiences connected with people's lives and needs. The paper presents the rationale behind the emergence of empathic design, the traits that characterize this approach to design, a collection of empathic design methods and practices, and a critical discussion of the limitations of empathy in design. The paper is developed based on a systematic literature review on empathic design, human-centred design, and empathy. The paper contributes to the broader discussion of how traditional design practices are adapting and evolving to respond to new realities, and how new design paradigms are needed to address the very complex challenges that we are facing in the 21st century.

The fourth paper by Capra, Berger, Szabluk and Oliveira, *Experience design applied to research: an exploratory method of user-centered research*, is presented based on the rationale that an accurate understanding of users' needs is essential for the development of innovative products. The paper presents an exploratory method of user-centered research in the context of the design process of technological products, conceived from the demands of a large information technology company. The method is oriented - but not restricted - to the initial stages of the product development process, and uses low-resolution prototypes and simulations of interactions, allowing users to imagine themselves in a future context through fictitious environments and scenarios in the ambit of ideation. The method is effective in identifying the requirements of the experience related to the product's usage and allows rapid iteration on existing assumptions and greater exploration of design concepts that emerge throughout the investigation.

In conclusion, the track facilitators are glad to see that the four papers are enriching the knowledge and skills regarding experience design and informing potential directions for further research.

This article contributes to the methodology literature of experience design by analysing banner ads on Tmall with a synthesis of social semiotics, multimodal analysis, and interactivity which guides our analysis of consumer-oriented advertising in e-commerce. Departing from Tmall's annual Double 11 Carnival, our analysis shows that the banner ads have been incorporated into a gamification design to encourage consumers to spend more and buy things they may not need even after the event has been completed. Our approach of analysing the ads on both the syntagmatic and paradigmatic dimensions is explicitly multimodal, taking the linguistic, visual and interactive resources (the tri-fold convergence) into consideration to study new phenomena in an e-selling environment. The approach of this study could be helpful to scholars and practitioners in the field of experience design, where multimodality and textual analysis of visual information is of great importance.

Keywords: Social semiotics, multimodal analysis, interactive banner ads, experience design, e-commerce

Introduction

In recent years, experience design has been advocated and practised in a variety of projects as it can bring significant human, social and economic benefits to nations and organisations worldwide. According to Cheung (2016), experience design is the process of enhancing users' trust, satisfaction and recognition of a product, service or system by improving users' perception of the innovativeness, aesthetics and relevance of the experience provided in the interaction between the users and the product, service or system's design elements in a particular context. It takes the users' cognitive and emotional needs as its starting point and focuses on developing products, services or systems that could enable an experience to address the needs. Experience design elements include information, navigation, engagement, entertainment, and personalisation (Cheung, 2016). This study focuses on the element of information in one of the most influential e-commerce platforms in China, namely Tmall owned by Alibaba. It investigates Tmall's information design strategy with a primary focus on its banner ads for advertising and promoting consumption experience.

Advertising plays a crucial role in pervasive marketing for organisations and businesses to build brand image, engage with their targeted audience, and promote their goals and activities (Sifaki & Papadopoulou, 2015). For e-commerce, advertising is particularly aimed at turning attention into transactions. Of the various types of ads, banner ads are an important genre. They are placed at a prominent position on a website or mobile app to attract consumers' attention during their visits, in accordance with web design and search engine optimisation practices. Unlike advertising through third-party intermediaries such as traditional mass media or

social media, banner ads on e-commerce websites function as a direct touchpoint to facilitate consumer navigation. They are an effective tool for targeting consumers to boost sales and spending. This is in line with the concept of "e-selling", which is different from e-commerce or e-retailing, in that it has a more nuanced focus. E-selling is a term intended to conceptualise human-computer dialogue "characterised by the digital spatio-temporal locus, the psychology of online persuasion, and complex perceptions of value" (Parvinen, Oinas-Kukkonen & Kaptein, 2015, p. 214). It is closely linked to concepts such as human interactivity, intentionality, persuasion, and value creation.

This article aims to contribute to the methodology literature of experience design by examining banner ads on Tmall with a social semiotic and multimodal analysis approach. We examine a selection of banner ads designed to attract consumers' attention and develop user trust for "e-selling" a brand, product and/or service. We also look at gamification design and how it drives consumer experience in the annual Double 11 Carnival on the e-commerce platform. Gamification design has been experimented by retailors, a practice of creating a game around the shopping experience, for example, to collect coupons and stamps (see more in Frith, 2013).

Tmall, literally Sky Cat, is China's largest third-party platform for brands and retailers. It was originally named Taobao Mall or *Taobao Shangcheng* (Alibaba, 2017a). It is a business-to-consumer (B2C) web domain launched in 2008, parallel to Alibaba's consumer-to-consumer (C2C) platform Taobao. Tmall has achieved a 136% year-on-year increase in cross-border retail revenues and remains the number one e-commerce platform in terms of market share (Alibaba, 2017b). CIW (2018) reports that the listing of more than 16,400 international brands from 68 countries on Tmall has attracted more than 529 million mobile Monthly Active Users (MAUs). Tmall now occupies almost 60% of the Chinese B2C market sales in fashion and apparel and maintains steady growth in consumer electronics and fast-moving consumer goods (FMCG). A particularly significant figure is connected to the 11th of November (*Shuang* 11, or Double 11), known as Singles' Day (Meng & Huang, 2017). The annual Double 11 Carnival is a spectacle celebrated by the platform, endorsed by the government, and participated by consumers. Every year Alibaba organises a grand live show and conducts a 24-hour countdown to see how much money it makes during the Carnival. In 2018 Tmall generated over USD 30.8 billion in just 24 hours (see Figure 1, Alizilia, 2018). Together with Alibaba's offline infrastructure (*Yintai* Mall and unmanned supermarkets), cloud computing (Ali Cloud), payment gateway (Alipay), and logistics (*Cainiao Yizhan* Delivery), Tmall has made a huge global impact in e-commerce consumption with its well-rounded industry ecosystem.

Literature review

Our research focuses on Tmall banner ads, which are multimodal. Such ads make and convey meanings through a combination of textual, audio-visual and interactive modalities (augmented reality, virtual reality, clicks and hyperlinks, thus hypertextuality), all in one entity. We first follow the work of social semiotics and multimodality. It holds that semiotic resources such as signs and codes are socially constructed (Kress & Van Leeuwen, 2006; O'Halloran et al., 2011). The experience design element of information, in this case, is signified by various signs and codes. These conventions in the form of language and visual images are not static. They are subject to change and transformation and should be interpreted in specific social and cultural contexts.

The underlining theoretical rationale is that meaning-making and discursive processes with the help of semiotic resources are shaped by the motivations and interests of the sign-maker (He, 2016). However, we know little about the discursive constructions that aim to persuade consumers and change their minds (Van Dijk, 1993). This is particularly the case for the process of discursive construction in post-reform China after 1978, where consumerism is on the rise yet seldom investigated with a perspective of multimodal analysis. In the case of Tmall, the motivation and interests of the sign-maker can be investigated through a social semiotic and multimodal analysis of banner ads. In addition, because these banner ads are situated within an e-commerce website, we also examine the hypertextuality and affordances as part of interactive modalities for facilitating the discursive process through digital and multimedia texts. Here, we focus on the two-dimensional aspects of banner ads as interactive signs and sites, a departure from traditional multimodal analysis. In banner ads, hypertextuality is achieved through the affordances of digital text (search, scan, click, and tap). This interactivity allows and enables consumers to travel between texts and pages through hyperlinks and interactive functions. Informed by Adami's semiotic analysis of website interactivity, we aim to examine the interactivity in banner ads as both signs and sites (the two-fold nature in Adami's term, 2014). We investigate affordances available to activate interactivity, in addition to the communication of meanings achieved through traditional textual forms such as still and dynamic images, graphics, and words. To achieve this, we adopt and extend Halliday's (1978) three metafunctions (the ideational, interpersonal, and textual) to analyse both the (previously static) discursive process and the now interactive banner ads in e-commerce websites.

In advertising and marketing research, discourse analysis guided by metafunctions has been widely used to study information and persuasion conveyed via a diversified range of texts (Wagner, 2015). The first strand of work is centred on language and text. In recent years, a visual turn has occurred, as identified by several scholars in advertising (see a review in Holsanova, 2012). Following this turn, there has been a growing body of interdisciplinary literature that employs social semiotics and multimodal discourse analysis to analyse advertising and media formats (Thomas, 2014; Holsanova, 2012). These include food and product packages (Wagner, 2015), magazines (Lick, 2015; Chen & Machin, 2014), posters (Sifaki & Papadopoulou, 2015; White, 2010), picture books and animated movies (Unsworth, 2015), photography on social media (Zappavigna, 2016), automobile commercials (Chen, 2016), website and TV ads/reviews (He, 2016; Adami, 2014; Jessen & Graakjær, 2013), café design and architecture (Aiello & Dickinson, 2014), as well as political speech and presentation (Wong, 2016), to name just a few. Against this backdrop, we champion a tri-fold convergence of the multimodality of texts, visuals and affordances (interactivity) and use it as a framework to guide our analysis.

The social semiotic framework of interactive banner ads

The tri-fold nature of the text, visuals and interactivity of banner ads contributes to the meaning-making process in Tmall. This is in line with social semiotics which regards codes of language and communication are shaped by social and cultural processes. In this study, we are particularly interested in visual information, that is, how the producer, mediator/interpreter and audience/consumer are connected through banner ads. There are a few theoretical approaches to this, including the semiotic and cognitive approach – a seamless circle in line with experience design strategy and practice. The semiotic approach focuses on visual segmentation as a result of "intentional, socially typical choices that are made to achieve the optimally desired communicative effect on a hypothetical model reader/viewer", whereas the cognitive approach treats the dynamic and engagement process between the audience and the visuals as a point of departure from a reception perspective (Boeriis & Holsanova, 2012, p. 263). The distinction between the production and reception study shows that the semiotic approach focuses more on the factors that can shape perception and segmentation process as a shared knowledge, whereas the cognitive approach investigates the general and individual patterns that unfold in the actual reading of such constructed discourses. How consumers actually engage with various banner ads (subjectivity and agency) is out of the scope of our study. At the outset, the tri-fold approach we take in this study is semiotic in nature. In fact, such an approach is widely used in investigating the socially and culturally entangled semiotic system (see Kress & Van Leeuwen, 2001). This strand of work focuses more on the construction and communication processes (and their effect) than on individual preferences. However, both approaches value the principles of perception structure and organisation of textual and visual resources, in a predicted and interpretative manner. Therefore, in analysing banner ads, our study will particularly look at the structure and organisation of the multimodal resources of interactive banner ads. In doing so, it allows us to investigate these resources from three levels, namely the macro (ideological), the meso (organisational), and the micro (semiotic) level of shared social and cultural contexts in China. This is

in line with Foucault's theory that places interaction and communication under specific power-knowledge regimes (Pereira, 2015).

Contextualise the three metafunctions with interactive affordances

In this section, we look at existing literature about how multimodal discourse analysis is incorporated with such an approach to study both the textual and visual aspects of advertising and digital marketing. Multimodal analysis can be traced back to Halliday's (1978, 1994) Systemic Functional Linguistics (SFL). It is used to study the "functional and situational organisation of language in the social context" (He, 2016, p. 171). As a "functionalist", Halliday regards "language as a device designed for accomplishing communicative ends, and insofar as function the basis for his description of language" (Urban, 1981, p. 660). Halliday (1978) views linguistic signalling as an intersubjective phenomenon. He therefore contends that language study should begin with discourse analysis (linguistic signalling in action). As language users also encode individual and multiple layers of meaning within a given discourse, the distinct functional modes must be analysed. He suggests that the discourse is constructed by the intertwined meaning and function. He then develops three abstract metafunctions (the ideational, interpersonal, and textual), a framework that can be mapped onto a given discourse, textual, visual or both. First, the *ideational function* is to say something about the world, referring to particular "objects, people or even ideas" for a given socio-cultural group (Sifaki & Papadopoulou, 2015, p. 473). Second, the *interpersonal function* is to say something about the actors who participate in the communicative process. Finally, the *textual function* focuses on the text as a whole. Another important component of this framework is "contextualism", that is, to view language use in relation to both linguistic and non-linguistic contexts (Urban, 1981).

Drawing on Halliday's SFL, Kress and Van Leeuwen (2006) adapt the metafunctional theory to study multimodal information in the face of the visual turn (He, 2016, p. 171). They have developed a theoretical framework called Visual Grammar (VG), mirroring and naming Halliday's three functions as representational, interactive, and compositional meanings. They suggest that visual information is a semiotic mode of its own kind. Therefore, the three metafunctions can also be applied in visual analysis. In doing so, VG provides new terms as "grammatical realizations of metafunctional meaning in visual social semiotics" (Boeriis & Holsanova, 2012, p. 265). This is particularly useful in our case of analysing interactive banner ads. Representational meanings follow the ideational function, unfolding "actions and events, processes of change, transitory spatial arrangements" (Kress & Van Leeuwen, 2006, p. 56). Interactive meanings are coordinated via a number of interpersonal systems: gaze, social distance, perspectival angle, and modality. Compositional meanings at the textual level are achieved by leveraging resources such as information value, framing, and salience. Lemke (2002) further develops three equivalent terms, presentational, orientational, and organizational, to analyse hypermodality, whereas Zammit (2007, as cited in Adami, 2014) follows the terms in VG, adding an additional logical function. Here, to study the interactivity together with the multimodal VG of e-commerce banner ads, we stick to the terms of Halliday refined by Adami to avoid the possible confusion of an "interactive" function with different connotations and theoretical underpinnings (see more in Adami, 2014). As shown in Table 1, we present the refined framework for the examination of interactive banner ads on Tmall to facilitate both analysis and evaluation and to avoid turning our study into a mere description of the banner ads.

Table 1 Axis of metafunctions and the two dimensions of interactive sites/signs, adapted from Adami (2014, p. 142)

Dimensions	*Ideational function*	*Interpersonal function*	*Textual function*	*Interactive value*
Syntagmatic (within the page)	What it is: form/meaning (representation of the world)	What it says about: authors and users	How/where in the page: salience; information structure	Aesthetics of interactivity
Paradigmatic (optional realisation)	Which action; which effect; where	Directionality/power: who towards whom; authors/users/others	Before-After; Given-New	Functionalities of interactivity

In Table 1, we synthesise the framework adapted by Adami with SFL and VG to analyse the source text in two dimensions, namely, the syntagmatic dimension and paradigmatic dimension. The synthesis is useful for explaining the two dimensions (space and time) of interactive banner ads on top of SFL and VG: (1) the spatial

dimension of the ads, for example, where it sits on the page, and how a sign is made up of multimodal texts; (2) the intertextual dimension, which works as a gateway for realisation of potential meaning-making through specific functions such as clicking, hovering, searching, and sharing (Adami, 2014, p. 140). These two dimensions will guide our analysis given the two-fold nature of interactive banner ads as both signs (forms of meanings) and sites (for actions to produce certain effects).

Table 1 illustrates how the three metafunctions are mapped with the two dimensions (the totality of the sign and the site), creating an axis of meaning-creation. Syntagmatically, this contributes to the ideational function capable of presenting the world with various arrangements. Paradigmatically, it contributes to the effects endowed by the sites, activating potential meanings through various inflections and actions with these sites. In terms of the interpersonal function, syntagmatically, it communicates to the users with diversified expectations. Paradigmatically, it sets the directionality within a connection, a power-knowledge regime built between the authors and users (who acts upon whom). As for the textual function, syntagmatically, it concerns the structure of the information and its value created by the ideational and interpersonal function of the text as a whole. Paradigmatically, it relates to the time-space pair of interactive banner ads as both signs and sites, mapping the two dimensions in a before-after relationship within a certain change, that is, the text that is given as it is and the text it becomes if activated. These two dimensions (the syntagmatic and paradigmatic) mark two distinct yet relevant processes on a continuum: one is the arranging process of the texts, images, and affordances (for interactivity) of the banner ads (once activated); the other is the completed arrangement and layout, an equilibrium presented as the banner ads in a static state.

As we will demonstrate in our analysis section, the syntagmatic dimension (the ideational, interpersonal, and textual) guides our interpretation of interactive banner ads as signs in a relatively static way compared to "sites" to be activated. In turn, the paradigmatic dimension guides our analysis of the interactivity to be activated in a more dynamic manner. That is, the interactive affordances are designed to achieve interactivity with certain effects through consumers' actions to make the meaning-making process complete.

Methodology

Following the theoretical framework developed above, we use a combination of the visual, textual and interactive analysis of the banner ads on Tmall as our primary methodology. We select banner ads from its 2018 Double 11 Carnival, as well as other banner ads as an extension of the carnival metaphor. Because we do not aim to conduct a reception study, nor validate the effects of designated design campaigns, the eye-tracking method (Boeriis & Holsanova, 2012) or retrospective interviews (Gidlöf, Holmberg & Sandberg, 2012) are not used. The detailed working process of semiotic and multimodal analysis involves an "analytical zoom" in and out of the banners examined (Boeriis & Holsanova, 2012, p. 264). We then regard the zoom levels as a point of departure to closely investigate elements of the banner ads with the guidance of VG. These include images, texts, fonts, colours, and the banner as a whole. The relationships between the various elements will be explained in detail during analysis. We then put the banners in the wider social and cultural context with the message that it is designed to convey, zooming out from the separate and segmented clusters of elements to the comprehensive and interactive view of the banner ads as a whole again. As we merely aim to explore the production aspect of banner ads, these methods are deemed sufficient because they have proven to be fruitful in a number of social semiotic studies (Chik & Vásque, 2016; Grumbein & Goodman, 2015; Feng & Wignell, 2011; Tan, 2009).

Data analysis

As indicated in Table 1, the syntagmatic dimension utilises several modes of textual and visual semiotics to fulfil the ideational, interpersonal and textual functions, whereas the interactive value is achieved through the paradigmatic dimension with affordances of intertextuality and interactivity. These two dimensions will in turn be analysed in conjunction with multiple banner ads. At the outset, these two dimensions often work together in digital and multimedia environments. It is hard to separate them, even within one banner ad. Therefore, it makes sense to analyse these two dimensions together as a whole and as a complete process. However, to test our proposed framework, we have to separate and analyse them respectively at a later stage to achieve better clarity.

Figure 2: Banner ad on 2018 Double 11 Carnival's landing page. Source: Alibaba

We first take a holistic view in analysing both dimensions with the banner ad in Figure 2. For the ideational function, this ad shows the Double 11 Carnival is on. It also provides a video depicting the myth of the traits of 12 constellations and the responses of consumers when they receive their parcels delivered from the Carnival. It is extremely simple in terms of design as the concept and navigation of Double 11 Carnival are well known in China. As stated, the celebration of carnival and gamification has extended to everyday consumption on Tmall as an organisational marketing strategy. We will look at two banner ads of the 2017 Double 11 Carnival (Figure 3) and then other banner ads in everyday scenarios (Figures 4-6).

Figure 3: Banner ads of 2017 Double 11 Carnival. Source: Alibaba

In Figure 3, the key message is that Tmall is a creator of comfortable life. The cat-shaped icon is marked with 11.11 as the nose and eyes of the Sky Cat icon. The cat stretches its two arms, embracing a banner with multiple "red envelopes" indicating good fortune, money, and coupons on offer during the Carnival. In 2017 Tmall used the gamification design of spreadable red envelopes worth RMB 250 million to stimulate sharing through digital word-of-mouth. According to Chen (2017), Tmall also ran a series of pre-carnival campaigns to

attract consumers' attention and engagement (see Table 2). Such campaigns realise the important role played by gamification design in promoting Tmall's annual Double 11 Carnival. Such design has been widely deployed into after-carnival operation which we termed as "extended carnival" in everyday online consumption in China.

Table 2 Tmall pre-carnival campaigns 2017. Source: Chen (2017)

Campaigns	*Timeline*	*Events*	*Type*
Red envelopes torch relay	19.10-10.11	Ask friends to click and sign up through various social media to share the red envelopes	Red envelopes
Prepaid order	20.10-10.11	Prepayments, secure chosen goods, predelivery (with anticipated traffic jam based on past experience)	Prepayments
Coupons and discounts	20.10-11.11	Store/brand-specific coupons and discounts	Discounts
Huabei lucky draw	21.10-10.11	Deals of more than RMB 200 will gain a lucky draw of a free deal up to RMB 4999	Free lucky draw
Group red envelopes	25.10-11.11	Create social media groups, accumulate impact to get further discounts	Red envelopes
Cat hide-and-seek	26.10-11.11	Red envelopes worth RMB 50 million will be distributed on Double 11, and Golden Cats will randomly appear in 50 categories, with the smallest red envelopes worth RMB 100 each	Red envelopes

The three banner ads in Figures 4-6 present the goods on sale with instructions and invitations. The text "shop now" together with product images achieves the overarching function of informing consumers that they are ads, selling FMCG (Figure 4), mooncakes (Figure 5), and tailor-made outfits (Figure 6). The "informing" process is the interpersonal function in action, realised by designers and consumers within a communication and meaning-making process. For the textual function, these ads are placed at the top of the page to increase salience. The three metafunctions are achieved through a combination of multimodalities, with texts, images, and icons. In addition, the intertextual dimension is achieved through interactive affordances such as scrolling gadgets and links (clickable text together with text boxes) for interactivity, providing a gateway and site for the realisation of potential meaning-making and actions. Putting together, these banner ads not only work as signs, but also sites, realising the two-fold nature discussed in the literature review. In the following two sections, we will zoom-in and analyse the syntagmatic and paradigmatic dimensions, respectively.

The syntagmatic dimension under the framework of VG

Colour. Colour is associated with effects and functions as a communicative carrier and vehicle. Van Leeuween (2011) points to two important functions of colour: identity and textual meaning. For identity, colour can be associated with a certain brand or product that the banner is advertising. For textual meaning, it has an ability to convey structure of an ad (its coherence and overall "feeling"). In Figure 4, Fulinmen (福临门, literally, blessing comes to your doorway) is a rice brand in China. By using light green, Fulinmen tries to create a brand image associated with nature to signify that it is healthy, organic and environmentally friendly. The Chinese character 福 (fu, blessing) in gold is to express prosperity and glory. The brown Snickers chocolate and the yellow AXE cleanser essence made of lemon extract are in their "natural" colours to deceive and persuade consumers, that is, to make consumers believe that "what you see is what you get". Tmall has various festival-related campaigns, such as Spring Festival, Mid-Autumn Festival, Mother's Day, and Christmas, beyond its self-created Double 11 Carnival for Singles' Day. Colours are tailored for different festivals to celebrate a certain festive mood. Despite red is deemed alarming and aggressive in certain cultures, it is widely used in China, particularly during Spring Festival and weddings. It is believed that red discourages bad luck and evil spirits, thus bringing blessings and happiness. Figure 5 uses pink, gold and red to create a festive mood for the Mid-Autumn Festival. In particular, red is used for the characters of 抢100元优惠券 (to snatch the RMB 100 coupons). It makes the "instruction" stand out from the already crowded space of an ad full of symbols and texts in large font. In comparison, the banner ad in Figure 6 uses black to represent premium products (the texts indicate premium and tailor-made female outfits) and therefore coupon and low-price strategies do not apply. Similarly, as presented in Figure 7 in the next sub-section, the banner ad advertising an automobile uses blue to signify trustworthiness.

Text. Text includes brand name (including the logo), basic information about a certain product, and most importantly, storytelling. Because text is one of the most conventional modes used in advertising and many

studies are dedicated to it, we will not conduct detailed textual analysis for banner ads. The general observation is that banner ads on Tmall seldom uses a storytelling approach as they predominately use text as instructional information. This is often price-related, for instance "to snatch red envelopes and coupons", "it is cheap now" and "if you love your mom, dress her up like this" (see Figure 8 in the next sub-section).

Typography. Typography is closely related to text. Some typography is meant to be decorative. Chinese calligraphy, for instance, is deemed a form of art in itself. Other types are mundane to indicate mandatory information. Typography is a useful device to achieve evocativeness and contains rich connotations and metaphors (Kress & Van Leeuwen, 2006). Figures 4-5 are examples each using a different typography for a distinct occasion. The ad in Figure 4 uses a computer-enabled art font that is both functional and decorative, while for a traditional Chinese festival the ad in Figure 5 uses Chinese calligraphy, which adds a cultural touch to create a positive association within the Chinese market.

Imagery, symbols, and icons. These include both informational or non-informational elements within a given banner ad. These elements are first of all ideational, to show consumers what the ads are promoting. These elements are also interpersonal. For example, for human figures (Figure 6 and Figure 8), two unknown models rather than celebrities are presented. The "mom" in Figure 8 directly connects herself to the consumers through her gaze. According to Kress and Van Leeuwen (2006, p. 117), this is a "demand" (compared with an "offer"), where represented participants look at the viewers/consumers. Through such an image, the producer of the ad (Tmall) also does something to the consumer. The gaze and the gesture of the represented mom "demand" the recipient/consumer to create an imaginary relationship. This relationship is intended to arouse certain reactions on the part of the consumer (Kress & Van Leeuwen, 2006, p. 117-118). In Figure 8, the "mom" looks directly at the consumer with an elegant smile on her face. Her gaze, smile, and gesture (presenting a bracelet) are aimed at establishing a relationship with consumers and thus garnering favourable attitudes towards her and, more importantly, the outfit and bracelet. If we zoom out to investigate the textual or compositional function of this ad, it uses golden colour to signify prosperity and festive mood of Mother's Day as a whole. Zooming in again, a cluster of the model, outfits, and the background imagery such as flowers are also worth exploring. The flower presented is a peony (mudan), the national flower of China, signifying prosperity and blessing. For Figure 6, the ad uses a low angle where the model looks down on consumers, creating a symbolic power over them. The power within such an interpersonal relationship derives from the fact that the model presents fashion outfits and premium tailor-made services to consumers.

Graphic devices such as abstract lines and shapes are also used. These devices are non-informational as symbols or icons per se. However, with certain appropriation or arrangement, they can convey certain meanings. For example, for the automobile ad in Figure 7, the variation that makes the background of the car blurred is intended to signify speed and dynamism.

The above analysis has demonstrated how multimodal analysis can be conducted across the various modes of Tmall banner ads including colour, texts, typography, and imagery. At the same time, the analysis has been conducted at different levels, zooming in and out to focus on specific elements and clusters following the ranking mechanism of the whole, group, unit, and component (Boeriis & Holsanova, 2012, p. 262-265).

The paradigmatic dimension on interactivity

The second part of the analysis is devoted to the investigation of interactivity and its associated interactive meanings in banner ads. Interactivity is defined as the affordance of a text with multimodality to be acted upon, realising the full capacity of hypertexuality, and thus meaning-making. As for banner ads, the meaning-making process is embedded in the affordance of interactivity to make the consumption experience easier and playful (gamification). A symbolic and discursive process as such is used to boost sales and also contributes to (not necessarily causes) the cultivation of a materialist and consumerist culture in contemporary China. Figures 7 and 8 show two Tmall banner ads, advertising automobile and Mother's Day outfits respectively. We will use these two ads to analyse the interactivity value achieved through the framework we proposed as an extension of the Double 11 Carnival.

Figure 7: Banner ad with interactive functions advertising automobile. Source: Alibaba

Figure 8: Banner ad with interactive functions advertising Mother's Day outfits. Source: Alibaba

Ideational function. At the top of the screenshots, above the banner ads, there are three interactive sites/signs from left to right. Syntagmatically, the top left ad places a QR code and AR (augmented reality) scanner with two Chinese characters 扫码 (to scan code); paradigmatically, touching or tapping the scanner activates the QR code scanner to direct consumers to anything that can be scanned. Scanned items can be a

product image online, or a physical product with coded information on its packaging. In the middle of the top bar, a lens symbol is presented. It is often used to represent a "search" function. It also uses text to advertise hero goods placed in front of many goods lined up for consumption, just as supermarkets do in their physical stores. The search bar in Figure 7 displays "**穿小白鞋 来一**场和青春的约会" (wear the little white shoes on a date). The "little white shoes" are hero goods that went viral online and have gained popularity among Chinese youth. The text displayed on the search bar in Figure 8 promotes a newly released model from the Chinese smartphone manufacturer Huawei, model Honour5c, and announces its exclusive release on Tmall. Following this text, the symbol of the lens syntagmatically presents an additional camera symbol. Paradigmatically, this function (called "miaopai") allows consumers to take a picture of any desirable good they see and search for. It can bring up search results with similar and even identical goods on Tmall. Alibaba has incorporated this function on various video platforms to form strategic partnerships (for the camera symbol and "search with picture" function, see Figure 9). Of course, the search area can be filled through conventional typing, which is a conventional interactive affordance. In Figure 9, a symbol of a text box on the top right corner is presented syntagmatically. Clicking or tapping it, paradigmatically, opens up a new page with the Tmall notification box, filled with various messages (currently four). The message box may include, retargeted promotions (based on consumers' search history and previous purchasing behaviour), direct marketing messages pushed by official shops that consumers follow, social media chats with friends on Tmall, and notifications of delivery tracking status.

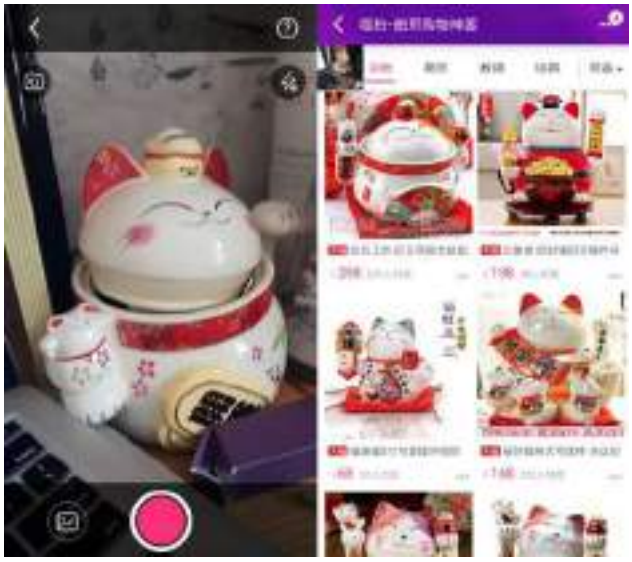

Figure 9: Built-in miaopai function located within the search bar of Tmall ads. Source: Alibaba

Within the banner ads, the ideational function is embodied in clickable/touchable links and icons, such as "**去**抢购 go" (to snap up and go), "**火速下**订>>" (order now) with an arrows symbol, and "**美**妈新衣满减包邮 **更有好礼相送**" (new outfits for pretty moms, in addition to free delivery if a purchase exceeds a certain amount, and other nice gifts). Syntagmatically, these texts and symbols all send similar information to encourage spending as in the Double 11 Carnival. Paradigmatically, clicking or tapping on the ads, the "go" sign, or the arrows ">>" directs consumers to the relevant Tmall product page. In addition, below the banner ads there are ten rectangles with rounded corners. They present ten other services in the Alibaba ecosystem, including e-payment, fans' party (social media function), free gift samples, as well as coupons and memberships, to name just a few.

Ideationally, the landing page of the Tmall app is dense with interactive signs and sites. Syntagmatically, it incorporates various formats such as dynamic elements (flash), symbols and icons, still images, and writing. Paradigmatically, it requires possible actions such as clicking, tapping, scanning, typing, and taking photos. These interactive actions have greater effects than mere reception of the text and enable access to new texts and sites. The interaction consumer has does not necessarily limit to banner ads themselves. These interactive affordances achieve hypertexuality by linking to and opening up new sites in a variety of ways, such as sliding for new images (dots placed at the bottom left of the banner ads), page changes, and pop-up windows.

Interpersonal function. The interpersonal function is orchestrated at an organisational (meso) level through technology-enabled affordances. These include search engine optimisation and algorithm-based re-targeted ads. However, due to limited space, our focus is on the front-end, including the graphic design and the intended affordances the interactive icons are embedded with. Syntagmatically, the icons and symbols on top of the banner ads signal to consumers that Tmall is all-purpose and ubiquitous: consumers can buy everything and socialise with friends on it. According to Adami (2014), such interactive functions are expected by consumers (perceived interactivity) and once provided, they create a complex dynamism to augment consumers' experience. As a B2C e-commerce platform, Tmall uses other features such as colour palette and modular layout to differentiate itself from the C2C Taobao platform, which is seen as filled with counterfeits. Tmall aims to build a different brand image. By collaborating with well-known brands home and aboard, Tmall aims to emphasise professionalism and its official status. This carefully constructed identity can be seen from the multimodal resources it uses. The richness, coolness (enabled with up-to-date technology), and exclusiveness are constructed from both the syntagmatic and paradigmatic dimensions, converging on various non-interactive and interactive modalities. Banner ads are created to show consumers what products and services are on offer with an "official tone", for example, through branded trademarks.

Paradigmatically, the interpersonal function can be achieved through a range of affordances and interactive functions to be activated. However, this interactivity is controlled and restrained to a certain degree. The modality configuration of the banner ads uses more images than text, exemplified by dynamic and still images, as well as icons. These images and icons are used to present both products and interactivity signifiers. Such configurations are intended to encourage consumer actions to achieve selective effects – not to allow consumers to create and manipulate ads or products (as they can to a certain degree on Taobao as shop owners) – but to provide mere access to further pages within Tmall, selling more products and services provided by certified brands (strategic partners). Even the social media function is limited to actions such as providing reviews, posting pictures after purchase, and befriending shop owners or other buyers within the Tmall platform. Therefore, the interactive affordances are enhanced, but only to a certain degree. There is a clear directionality (self-referencing) in the realisation of the interpersonal function, recursive within the larger Alibaba ecosystem. In addition, Tmall not only shapes its own professional, cool, official and exclusive image, but also projects a controlled "identity value" to consumers who visit the site, with a preference for visual modalities (signs and sites to be activated) over conventional texts (deemed non-interactive).

Textual function. Syntagmatically, the design and positioning of the interactive functions follow Tmall's conventions, cultivating a habit and particular aesthetic experience for its consumers. Once consumers open the Tmall app, they will expect the same layout that they experience in a physical store process. In addition, the banner ads are also placed in a very salient position (at eye level) and at the top of the landing page. There is also a sliding function so that consumers can switch between the ads (the dots sign). Overall, the banner ads allow for a level of manipulation, enhancing their interactive aesthetics as a whole. Paradigmatically, the transformation process marked by the before-after (interaction by clicking or hovering over) relationship between the signs and sites is quite cohesive and limited in scope, because Tmall does not allow third-party expansion. Whether it involves scanning, searching or redirecting, the interactive affordances are restrained within Tmall and are connected with purchasing. In this sense, the experience provided by Tmall has little to do with sociality or life uplifting, it is all about purchasing under the disguise of gamification and carnival. For example, the coupons and red envelopes with deadlines (the icon of countdown) creates an interactive stimulus for consumers to click and pay, timely. Otherwise, consumers may lose such an opportunity to get a bargain.

Conclusion

Combining a detailed multimodal analysis and social semiotic study of the meanings of the banner ads (micro), the Tmall platform design (meso) and wider Chinese society (macro), we have demonstrated that banner ads of Tmall have been constructed as a commodity. Tmall also has commodified the interactive and social sphere through social media functions to share pictures and reviews on purchased products and services. In doing so, we have shown that experience driven by a communicative consumerism is underway in contemporary China. Through an analysis of both the non-interactive and interactive functions of Tmall banner ads, we present a picture of the development of such visual information as both signs and sites. Equipped with the two-dimensional framework, the textual and visual modalities (texts, colour, typography, and imagery) are analysed as the initial state, followed by the interactivity as "what happens" if they are activated – a before-after relationship within a "becoming" process.

Based on the analysis of Tmall banner ads on both the syntagmatic and paradigmatic dimensions, we find that the ads have been incorporated into a gamification design to encourage consumers to spend more and buy things they may not need, even after the Double 11 Carnival. The banner ads of the Carnival are largely the same as those for the everyday consumption on Tmall, however, with intensified modalities to encourage consumers to spend. These include, festive colours and gamification design (red envelope campaigns) and more importantly, an emphasis on "low cost" such as special discounts, coupons, and free delivery services. Combined with words such as "buy now" and "go", terms such as 低价 (low price), 特价 (on sale), and 抢 (snap up), the intentionality of purchasing (panic and scare of losing a bargain) is intensified through such gamification design. The message of "there will be no chance to get the goods at such low price later (after the Carnival)!" is expressed explicitly through the aforementioned terms and icons. The reason why we see the Carnival has been extended to non-carnival, everyday consumption is because coupons and red envelopes (*hongbao*) are becoming a norm for most Tmall shops. These banner ads and coupons with clickable and touchable links are directly linked to a user's Tmall account, offering discounts, special deals, and "buy 1 get 1 free" services. In addition, if one's purchase exceeds a certain amount of money, a free gift will be sent with the delivery or the shipping fee will be waived. These discourses and visual constructions (afforded by interactivity) are primarily monetary stimuli. Such stimuli work particularly well on Tmall because users are attracted by cheap, quick and convenient shopping and delivery services, again, on a daily basis. The Double 11 Carnival is an important case in focus, extending its reach even after the event has been completed.

In sum, our approach is informed by existing studies but provides original insights in two ways. First, it departs from a social semiotic approach, combining both the textual and visual analysis and employing the VG framework at a more detailed level. Second, we have conducted much-needed testing of the tentative framework developed by Adami (2014, p. 150), a nuanced development focusing on the 'meaning-potential of interactive sites/signs'. In conclusion, the multimodality and interactivity examined in this study support Cheung's (2016) model in experience design. That is, experience design elements such as information, navigation, engagement, entertainment (in our case, gamification), and personalisation all work together to enhance users' trust, satisfaction and recognition of Tmall as a service provider. Our approach is explicitly multimodal, taking the linguistic, visual and interactive resources (the tri-fold convergence) into consideration to study new phenomena in an e-selling environment, contributing further to research on multimodality, textual analysis, and experience design. Due to the limit of space, we only focus our discussion on one single most influential e-commerce platform, that is Tmall, in China. In future, comparative studies of different platforms may yield additional insights to the field of experience design for generalisation purposes.

This study explores the question: Within the context of global brands management and the need for integrating local identities, how does Starbucks achieve global consistency and meaningfully localised experiences? Through a review of literature and a series of interviews with store designers, design managers and brand concept experts at Starbucks, we compiled the most commonly applied branding and design methods, with an emphasis on the locally relevant spatial experiences the global brand delivers. Moreover, we set out to classify our findings in a way that can assist other brand and experience design teams in overcoming shard challenges. Our findings focus on the management of the grounding brand concept, as well as operations and real estate teams. Through presenting some tools, manuals, guidelines and sample checklists, we suggest that store design teams in different locations can build strong, locally relevant spatial experiences that tie in successfully with the brand's global principles.

Keywords: Starbucks, spatial experience design, local identities integration

From Global Brand Management to Spatial Experience Design: an introduction to the research space and the impetus for our interest

Among the principal challenges that globalisation presents for global brands, including Starbucks, is the need to create experiences and to localise these experiences to various markets (Hands, 2008; Holt et al., 2004; Eldemenery, 2009; Boutros, 2009). There is increasing pressure from consumers to eliminate the unrelatable one-size-fits-all model. Therefore, successful global brands need to create a balance between sending a coherent message, while still tailoring it to different cultural local customs (Hands, 2008; Holt et al, 2004; Eldemenery, 2009; Boutros, 2009). He and Wang (2017) clarify that global brands will occasionally err on the side of inconsistency in order to better suit a particular locale.

Aligned organisations work across all functional boundaries as Kalback (2016) suggests, and they have to do whatever it takes to ensure their constituents have a great experience. This need propels the formation of multidisciplinary teams specialised in experience design.

Pine and Gilmore (1998) started a boom by introducing the experience economy, founded on the core distinction between tangible goods and memorable experiences. Kalback's (2016) multidisciplinary view and Pine and Gilmore's experience economy study lead to the use of the term 'spatial experience design' to refer to a holistic view of spaces. This usage moves away from seeing the visitors of such spaces as simply seeking out aesthetic rewards, and instead considers them as complex, emotional beings. In this view, places exist not

only physically in space, but also in people's minds, memories and imaginations. The identity of a specific space becomes interesting when it recalls a certain experience or evokes associated memories. In those instances, localisation becomes a major factor in fostering positive emotions within branded spaces.

Dealing with all touchpoints and teams with different disciplines in order to accomplish an effective localised spatial experience design has become an undeniably perplexing task. For designers to deliver, competitive organisations rely on multidisciplinary teams, including interior and graphic designers, marketers, and other professionals, so as to achieve the organisation's goals and aims. Designers may comprehend, shape and communicate new, innovative products and visualise brands, but design always needs to be harmonised and carefully associated with a firm's approach and core capabilities, as Hands (2008) has emphasised; this describes the manager's job to a tee. According to Steers et al. (2012), the better the toolkit, the better the chance of success.

On the basis of these core concepts, we look into a global leading brand – Starbucks – to uncover how it confronts the plethora of issues related to localised spatial experiences.

Why Starbucks?

The company selected for the study was Starbucks, a leading global brand with thousands of branches around the world. Its adaptations are successful and include a large number of employees, which made recruiting possibilities more abundant. Several factors supported the choice of Starbucks, including Grinyer's (2001) classifications, as well as Teufel and Zimmermann's (2015) overview of holistic retail experiences, as outlined below.

Starbucks has been identified as a dominant global brand that seeks a balance between consistency and local meaning; therefore, it has occasionally identified the need for its methodology to change, as our research indicates below. Starbucks is a noteworthy example of a brand that typically adapts its spaces in order to suit local environments. *Khaleeji Times*, a newspaper published in the United Arab Emirates, published an article in 2010 entitled 'Global brands, local tastes' (Khaleeji Times, 2010), which suggested that brands such as Starbucks are too standardised.

Our interest for the present research is based on the observation that Starbucks seemed to be picking up on consumers' preference for localised experiences, and dissatisfaction with its standardised shops. In 2012, two years after the article was published in *Khaleeji Times,* the company opened Starbucks 'The Bank' (designed by Liz Muller) in Amsterdam. The corporate website (Starbucks, 2012) suggested that this shop was 'a glimpse of Starbuck's vision for the future'. The design of the shop was highly individualised, revealing a radical aesthetic departure from the usual standardised Starbucks stores. The strategy seems to have been successful, as Starbucks has since designed localised shops for most of its locations.

Furthermore, Grinyer (2001) concludes that brands tend to be either 'value exporters' or 'value collectors', explaining that value exporters have a strong identity and change only minimally from one country to another, whereas value collectors put a tremendous amount of energy into adapting to the different countries in which they establish themselves. Of course, value exporters still have to adapt content to local cultures; however, value collectors have an outward style that is less identifiable from one country to the next, despite the considerable strength of their internal culture.

As we were interested in how global brands adapt to local environments in terms of experiential spatial design, a study of value collector brands would be more beneficial and provide better insights into how global brands have successfully adapted. As Grinyer mentions, even value exporters must adapt slightly; however, collectors such as those often do so drastically. Through the literature and review of images of different Starbucks stores around the world, we established that Starbucks does adapt its stores to their surrounding local environments.

Moreover, among the brands that Teufel and Zimmermann (2015) mention in the book *Holistic Retail Design*, Starbucks stands out as both a value exporter and successful in experiential design. Teufel and Zimmermann include Starbucks specifically because it provides both a holistic retail experience and adapts to local tastes. He references *The New York Times* (2010), stating: 'When Starbucks stock began dropping in 2007, the cookie-cutter approach to store design had fallen out of fashion. In 2008 Starbucks announced it would renovate company-owned stores to be more sustainable and to look less global and more local'.

The emphasis on adapting is also evident on the brand's website, which mentions the importance of local adaptation in store design strategies. This shows that companies put both experiential design and adaptation at the centre of their brand strategies. The Starbucks website (2018) states: 'Our new approach to store design means that our designers are looking at each store individually to ensure that it looks distinctively local. This represents a new level of coffeehouse comfort, meaning that no two Starbucks will ever be entirely the same'.

Starbucks is an interesting case because it was once a value exporter and has more recently changed its strategy. However, Starbucks still does have some standardised new stores, as some of its new designs are more adaptable than others. The method for this study was geared towards understanding Starbucks's strategy in terms of how it selects stores to be localised, as well as how it strikes the right balance between achieving consistency as a global brand and appropriately adapting to different markets.

Through this examination of Starbucks, we set out to understand the strategy used to strike the harmony between consistency and surprise that the branding teams use to convey corresponding experiences.

In order to capture the methods successfully used to tackle such issues, we reviewed secondary sources and developed an empirical study in order to describe the brand strategy. This essential information was gathered through semi-structured interviews with individuals who hold different positions within the Starbucks store design team, so as to comprehend its group structure and how it propels the progress from global to local when planning for spatial experiences.

Research Question and Methodology

In this study, we asked the following question: Within the context of globalisation and the need to reflect local brand identities, how does Starbucks manage the brand in order to achieve global consistency and meaningfully localised experiences?

The first objective was to understand how Starbucks is represented in local spaces. The second was to examine contemporary developments in brand management and experience design and to explore in detail their interrelations.

Therefore, to address the research question and objectives, we first conducted a literature review in order to understand Starbucks's operating context and study how the brand is seen through the lens of external observers. Specifically, we examined empirical data related to the company's spatial experience design methods. Through this approach, we were able to illustrate the successful methods employed by the organisation.

Yin (2014) defines case study research as a technique that explores an existing phenomenon in detail and within its real-world context. This paper used a single case, whereby the attention is focused on the multilayered nature of a single case, so as to comprehend the method used within these specific conditions (Stake, 1995). Flyvbjerg (2013) promotes the single case approach as a method for exploring a phenomenon, suggesting that it can deliver a precise comprehension of the phenomenon's causes and results, and a solid understanding of the qualities of the unique situation at hand, so as to encourage new theories and generate novel research questions.

Literature Review – Starbucks's Operating Context

The following section lays the foundation for the questions posed to the interviewees, including examples of Starbucks's spatial experiences that have been localised, the prior establishment of the importance of teams, as well as the origins of the development of the team responsible for the spatial experience design translating process.

It examines images of Starbucks spaces as well as the company's explanation of those spaces through their archive on 'Pinterest' patterns, showing how its adaptations emerged. Some approaches took their inspiration from surrounding history and heritage, while others included working with local artists or designers, incorporating surrounding landmarks and local customs, and sourcing local materials.

- Geographical inspiration: This approach takes its inspiration from the store's surroundings, be they natural wonders or manmade structures — anything around the area can serve as inspiration. A Starbucks store in Santa Cruz, Bolivia drew inspiration from one of the country's most spectacular

natural wonders, the world's largest salt flat. The geometrical patterns formed by the salt flat inspired many decorative elements found throughout the store (Pinterest, 2018) (Figure 1).

- Local heritage: Starbucks is committed to preserving the environment and showcasing local heritage. For example, its store in Hanoi, Vietnam, has several walls featuring work made by local artists, including a woven bamboo piece, which was made using the same technique as that used to produce Vietnam's iconic conical hats (Pinterest, 2018) (Figure 2). Also, the Starbucks in Fuzhou, China is all about "Wei Qi," the ancient Chinese board game. It houses the famous, world class, first "Wei Qi" master museum (Pinterest, 2019)(Figure 5). Moreover, the design of the remodelled Starbucks store near the bustling Kadikoy Carsi ferry terminal in Istanbul took its inspiration from the aesthetic boats and ferry buildings (Pinterest, 2019) (Figure 6).
- Sourcing local materials: Starbucks also locally sources materials in many of the stores around the world. An article published on its website explains that the decision to locally source is not driven solely by economic factors, but is instead motivated by a desire to be 'respectful' to the country (Starbucks, 2018). Examples include the store next to the flower market in Amsterdam, as mentioned above, which uses local materials including Belgian bluestone, classic white tiles, green marble, and a concrete floor (Figure 3). Also, Panama's store features tilework resembling a hand-painted style germane to the local culture. Starbucks also incorporated design elements from neighbouring regions, including furniture from Colombia and wood slatted light fixtures from Brazil (Starbucks, 2015 (Starbucks, 2015) (Figure 6). Finally, the Starbucks store at Taipei's Longmen building in Taiwan includes Taiwanese-designed wood tables and chairs to create indoor seating that reflects local styles (Starbucks, 2015) (Figure 7).

Figure 6: Starbucks Panama. Source: Pinterest (2018)

Furthermore, the literature review established that teams were paramount within global organisations (Senn & Atanasova, 2011; Marks et al., 2001; Caldwell & Gladstein, 1992; Kirkman et al., 2004; Donnellon, 1993).

However, existing literature does not offer a precise explanation of what constitutes the process that grounds the transition from 'global' to 'local'.

By reviewing the literature, we were able to determine that Starbucks has an in-house design team split into two main categories: 'The Starbucks Global Design Team' and the 'The Store Design Team'. However, it should be noted that outsourcing is also used on some occasions. The Design Council (2007) identified that 'The Starbucks Global Design Team' is responsible for the delivery of all in-store collateral and packaging, for the design of much of advertising and marketing materials, and for a visual merchandising group that works on visual presentation in the stores and of the products. A separate store design team is responsible for the design of the furniture, fittings, and the layout of Starbucks' spaces. However, it did not specify how these different teams relate and the concrete roles they are assigned; therefore, the interviews were conducted in order to understand the teams' structure, the nature of communications within and across different teams, as well as the outsourcing model.

Moreover, secondary sources established that Starbucks still has some new stores opening that are standardised; therefore, identifying the strategy behind selecting which stores to localise was also a goal of the interviews.

Consequently, the interviews were designed to explore and capture the methods that the teams use regularly and also specifically when transposing the brand to local environments. They also included the need to understand the inspiration for localised designs and the challenges that the teams face in order to design tools to address those challenges.

The information explored in the literature review section was then used to formulate the questions for the purpose of data collection. The questions were designed to capture information including: (1) understanding the basics of its general practice, (2) understanding the process of localising in more detail, (3) understanding the teams, (4) discussing specific examples of projects and shops worldwide, and (5) seeking solutions to challenges faced.

Primary Data Collection – The Study of the Case of Starbucks

Interviews

We used primary data gathered through in-depth semi-structured interviews. Accordingly, the research method we chose in this study was mainly based on a qualitative approach. Semi-structured interviews are commonly applied in qualitative research (Kitchin & Tate, 2000) and also feature prominently within design research (Michlewski, 2008; Gary, 2014; Roise et al., 2014). Within this study, four semi-structured interviews were conducted.

Table 1: Participants' Information

Participant Code	*Job Title*	*Interview Duration*	*Medium*
Store Designer A	Senior Designer – International Store Design & Concepts at Starbucks EMEA	1:03:02	Video Conferencing
Store Designer B	Interior Project Designer at Starbucks EMEA	27:58	Video Conferencing
Designer Manager	Design Manager at Starbucks EMEA	51:30	Video Conferencing
Store Designer C	Store Designer at Starbucks, Miami, U.S.	37:28	Face to Face

Question included:

- What does your work involve on a more or less everyday basis?
- What is a typical project?
- Describe a typical project structure of a team.
- What are your roles and responsibilities in the context of a wider brand team?

- How do you facilitate the transition ‘from global to local’?
- Which store in your opinion is very successful and why?
- What does successfully representing global identities to local territories mean in relation to these particular examples?
- What are the main challenges that you are facing in terms of the things that we discussed, such as context vs. brand? What type of support do you need?
- What tools would be useful to you to address the issues of localising design in your practice?

Additional questions were available for lapses in conversation, or in cases wherein the participant failed to address the aspects needed to answer the research question. These supplementary prompts were used in order to encourage or guide participants towards the information required. These questions include the following:

- Which part of the work is systemised and which is manual?
- There are still some Starbucks shops that are standardised. Why is that?

Data Analysis

The analysis followed several steps according to the guidelines of case study and qualitative data analysis methodology (Eisenhardt, 1989; Miles & Huberman, 1994). Thematic analysis (TA) was used to analyse the qualitative data collected during the interviews. To ensure reliability, this method must be conducted systematically. Transcribing and coding can be very flexible and conducted on every sentence, word or paragraph, depending on the need, followed by an examination of the codes and their relationships with each other, and eventually revealing overarching themes. Then, an initial list of the main themes, construct and insights was completed. The list was further refined when compared with relationships found in the literature, in order to identify similarities and differences, increase the internal validity of results, and refine recurring themes and constructs. The iteration between data, literature and analysis was repeated several times. The results of this iterative process are presented and discussed in the following paragraphs.

Thematic analysis was adopted because of its flexibility — not simply in terms of theory, but also in terms of the research question, sample size and constitution, data collection method, and approaches to meaning generation (Clarke & Braun, 2017).

The main aim of the questions was to understand how Starbucks manages consistency and local relevancy. However, in order to extract the information sought, some general information about Starbucks was needed in order to understand the context in which local relevancy is achieved. Therefore, the findings begin by first outlining the general information such as ‘Team Structure’, ‘Available Tools’, ‘Spatial Restrictions‘ and ‘Strategy’. Later ‘Local Relevancy’ is explained, and various issues are addressed, including the challenge of local relevancy according to the store design team, where the team finds inspiration to tackle the issues, and the method they use to do so. Finally, the questions broach the topic of new tools that can help tackle these issues.

a. Team Structure and Method

This theme encapsulates the structure of the store design team at Starbucks and the way in which it communicates with the other teams. The interviewees were selected from two different Starbucks offices. Three of the participants were based in the Amsterdam office and responsible for the Europe, Middle East and Africa (EMEA) markets, while one of the participants was based in the Miami, Florida office and responsible for the South East America, Florida and Latin America markets.

The interviews established the fact that the EMEA market is split into two offices: one in Amsterdam and one in London. The London office is responsible for the U.K. stores and a small portion of Europe, while the Amsterdam offices are responsible for the rest of the stores in that market.

The store design teams are split based on the licensee, and vary from two to five members, depending on the size of that market. The teams are always composed of one designer manager and varying levels of designers with a 3D degree background. One participant mentioned:

“We in Amsterdam are covering what we call the GEO licensee market and that means that we have divided Europe in different areas related a licence store. For example, the Middle East, Turkey and Russia are covered by once licensee; they are quite a big company and they are operating the Starbucks stores in that area. Then we have a few teams, as they are really large; we have a few smaller teams that are developing new stores with that local licence, so the large design pool of people are divided in separate smaller teams. They vary from small teams are two persons and bigger teams are four to five persons and each team has a design manager and at least one project designer.” – Design Manager

Graphic designers were previously part of the store design team; however, they are now part of the concept team. Therefore, for artwork needs, the store designers use a program called the Starbucks art program. The design manager within the store design team is responsible for maintaining the relationship between the licensee and the internal team. The store design team takes care of not only creating the layouts, but also ensuring that the brand is expressed properly by the design and implemented in the right way. The design is rarely outsourced, but for very high-profile cases, this is sometimes used. For smaller design elements, outsourcing is also possible, but rare. The store design team in Amsterdam work with the operations, marketing, and real estate departments and with local construction teams. In the EMEA Starbucks office, the store designers speak to the operations and real estate teams on a weekly basis. Within the store design team, there are weekly meetings per market. Therein, the different teams meet to talk about the challenges faced, so it is important for the design team to present their project in order to receive feedback from the market. Meanwhile, the store design team itself holds a daily meeting at an assigned time.

The operations team are responsible for regularly evaluating the store’s efficiency and devising the templates and manuals.

In the U.S. office, the teams are usually composed of a project manager and a designer, and rarely comprise more than two members.

The design team begins by receiving the brief through a digital system. They view the brief and if there are any questions, they clarify those with the relevant department, usually operations or real estate. Then they start by understanding the customer and the needs of that specific store, followed by the creation of the preliminary layout, schematic layout, and packages — this is the stage wherein the drawings become increasingly more detailed. Then it goes to the market, operations team and market team. Once it has been approved, it either goes to a local firm to translate the drawings (if mandated by the laws of the country) or straight to construction. If the construction team has an issue, they contact the manager to resolve the problem.

b. Available Tools

It was paramount to understanding the tools that the store design team use in a leading global brand such as Starbucks. These tools include the following:

Briefs for new and renovation projects database: Project requests from the market are represented to the designers on a sheet which lists all stores that are yet to be completed, including new projects and renovations. The store designers receive a project request containing details such as a number, project rules along with tick boxes, and a survey package. If there is an issue, the store designer can flag the project to be discussed with the related department.

Fixed items template: A template for the focal point of the Starbucks stores (which is the bar) is available for designers. It includes information such as the amount of equipment and the spaces between items, with some variations depending on countries. The material finishes, artwork, and seating arrangements are subject to change from store to store. Furthermore, the back of house is fixed with a template and guidelines. The operations team are responsible for regularly evaluating the store’s efficiency and devising the templates and manuals.

Brief calculations: With each brief handed to designers, the real estate team has already calculated the number of people who can be accommodated by the store in order for the store to generate money. This covers how much space should be allocated to each function, depending on the chosen site.

Starbucks Art Program: The U.S. office develops pieces for the store designers to use. This is renovated constantly and varies from area to area.

Software: A furniture and materials library that includes 3D models of the catalogue items. The test results on a specific piece of furniture can be viewed, with the test having been carried out in the main office in the U.S.

Report: A report from the market addressing the local demographics and preferences of that specific area.

Database: This includes marketing guidelines, correct logo usage guidelines, brand wording, etc.

c. Spatial Restrictions

In terms of spatial challenges, budget constraints typically limit the type of furniture and finishes the designer can select, while attempting to satisfy the brief in terms of managing spatial restrictions, such as providing the amount of seating needed to make revenue, as well as ensuring that the emergency exits remain clearly marked, while also keeping the budget in mind. As a Starbucks store designer remarked:

"The challenges are not only bringing the identity of the brand into the café, it is also having the number of seating that the company requires to make that much money per year; sometimes it is impossible because you need to keep in mind fire exits, and some states have different rules: some states the require two exits, sometimes one exit. We receive many transfers from one Starbucks to XXX [another brand]. They left and we are taking over, so there is no plumbing. You start from zero from scratch and you have to minimise the cost. I cannot get my construction team to do plumbing wherever I want — that is cost — so sometimes I should keep the flooring; we are not changing it, so those small changes, the do's and don'ts, are what make things difficult." – Store Designer C

d. Strategy

Figure 7: Starbucks Store Hierarchy. Source: Forbes (2016)

The literature showed that Starbucks still has stores that are somewhat more standardised than others. The interviews explained the strategy visualised in Figure 4. At the top of the pyramid are the premium Starbucks stores; the core stores sit below, and become less and less premium towards the bottom. The most premium stores offer the maximum look, feel and experience of the brand. The budget decreases based on the store's position within the pyramid. Thus far, the Starbucks strategy is to localise all locations, but to pay closer attention to the highest-placed stores in terms of delivering the maximum experience of the brand.

d. Local relevancy:

1. Challenge

It is a challenge to create designs that people can claim more or less as their own, designed by a foreign designer. Moreover, creating works that are not cliché is a particular feat.

Staying relevant is also a challenge in a competitive market space, especially since online stores came to be; therefore, stores rely on experiences, but since many stores rely on that method to compete, there needs to be a differentiating factor to attract people to this specific experience. Participants mentioned:

"I mean, we do what we can, but it is a challenge working for the world and making stuff that people can claim more so their own. It is a big challenge honestly. Some people like it more than others." – Store Design A

“The difficulty there, you need to be sure that you are doing the right thing and you are not creating a cliché that everybody is living in this area already knows, so you can go wrong there as well.” – Design Manager

2. Inspiration

Currently, the company supplies the store designers with a report on the local demographics and market preferences. This is given to the store designers along with the brief, and serves as part of the inspiration which the designers work from in order to develop a localised shop. After the design has been developed, it is also presented to the market and feedback is offered in order to resolve any issue that arose. As designers mentioned:

“I would say the majority will arrive through the knowledge of the market itself. It kind of teaches us and guides us and, of course, the rest is common sense. It is what we know; it is the sensibility that we have, but the majority is the market itself.” –Store Designer B

Visiting the relevant country is often a good way of becoming acquainted with the culture, but this is not always possible. As a design manager at Starbucks mentioned:

“For example, if we travel and that is always a big budget issue we cannot endlessly travel; and especially the project designers, they cannot endlessly travel. Then that is something that even limited, but we always try to do, for example, is bring a few products that are locally relevant and they can be things to eat, coffee that is not from Starbucks but another brand, local tea, even some other products.” – Design Manager

To understand the people with whom they are working, store designers take the initiative to research real books, watch films and test local products that are brought by company personnel who could travel in order to understand the culture. As mentioned above in the previous example, a designer also commented:

“It is not asked for us but we take initiative on, let’s say, research and books. We watch films; we would do anything just to absorb and to actually understand who are the people we are working with, but there is no (to me), there is not a clear blueprint on how to do that, so this is (to me) something that you need to do on your own, and (to me) I take that really seriously, because if we are actually talking about being locally relevant the best would be is that we immerse ourselves in that culture.” – Store Designer A

Travelling to the country in which the store is being designed is a way of gaining inspiration and understanding the culture; however, for a number of reasons, including budget and timeline issues, the designers typically can’t spend a month or two in that country, and junior designers sometimes do not visit at all. The store designers try to work closely with the local team in the country, especially if they are not able to travel themselves, a situation which also presents its own challenges. These include inaccurate information or linguistic or cultural barriers. Miscommunication with local contractors can lead to difficulty in assessing whether the design has been executed in the way intended. As a participant mentioned:

“So we try to do as much as we can and also to work closely with our guys on the ground. Look, I have seen this, I have seen that. We see some feedback from people when we say this. We also discuss with operations. Normally they give us feedback on things and the problem with that is we would expect a bit of quality, or much more insight from our partners but we don’t always get that.” – Store Designer A

3. Method

There is no rulebook on how to be locally relevant — the inspiration and work are quite organic. However, there are certain core values against which every design is judged. Those values can easily be translated into different locations around the world. The first is human connection, followed by warmth and honesty. Connecting people over coffee can be translated into different seating arrangements, depending on the country. Meanwhile, warmth can be translated by the use of certain colours and materials. Honesty translates by paying farmers and artists in an honest way, and in terms of space, selecting real, honest materials.

e. The Need for New Tools

The interviews with the participants from the Starbucks store design teams verified the need for the tools being developed. It was key to determine the importance of developing such tools and to confirm that they are being targeted towards the right audience. The following statements by the participants confirmed the need for such materials.

When asked if the team would be interested in the tools developed, one of the designers replied:

“Oh, yeah, I think they would be interested to hear on the learning on that… absolutely! I think it would be useful, really useful, especially for Starbucks and other brands. I think a lot of brands would. This is also my perception from some of the things I have learned there. It is like a lot of the brands would like to hear about that because for them it is a major challenge staying relevant.” – Store Designer A

Another participant stated: “I think that it could be really interesting to have a platform that goes a bit deeper into a local culture and giving an image for an outsider of what is really important for a specific area.” – Design Manager

Conclusion

In conclusion, the strategy used to strike the harmony between consistency and local experience involves a combination of aspects, some of which are management’s responsibilities, while others fall into the domain of the designers.

Starbucks store images available in the literature allowed us to see the end results of localised spatial experience as produced by the Starbucks teams’ process. Subsequently, the interviews showed the method and tools the teams use to create localised Starbucks experiences. The interviews also confirmed the need for teamwork and communication, as previously discussed by Senn and Atanasova (2011), Marks et al. (2001), Caldwell and Gladstein (1992), Kirkman et al. (2004) and Donnellon (1993).

To conclude, the Starbucks case study shows that the method of imposing restrictions on functional elements is a necessity; however, having more flexible values when it comes to design is preferable. Instead of equalising the values reflected in colours and fixed materials, the use of more flexible words that can then be translated by designers into what they mean in different cultures helps to create a distinctive experience that people can claim as their own, while still remaining connected to the larger global brand.

The aim of this paper was address how a global leading brand such as Starbucks addresses the pressures of globalisation internally. Literature and observation easily establish that Starbucks localises spaces, but the process the design teams follow to arrive at such outcomes was previously unknown.

Semi-structured interviews revealed that the Starbucks team, even without visiting the relevant country, had to design a customised spatial experience that a local customer would enjoy, while still keeping some consistency. Where possible, travel facilitated this process; however, even a visit of a few days does is often not enough to deeply understand the local people’s perspectives. That is where tools come in handy, as these help the teams ensure that multi-disciplinary perspectives are taken into account to produce a holistic vision.

This suggests that tools are powerful enough to aid local knowledge, even when the designers have to design for local audiences remotely. Further research and improvement of these tools could save global brands travel budgets, as well as relieve the need to install a large local team in every part of the word.

The interviews also confirmed the need for assistance when it comes to this issue, as all interviewees agreed that locality is a frequent challenge of spatial design.

Further Research and Implications

This paper contributes to the wider research topic of investigating the connections between brand management and experience design under the pressures of globalisation. The aim of the research is (a) to explore how brand managers and experience designers on global teams relate to local identities that influence them, and (b) to develop a set of tools that those teams can use when creating local identities in specific sites, in the face of globalisation.

In order to achieve the objectives of the wider research topic, a number of methods could apply. This paper presents findings from part of the approach adopted in order to achieve the aims and objectives of the larger research topic.

The findings will be combined with additional methods so as to create tools that can aid practitioners in transposing global brands into local environments. Further research on other global brands is an important step in understanding the similarities and differences across organisations. That knowledge will help us develop tools with which to tackle the challenges that global brand teams face as a result of globalisation. Understanding the methods and tools employed by one of the most successful global brands ensures the future development of appropriate tools.

This paper introduces empathic design as a framework and a strategy that can be adopted by the emerging field of experience design (XD) to create meaningful experiences connected with people's lives and needs. The paper presents the rationale behind the emergence of empathic design, the traits that characterize this approach to design, a collection of empathic design methods and practices, and a critical discussion of the limitations of empathy in design. Methodologically, this paper is based on a systematic literature review on empathic design, human-centred design, and empathy, which is synthesized and focused its application in experience design. Ultimately, this paper intends to contribute to the broader discussion of how traditional design practices are adapting and evolving to respond to new realities, and how new design paradigms are needed to address the very complex challenges that we face in the 21st century.

Keywords: empathic design, experience design, human-centred design, empathy, soft skills

Introduction

In recent decades, as Western societies move towards a post-industrial era, the scope and focus of design have changed from creating functional and aesthetically pleasing artefacts to tailoring meaningful human-centred experiences. In this new scenario, design is expected to create value by improving, enriching, and helping people make sense of their experience within the built environment, which implies that designers are required to have a profound understanding of users so that they can create meaningful experiences mediated by products, environments, services, and systems (Krippendorff, 2006; Sanders & Stappers, 2008; Norman, 2014; Davis, 2016).

Whereas in most of the 20th century "hard skills" were appreciated and needed to design new products, messages, and environments, in the post-industrial scenario of the 21st century, the so-called "soft skills" are becoming increasingly important to create experiences that connect meaningfully with people's lives and dreams. Among the broad set of "soft skills," empathy has been gaining attention since the late-1990's when companies realized that they needed a closer and a more sensitive relationship with their customers, which led to the emergence of people-centred approaches to design (Sanders, 2006). This shift has favoured the appearance of design approaches, methods, and techniques that place people at the centre of the process such as user-centred design, human-centred design, participatory design, and empathic design (Liem & Sanders, 2013; Steen, 2012; IDEO, 2011).

This paper presents empathic design as a framework and a strategy that can be adopted by the emerging field of experience design (XD) to gain a deeper understanding of the human condition and, consequently, create experiences that meet people's needs, preferences, expectations, and aspirations.

The Seeds of Empathic Design

As technologies have matured and basic needs have been satisfied in most Western urban environments, the demand for more meaningful experiences has increased (Koskinen and Battarbee, 2003). This increasing demand in the last two decades has motivated a movement toward context-sensitive design (i.e., human-centred design approaches) as a response to the limited perspective that practitioners and organizations used to have about people's lives (Kouprie and Sleeswijk Visser, 2009). These changes marked a transition in how industries and designers conceived their relationships with the people they served, which in turn transformed how they approached, got involved with, and understood these same people (users and stakeholders).

As Sanders points out, "designers have been moving increasingly closer to the future users of what they design" (2008, p. 5), which has impacted design philosophies, values, methods, and practices. In this emerging scenario, roles have changed and evolved. Designers have become explorers of people's realities, and people have become partners and experts of their own experiences (Postma, 2012; Michlewski, 2008). Adopting these new roles has required from designers the development of new skill sets, in which empathy is fundamental as it allows for rationally understanding and emotionally connecting with other people's lives and circumstances (Segal & Fulton Suri, 1997).

Empathy and Design

Empathy, the ability to feel and understand other's emotions and circumstances, is considered a fundamental skill for designers to acquire an in-depth understanding of people (i.e., end-users and other stakeholders) so that products, services, environments, systems, and experiences meet human needs, expectations, and aspirations. Likewise, empathy is integral to the design process since it enables practitioners to approach other people's realities and perspectives, to uncover insights, and to develop solutions informed and inspired by people's experiences and behaviour. Additionally, empathy has been described as an ability that promotes "people-centred" innovation, and as a competency that is deemed crucial to dealing with the complex socio-technical issues that humanity faces in the 21st century (Brown, 2009; Brown & Katz, 2011; Howe, 2013; IDEO, 2011; d.school, 2010; Plattner et al., 2012; Norman, 2014; Kouprie & Sleeswijk Visser, 2009; Dandavate et al., 1996; Carroll et al., 2010; Sanders, 2006a).

According to Goldman and colleagues, empathy helps designers to move "beyond [their] egocentric views of the world and no longer design based on their own needs, desires, experiences or preferences" (2012, p. 18). By considering other people's perspectives while keeping their focus on the design problem, designers can uncover users' needs and requirements, identify and balance possible conflicting demands, and design satisfactory solutions that are functional, understandable, usable, and enjoyable (IDEO, 2011; Norman, 2013).

For Thomas and McDonagh, empathy is a critical component in current design approaches, as it allows for the generation of holistic design solutions that address the functional and emotional needs of people. This holistic approach is possible thanks to empathy, which "enables designers to gain intimate insights and understanding into human experiences" (2013, p. 3). Likewise, Altay (2014) argues that the practice of human-centred design requires empathy, as it increases designers' awareness of how diverse people interact and experience their social environments. According to the author, this awareness is achieved by interacting with users, sharing their everyday experiences, and inviting them to participate in the design process.

Likewise, some authors argue that empathy is especially crucial in human-centred design when designers have less in common with the populations for which they are designing and when they have little or no experience in the contexts and situations that frame the design problem. For instance, Carmel-Gilfilen and Portillo (2016) suggest that skills associated with empathy like listening, observation, and attention to the human experience are particularly essential in the context of health-care design. Additionally, Lee (2012) highlights the importance of empathy when designing for older adults, as it helps in dislodging designers' preconceptions and prejudices, and build an emotional commitment with them. As stated by Lee, these changes in the designers' mindset can lead to reframing the design problem and proposing more successful design concepts.

A key player in communicating the importance of empathy in design has been the international design consultancy IDEO. This firm pioneered the use of human-centred design methods and influenced the inception of an empathic approach to design (Battarbee et al., 2014, Mattelmäki, Vaajakallio & Koskinen, 2013). For instance, in one IDEO's toolkits, empathy is presented as a strategy and an ability that enables design teams to create products, services, and systems that reflect a deep understanding of people's problems and realities (IDEO, 2011). According to this publication, empathy for users emerges when designers use qualitative research methods to uncover insights, evaluate people's response to proposed solutions, and, especially, understand people's behaviour. Building this understanding enables designers to "identify physical, cognitive, social and/or cultural needs that we [designers] can meet through the products, services and experiences we create" (IDEO, 2011, p. 68).

In conclusion, authors agree in considering empathy a fundamental ability in current approaches to design, since it allows designers to transcend their assumptions and egocentrism, get immersed into the lives of users and stakeholders, and uncover their latent needs and expectations. Also, it is instrumental for designers in building an emotional connection and a deep understanding of people's reality, which is of particular importance to design for a diverse range of users in contexts that are new to the design team.

Empathic Design

Empathic design is a branch of human-centred design that aims at building a cognitive and affective understanding of people (potential users and stakeholders) for the development of concepts, products, services, strategies, and systems. This approach has its roots in design practices that focus on people's daily experiences, emotions, behaviours, and desires (Postma, Zwartkruis-Pelgrim, Daemen, & Du, 2012; Wright & McCarthy, 2008; Mattelmäki, Vaajakallio, & Koskinen, 2013; Battarbee, Fulton Suri, & Gibbs, 2014).

Empathic design comprises methods and techniques that help design teams to uncover people's latent needs, expectations, aspirations, and preferences. These methods aim at understanding people's emotions and life experiences to inform and inspire the design process. They involve collecting and analyzing data from people's everyday lives through the designer's immersion and direct interaction with potential users and stakeholders to provide a unique perspective based on people's experiences and emotions that enrich and complement the insights uncovered by other methods of inquiry such as market research (Battarbee et al., 2014; Leonard & Rayport, 1997; Mattelmäki et al., 2013; Fulton Suri, 2003; Postma et al., 2012).

Origins and Evolution of Empathic Design

The first mention of empathic design was in 1991 when Professor Dorothy Leonard-Barton, a researcher on innovation and creativity at Harvard Business School, published "Inanimate Integrators: A Block of Wood Speaks" in the Design Management Journal. This article discussed the use of models and prototypes to foster effective communication in the product development process. Leonard-Barton mentioned empathic design for the first time when discussing strategies to communicate with potential users of those new products and services in development. She presented empathic design as a process of gathering information about potential users to uncover their unrecognized needs and desires (Leonard-Barton, 1991). The author stated that empathic design was inspired by the work of renown industrial designer Henry Dreyfuss, who advocated for an approach to design based on "[direct] experience, observation, and research" (Dreyfuss, 1955, p. 65).

Another important influencer of empathic design was Bill Moggridge, co-founder of the international design consultancy IDEO and former director of the Cooper-Hewitt Design Museum in New York. According to Battarbee and colleagues (2014), in the 1970s Moggridge's studio introduced the observation of people and their context as a method for informing their design work. When Moggridge's studio merged with other firms to form IDEO in 1991, this human-centred approach was adopted by the newly created consultancy (Battarbee et al., 2014). Mattelmäki, Vaajakallio, and Koskinen (2013) also acknowledge the influence of IDEO in the inception of empathic design in the mid- and late-nineties and identify other influencers such as Liz Sanders at SonicRim, Patrick Jordan at Philips, and Dorothy Leonard-Barton at Harvard Business School. Additionally, the authors argue that empathic design originated from the human-centred design community as part of "a larger movement toward context-sensitive design" (Mattelmäki et al., 2013, p. 68).

According to Kouprie and Sleeswijk Visser (2009), this movement was a response to the limited information that current methods offered about the experience, situation, and emotions of users, which in turn limited the designer's capacity to innovate and develop new and successful products. The user-centred perspective

brought by this movement was embraced by the business community, which saw in these new approaches an opportunity to strengthen the connection with their customers at an emotional level (Postma et al., 2012). Since its emergence, empathic design has evolved and has influenced other approaches to design. Initially, empathic design intended to make sense of the human experience with the purpose to inform and inspire the design process. Later, it involved users more actively through co-design and participatory design methods and recently has been used to foster imagination and explore and build possible alternate futures.

Likewise, empathic design has spread and influenced the work of people working in places such as Aalto University in Finland; TU/Delft, TU/Eindhoven, and Philips in The Netherlands; Carnegie Mellon University, Ohio State University, University of Illinois, IDEO, and SonicRim in the United States; The Hong Kong Polytechnic and Tongji University in China; Politecnico di Milano in Italy; and Universidade Federal do Rio de Janeiro in Brazil (Mattelmäki et al., 2013; Sanders & Dandavate, 1999; Battarbee et al., 2014; Ho, Ma & Lee, 2011; Cipolla & Bartholo, 2014).

Characteristics of Empathic Design

Empathic design is characterized by proposing a balance between rationality and emotion (Postma et al., 2012). Several authors argue that designing under this framework requires finding equilibrium between the affective involvement of empathizing with another's experience and the cognitive process of analyzing it (Kouprie & Sleeswijk Visser, 2009; Battarbee et al., 2014). For Postma and colleagues, this balance implies combining "objective observation of people behaviour with more "subjective" interpretations of "what people think, feel and dream" (2012, p. 60). As Fulton Suri points out, "through observation, we become informed, and through empathy, the human connection, we are inspired to imagine new and better possibilities for people" (2003, p. 54).

Another important characteristic of empathic design is the involvement of users and stakeholders as partners in the design process. According to Mattelmäki (2006), such participation requires the designer to develop a sense of respect and commitment to their needs and to build a holistic understanding of their experiences. From an empathic design perspective, users and stakeholders are considered "experts of their experiences and crucial partners in building creative understanding of these experiences" (Postma et al., 2012, p. 60).

Additional to this balanced approach and respectful attitude, empathic design is guided by a set of underlying theoretical and methodological assumptions that Mattelmäki, Vaajakallio, and Koskinen have synthesized in the form of "four key beliefs" (2013, p. 68). These assumptions revolve around the creation of meaning by people, the discovery and interpretation of these meanings by designers, and the nature of the methods used in empathic design. These key beliefs are as follows:

1. People construct meanings that arise and change through interaction with the environment.
2. To explore these meanings, empathic design needs to be done in real life, where these meanings are created and transformed.
3. This meanings exploration should use design-specific methods such as visualization, mockups making, and storyboarding.
4. The research methods used in empathic design are "visual and tactile, inspiration-enhancing, deliberately cheap and low tech, playful, tested in reality, and targeted at the fuzzy front end of the design process" (Mattelmäki, Vaajakallio, & Koskinen, 2013, p. 69).

Role of the Designer in Empathic Design

In empathic design, practitioners are expected to have direct interaction with people (users and stakeholders), which means that the designer's role requires getting immersed in the user's world, their lives, and experiences to learn from them and inform and inspire their designs (van Rijn, Sleeswijk Visser, Stappers, & Özakar, 2011). This immersion also comprises user participation, since they are considered "experts on their experience" (Sleeswijk Visser, Stappers, van der Lugt, & Sanders, 2005). As a consequence, designers are expected to set the stage for users to participate and to facilitate activities for them to share their expertise with the team (Battarbee et al., 2014, p. 10). However, to maintain a balanced perspective, the user's viewpoint needs to be combined with the designer's personal insights, creativity, vision, and experience (Kouprie & Sleeswijk Visser, 2009; Postma et al., 2012).

These competencies are part of the skill set that empathic designers require according to several authors. The set is comprised of abilities such as being open-minded, aware of one's context, and self-aware about how one

thinks and feels. Also, this empathic skill set includes the capacity to observe meticulously, use visual information and tools of visual communication, and switch between empathizing and analyzing modes (Leonard-Barton & Rayport, 1997; Mattelmäki et al., 2013; Battarbee et al., 2014; Kouprie & Sleeswijk Visser, 2009).

Empathic Design Methods and Practices

Perhaps the most transferable aspects of empathic design to experience design (XD) are the methods and practices created or adapted within this approach to design. Most of these methods and techniques are intended to be used during the research phase of the design process, and their primary purpose is to prompt an empathic understanding of other people's experiences (Vaajakallio, 2012).

Empathic design methods are characterized by being user-centred (as they involve users and stakeholders at different extents); visual and tactile (as they provide inspiration and a means of communication to designers); cheap and low-tech (as they are easily and quickly deployed in any context); interpretive (as they are intended to make sense of other people's reality), playful and fun (as they offer opportunities to dream about alternate futures); tested in reality (as they are used to address real-world issues); and targeted at the fuzzy front end (as they are most effective in the early stages of product development) (Koskinen, Mattelmäki, & Battarbee, 2003).

Even though most methods are focused on the research and concept development stages of the process, Leonard and Rayport (1997) offer an overview of the empathic design process that goes beyond these initial phases. This process is comprised of five steps, namely, (1) observation, (2) capturing data; (3) reflection and analysis; (4) brainstorming for solutions; and (5) developing prototypes of possible solutions. In this model, observation is presented as the preferred method for learning about users on the basis that it allows for uncovering their unarticulated and latent needs.

Kouprie and Sleeswijk Visser (2009) propose a four-phase framework to practice empathy in the design process. This model is based on current literature in psychology and is intended to support designers in implementing empathy in their practice by offering them a guide to approach, interact, and understand users and stakeholders. The four phases proposed by the authors are (1) discovery, in which the designer makes a first contact with the user that raises his curiosity, interest, and motivation; (2) immersion, in which the designer explores the user's world to expand his knowledge and understanding of another's experience; (3) connection, in which the designer connects with the user on an emotional level by recalling his own feelings and experiences; and (4) detachment, in which the designer detaches from his emotional connection with the user to analyse and distil insights from his immersion.

The same authors also propose a system to classify a variety of empathic design methods depending on the purpose and phase of the process in which they can be applied. The categories offered by these authors are as follows: "(1) techniques for direct contact between designers and users (research); (2) techniques for communicating findings of user studies to design teams (communication); and (3) techniques for evoking the designer's own experiences in a domain relevant to the user (ideation)" (Kouprie & Sleeswijk Visser, 2009; p. 439).

The first category— "techniques for direct contact between designers and users"—includes methods based on user observation (e.g., observing users performing a task at their workplace); designer immersion (e.g., spending the night at the user's home); and generative sessions (e.g., facilitating a session in which users make a collage that captures their experience using public transit) (Kouprie & Sleeswijk Visser, 2009; IDEO, 2011; Stappers & Sanders, 2003).

The second category—"techniques for communicating findings of user studies to design teams"—involves methods used when direct contact with users is not possible. This category includes storytelling techniques such as personas (i.e., fictional characters based on user data); scenarios (i.e., fictional situations based on data from users and context); and storyboards (i.e., sequence of images that represent specific situations in the life of a user). Such methods are effective when they "convey the flavour of the user's world, as well as an understanding of it" (Kouprie & Sleeswijk Visser, 2009, p. 446; Sleeswijk Visser, 2009).

The third and final category— "techniques for evoking the designer's own experiences in a domain relevant to the user"—refers to methods that simulate the user's reality so designers can experience them and adopt their perspective. This category includes role-playing techniques such as product handling (i.e., use of sample products or prototypes by designers); experience prototyping (i.e., simulation of the experience mediated by a

product or service); bodystorming (i.e., brainstorming that uses body and space); and informance (i.e., informative performance of a situation or behaviour witnessed or researched) (Kouprie & Sleeswijk Visser, 2009; McDonagh-Philp, 2000; Buchenau & Fulton Suri, 2000; Moggridge, 2007).

Another classification of empathic design methods is offered by Jane Fulton Suri, Partner Emeritus and Executive Design Director at IDEO, who proposes the following three categories: (1) "looking at what people do," which includes techniques such as observing people in their natural environment, and exposing potential users to prototypes to observe their behaviour; (2) "asking people to participate," which includes techniques that help to reveal people's unarticulated attitudes and thoughts such as drawing, collage-making, storytelling, and diary-keeping; and (3) "trying things ourselves," which includes immersive techniques such as role-playing, experience prototyping, and simulations (Fulton Suri, 2003).

An example of the first category— "looking at what people do"—is the immersion of members of the design team into the users' context, as discussed by IDEO in their human-centred Design Toolkit (2011). This technique aims at providing designers with an experiential understanding of the users' everyday life through an immersive and prolonged exposure to their context and experiences. When using this method, designers spend two to four of days with members of the community of potential users, sharing their daily experiences in the context in which they live, work and socialize. According to IDEO "this kind of deep immersion gives us [designers] informed intuition that we take back with us to design solutions. We begin to take on the perspective of the interview participant which enables us to make design decisions with their perspective in mind" (2011, p. 59). Also, this strategy allows designers to contrast what the potential users say they do, with what they really do, which might not coincide.

An example of the second category— "asking people to participate"—is the use of empathy probes proposed by Mattelmäki and Battarbee (2002). This technique aims at uncovering what people say, do, and make (Sanders, 2002) through self-documentation. The package given to potential users includes a diary, a sheet of stickers (to use on the diary), disposable camera with a list of photos that users need to take (e.g., an object they user every day), and set of cards with questions to be answered depending on the nature of the project. The design team analyzes the information collected by potential users, and later conducts interviews with some of them to validate their preliminary findings. This method helps to promote empathy by providing the design team with a glimpse into the users' reality from their perspective.

An example of the third and last category, "trying things ourselves," is modelling everyday activities as a person with a disability as proposed by Thomas, McDonagh, and Strickfaden (2012). This strategy offers designers the opportunity to undergo the challenges and experiences that a person with a different level of ability encounters every day. An immersive technique is preferred when the presence of the design team into the user's world can be intrusive or when time and resources prevent the team from conducting extensive research with external participants. When using this method, designers execute everyday activities while reducing their specific abilities. For instance, designers can wear devices that limit their range of motion, obstruct their hearing, or restrict their peripheral vision. While they are wearing these devices and executing everyday activities, designers document their experiences in order to reflect on them and present findings to the team in a debriefing session. The purpose of this strategy is to promote empathy with potential users who represent physical disabilities.

Another remarkable example of this third category is offered by industrial designer and gerontologist Pat Moore. In her book Disguised!, Moore (1985) recounts her experience living and traveling for three years prosthetically disguised as an elder woman. This empathic experiment—initiated when Moore was at the age of 26—gave her an immersive experience of an older adult. In an interview conducted by author Roman Krznaric, Moore expressed her intention to gain true empathy with this population through total immersion: "I didn't just want to be an actress pretending to be an elderly person… I wanted a true immersion character, an empathic character, where I could really walk in someone else's shoes" (Krznaric, 2015, loc. 69-70). During this empathic experiment, Moore created different personas to explore the experience of elderly women of diverse health and economic conditions. She visited more than a hundred cities in disguise, and almost lost her life after being attacked by a gang on the streets of New York City (Moore, 1985).

Limitations of Empathic Design

Empathic design has limitations and is not well suited for addressing every experience design problem. According to Postma and colleagues (2012), this approach is most valuable in the early stages of the design process when opportunities are being identified and new concepts are being proposed. For Koskinen and

Battarbee (2003), the insights from the user's perspective obtained through empathic design have the most value in the "fuzzy front end" of the process; that is, in the search for new concepts for products, services, strategies, and systems. Sanders reiterates the importance of empathic approaches in these early phases of the development process and highlights that "the action in the fuzzy front end is all about new ways to understand and to empathize with the needs and dreams of people" (Sanders, 2006, p. 1).

Another limitation to empathic design is the risk of running into what has been called the "empathy trap;" that is, focusing only on another's needs while ignoring the designer's own concerns (Stern & Divecha, 2015). In the case of empathic design, this situation is seen when the design team focuses only on the user experience and loses its drive to find insights that inform and inspire new products and services (Mattelmäki et al., 2013). This situation is often accompanied by the loss of objectivity and a global frame of reference, which occurs when designers establish a strong connection with another person's feelings and perspectives (Fulton Suri, 2003). According to Segal and Fulton Suri (1997), the key to avoiding this trap is to maintain a balanced perspective by combining "loose" empathic strategies with "strict" observation techniques. However, keeping this balance between an empathic and an analytic mindset may be challenging for design teams and individuals. This requires of self-awareness and the capacity to make the switch between these two mindsets (Battarbee et al., 2014).

Another difficulty that empathic design poses to experience design is the uncertainty of the process in its early stages. As the initial phase of the process is devoted to getting immersed into the user's world and does not provide an immediate solution to the posed problem, designers and organizations may not perceive its value at first and may be reluctant to embrace this approach (Kouprie & Sleeswijk Visser, 2009). For this reason, Kouprie and Sleeswijk Visser highlight the importance of motivation and willingness to pursue an empathic design process. For them, "motivation is crucial for an effective process. When designers do not see the advantages of empathy in design, the results can be unsatisfying" (2009, p. 447).

For design anthropologist Dori Tunstall (2014), the use of empathy in design strategy has serious limitations. Empathy may offer the designer an understanding and/or an emotional connection with people, but it does not necessarily offer a path to take action for others. She proposes that more than having empathy for users and stakeholders, designers should have compassion and design from a position of caring. This approach means for design practitioners to have a "sustained emotional investment in an individual's well being, characterized by a desire to take actions that will benefit that person" (Tunstall, 2014, paragraph 4).

In an op-ed published in AIGA Eye on Design blog, Lilly Smith (2016) questions the use of empathy in the design and business communities. For her, empathy has become a "buzzword" that is being used by companies mostly as a sales pitch. She argues that even if designers use empathy to understand people's needs and create legitimately better products, the purpose is to sell those products. From her perspective, empathy in business and design is less about compassion and more about profit. This viewpoint is summarized by Roman Krznaric, who calls this strategy "empathy marketing" and argues that when businesses apply empathy, they are only "stepping into someone else's shoes to sell them another pair" (as cited in Smith, 2016).

Similarly, Kamil Michlewski, author of the book Design Attitude, differentiates real empathy from that with commercial purposes, which he calls "commercial empathy" (2008, p. 383). He argues that firms such as IDEO have incorporated a light version of practices and methods from anthropology, psychology, and sociology, which fail to offer the same in-depth understanding shown by their academic counterparts. For Michlewski, designers working in these environments "exhibit an attitude that might be described as commercial empathy. That is to say they are sympathetic towards commercially bound reference points of their work" (2008, p. 383).

Even designers who work within this commercial framework recognize that empathy poses its own challenges in the design process. For instance, Steve Selzer, design manager at Airbnb and former creative director at Frog Design, argues that the human-centred design process requires not only a deep understanding of others through empathy but also a deep understanding of oneself (2015). Selzer warns against the "empathy trap" mentioned before, in which designers and researchers centre their attention only on the user's needs while ignoring their own perspectives. He proposes that an alternative to avoid such situations is to acknowledge and understand one's values, perspectives, goals, and biases before trying to understand others through empathy.

Likewise, Dan Saffer, vice-president of product at Mayfield Robotics and former creative director at Smart Design, claims that empathy is not enough in human-centred design, but it needs to be combined with an objective understanding of the problem, and the informed perspective of the designer (2015). According to Saffer, empathy helps to designers see a problem from the user's perspective, but does not help them to see the solution. For him, empathy is only a stepping stone that helps designers moving from their egocentric perspectives to a real understanding of people and context

In sum, designers have acknowledged the value of empathy in the design process, but there are also voices that warn about the limitations and the pitfalls of using empathy as a design and business strategy. The strongest criticism of this kind of approaches is that they commodify empathy reducing its power to strengthen human relations, as they adopt it as a disposable buzzword to increase sales and profits.

Conclusions

Based on a systematic literature review, this paper presented and discussed empathic design as a framework and a strategy whose principles, methods, and practices can be adopted and applied by the emerging field of experience design (XD) to create meaningful experiences connected with people's lives and dreams. The paper presented the rationale behind the emergence of empathic design, the traits that characterize this approach to design, a collection of empathic design methods and practices, and a critical discussion of the limitations of empathy in design.

Even though empathic design emerged in a context where digital experiences were not as pervasive as they are today, its principles, practices, and methods can be very well applied to their design, since these are rooted in a profound understanding of people's daily experiences, emotions, behaviours, desires, expectations, and aspirations. It is important, however, to take into consideration the methodological and epistemological limitations of empathic design to avoid running into common pitfalls, such as falling into the "empathy trap," understanding empathy at a "buzzword level," or commodifying empathy to sell things to people instead of addressing their real needs and expectations.

Finally, this paper intends to contribute to the broader discussion of how traditional design practices are adapting and evolving to respond to new realities and scenarios, and how new design paradigms are needed to address the very complex challenges that we face in the 21st century.

Experience Design Applied to Research: An Exploratory Method of User-Centered Research

CAPRA Andrea*; BERGER Ana; SZABLUK Daniela and OLIVEIRA Manuela

Pontifical Catholic University of Rio Grande do Sul, Brazil
*corresponding author e-mail: andrea.galina@pucrs.br
doi: 10.33114/adim.2019.04.351

An accurate understanding of users' needs is essential for the development of innovative products. This article presents an exploratory method of user centered research in the context of the design process of technological products, conceived from the demands of a large information technology company. The method is oriented - but not restricted - to the initial stages of the product development process, and uses low-resolution prototypes and simulations of interactions, allowing users to imagine themselves in a future context through fictitious environments and scenarios in the ambit of ideation. The method is effective in identifying the requirements of the experience related to the product's usage and allows rapid iteration on existing assumptions and greater exploration of design concepts that emerge throughout the investigation.

Keywords: design research, user experience, low-resolution prototypes

Introduction

In contemporary society, the old method of judging products - comparing only its practical benefits - does not work anymore. People began to attach greater importance to the search for meaning and to phenomena that bring greater significance to their daily experiences (Semprini, 2010). Design, as a transforming agent and a factor of competitive advantage, extended its performance to the experiences that consumers have with products, services, spaces or set of these (Freire, 2009). Regarding the relationship between people and the products and services they consume, experience involves the emotions, beliefs, and expectations that occur before, during and after consumption (Chammas, Quaresma, & Alvão, 2015), and its development depends on a deep understanding of the user.

To Freire (2009), the experience is the result of the interaction between people, products and the context in which this interaction occurs - and must be functional, determined, engaging, attractive and memorable. It involves the senses, motor, and mental abilities, intentions, expectations, desires, concerns, values and previous experiences - and therefore people become more and more sensitive to the dimensions of the product, which go beyond the traditional aspects of usability and imply the need to understand emotions, experiences and their implications for product design.

Differentiation in the market is driven by the meaning of the products, which means that the differentiation happens much more for the reasons that make people want a product than for the necessity that this product supplies (Verganti, 2009). Once the evolution of production systems and market dynamics has transformed design, technology itself is no longer a differential: it is necessary to create value for users (Zurlo & Cautela, 2014). As a result, approaching the potential users within the intended target market should be a basic

premise for the entire design process. Along the design process, the user should be considered as an individual who possesses individual skills and unique needs, with the potential to represent the knowledge and limitations of the intended ultimate target audience.

One of the purposes of design, in the experience dimension, is to create the conditions that allow the experience to be created in a planned way. The understanding of the environment in which an emotional experience occurs, and the way objects become emotional triggers for people opens space for the discoveries of new opportunities for designing meaningful products (Forlizzi, Disalvo, & Hanington, 2003). In order to happen, it is necessary to involve the users along in the design process, not only by questioning them about their needs and desires but also by providing an environment where they can interact with the product or service under development and imagine themselves in future scenarios within this context of use. Furthermore, considering that design is an eminently projectual activity in which specific methodological procedures must be used to accomplish investigations, planning, projections, and analysis(Meurer, 2014).

This article aims to document an exploratory method of user-centered research, applicable in design processes that aims to create or investigate user experiences related to products/services. This method follows an action-research approach. Action-research consists of a cyclical process in which improvement is sought through a systematic oscillation between acting in practice and investigating it (Tripp, 2005). This type of research comes from the social psychology applications by Kurt Lewin, in the 1940's USA, and have in its proposal and procedures an egalitarian need, considering participation and co-operation between the actors involved (Thiollent, 2011). Also, action-research uses less formal and prescriptive methods when conducted, because its goal is to address practical problems of a specific context, rather than produce independently validated and reproducible findings for others to use as guides for their future actions.

The method presented in this article arises in the context of projects under an agreement between HP Inc. Brazil R&D Center and Tecnopuc Crialab, the creativity laboratory of the Pontifical Catholic University of Rio Grande do Sul - Brazil. In this partnership, Tecnopuc Crialab is configured as an external design team, which co-creates with the company's development teams in projects of products, services, and experiences. The method was applied 8 times in three different projects, and involved a total of 180 participants. The projects addressed research problems from 3 different contexts: home spaces, corporate meeting spaces, and home business working spaces, and were applied to investigate scenarios of interaction between users, ambient, and devices. All applications of the method were done in the initial stages of investigations to design technological products for these different contexts.

In this article, the first section explores the concept of experience design, followed by the conceptualization of user-centered design as a process by which experiences are conceived. In the second section, the method is presented, followed by a later discussion. Finally, we present conclusions that discuss the potential impact of the method in user centered experience design.

User centered design

The importance of design in innovation processes is a consensus in many different studies (Borja de Mozota, 2007). For Mitchell (1993) focusing on the needs and desires of users is central to the design, and therefore it is necessary to redirect design thinking to go beyond the product. Designers can design more than just products - and among the key qualities of these professionals are the skills to explore new tools and to create tangible versions of abstract ideas, representing different dimensions of the user experience (Suri, 2003)

Experience is a broad concept and it is related to how people interact with a product and what they learn in this process (Freire, 2009). An experience involves the relationship between the user and the product - therefore, the design is not limited to designing objects, but is also related to designing the contexts in which they are used, the systems in which they are organized, and the environment in which they operate. In addition to other factors, the potential commercial success of artifacts depends on the experiences they provide - and hence understanding consumer motivation is essential for designing significant experiences (Pine & Gilmore, 1998).

The term "user experience" is consolidated and widely diffused by the acronym "UX" (user experience), and especially in the business world has been used as an approach to understand how to give the consumers better experiences with their products in order to develop better products. According to ISO 9241-210, the term UX can be defined as the perception and response of people as to the use (or anticipation of use) of a

product, system or service. Therefore, it refers to the description of the totality of an individual's experience with the products and businesses with which he interacts.

When designing experiences for users, user-centered design approaches, methods, and tools should take place. To Krippendorff (2006) center design on human beings implicates in developing technology in human terms, guided by meaning. When designing by user-centered design recommendations, we should know that users are the ones who determinate products meanings, and it is the designer's role to take care of users and make sure that their concerns are being taken care of (Krippendorff, 2006).

For Keates and Clarkson (2003) user-centered design involves an approach that aims to create interfaces, artifacts, products, and services that are applicable, appropriate, and accessible to as many users as possible. In the creation process, which also includes research, users must be constructively oriented so that they can provide the information needed for product development (Lowdermilk, 2013). For that, the use of methods, techniques, tools, and approaches that actually help in understanding the project context and promote user participation in the design process is essential.

User-centered research methods

Observing the expansion of the concept of design and of the possible outcomes of the design process, we can clearly see changes in the designer's procedures in projects. The designer comes to be understood as a specialist in the relationship between people and things. Understanding interactions in the perspective of experiences, designers seek solutions to problems through processes that aim to develop products, services, and experiences. Considering the various roles that the designer can have and the types of projects that he can execute, choosing the most appropriate method for each project is of a contextual and subjective nature. High complexity projects require a high degree of structuring to be developed, and innovative projects face some level of uncertainty, being difficult to structure (van der Linden & Lacerda, 2009). The designer, which has multidisciplinary competencies, should be able to apply more than one approach to the same project (Chammas et al., 2015).

In traditional design methods, the designer is focused on the product/service being designed and looks for ways to ensure that it meets the user’s needs. These methods include research phases, where the researcher collects primary data or uses secondary sources to learn about the user’s needs, so the designer can interpret it through concept sketches or scenarios. However, in these cases the focus continues on the design development of the product/service, and the roles of the researcher, the designer, and the user are distinct, even they depend on each other. The user is not really a part of the team (Sanders, 2002), and a gap might exist in the communication between these actors.

In ideal participatory experiences, the roles of the designer, the researcher and the user are mixed, what enriches the results (Sanders, 2002). This new understanding calls for new studies. In this way, developing new methods to optimize processes focused on understanding and creating user experiences must become part of the designer's work. People want to express themselves and to participate directly and proactively in the design development process (Sanders, 2002). Users participation and co-creation in the product development process, demonstrating their behaviors and thoughts can lead to a more assertive result, since learning from users is very strategic (Schrage, 2015) so it must be strongly considered in new user-centered research methods.

In addition, it is relevant to establish an alignment between designers, engineers, and developers’ perspectives from the beginning of the project, bringing dimensions of the user experience to the technological interactions that will be developed. This meets the need of applying flexible processes, with iterative phases, in order to be able to review previous decisions whenever needed. The lack of integration between design and other actors (or factors) in the product development process is a serious problem to be overcome in companies and in societies that wish to be successful in innovation processes (van der Linden & Lacerda, 2009). These subjects were considered throughout the projects under the agreement between HP Inc. Brazil R&D Center and Tecnopuc Crialab, and are addressed in the method presented in the following pages.

User centered design

As the user experience becomes central to the design process, the need to establish means by which designers and users can act as equal partners emerge, impacting not only the results but also the design goals and procedures. In the process of designing new products and services, the users’ participation is essential to

contribute with their vision about what is being developed or planned. In this context, and based on the perspectives previously presented, we will present a research method directed - but not restricted - to the initial stages of a technological product and/or service development process, from a user-centered design perspective. The method brings in its structure, processes, and concepts from several design thinkers and other adjacent areas, which makes it ideal for projects of medium or high complexity.

The method presented in this article proposes not treating the users as objects of research, but rather as co-researchers. As previously mentioned, in classical research settings, the relationship between researchers and researched seems to be very clearly defined as a "non-relationship", in which the researcher is, as far as possible, neutral or invisible. In this classical perspective, anything else is considered to lead to the distortion of the results or to threaten the internal validity (Bergold, J. & Thomas, S., 2012). This is different in participatory methods, as the perspectives of various stakeholders and their opinions are important for the process of discovery, so objectivity and neutrality are replaced by reflective subjectivity. In this sense, research with stakeholders to whom the proceedings of academic research are unfamiliar, calls for new methods of data collection that should, therefore, be developed appropriate to the concrete research situation and partners defined.

Because it can be difficult for people who have never had anything to do with research to understand methodological procedures, the knowledge created by the research is built on the participants' everyday experiences by immersing the user in a fictitious environments that are similar to their real ones, where they can imagine new scenarios of interactions while they simulate known daily activities. This transforms research by providing a structure for new roles of researchers and researched ones. The researcher acquires new and unfamiliar roles, being an enabler to the users undertaking research, while the users involved bring their perspectives into the knowledge-production process.

The presented method uses the concepts of low-resolution prototyping and storytelling to construct a visibly fictitious and immersive environment with the intention to involve the user in a simulation of usage of a product and/or service in order to reveal the behavior of a population through participatory practices. Considering that technological innovation is one of the major sources of competitive advantage in the long term, but often requires costs and structure that few companies have the capacity to supply (Verganti, 2009) the method relies on the idea that it is possible to raise the maximum input of users in stages prior to technological development. Moreover, considering that people use emotional, psychological and sociocultural reasons when choosing a product, in addition to the practical and functional reasons, this method creates possibility for a greater interaction with the users, so that ones can think beyond functional characteristics, extending to the real value they attach to things (Krippendorff, 2006; Verganti, 2009) resulting in a big opportunity for designers to qualify their design process. Next, the four phases of the method are presented: context, plan, action and analysis.

Phase 1 - CONTEXT

The first phase of the method is related to the understanding of the project context (Figure 1). It defines the **research goal** and the directions to be followed in the experience application, in a joint decision between designers, managers, and development team. The circumstances of the research - which can be driven by the idea of a product to be developed, by the need to validate a product that is already under development, or to review a product already launched, for example - are also clarified.

In this phase, we also try to **understand the user**, and for that, we can use several techniques that help understand their profile, such as personas (Kalbach, 2009) and empathy map (Osterwalder & Pigneur, 2010), for example. It is important to emphasize that the user's understanding at this moment is important to guide the definition of the hypotheses and the application of the experience - however, there are projects in which the experience is planned to explore behaviors and situations of use to later define the target audience of the product.

In order to better understand the delimited public and the context of the project, desk research - that is exploratory research in academic bases and websites on the Internet to investigate cultural, behavioral and market aspects related to the project - is done. This research aims to bring a theoretical foundation that will help in the definition of the protocols of the next phase, and that will base the elaboration of the hypotheses.

Next, we identify the **behavior settings** related to the experience, which configure patterns of behavior that occur in a given time and space. The behavior settings theory (Barker, 1968; Wicker, 1987) provides the

classification of behavioral patterns linked to a physical environment where they occur in a coordinated way. Based on these behavior settings, it is defined what **technological interactions** should occur in the experiment, and that are pertinent to the project scope - such as voice interactions, use of graphical interfaces, use of touch interfaces, passive user recognition, among others. Finally, we define the research hypotheses that will be validated with the application of the experiment.

It is important to emphasize that the method has an iterative character, and each phase or step can be revisited, whenever necessary. The CONTEXT phase creates the fundamental basis for the later phases of the method since it gathers all the information necessary for the effective design of the experiment, which follows.

Figure 1: Context Phase. Source: the authors.

Phase 2 - PLAN

There are many possible strategies to be applied for user participation in the design process. In this method, the application of an experience in which the user will immerse and interact with the product is prioritized. The PLAN phase consists of the design of the experience to be applied and simulated. This phase begins with the elaboration of the narrative (storytelling), which is written based on the hypotheses, behavioral patterns, and technologies defined in the previous phase, and that is consolidated as a text or storyboard. The narrative aims to tell stories that will be experienced by users in a relevant way to assist them in their immersion on the simulated experience, involving the interaction with the product being tested and sharing ideas and knowledge in a persuasive way in a script (Denning, 2005). For that, researchers can use specific methodologies for the construction of narratives, such as Smith and Wintrob's narrative framework (2013), Denning's template (2005) or Smith's storytelling model (2012).

The next step is to elaborate on the research protocols. The scripts for simulation are elaborated, which cover from the user's arrival to the research site until their exit. Also, the interview scripts are defined - which, in this method, will be semi-structured scripts with questions pertinent to the project context, and that will be done before, during and/or after the experiment.

The physical construction of the ambient for the experience simulation then begins, through the use of prototyping techniques, which aims at the conceptual or analogical representation of a product, service and its environment of use, in order to turn tangible an imaginary future for idea validation. Prototyping is a common step of any product innovation process and is an activity and tool that has received considerable attention in the product development process (Zomerdijk & Voss, 2010). By broadening the understanding of the design process in business and development domains, early-stage prototypes in the design process have become an important practice. Unlike the traditional role of the prototypes in the engineering process, in which they are more used for product testing, prototypes in the design process - especially in product design - has an exploratory role (Elverum, Welo, & Tronvoll, 2016). At this stage of the method, low-resolution prototypes of the artifacts that compose the experience to be simulated are constructed, considering the products involved and the scenario where the interaction takes place (Figure 2).

The **low-resolution prototyping of the scenario** is done considering the narratives that were previously created - the space to be constructed will be the scenario in which the experience will occur, and will assist the user to immerse himself, imagining in fact in the situation in which he would perform the requested actions. It may be risky to make decisions based solely on the users' interaction with the product prototype without an understanding of the context of use of the product - hence the prototyping of the scenario is essential for the completeness of the experience and the identification of the contextual factors that drive the use of the product. Finally, the **low-resolution prototyping of the product** with which the user will interact in the experiment inserts the product into its context of use and serves not only to test functionalities, ergonomic issues, and other aspects of the product itself, but also to investigate the meaning that this product has for the user. All prototypes must be constructed in order to stimulate imagination, explore ideas and validate hypotheses, as a tool to build to think (Seidel & Fixson, 2013). It is interesting to emphasize that low-resolution prototyping also has the advantage of bringing a playful aspect to the experience so that the user feels more comfortable doing simulations.

Figure 2: Example of low-resolution prototyping of scenario and product, as part of a project between Tecnopuc Crialab and HP Inc. Brazil R&D Center. Source: the authors.

Still, in the planning phase (Figure 3) it is defined the recording media - which can be video, audio, and photography, for example - and tools of support - that will be used in specific parts of the interaction. These support tools are used jointly by the user and the researcher, and help the user to imagine hypothetical scenarios and to more fully demonstrate their thoughts, opinions, and feelings. Some examples of support tools are cards to help scenario creation, image sorting (Kumar, 2013) the emotional response test (Memória, 2006; Meurer, 2014), among others.

Finally, we recruit the participants to take part in the experiment and schedule them with enough intervals to reorganize the experience space, if this is the case. Recruited users must be within the profile traced in the context step, in the first phase. Recruitment does not necessarily need to be started at this stage but must be finished before the beginning of the next phase - again, it is emphasized that the phases have an iterative character, for better application of the method.

Figure 3: Plan Phase. Source: the authors.

Phase 3 - ACTION

The third phase of the method (Figure 4) is focused on the effective simulation of the experience that is being designed. In this phase, a pilot application of the experience with a few users is done to verify the operation of the scenario and the research protocols. Once this verification is done, the experiment will be applied according to the scheduled participants. This research procedure provides the testing, evaluation, and analysis of hypotheses, exploration of ideas, generation of insights or confirmation of facts already known (Hevner, March, Park, & Ram, 2004), so it is advantageous to perform this application in short rounds, interspersed with pauses for a reassessment of the protocols. Possible adjustments may occur in these reevaluation intervals, and these adjustments should be recorded for consideration in the final analysis. Throughout the application rounds, it is also essential to make sure all recording media are working so that the experiences simulated by each participant are registered so that they can be analyzed at the end of the research.

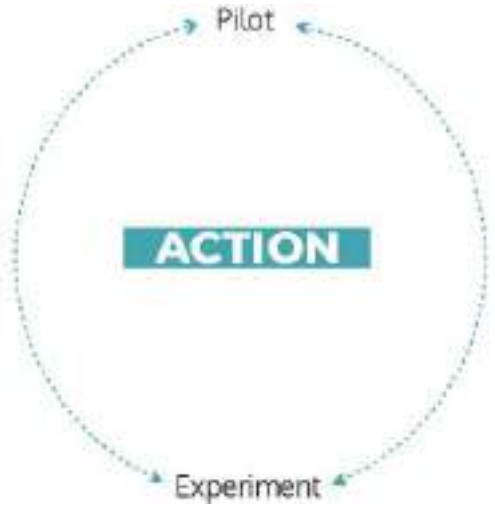

Figure 4: Action Phase. Source: the authors.

Phase 4 - ANALYSIS

The last step of the method refers to the analysis of the evidence generated with the application of the simulation of the experience (Figure 5). The analysis of the data obtained is done qualitatively since this approach allows to describe the complexity of the phenomena related to the objects of the study. For that, it is important to first make **transcriptions** of all the audios and select important parts and images from the videos

recorded - this is important to help to cross images and texts of the transcription later. Ideally, more than one video camera is used for recording the user in different angles. After that, evidence from each recording media (data from interviews and observation) are **crossed** and **categorized** and, finally, **analyzed.** The analyzed results are compiled, and **design principles** are generated. Design principles propose to transform the insights collected and generated into project recommendations and indicators for the development of a future solution related to the desired experience (Kumar, 2013).

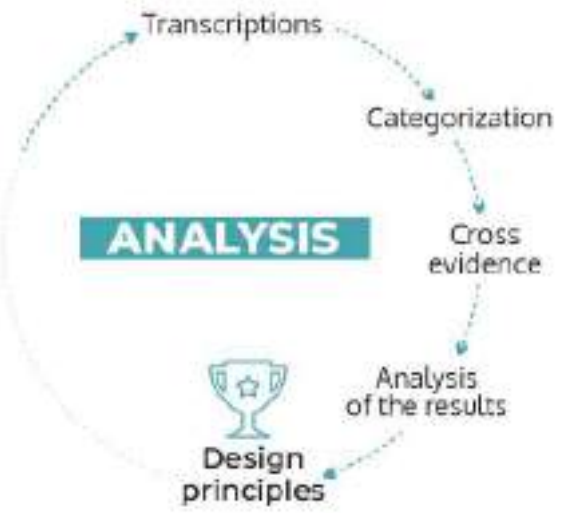

Figure 5: Analysis Phase. Source: the authors.

This method allows constant iterations throughout its application and predicts and suggests them especially in its central phases - plan and action. This means that the experience plan can be reviewed at any time, which will impact the application of the simulation with the users, resulting in a new version of the experience. This new version can take place whenever a change in the research process is defined, whether it is a new premise to be explored or the reformulation of an old one (Figure 6).

Discussion

After applying this method in several projects within the partnership between Tecnopuc Crialab and HP Inc. Brazil R&D Center, there are two relevant points that can be discussed. One refers to the participatory characteristic of this method, that is entirely based on the involvement of the users as co-creators of the product/service that is being tested or validated. Other refers to the contribution of its exploratory aspect to the design process.

According to Sanders (2002), there are many ways we can learn from people using research methods: we can listen to what people say, we can watch what people do, we can observe what people use, and we can interpret what people express and make inferences about what they think. Each method can reveal different

stories and peculiar aspects of the user's perceptions. But, seeing the whole picture is only possible putting these perspectives all together. As an example, listening to what people say in an interview can tell us just what they are able to express in words, as well as observing them while using a product can provide us just observable information. So special tools are needed to access the deeper levels of user expression, such as non-verbal ways of communicating. For that, bringing the user to create together is essential to understand what is truly meaningful to them (Sanders, 2002; Preece, Rogers, & Sharp, 2002).

This method was built and repeatedly tested to enable a scenario in which the users can simulate specific situations, interacting with product and environment prototypes, interacting with the researcher to freely talk about their perceptions, physically interfering in the prototypes in order to demonstrate new ideas, and, from that, using their imagination to immerse themselves in hypothetical situations. In this way, the designers and researchers not only interview and/or observe the users, but create with them, having as results a deep understanding of what people say (their thoughts), what people do (their actions), and what people make (their feelings and dreams), to create innovative and significant products/services (Sanders, 2002).

Another valuable point of this method is its exploratory aspect. The purpose of this method is not only to validate certain hypotheses related to the design problem but also to make new discoveries that will influence the design experience - and therefore it is considered to be explorative. As the simulations are applied with flexible scripts and protocols, the results obtained with this method can bring ideas to new projects, and start new research cycles.

Some advantages are perceived specifically in each method's phase. In the first phase, called "context", the stages of "behavior settings" and "technological interactions" stand out. It is suggested that these steps be carried out in sequence, as presented in the text, so that existing contracts between people and products already available in their contexts are not disrespected. That is, interaction with a known product has a clear purpose for the user, and this purpose must be considered when casting the eye of the technological interactions on the product or context in which it is inserted. The contract that a person has with a mirror, for example, is the reflection of his image, so it is not possible to conceive an experience in which the primary use of the mirror is no longer a place where the person sees his reflection for beauty and / or health purposes.

In the "plan" phase, the formulation of scripts and protocols associated with prototyping of products and scenarios gives a systemic perspective for the research under development. This clarifies and relates "what you want to know" with "how it will be asked to the user" and "what kind of experience it will simulate" in order to get the most out of this participatory interaction.

The presented method allows constant iterations throughout its application between all phases, and predicts and suggests them especially in its central stages ("plan" and "action"). This means that the planning can be reviewed at any time, which will impact the application of the experience with the users, resulting in a new version of the research experience. This iterative structure corroborates its characteristic of being open to the influence from the users' imaginative participation in its results. This influence might result in a new version of the under development experience and can take place whenever a change in the research process is defined, whether it is a new premise to be explored, the reformulation of an old, a new identified behavior setting, or new technological interaction that is considered.

The "action" phase, in which simulations of interactions with artifacts occur in visibly fictitious built environments, has shown to be efficient to verify user behaviors in interaction scenarios unknown by them. Still, this phase transcends verification, as it also encourages and supports imagination so that participants in the experiment can in fact project the future and imagine themselves in the simulated situation. As opposed to answers collected from interviews (or another traditional method of inquiry), for example, the comments of the participants become more spontaneous, without much prior elaboration before their speech, and therefore more reliable to their feelings and real opinions.

In the "analysis" phase, audio and video recordings make possible to observe behaviors that are not verbalized, from speeches, gestures, body and facial expressions that neither the user perceives himself to be doing or speaking. Interestingly, sometimes these gestures and expressions even contradict speech, which reaffirms the importance of a method that considers data triangulation. This triangulation give space for the manifestation of the paradoxes and idiosyncrasies of users, so the researcher can truly understand their needs and intentions. Thus, the phase called 'analysis' is qualified by the crossing of what the user consciously speaks, automatically does and unconsciously expresses while simulating the research experience.

It can be stated that the presented method is directed to research steps inserted in design processes, but it is not restricted to them. As a flexible method, it can be used for designing products and services, and also for validating existing products and services. When used for validation purposes, the 'context' phase may not be entirely applied, since hypothesis, behavior settings and technological interactions might have already been defined by the product in case. The method, when applied for conceptual purposes, adds value by its "build to think" characteristic, in which prototyping is used in moments of ideation for generating ideas and exploring unforeseen possibilities. When applied for validation purposes, its focus may be directed to the confirmation of product or service requirements.

Stands out the importance of the involvement and alignment of designers, engineers and developers in the conception of the design research focused on the user, strongly acting together in the phases "context" and "plan" so that the defined hypotheses at the beginning of the process are of common interest and cover questions related to the various areas involved in the design of the technological product or service. Structuring work in teams, joining skills, knowledge, attitudes and other personal characteristics is paramount for achieving the company's goals (Peeters-Baars, 2006). With this in mind, aspects of the experience simulation have a direct impact on its development (technological or not), leading to a review of priorities and adjustments in the requirements. The simplicity of the method allows the dimensions of the experiment to be rebuilt whenever necessary throughout the research process and works with the bias towards failing early and iterating fast. This way the process can be repeated several times, with low costs in terms of material and technological resources, which helps to deepen the design of the experience.

Final considerations

This article aimed to present a method that brings the approach of experience design applied to user centered design research, focusing on using low-resolution prototyping to create interactive meaningful experiences. With the repeated applications of this method in different project contexts, it is verified that the carefully planned simulations provide a deep immersion of the participants in the context of the project, which allows more significant contributions from the respondents, far from those resulting from traditional methods of inquiry such as interviews or focus groups.

Simulations help users visualize and understand the new technologies represented in the experience, and also to relate them to their daily lives, so they can assess their relevance and meaning in the midst of their routines. In addition, the application and registration of simulations with low- resolution prototypes are advantageous for the observation of small subtleties of user behavior, such as facial and body expressions that support or contradict speech, and which enrich the analysis of the research evidences.

Just as personas and scenarios help the imaginative process of designers, prototypes and simulations have the potential to do the same for users who are immersed in the co-creation process. The use of low-resolution prototypes proved to be efficient in stimulating the imagination of users, since it allows a higher level of abstraction, surpassing their previous experiences with related product or services and opening room for ideating new scenarios of usage. Also, low-resolution prototypes represent low costs in terms of material and technological resources, which enables new applications of the experience whenever necessary.

The method also transcends the idea of the designer as the only definer of the subject-object relationship within a system, since it has as fundamental the participation of the user. It is believed that the researcher is able to identify and report the tangible and intangible aspects assessed by the participant user from the simulations and interactions that he / she performs.

Finally, the usefulness of the method in several stages of technological product design processes is emphasized, since its iterative structure considers inputs of the users. We highlight the impact of the use of the method for the subsequent technological development, which then has as a starting point an experience (its artifacts and contexts of use) that is significant for the user of the solution under development.

Introduction

Complexity is a key characteristic of many participatory and community-oriented design activities. Designers' varied roles are being transformed as they have to manage the complexities and entanglements associated with global societal, technological and environmental change. As design turns towards a social mode of operation and application, this session 'Transforming Complexities through Design in Collaborative Community-based Processes' seeks to open a discourse on the role of design in managing the complexities that affect communities and individuals, alongside their attendant processes and practices. A range of approaches, skills and competencies currently demonstrated across instances and experiences of complexity, and across a range of contexts for collaborative and community-oriented design, are mapped through the contributions in this track.

Alongside design's traditional role of creating solutions, there is evidence of a shift towards a role for design in diagnosing, facilitating and aiding deeper understandings of the challenging contexts through which complexities emerge and are experienced by individuals and among communities across a variety of situations. The role of design in creating solutions that result from understanding, interpreting and analysing multi-disciplinary processes, whilst seeking to adapt to sensitive societal and political situations, is considered. The practical solutions and outcomes that can be produced when (sensitive) social complexities are managed through design are also explored. Practitioners and academics contributed discussions through case studies, methods, theories and initiatives that deal with complexities through design research and practice. The papers in this session introduction are presented according to the order of their presentation during the conference.

Topics that are explored in this session include the roles, skills and competencies of designers in mitigating complexities, in particular, those that emerge during collaborative processes and projects of community-oriented and practice-based design. Another topic explored is the complexities associated with design interventions that are aimed at social transformation and the opportunities they deliver for designers to envision new possibilities for better futures. The papers share insights into ways in which complexities affect upon both design researchers, the communities they collaborate with, and their impact on methods used in these collaborations. Additionally, some contributions consider the methods and methodological approaches for managing complexity or supporting community-oriented initiatives and in particular, with communities at the edge or margin, in transition or in a state of precarity. The discussions attempt to frame or suggest a potential way out or around the challenges that have been identified so that concrete guidance for others becomes a key outcome.

Complexity is often experienced locally, but common challenges exist across countries and within continents. DESIGNSCAPES is a European Commission funded project whose aim is to select a variety of promising ideas and projects across a number of European cities and provide them with the funding, support tools and mentoring to embed and implement design approaches to support their activities. Taking an approach of *emerging intervention,* the project aimed for an agility and flexibility that, given the complex scenarios, embraced change and would actively evolve in its own implementation. It was also grounded in local action between independent stakeholders thus providing its ascribed system behaviour, whilst the realities of dealing with and interacting with local contexts and agents in urban settings were carefully negotiated. These complexities unfolded by continuously documenting and analysing the stakeholders' 'change journeys' over a two-year period. This paper by Simeone, Drabble, Iacopini, van Dam, Morelli, de Götzen and Cullen presents a rigorous literature review on the significant role of Theory of Change and design in mitigating complexities and while a relatively formal strategy is presented, an argument is made for strategic flexibility and adaptability. Theory of Change was practically implemented and enabled in DESIGNSCAPES by a strategic kernel that allowed for the development of a diagnosis, thus guiding policy and actions that served as an effective logical tool for analysis. The approach stimulated agile adaptations to the intended actions when needed as it enabled the presentation of strategy in a simplified version that is easily understandable by stakeholders and external individuals. Additionally, as the strategy was not fully specified it allowed flexibility for the project partners to interpret and apply it according to their interests and needs. A critical view the paper presents towards a Theory of Change is that the approach was not necessarily reliable as a predictor for a project pathway. As the project is still ongoing, analyses of the project outcomes will enable a deeper examination of the potential of Theory of Change and the practical implications of its application in relation to a broad array of design-driven projects. This contribution is one regarding a complexity of opportunity in determining and framing, as well as of application as the contexts shift or change in response to conditions of implementation. The paper opens up discussions on human messiness and a necessary degree of flexibility and agility that are evident on the part of projects themselves, thus complexity can be perceived as something not always considerate of the more formal theoretical methods that might be used to attempt to understand and respond to it.

The complexities of local contexts, as we have seen, are often particularly challenging and such contexts are often relatively under-researched, in particular when they challenge researchers' own knowledges and experiences. The paper by Corsini, Aranda-Jan, Henderson and Moultrie describes a project which applies a participatory design approach in the context of design-for-development in the Global South and, more specifically, what they articulate as 'low-resource' settings (LRS). The paper presents the outcome of their initial systematic literature review that identifies a series of key challenges for such an application which they then map against an analysis of Simprints fieldwork data and interviews with three of the company's employees. Each of these activities looks to frame key challenges in the participatory design (PD) process and how it might have been addressed via a practical or tangible instance or experience. The results of this are a set of eleven key insights, which are discussed in some detail, making reference to both interview data and relevant literature. The authors outline what they feel is a theoretical gap they seek to address - that while there are PD approaches practiced in the Global North and models for methodological application in the Global South, little is available which illustrates or demonstrates an application within technologically-led design for development. The authors make use of a case study (Simprints) which allows for an overview of practical challenges and recommendations as to the use of PD in the complex contexts of LRS, where designer's lack of experience and unpreparedness is clear. Simprints develop biometric identification solutions for organisations developing mobile solutions for wicked problems: integrating fingerprint recognition into development projects, developed initially for patient identification in healthcare in Bangladesh and is being applied into other contexts in the Global South. Taking a PD approach from the outset, the founders quickly realised that there was little practically to help navigate the complex challenges of applying them within LRS. Thus, they set out to bring together research to develop a framework of insights, which act as guidance for future work and as a lens through which scenarios of complexity can be observed and understood. This contribution investigates how researchers may engage with the complexities under discussion. Complexities emerge at the limits of a designers' own experiences, thus they may consider the potential of what they do other than via direct participation in the context of application. As a result, opportunities to consider characteristics of complexity and systems for mitigating challenges or managing them, may emerge. The potential for developing the eleven insights into a workable toolkit or functional project-planning tool is clear - there is good evidence of synthesising a set of challenges that proactively and practically assist in these

complex and challenging scenarios. Research is important not only to address or manage complexity, but to reveal it given the 'unfinished' nature of much PD activities.

As we have seen, a discussion of complex scenarios can (and perhaps must) allow for a focus on the local and lived experiences of those whose needs might only be met by an engagement with, and exploration of, the potential of PD actions. The paper by Woo, Kim and Nam argues for the neighbourhood as a context for challenging designers in unique ways as local knowledge is the key to successful neighbourhood regeneration. The complex heterogeneity of stakeholders, multiple roles, new power relations and the role of residents as local experts with their own expertise can make it particularly difficult for designers to collect and coordinate local knowledge alongside any attempt to turn it into practical solutions. The paper is based on a thorough ethnographic study, and presents evidence that local businesses can have a major role in negotiating the complexities of regeneration projects, thus complementing designers' knowledge as well as helping to ease the challenges that they might face. Based on literature review, the paper presents three key roles of local businesses in participatory neighbourhood regeneration processes. Local knowledge is handled by a: 1) Possessor, 2) Processor and 3) Implementer. Possessors reveal undetermined and flexible local knowledge and inspire others by voluntarily providing their local knowledge for the use of the project. Processors conceive possible solutions, enable collaboration and set up spaces or conditions for cooperation. Implementers deliver and sustain the outcomes of a project. Local businesses can play important roles in discovering local community knowledge, processing it into useful design resources and incorporating it into participatory neighbourhood regeneration. The authors propose that: 1) Local businesses are reservoirs of local knowledge that can assist designers to collect diverse local knowledge, and 2) Local businesses are synergetic partners that can assist designers to mediate cooperation by using their social skills and human networks. A key theme emerging in this paper is of a complexity of the local, a necessity to identify and acknowledge power as it is situated and experienced, but also the potential to excavate knowledge within communities by drawing on local knowledge. The paper presents details concerning a modelling of how local knowledge might be positively mobilised and that co-operation is in itself a complex event.

Shifting perspective from the micro to the macro, Sedini argues for the strategic role of design to influence policy making alongside support from authorities and institutions to sustain the creation of social environments. This collaborative study that is situated within the Sister Cities Policy Programme, was developed by the School of Design of Politecnico di Milano, Institute of Design of Illinois and Institute of Technology of Chicago. The research investigates the complex relationships between design, manufacturing and social inclusion, with a specific focus on the maker's movement, (and again) ideas of locality and spaces within marginalised urban areas in Milan. This first stage of the research concludes that both making and design activities can be perceived as more inclusive and accessible, thus able to facilitate dialogue between different people and stakeholders. Additionally, making and design can stimulate social revitalisation due to the opportunities that emerge for marginal population groups with a positive impact on the creation of socially sustainable working environments. The contribution this paper makes to a discussion on how complexities can be transformed through design in collaborative community-based processes, is that being and acting from the local can activate partnership and dialogue. The need to develop methods to achieve these goals is the primary impact and well-considered in this contribution.

Developing these ideas of design having a role to play in the mitigation of complexities may foster innovation, entrepreneurship and collaboration amongst small-scale producers and designers. Working within and between communities at differing scale, the paper by Hertz presents research conducted with small and medium-sized footwear factories and organisations in Israel. The aim of the research is to identify challenges in the value chains of small and medium footwear factories. A significant insight in terms of a complexity developed by changes in scale of operations is that larger factories, who are more focused on production chains, become distanced from their users with the result that information from the users does not readily flow back to the company. The paper also looks to address how the roles, skills and competencies of designers, and design as such, can mitigate the complexities that emerge during collaborative processes. The proposed design solution aims to minimise the distance between the manufacturers by introducing suitable digital operations, access to digital marketing functions, including customer services and online selling sites. The suggested use of a digital platform that may offer new knowledge sharing and exchange regarding products and consumers, hopefully leads to a competitive advantage for the Israeli footwear industry. Additionally, the platform will serve as a joint R&D system with the potential to develop strategies, production methods, and innovative products, thus minimising the risks associated with investing in innovation by creating a co-production and co-R&D network for manufacturers. This paper's practical contribution to problem solving and

mitigating complexities within and amongst product producing communities is to draw on digital means to achieve a close-ness as opposed to more research-focused approaches found in other papers. This contribution is important for understanding why maintaining links with the local and with a user-derived context are paramount to success in small and medium-scale producer communities.

Design's power to encourage positive and meaningful connections and action is further discussed in the context of its potential for transitioning and transformation in the complex domains of organisational and social change. The authors Mysore and Gady argue for design as a social practice and it is in these complex contexts and dynamic environments that designers can play important roles as facilitators where the embeddedness of practices of facilitation in social design become a vehicle for transformative change. Drawing on a case study of an international design facilitation project managed by the UN Women's Fund for Gender Equality, the authors shed light on some of the critical features of a design-led facilitation process. These features include mediation, the navigation of systems of power and hierarchy within organisations, and important pre- and post-intervention activities during which designers also need to draw on their designerly abilities. The potential for a further development of design facilitation as a critical component in contemporary design practice is explored with the suggestion that it needs more and varied critical approaches together with robust models that are based on mediation and participatory processes. A design facilitation model is proposed as a means of 'working-with', a key need defined by complexities of the social and of how designers can identify and navigate power (as it is situated within pre-determined hierarchies of work and life). Designers have the skills necessary to manage instances and experiences of complexity - they are particularly suited to helping others with this. The contribution of this paper is that a specific context of complexity is addressed, relating to entrepreneurship with a key behavioural outcome (enabling) where methods of design thinking seem particularly suited to help manage this context.

Holierhoek and Price discuss complexity at the logical level of policy making and proposes some reflections on the role and contribution design can offer. The paper conducts a literature review looking at two fronts: 1) Proposing a wicked problems perspective to understand a possible approach to the solution of complex societal problems, and 2) Analysing the design activity as a non-linear problem solving process, which may prove to be more effective in dealing with the complexity of wicked problems. In the second part of the paper the authors analyse two case studies of public design labs, Helsinki Design Lab and MindLab (Copenhagen), to clarify the contribution design can provide to the definition of a new approach to policy making. Design, on the other hand, has been dealing with increasingly complex problems and are now moving to a level of complexity that is also common to policy making. Yet, there is no unified view of how design could contribute to policy making, which role this discipline can have and what specific design competences can contribute to a new way of working. The approaches considered in the two design labs were quite different: In Helsinki complexity was faced by reproducing a similar level of complexity in multidisciplinary teams, whereas the focus of MindLab was to introduce aspects and tools of design to policy makers in order to promote actions that cut across the traditional silo structure of public administration. The analysis of the two cases suggests some common characteristics of design action, namely to be user-centred, iterative, interdisciplinary, and to facilitate collaboration and participation. Additional aspects emerged from the specific cases: The multidisciplinary collaboration in Helsinki highlighted the role of designers in breaking through knowledge and policy domain silos. This was also possible through the designers' typical exploration strategy that is non-linear, and based on the creation of provisional solutions. The user-centred approach in Copenhagen instead, put the civil servant in a better position to develop empathy with the subjects of the policies. Although the focus of design action is moving towards more complex problems - and thus tends to meet the instances of policy makers – the specific contribution that design can provide to policy making, in terms of competences and tools, has not been clearly defined. This is where this paper offers a significant contribution. Competences and strategies considered in the two cases analysed in this paper offer fertile ground for clarifying the contributions that designers can offer to policy makers and the role design can have when working at this level of complexity.

By bringing together the experiences of researchers and practitioners, and the suggestions made by literature, the insights reflect on the complex nature of participatory approaches that are relevant for engaging with participants in and through the design process. Being able to identify and respond to stakeholder needs, including the designers themselves, enables the mapping of expectations against project and work objectives. The necessary ambiguity of participatory work, such as imagining, responding to unfinished ideas, and needs for visualization, generating an understanding of local contexts and culture, in addition to sensitive time-management strategies, relationship-building and the uncovering of issues of where power resides (between designers and stakeholders and within the stakeholder communities) inform the responses to stakeholder

needs. Thus, planning for user-testing and evaluation underscores the importance of risk awareness. Often opportunities can be identified for applying designerly ways of thinking and problem-solving in complex situations (although the contribution of design often reaches significantly further). The contributions in this conference session opens a process of offering suggestions, models, methodologies and tools through which complex problems (and their equally complex scenarios and contexts) can begin to be addressed and the processes for managing and gaining insights and new knowledge are able to emerge.

Articulating a strategic approach to face complexity in design projects: The role of Theory of Change

SIMEONE Luca[a]*; DRABBLE David[b]; IACOPINI Giorgia[b]; VAN DAM Kirsten[a], MORELLI Nicola[a]; DE GÖTZEN Amalia[a] and CULLEN Joe[b]

In today's world of global wicked problems, constraints and imperatives imposed by an external and uncertain environment render strategic action a quite complex endeavour. Since the 1990s, within community initiatives and philanthropic projects, the construct of Theory of Change has been used to address such complexity. Theory of Change can be defined as the systematic and cumulative study of the links between the activities, outcomes, and context of an intervention. The area of focus for this paper is to explore whether Theory of Change can support more strategic approaches in design. In particular, the paper examines how Theory of Change was applied to DESIGNSCAPES - a project oriented, among other things, toward offering a supporting service for all those city actors interested in using design to develop urban innovation initiatives that tackle complex issues of broad concern.

Keywords: Theory of Change, design strategy, strategy, DESIGNSCAPES

Aims

In today's world of global wicked problems (Rittel and Webber, 1973) such as climate change, social exclusion, economic crisis, and quality of life, design can help frame such problems and work towards solutions. Design can play a role in "sustaining, developing, and integrating human beings into broader ecological and cultural environments, shaping these environments when desirable and possible or adapting to them when necessary" (Buchanan, 1992, p. 10). In most cases, a single design solution is insufficient to address wicked problems, especially when these problems are ultimately global in nature. Instead, a series of concurrent, overlapping design interventions are needed. As such, planning and coordination become a central part of design activities (Boland and Collopy, 2004; Simeone, 2016) especially when intransigent issues or wicked problems are to be addressed systematically as to trigger multiplier effects.

How this coordination is organized is a matter of strategy, seen as a way of "discovering the critical factors in a situation and designing a way of coordinating and focusing actions to deal with those factors" (Rumelt, 2011, p. 3). For long, studies in strategy have acknowledged that the influence of external and unpredictable factors can highly affect even the best-executed plans (Mintzberg, 1994b). Strategy is a paradoxical process where the more organizations plan ahead for success (e.g. committing resources, developing specific capabilities, etc.), the more they may actually increase their chances for failure as the future is uncertain and unpredictable (Raynor, 2007). This is why John Friend and Allen Hickling argued that strategy should accommodate uncertainty and elaborate complexity rather than simplify and reduce it (Friend & Hickling, 2012).

One particular way to elaborate such complexity and improve the quality of planning is by using a framework labelled as Theory of Change (Anderson, 2004). Theory of Change emerged within community initiatives and philanthropic projects in the 1990s and has since been used for planning and evaluating social practice (Stein & Valters, 2012). Broadly, a Theory of Change approach is a process of identifying the current situation (in terms of needs and opportunities), the intended future result (expected or hoped for outcomes), and what needs to happen to move from one situation to the other (Rogers, 2014). The articulation of this 'change journey' through the use of Theory of Change can help identify more realistic goals and the strategies required to achieve the goals (Rogers, 2014). Interest in, and use of, Theory of Change as a programme/policy planning and evaluation tool has increased exponentially, as has the explicit link between Theory of Change approach and complexity (Ling, 2012; Rogers, 2008).

Even though the need to reflect upon theories of change has been deemed as necessary to craft strategies (Mintzberg, 1987) and Theory of Change has been examined as a way to support strategic approaches, e.g. in strategic negotiations (Walton, Cutcher-Gershenfeld, & McKersie, 2000), the nexus between Theory of Change and strategy remains understudied.

Within design research, strategy has long been a central theme explored from various angles (Borja de Mozota, 2003; Boztepe, 2016; Heskett, 2017; Kotler and Rath, 1984; Lockwood and Walton, 2008, Simeone, 2017). However, fewer authors more specifically focused on the ways in which a strategic approach in design could tackle complexity and unpredictable external conditions (Cross, 2008; McCullagh, 2008) and help to deal with systems influenced by a great variety of factors (Meroni, 2008). To this end, it has been suggested that design needs to make more explicit use of Theory of Change (Tonkinwise, 2015). This paper goes precisely in this direction and, as a main research question, aims to explore whether and how Theory of Change can support the articulation of strategy in design. As a case, the paper will look into DESIGNSCAPES, a European Commission-funded project oriented, among other things, toward offering a supporting service for all those city actors interested in using design to develop urban innovation projects and tackle broad problems of a complex and wicked nature. At its heart, DESIGNSCAPES acknowledges the generative potential of urban environments – or urban ecosystems (Peltoniemi & Vuori, 2004) – in which design can support collaborative and innovation processes that engage a variety of actors, including enterprises, start-up companies, NGOs, community-based initiatives, public authorities and agencies (Abbasi et al., 2019). This paper follows the 'change journey' that DESIGNSCAPES intends to spur by supporting these actors in their projects to make our cities more liveable, sustainable and prosperous.

Literature review

Designing for complexity

In this paper, we refer to design as a process to identify, frame and address problems and that uses modelling as an analytic approach to create and evaluate multiple alternatives and a wide solution space (Conley, 2010). Design generally harnesses divergent and convergent thinking (Brown, 2009) through an array of tools, methods, techniques and activities such as early, rapid and frequent prototyping, iterative development, visualization / materialisation techniques at varying levels of abstraction and user research, participation and testing (Buchanan, 2004).

For many years, researchers have explored how such design approaches could be used to tackle contemporary global wicked problems. The notion of 'wicked problems' was formulated by Horst W. J. Rittel in the 1960s and later further developed with Melvin M. Webber to indicate the complexity of some of the problems tackled by design as per their incomplete, contradictory, and changing nature (Rittel and Webber, 1973). Reflecting upon the ideas presented by Rittel and Webber, Richard Coyne (Coyne, 2005) noted how the notion of a wicked problem was formulated as a reaction to Herbert Simon's rationalistic proposition of a "science of design, a body of intellectually tough, analytic, partly formalizable, partly empirical, teachable doctrine about the design process" (Simon [1969], 1982, p. 58). Against this rationalistic view, the notion of wicked problems more clearly represents those situations characterized by a high level of indeterminacy and in which multiple and conflicting points of view emerge (Buchanan 1992; Teixeira, 2017; Bayazit, 2004). The related conceptualization of VUCA - short for volatility, uncertainty, complexity, and ambiguity (Bennet & Lemoine, 2014) – has gained popularity not only in management studies but also among those scholars more closely interested in how the interplay of strategy and design – as an array of tools, methods, techniques and activities and as a way of thinking (Brown, 2009) - can help organizations to cope with global competition,

geographically distributed supply chains and the growing centrality and proliferation of data (Lafley & Martin, 2013).

In design, one way of dealing with such complexity is to adopt strategic approaches which deliberately acknowledge that plans and decisions are often affected by a certain degree of uncertainty and confusion, turbulence and volatility, pressure of urgency and, possibly, cognitive and emotional overload (Friend and Hickling, 2012). Such strategic approaches might value those design processes that are open to emergent opportunities and that specifically design flexibility into the proposed solutions (Liedtka, 2002).

Strategy articulation and the strategic kernel

Definitions of the word 'strategy' in design differ, even though recurrent components of strategy can be considered: (1) being aware of resources and capabilities (Barney, 2001; Eisenhardt & Martin, 2000; Teece, Pisano, & Shuen, 1997) in the designer's hands and knowing where to direct effort and energies, (2) the related ability to frame complex problems as to identify a set of objectives that can be realistically reached (Rumelt, 2011), (3) being aware of the competitive context and the limiting circumstances in which our actions unfold, e.g. competitors or external factors that might affect our plans (Mintzberg, 1994a) and (4) the processes for defining and implementing sets of actions that take into consideration all the above. A recent systematic survey of literature carried out by one of the authors of this paper found that a consensus and quite broad definition of strategy is: "finding a balance between ends, means and ways while keeping an eye on risks as to achieve the impact needed to address a challenge".

Overall, within design research, strategy has long been a central theme explored from various angles and with contributions ranging from engineering design (Holt, 1991; Hsu, 2009), to design management (Boztepe, 2016; Cooper, Junginger, & Lockwood, 2011; Lockwood & Walton, 2008), and all the way up to collaborative design (Hyysalo & Hyysalo, 2018) and architecture and urban planning (Hill, 2012; Kempenaar & van den Brink, 2018). This paper is concerned with the specific processes of strategy articulation, i.e. those processes in which strategy is more or less strictly and explicitly identified and described, e.g. in relation to key ideas, directions to follow, goals and expected results (Love, Priem, & Lumpkin, 2002). In this sense, articulation is regarded as a discursive practice in which representations of what the organization "has been, is, and will be doing" (Mirabeau & Maguire, 2014, p. 1219) are formulated, but also circulated among stakeholders and subjected to their various interpretations. Rather than considering these processes as confined to the initial phases of a project, strategy articulation should be seen as an iterative process in which strategy is continuously re-evaluated and re-adjusted along the way and in relation to the impact of external and unpredictable factors (Liedtka, 2002; McCullagh, 2008; Mintzberg, 1978).

Methods and approaches to articulate strategy abound across fields as diverse as corporate (Andrews, 1971; Ansoff, 1965; Johnson, Whittington, Scholes, Angwin, & Regnér, 2017; Porter, 1980), political (Freedman, 2013) and military strategy (Echevarria, 2017). We will here consider as a starting point of our considerations the approach proposed by Richard Rumelt (Rumelt, 2011), which has spurred further reflections on what constitutes good and bad strategy (Freedman, 2013). Rumelt argues that at the center of good strategy there is a kernel, a coherent logical structure that connects thought and action:

> *Good strategy is coherent action backed up by an argument, an effective mixture of thought and action with a basic underlying structure I call the kernel. […] The kernel of a strategy contains three elements: (1) A diagnosis that defines or explains the nature of the challenge. […] (2) A guiding policy [that is] an overall approach chosen to cope with or overcome the obstacles identified in the diagnosis. […] (3) A set of coherent actions to carry out the guiding policy (Rumelt, 2011, p. 77).*

In the words of Rumelt, coherent actions are those feasible coordinated policies, resource commitments, and actions that are designed to carry out the guiding policy and that are aimed toward reaching long-term objectives or closer proximate objectives. In DESIGNSCAPES, the strategic kernel proposed by Rumelt has been used to initially frame the strategic approach of the project. The subsequent application of Theory of Change allowed to further articulate strategy and to more fully develop the logical connection between the various components of such strategy.

Theory of Change

Theory of Change emerged in the mid-1990s within the Aspen Institute Roundtable on Community Change as a new way of analyzing complex community initiatives working for social and political change. In a publication developed by the Roundtable in 1995, *New Approaches to Evaluating Comprehensive Community Initiatives*, Carol Weiss, an evaluation practitioner and methodologist, argued that a key reason complex social programs are so challenging to evaluate is that the assumptions and theories about how change will unfold as a result of them are poorly articulated (Weiss, 1995). The consequence, she argued, is that little attention is placed on articulating the steps required to achieve a long-term goal. Theory of Change therefore emerged as a way of overcoming this challenge by describing "a process of planned social change, from the assumptions that guide its design to the long-term goals it seeks to achieve" (Mackinnon & Amott, 2006, p. 2).

Overall, the core idea behind theories of change is that they define a sequence where one step (or one activity) leads to another one through cause-and-effect connections. The Tavistock Institute defines Theory of Change as a process which:

> *(...) involves the specification of an explicit theory of how and why an intervention might cause an effect which is used to guide the evaluation. It does this by investigating the causal relationships between context-input-output-outcomes-impact in order to understand the combination of factors that has led to the intended or unintended outcomes and impacts. Theory of Change, therefore, tests, and normally develops the implementation theory of an intervention and allows this to be modified or refined through the evaluation process* (Cullen, Iacopini, Junge, *&* Spielhofer, 2018)

Theory of Change is, on the one hand, a strategic planning tool. It articulates and graphically illustrates the intervention logic of a project, in other words the steps that need to be taken to realise a desired goal or impact, and the expected results of these steps. Theory of Change builds on a set of assumptions and hypotheses about what causes a problem, what particular actions will change that problem and what are the likely outcomes of these changes. In other words, it articulates a project's 'change journey', and shows the theorised causal pathways between a project's objectives, its activities, and its expected outcomes and impacts. It says: "if we take action X, then this will cause effect Y and this will eventually lead to outcome Z" (Cullen, Iacopini, Junge & Spielhofer, 2018). Theory of Change is, therefore, also a key evaluation tool because data collected along the way enables these assumed causal pathways to be tested. After the problem, project aim, expected outcomes and activities are mapped for a project, indicators should be developed to "assess progress and achievements along the 'change journey', and will be used to test the theory" (Cullen, Iacopini, Junge & Spielhofer, 2018). The integral link between Theory of Change and indicator development means that Theory of Change is a useful tool for both strategic planning and continual improvement. As Weiss stated, "The evaluation should surface those theories and lay them out in as fine detail as possible, identifying all the assumptions (…) built into the program. The evaluators then construct methods for data collection and analysis to track the unfolding of the assumptions" (Weiss, 1995, p. 67). This, in turn, opens up the possibility for assumptions to be modified or refined through the evaluation process, supporting the refinement of a strategy or initiative.

A good number of methods are nowadays available to help crafting theories of change for specific projects or programs. Although these methods build on slightly different conceptual theorizations, they share the idea that a Theory of Change should articulate logical steps that lead to change.

Theory of Change has been criticised on the ground that it might oversimplify complex contexts of interventions (Ruesga, 2010) and might not decisively contribute to clarify ill-defined issues (Stein & Valters, 2012). A way to address these issues is to keep a critical eye while taking into account beliefs and assumptions underlying a specific Theory of Change (Archibald, Sharrock, Buckley, & Cook, 2016) and while drawing sequences of steps and related cause-and-effect connections (Ruesga, 2010). Along these lines, DESIGNSCAPES proposed its own model for Theory of Change as "a way of mapping the 'change journey' of a project or innovation so you can see the connections between the 'presenting problem' the project wants to solve, the expected impact on that problem at the end of the project and everything that's supposed to happen in between" (Cullen, Iacopini, Junge & Spielhofer, 2018). Figure 1 shows an overview of the steps needed to identify the five key elements of a Theory of Change for a specific project.

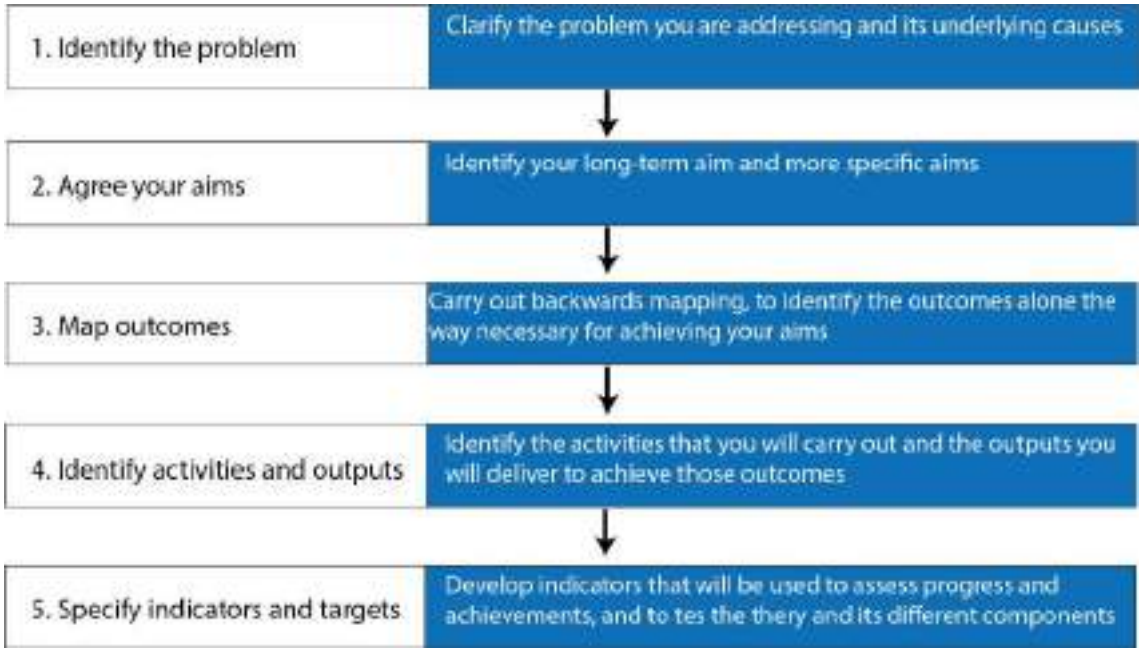

Figure 1 Steps needed to identify the five key elements of a Theory of Change for a specific project. Source: Adapted from Cullen, J., Iacopini, G., Junge, K., and Spielhofer, T (2017)

In the next sections, we will more closely look into how Theory of Change has been applied in DESIGNSCAPES.

Research approach

Methods

This paper uses a case study approach (Eisenhardt, 1989; Eisenhardt and Graebner, 2007; Yin, 2009) which allows analyzing the phenomenon with a certain degree of depth and which is suited to the exploratory nature of this research. Case studies allow identifying key insights over time (Paré, 2004) and work especially when the focus is on a contemporary phenomenon within real-life contexts (Yin, 2009). Case studies have been steadily used in organizational studies in the past decades (Berg, 1968) and more recently (Breslin and Buchanan, 2008, and scholars analyzed the relevance and the limitations of this approach (Dasgupta, 2015).

The authors of the paper are active members of the DESIGNSCAPES consortium and directly contributed to the definition and the development of this project, also through the methods and tools here presented. This role gave the authors the chance to gather data during the first two years of the project, also using ethnographically-inspired methods (Czarniawska, 2012).

The case

DESIGNSCAPES is a project funded by the European Commission and carried out by an international consortium that brings together a group of researchers with backgrounds in design-enabled innovation in cities and urban contexts, expertise in stakeholder involvement, collaborative research and learning processes and experience in linking practice, evaluation, policy and research. One of the core ideas of DESIGNSCAPES – inspired by the work of Jane Jacobs (1969) - is that cities offer particularly promising environments in which local design-driven projects can spur creativity and innovation, improve performance and efficiency (and hence increase the competitiveness of European organizations) and tackle wicked problems and important issues of broad concern. The overarching aim of DESIGNSCAPES is to select a number of promising ideas and projects from various European cities, to provide them with some direct funding and to support them with mentoring and coaching activities on how to use design approaches and methods. In more practical terms, DESIGNSCAPES organizes various open calls in which it asks European enterprises, start-up companies, NGOs and public authorities to submit a description of their design-driven projects. DESIGNSCAPES then selects a total of about 100 projects and backs them through (1) funding up to 25.000 euro, (2) a series of freely

distributed publications, toolboxes and training modules on how to use design methods and tools to support urban innovation processes and (3) a mentorship program.

DESIGNSCAPES acknowledges that the organizations behind these design-driven projects carry out their activities not as isolated entities, but rather as components of a business and innovation ecosystem, i.e. an interconnected population of organizations in which single units are strictly interdependent and influence the whole system (Peltoniemi and Vuori, 2004). Urban innovation has to do with processes of co-creation that actively seek the inclusion of diverse actors. This is why DESIGNSCAPES is particularly interested in supporting those projects that heavily rely on collaborative processes and local communities. The 'change journey' that DESIGNSCAPES intends to spur is precisely a change in some existing business and innovation ecosystems of European cities by offering funding and support to those design-driven projects that have the potential not only to tackle local urban issues, but also to propose solutions that can be scaled and replicated in other urban environments.

A number of factors demonstrate the complexity of DESIGNSCAPES. First, DESIGNSCAPES is embedded in open systems thinking, where a system interacts with internal and external agents to the degree that boundaries are fluid. The funded design-driven projects and interested stakeholders form a dynamic innovation ecosystem which is characterized by a continual realignment of synergistic relationships of people, knowledge, and resources that promote harmonious growth of the system in agile responsiveness to changing internal and external forces. Therefore, DESIGNSCAPES has three complexity based attributes: an emerging intervention which changes and evolves as it is implemented; local interaction between independent units which give rise to system behaviour; and context matters due to local agents interacting in urban settings.

Analytical description of the case

Definition of the strategic kernel

The strategic kernel of DESIGNSCAPES was initially codified in the proposal that the consortium wrote in relation to a call for funding issued by the European Commission in 2015[1]. The strategic kernel initially elaborated in the DESIGNSCAPES proposal can be summarized in Table 1.

Table 1. The strategic kernel of DESIGNSCAPES

A *diagnosis* that defines or explains the nature of the challenge:	The specific challenge to be addressed is that a good number of European organizations miss out on the potential to utilise design as a source for improving their efficiency, stimulating growth and tackling current urban issues and wicked problems.
A *guiding policy* [that is] an overall approach chosen to cope with or overcome the obstacles identified in the diagnosis:	Offering a supporting service that provides these organizations with some funding and with some design-based approaches and methods that help them tap into the generative potential of existing urban ecosystems.
A *set of coherent actions* to carry out the guiding policy:	- Set-up of an open call that offers financial support and mentorship for about 100 design-driven urban innovation projects - Creation and free distribution of a design toolbox and of an evaluation toolbox for urban design-enabled innovation and some related training modules - Creation and free distribution of a series of reports and studies on urban design-enabled innovation (e.g., reports

[1] *http://ec.europa.eu/research/participants/portal/desktop/en/opportunities/h2020/topics/co-creation-02-2016.html accessed 21 November 2018.*

	on the results of the open calls, a white paper focused on policy implications and recommendations, city snapshots and academic and popular press publications)

This strategic kernel was further specified in relation to work packages, deliverables and milestones needed to operationalize the whole DESIGNSCAPES project.

However, the articulation of strategy as stemming from this kernel has some limitations which restricted its utility. First, whilst problem, actions and rationale are shortly articulated, a more fine-grained definition of outcomes and impacts is missing. Second, the links between aspects of the coordinated actions are unclear in terms of which steps are necessary and what these steps are a result of. As such, rather than a 'change journey', the kernel provides a logical flow that expresses a linear relation between diagnosis, guiding policy and actions. Third, the underlying assumptions of the programme, where existing knowledge is low or where the model contains risks, are not articulated. Finally, the strategic kernel is not iterative and it is difficult to use as a data collection tool.

For all these reasons, DESIGNSCAPES used Theory of Change to further articulate its strategy.

Application of Theory of Change

In this project, Theory of Change provides a transferable tool to enable i) the partners of the consortium to understand DESIGNSCAPES and its 'change journey', and ii) the stakeholders in the selected design-driven projects to identify the presenting problem they want to change; the desired solution at the end of their project (the project impact) and the steps required to get from problem to solution (activities, outputs and outcomes). In other terms, it is the main data gathering tool to assess the effectiveness and added value of design in the innovation process and its contribution to efficiency and competitiveness.

The Theory of Change is used to shape the plan of the whole DESIGNSCAPES as well as to aid with the evaluation of it, and as a subject of training for the 100 design-driven projects. The Theory of Change articulates the stages of DESIGNSCAPES and the premises underlying the project and guides the project whilst being adapted to changes in circumstance as it is frequently redrawn and reconceptualised. For example, the selection of the design-driven projects to be funded, the training topics, and the dissemination strategy are all considered to be causally interlinked and are considered stages towards the ultimate goals of the project.

The project is still in progress and its most recent Theory of Change articulation is presented in Figure 2.

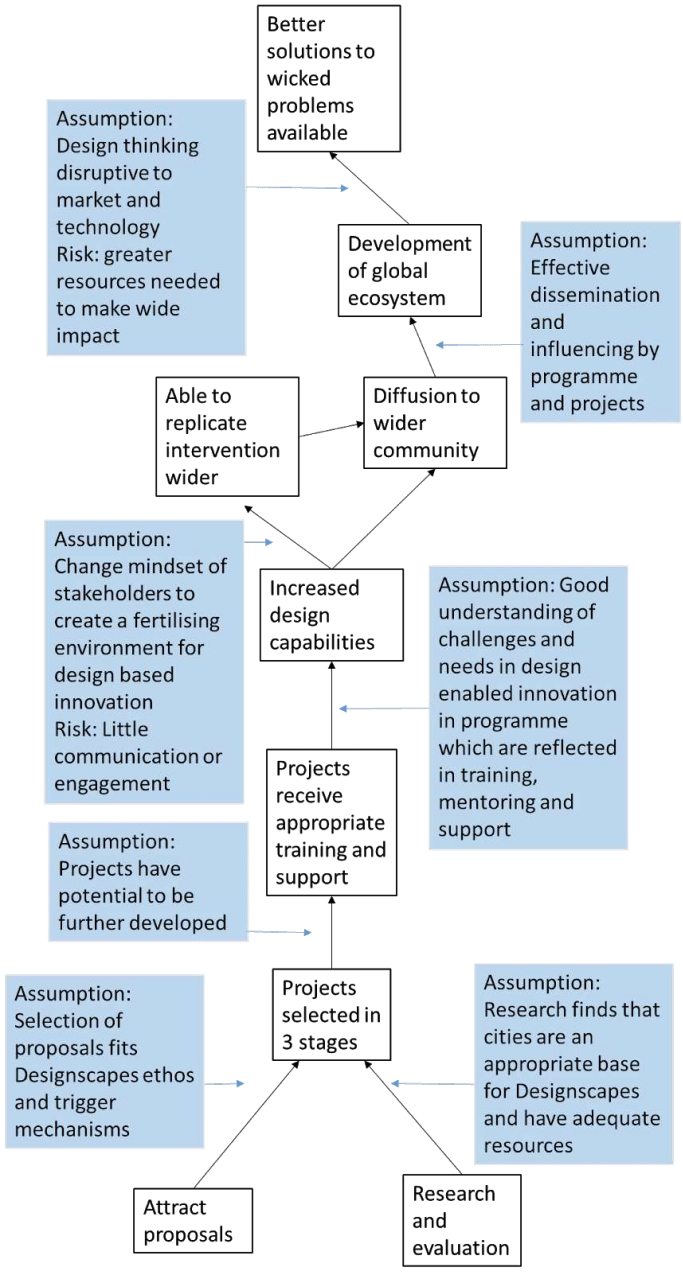

Figure 2 Articulation of Theory of Change for DESIGNSCAPES

The Theory of Change articulated above splits DESIGNSCAPES into seven stages, some of which occur beyond the life-time of the project. These stages are: research and marketing; selection of design-driven projects; training and support of design-driven projects; improvement in design capabilities; replication and diffusion; ecosystem development; and new robust solutions to wicked problems. Each of these stages is along a critical pathway and the stages are causally linked: for example, without appropriate support, project staff will not be able to improve their design capabilities. The assumptions underlying the Theory of Change ladder towards wider impact are articulated for each stage.

As an example of how Theory of Change can shape a project as well as describe it, an early assumption in the Theory of Change is that "selection of proposals fits DESIGNSCAPES ethos". If this assumption is fulfilled, the funded projects will be able to trigger a social movement. The development of local social movements is crucial to achieving later outcomes such as the development of a global ecosystem and the diffusion of innovations. If the approved design-driven projects are not focused on core values such as co-creation and social inclusion, then DESIGNSCAPES will struggle to achieve crucial outcomes; this may mean that DESIGNSCAPES must set up alternative levers and mechanisms to disseminate the innovations funded.

Because this assumption was identified at an early stage, the guidance for the jury members in charge of selection the design-driven projects to be funded was tailored to help fulfil the assumption through assessment questions. These questions asses whether the application submitted to the DESIGNSCAPES open call support co-creation in their proposals:

- Are people, users or citizens put in the centre of the innovation?
- Are users/citizens involved in the development and initiating the project idea?
- Is there any explicit co-creation planned with citizens, consumers or users?

By having an evaluation which uses the Theory of Change, the change potential of these design-driven projects is more likely to be realised. The evaluation assesses the programme – also through indicators and targets - whilst holding it accountable to the theory outlined in the model. By predicting areas of difficulty, plans are more likely to account for these potential issues.

Discussion and conclusions

DESIGNSCAPES is still in progress and various versions of its Theory of Change are being articulated over time. The first batch of design-driven projects are being selected and supporting material and processes are in place or are being finalized (e.g. freely available design toolboxes, training modules, mentorship programmes). While DESIGNSCAPES progresses, we will be able to more fully assess the impact of Theory of Change in the articulation of strategy and in relation to the outcomes of the project. However, we can already share some preliminary considerations.

The strategic kernel that, at an initial stage, was used to describe DESIGNSCAPES in the original application for the European Commission (Table 1) worked quite well to communicate the key strategic orientation of the project. The strategic kernel quite clearly represented the main challenge to tackle, the guiding policy to address such challenge and the related key actions to implement such policy. However, the strategic kernel expressed the relation between these components as a linear logical flow. As such, it did not fully render the complex interactions occurring during the envisioned 'change journey'. Theory of Change worked much better as an instrument to map the assumptions and hypotheses behind the main stages of DESIGNSCAPES and the causal relations among them.

In the 'Literature review' section, we characterized 'strategy articulation' as a process in which strategy is more or less strictly and explicitly identified and described. In DESIGNSCAPES, the strategic kernel provided a simplified and somewhat underspecified articulation. This kernel represented the DESIGNSCAPES strategy as a cascading flow (Table 1). Conversely, the strategy articulated by Theory of Change (Figure 2) is more of a reticular nature. Stages, assumptions and risks are mapped throughout a journey in which it is possible to see dependencies and linkages. While the logic suggested by the kernel is linear, the Theory of Change provides a more spatially distributed articulation in which the temporal dimension (i.e. the progression from one stage to the other) is plotted as to show stages as simultaneous, interdependent or sequential. In other terms, Theory of Change allows working with visual diagrams that articulate strategy at a more fine-grained level.

As Figure 2 above displayed, assumptions underlying a project are crucial to a Theory of Change. Whilst the strategic kernel outlines the overall plan of a project, the underlying rationale or potential flaws remain implicit. The Theory of Change makes these dependencies clear through outlining the implicit assumptions of the whole project logic, which are often unconsciously held by participants, yet are crucial to the success of a project. The Theory of Change model demonstrates that, at each stage of DESIGNSCAPES and before the outcomes can be achieved, the project must address the underlying assumptions. In addition, the theory on which DESIGNSCAPES has been based was inspired by Jane Jacobs (1969) and much of the success of the project will rely on the veracity of her theories as applied to European cities. Therefore, the theoretical aspects of any intervention are laid bare and testable in real-world settings.

The staging of Theory of Change is also worth consideration. Theory of Change requires participants to be specific as to hone an intervention in a clear and explicit way. This is often difficult to do at programme inception when the wider ecosystem that an intervention will be working within remains largely unknown. Because the strategic kernel is a more open and generalised tool, it may be a better starting point for a design strategy as has been the case in DESIGNSCAPES. The adoption of the kernel at an initial phase of DESIGNSCAPES was particularly suitable for at least two reasons: (1) it allowed to present a simplified version of the strategy in a way that was easier to understand by external people, e.g. the EU reviewers (i.e. of the call from which DESIGNSCAPES got funding) that, presumably, had very little time to read and evaluate many

applications; (2) the fact that strategy was not fully specified also allowed the project partners to interpret it in light of their interests, needs and agendas thus avoiding tensions and conflicts in the nascent consortium.

In DESIGNSCAPES, the integration of strategic kernel and Theory of Change helped to articulate strategy at different levels of refinement in relation to the needs of different phases of a project. Possibly, such integration worked particularly well precisely because it allowed to represent strategy at varying levels of abstraction and to translate such strategy for different stakeholders.

In addition, Theory of Change was introduced in DESIGNSCAPES by the Tavistock Institute, one of the partners of the consortium. Other partners of the consortium - some European design schools - were particularly intrigued by the possibility offered by Theory of Change to spatially and temporally visualize strategy in an iterative way. Such design schools saw Theory of Change as a way to use modeling - i.e. various visualizations of the articulation of strategy - as an analytical tool to more fully explore various strategic pathways and alternatives.

Theory of Change is not infallible or even necessarily reliable as a predictor for a project pathway. The assumptions outlined in a strategy are made without hindsight so it is difficult to predict the assumptions. Indeed, the reliability of a specific theory of change is a useful data collection point because if the theory maps poorly to 'reality' it can be an indication that the underlying premises of a project made poor assumptions. This is a particular risk in the complex contexts that projects are articulated within since there are almost always unintended outcomes for the activities undertaken.

However, the identification of poor assumptions and of where causal logic breaks down highlights a further strength of the Theory of Change approach: its iterative nature. In DESIGNSCAPES, the Theory of Change is revisited frequently, by the evaluation team and as a whole consortium at face to face meetings. This allows the project to understand where key blockages and success factors are so that the project team can adapt to circumstances and data as it is uncovered, rather than spend the funding period making similar mistakes.

We conclude this paper by highlighting an important shortcoming of the current study. While the usefulness of Theory of Change (e.g. for strategy and/or program planning, evaluation, reaching shared understandings) has amply been written about, DESIGNSCAPES is still ongoing. As such, future and deeper analyses of the project outcomes will allow a fuller examination of the potential of Theory of Change and the practical implications of its application in relation to a broad array of design-driven projects. This will also probably give us the opportunity to more closely assess some of the critiques presented in academic literature against Theory of Change (e.g. that it might oversimplify complex contexts of interventions). In its current iteration, the paper intends to present preliminary rather than conclusive considerations on how Theory of Change can help address some of the complexity specifically associated with collaborative and community-oriented design.

Acknowledgments

We would like to thank Drude Emilie Holm Ehn and the anonymous reviewers for their insightful comments and the entire DESIGNSCAPES consortium for their support and collaboration. The research leading to this contribution has received funding from the European Union's H2020 Programme under Grant Agreement No. 763784. This article reflects the authors' views. The European Commission is not liable for its content and the use that may be made of the information contained herein.

Participatory design is a widely recognised approach in Design for Development projects. It supports collaborative, community-based practices and it empowers users to take ownership. Despite the importance of participatory design in solving global challenges, the majority of research has focused its application in the Global North. Recently, some studies have explored participatory design methods in more low-resource settings. Still there is a gap between the existence of these methods, and designers being able to use them successfully because of the complex realities they face in low-resource settings. Existing knowledge is fragmented and there is a lack of best practice guidance for practitioners using participatory design in low-resource settings. We address this problem by reporting the experiences of Simprints, a technology company based in the UK, providing biometric identification solutions in the Global South. Our study reveals key recommendations for participatory design in low-resource settings, providing useful insights for practitioners and design researchers.

Keywords: participatory design, development, low resource, Global South, developing countries

Introduction

Design for Development (DfD) is a rapidly growing field in design research and practice (Margolin, 2007; Whitehead et al., 2014). DfD is defined as the process of designing products or services aiming to satisfy the needs and improve the wellbeing of disadvantaged or marginalised populations living in low-resource settings (LRSs) (Donaldson, 2009). Schumacher's 1973 publication *Small is beautiful* and Papanek's 1985 publication *Designing for the real world* marked an ontological turn in design, focusing on user needs and their surroundings. Since then, design practice has seen an increasing interest in participatory design (PD) (Björgvinsson et al., 2010). PD is particularly relevant to DfD as it leverages users' socio-cultural insights (Fuge, 2015), whilst empowering users (Puri et al., 2009) and supporting local ownership (Braa, 1996).

Despite the importance of PD in DfD, most research has focused on its practice in the Global North (Kraff, 2018). This limits the relevance of existing knowledge, as DfD contexts are vastly different (Aranda-Jan et al., 2016). Recently, a handful of studies have explored PD methods specifically aimed at use in the Global South. *Lean Design for the Developing World* (Pease, 2014) and the *Design for the Developing World Canvas* (Wood and Mattson, 2016) adapt existing tools to the needs of DfD. Drain et al. (2018) also propose a method for evaluating PD in technology for humanitarian and development projects. Still, there is a gap between the existence of these design methods and designers being able to successfully use them. This is particularly the case of technology-orientated DfD (Zewge, 2015)

In this respect, Simprints, a technology company based in Cambridge (UK), found little practical guidance on how to overcome challenges when using PD in DfD. Whilst Simprints' members had trained themselves in participatory design using tools such as IDEO's *Human-Centred Design Toolkit*, the team experienced challenges in translating the methods into their technical projects. Moreover, they found it difficult to access shared experiences from other organisations working in DfD.

Whereas existing studies have focused on the development PD methods, and some challenges of their implementation in LRSs have been well-reported, there is little precedent that advises designers on how to overcome these challenges. In this paper we investigate and report Simprints' experiences using these methods, highlighting the complex realities that designers face. We do so by uncovering practical recommendations for using PD in LRSs, therefore shortening the gap between existing design methods and their use in reality. We provide this report to help designers to move from knowing what to do to knowing how to do. These findings are particularly relevant for designers with a technical and science background, who are from the Global North and have little experience working in LRSs.

We focus on reporting Simprints' experience, which we consider to be highly valuable, as we are aware of similar projects taking place in the technology clusters around the University of Cambridge, MIT and Stanford University. We have documented anecdotal evidence of Simprints' experiences learning, planning and implementing PD for the design of their technology. We synthesise fragmented knowledge from existing literature and enrich it by providing an in-depth case study. Overall, this study makes an important contribution to the field, by providing practical insights for practitioners and drawing attention to aspects of PD that are particularly challenging, for which there are limited solutions.

The paper is structured as follows. First we describe the Simprints case study. Second we identify key themes in the literature and describe our methods. Finally, we discuss recommendations for PD in LRSs.

Simprints case study

Simprints is a non-profit technology company founded in 2014 and based in Cambridge (UK). They provide a system for integrating in-house designed fingerprint scanners with third-party mobile apps to facilitate identity verification (Storisteanu et al., 2016). Simprints provides accurate identification to organisations using mobile tools in healthcare, education and microfinance in order to tackle poverty. Standard biometric technology is expensive and has been developed for the high-resource settings, whereas Simprints has focused on a solution specifically designed to meet the needs of LRSs (Storisteanu et al., 2015). In August 2017, they were awarded a $2 million innovation grant, enabling them to scale their maternal healthcare project with BRAC in Bangladesh to reach two million mothers by 2020. Currently Simprints operate projects in Bangladesh, Nigeria, Uganda, Zambia, Kenya, Malawi, Somalia, Ethiopia, Zimbabwe and Afghanistan.

Simprints formed after winning a Hackathon in 2012 which introduced the challenge of patient identification in LRSs. The four founders were graduate students, who were inexperienced in product design and had limited experiences working in LRSs. The importance of using PD was clear to them from the outset, and they took steps to search for open-access tools and methods, and completed training using IDEO HCD Toolkit. However during initial field work they quickly found it challenging to use these PD methods because of the constraints of working in LRSs. Simprints found it difficult to access shared experiences from other organisations working in DfD. Moreover, they found that there was a lack of in-depth guidance on how to apply PD methods specifically for LRSs.

Methods

Systematic literature review

To gather PD experiences in technology-related DfD projects, we searched Scopus to conduct a systematic literature review (Kitchenham, 2004). Workshops, book chapters and any non-peer-reviewed papers were excluded. The key search terms were: (“participatory design”) AND ("low resource" OR "limited resource" OR "developing country" OR “third world” OR “Global South”). This resulted in sixty-seven articles. An abstract review was undertaken based on the following two criteria:

1. The paper describes the design of a product for Development, in a LRS
2. The paper describes and evaluates PD methods

Of the remaining thirty-nine papers, twelve papers could not be retrieved and seven papers were added by snowballing. After full paper review, twenty-five papers met the criteria. The literature was analysed using open and axial coding to group thematically similar concepts (Daengbuppha et al., 2006). Particular attention was paid to the challenges for using PD methods in LRSs. These challenges (Table 1) guided our case study analysis.

Case study

In order to expand on findings from the literature, a case study approach was taken (Yin, 2018). Efforts to ensure data triangulation and investigator triangulation were made as far as possible (Yin, 2018). Field work data from 2014-2016 was reviewed, including field guides, storyboards, card sorting decks, prototypes, original interview transcripts and communication logs. Semi-structured interviews were conducted with three members of Simprints, who were involved in the product development from the outset: Alexandra Grigore (Chief Product Officer); Daniel Storisteanu (Director of Research); and Toby Norman (CEO). Interview questions were structured around the eleven challenges found in the literature (Table 1). Each interview lasted approximately 60 minutes, and was recorded with the participants' verbal consent. The interviews were transcribed verbatim and imported into MAXQDA.

A code hierarchy was created based on the challenges reported in from the literature (Table 1). Multiple coder analysis was undertaken to identify the challenges and recommendations of using PD in LRSs, based on Simprints' experience. Following this, a validation workshop was set up with the Director of Innovation and Director of Research to verify these findings.

Results and discussion

Recommendations for participatory design for Development in low-resource settings

Encouraging participant engagement

Difficulty encouraging participants to engage with the design process was identified as a key challenge across all stages of the design process. In particular, this presents notable challenges for conducting interviews and focus groups, as well as implementing more PD methods, such as storyboarding and card sorting. For instance, as found in the literature, some participants may fail to contribute meaningfully in design sessions, and instead look to the designers for answers (Ambole et al., 2016; Del Gaudio et al., 2016; Kiura, 2006;, 2013; Wang et al., 2016). Similarly, Simprints noted this challenge as one of the most significant barriers to their work. The most important recommendation for designers in this case, is to make the purpose of the product specific and

relatable for users. If participants recognise the potential value of the design exercise, then this might encourage them to engage more meaningfully with the project. Including participants' ideas and feedback can also make them feel valued and encourage more confidence and participation later in the process.

> *"Some people are very excited to be part of the process and even proud to be part of the process. Especially when we've worked with them and then we come back four months later and they see that some of their ideas have been incorporated. They're very proud and they feel ownership over the product" (Daniel)*

In the short term, translators can also try to encourage participants to respond and emphasise the value of their participation. Moreover, establishing a rapport with participants can help to improve engagement. Empowering participants to feel confident is key to maintaining engagement, particularly in focus groups, in which less confidant participants may be reluctant to voice their opinions. In this case, the designer should be flexible and rearrange groups to establish new dynamics to encourage more participation from quiet participants. Additionally, designers should consider whether one-to-one interviews may be more effective. Alternatively, designers might choose to use more participatory techniques like card sorting or stack ranking to elicit engagement. Observing how participants engage with physical products also removes the need for direct engagement with the designer.

> *"Things like stack ranking are usually more engaging for people… because people have opinions now and you're forcing them to make judgement calls. For direct observation, you don't need their [the participants] engagement with you [the designer] but they definitely need to be engaged with the product or the technology you're testing. For interviews, socially it's hard to totally disengage, especially if it's a one-on-one interaction." (Toby)*

Finally, designers need to be realistic about how much engagement can be expected from participants. Ambole et al. (2016) find that participants do not engage with design exercises independently outside of structured sessions. Awareness of participants' capacities and capabilities is important to avoid burdening participants with unrealistic tasks. At the same time, designers should be aware of the dangers of tokenistic participation of users, which may undermine the value of PD approaches (Yee et al., 2015).

Creating awareness of design methods or reasoning

Participants may not be familiar with the design process and as a result find it difficult to generate solutions or to contribute (Del Gaudio et al., 2016; Hussain et al., 2012; Kam et al., 2006; Manen et al., 2015; Racadio et al., 2014; Roland et al., 2017; Wakil and Dalsgaad, 2013; Wang et al., 2016). Designers should be aware that methods used are typically based on Western orthodoxies of knowledge and reasoning that may be substantially different to approaches in other contexts (Cherlet, 2014). In this case, explaining the design process to participants, as well as the purpose of the product, is essential to improving their awareness of the methods and approaches.

> *"We started every session with an introduction… The translator had a text explaining who we are, why we are there for, what's the context. So giving them actual concrete examples of how the system will benefit them." (Alexandra)*

A major barrier to Simprints in their efforts to get feedback from participants was the lack of understanding about work in progress, also noted in Maunder et al. (2007). Participants struggled to give feedback on unfinished prototypes, as it was difficult to imagine something that had not yet been created. Whilst it is recommended to start field testing as early as possible to avoid incorrect assumptions, designers should be aware of the limitations of testing work in progress and pay attention to avoid including confounding variables in a set of prototypes. Explaining to participants the concept of work in progress is important to encourage more meaningful feedback.

In some cases, being sensitive to different participants' ability is important, and different tasks might be prepared for people with different skills and backgrounds. Generally, designers are recommended to avoid leading questions, however, Simprints found that participants were confused and unsure how to respond to open-ended questions. In particular, 'holding the silence', a commonly used technique to elicit responses in developed nations, was found at times to be particularly uncomfortable for participants. As a recommendation, designers should prepare open-ended questions, but be ready to use prompts or move

towards more closed questions if necessary. In general, designers should avoid unnecessary shortcuts to quick answers by asking leading questions.

The study also found that participants' illiteracy or technology naivety may be a challenge confirming findings in the literature (Ambole et al., 2016; DeRenzi et al., 2017; Gangadharan et al., 2011; Haque et al., 2015; Kam et al., 2006; Manen et al., 2015; Maunder et al., 2007; Puri et al., 2004). In this case, one option is to use narrative and culturally-appropriate styles of communication, such as storyboarding. There was some disagreement however, with regards to the effectiveness of visuals among the Simprints team. Daniel and Toby strongly supported the use of visuals, citing greater engagement among participants. Alexandra, on the other hand, considered that for the most part, visuals were not effective and resulted in greater confusion for participants. More research is needed to clarify the effectiveness of visual aids in PD.

Managing multiple and varying stakeholder needs

Conflicting needs and requirements from the different stakeholders were reported by Del Gaudio et al. (2016), Mohedas et al. (2014), and Roland et al. (2017). These resulted in inconsistencies and incompatibilities between some of the user requirements for the designs. For Simprints, the differences between the requirements of the end users and the donors resulted in conflicting needs. To minimise these conflicts, Simprints made sure that the value of the project was clear and agreed upon by all types of participant (users, program managers and local partners). In this way, stakeholders recognise that the technology is solving a problem which they face, either directly or indirectly. Simprints emphasise the need to choose a user champion and project champion, who take ownership of the project. For Simprints, these champions were effectively 'active citizens' (Yee et al., 2015), operating at various organisational levels to support product testing and adoption.

> *"In every project, we use a user champion and a HQ champion… We want to make sure that there is someone fighting for the users' interests when it comes to Simprints and then someone who is genuinely fighting for HQ interests." (Toby)*

It is important to recognise that impact can only be achieved with the buy-in of participants. Simprints have discussed ways to acknowledge champions more formally by providing certificates and including their bios on the Simprints website. Officially recognising the time investment of champions is an effective way of keeping them motivated and engaged.

Setting realistic objectives

Unmet expectations from participants can disrupt trust and undermine projects (Del Gaudio et al., 2016; Wang et al., 2016). Moreover, misalignment of stakeholder goals can also create confusion, disrupt progress, and divert resources. In particular, Ambole et al. (2016) criticises the 'unquestioned optimism' of design projects that may suffer from unrealistic expectations. This was not a challenge that Simprints readily identified with, however in general they pointed out that informing participants about the project goals and keeping them updated with project process was important.

More specifically, projects should have a clear, public output. In addition, a collaborative relationship should be established with the project partner in order to negotiate objectives and manage collaboration (Del Gaudio et al., 2016). Measuring long term project impact can be challenging, however, one approach suggested by Simprints is to measure impact against the pain points identified by users. Moreover, it is important to set up systems and establish relationships to provide feedback between and after field tests.

> *"We follow up with questions and every week for the first two months we have a project call where we follow up with the users and the managers to ask how the project is going. We also have some questionnaires for the users, where users will just fill in any errors or bugs that they encounter in the system." (Alexandra)*

There is another opportunity here to leverage the capacity of user champions who can be responsible for providing feedback from the field. Simprints recommend that relationships with user champions must be nurtured and they describe varying levels of engagement from different user champions. Designers can be proactive in training champions and keeping them updated with the project, however champions must fundamentally be people who engage with the project's purpose, and who are socially and emotionally connected to the project's value. Considering the most enthusiastic participants during field testing is a recommended way to select user champions.

Compensating for designer's lack of experience

Some designers in DfD projects may be working in LRSs for the first time and they may not have extensive training in design. For instance, designers may come from engineering or other technical backgrounds and have difficulties processing and analysing the information gathered through PD. Mohedas et al. (2014) reports some of the challenges faced by engineering students when using design ethnography. In the case of Simprints, the team also lacked formal design experience, although they did search for commercially available toolkits (i.e. IDEO and +Acumen Massive Open Online Courses). To compensate for their lack of experience, Simprints identified their own weak points and identified mentors and experts who could help them. After initial interactions, they built these relationships further to keep mentors engaged in the project, in order to receive further support from them. Simprints recommend that requests from mentors and experts should be small and tangible.

Another way in which Simprints tackled these challenges was through testing the methods in the field and going through iterative cycles of testing. It is only through learning-by-doing that designers will be able to learn and gain experience designing and connecting with the users.

> *"There is no replacement for field effort. When you do that process multiple times, then maybe you start to get build up a little bit wisdom in this space." (Toby)*

Building relationships with stakeholders

Access to users is a recognised challenge in PD and, hence, stakeholders with user access are fundamental for design projects. A frequently reported challenge is the selection of the local partners and the development of the relationships with them. Simprints found that local organisations often have existing strong relationships with users. They also identified project champions within organisations that could help them to build their network further. Some of the ways in which Simprints built their relationships with project champions included meetings, workshops and tours. For example, Simprints invited champions to visit their headquarters. During their visit, champions were invited to co-design sessions and some of the champions' recommendations were included in the subsequent iterations of the product design.

> *"One recommendation is first establishing a collaborative relationship with a partner in the field. Get them brought in into what you are doing. Make sure that you are going towards a solution that they need so that you are not in a position where you are just using them as a field testing site, but they are invested in you developing a product because it solves one of their real needs." (Alexandra)*

To establish these strong relationships with the local partners, designers need to prepare concise study and field test protocols, indicating benefits to the partners but also explicitly expressing the project goals and the purpose of the project. For Wang et al. (2016), local partners were fundamental for the long-term diffusion, and successful adoption, of PD in rural China. Specifically, identifying qualified stakeholders and sustaining their motivation were key factors for long-term PD processes.

Building rapport with the participants is also fundamental to PD projects. Simprints worked with organisations that had good relationships with the end users but also tried to establish positive direct relationships, by learning basic vocabulary in the users' first language and ensuring that their inputs were included in the iterations of the design.

> *"Show that you've incorporated their advice and then they will become champions for you and help you out." (Daniel)*

Flattening the hierarchy

Power imbalances are one of the key reasons for unreliable responses or lack of participation when involving several stakeholders. During field testing, Simprints noted that differences in gender, age and socially-defined caste groups were notable barriers to participation. Where such power imbalances are identified, it is recommended to separate participants by gender or roles for focus groups. In some other case, one-to-one interviews and interactions can be used to improved users' engagement and participation.

Power imbalances can also occur when individuals or organisations are perceived as having a higher authority. Simprints, for instance, observed power imbalances between the local partnering organisation or translators

and the end users. To avoid this, Simprints conducted workshops in which managers and supervisors were not involved.

> *"I was running a focus group with community health workers who would be our end user. Certainly, the quality of their answers changed significantly depending on whether the boss was in earshot or not." (Alexandra)*

Power imbalances can also result from designers' intervention in the local context. These could be between the designer and the local partner, or between the designer and the participants. Some participants assume that certain answers are expected or that the designer knows the situation better. This power imbalance results in the participant's inability or unwillingness to express difficulties understanding the design-activities, the purpose of the activities. Simprints, used local partners to encourage participation without pushing participants out of their comfort boundaries and allocated time for participants that were more engaged.

> *"They were very concerned of telling us that our product is bad, that something is not working properly. I felt that we did overcome that by training the translators to tell them that 'it's okay, you can tell' and some of them would be much more willing to just say 'this doesn't work.'" (Alexandra)*

Regardless of the source of the power imbalance, overcoming the lack of participation and getting honest feedback from the participants is important when conducting user research or testing. Hussain et al. (2012), as well as Simprints, report using anonymous written feedback, prioritising individual interviews rather than group discussions, and encouraging honest feedback by remarking that the product is only a prototype that needs to be improved with the participant's input as approaches to overcoming power imbalances between designers and participants.

> *"People gave better critical feedback when it was clear that this was really a process because [otherwise] nobody wants to say anything negative about it." (Daniel)*

Simprints also trained the translators to indicate that it was fine for participants to be critical about the product. They also effectively used methods such as stack ranking, which forced people to express preferences and made critical discussion more comfortable for participants.

Bridging language and cultural barriers

This challenge is reported as one of the most significant, as designers lack contextual understanding. Hussain et al. (2012) point out that projects should be based on an in-depth understanding of the history, culture and society of the product's use-context. Technology is not a sustainable solution in itself, but needs to be embeded in a social-cultural framework (Corsini et al., 2019). The recommendation for designers to spend as much time as possible in the local context is noted in Wang et al. (2016), however, as pointed out by Simprints, this might not always be feasible because of resource constraints. Furthermore, there is concern that these experiences may be enriching for designers but will not necessarily lead to tangible design outcomes. Emphasis is placed not just on visiting the design context as much as possible, but on iterating designs and testing them frequently.

Language barriers and translation issues are also frequently reported. If possible, it is recommended to organise workshops in the first language of participants. As noted in Ambole et al. (2016), when workshops were organised in English, participants did not feel confident speaking English and therefore only gave brief responses. It is recommended to hire and train an external translator before designers go to the field to avoid any potential biases. In particular, it is important to train translators on how phrasing questions in different ways can introduce bias, and to ensure that the translator understands the purpose of the design exercise so that they are motivated and engaged. Providing written questions in advance can assist translators and help to avoid leading questions in the moment. Finally, designers should also consider using other methods such as direct observation to complement and verify data from interviews and other exercises that require translation.

It is also recommended to carefully research any symbols and graphic styles being used to ensure that they are culturally appropriate and to test visuals before going to the field with someone familiar with the context. Simprints describe how cartoon style illustrations were recommended to them for producing visual support material for the Nepali context.

"a typical power button symbol wasn't always intuitive… Then there was a frowny face that was put into a positive pile." (Daniel)

Using time-effective approaches

Time constraints affect the design process with respects to both the participants' time and the designers' time. Firstly, finding an appropriate time to meet with participants can be challenging and designers should be aware of the opportunity cost of participants' time. Designers should be flexible and should recognise when particular exercises may have a negative impact on people's responsibilities. On one occasion, Simprints describe cutting short an interview with a doctor, as they were aware of a long line of patients waiting for appointments.

In general, designers should prioritise questions, and have clear and streamlined protocols. Keeping tests concise, simple and focused is highly recommended. Hussain et al. (2012) recommends that it is possible to visit participants in their homes to reduce the participation burden, however, this does not completely eliminate the burden, as described in the extract below.

"There were definitely cases when it was apparent to us that we were taking up time from people that was valuable to them and we would cut something short… I remember doing some shadowing and there was a woman in a slum. We were trying to look at her interaction with the community health workers and it was clear that she didn't want to give the time of day. She was cooking, she was running around, talking to other people" (Daniel)

Ambole et al. (2016) suggest that designers can consider using different groups of participants to minimise the burden on any individuals. Perhaps most importantly, it is recommended that the direct value of the project is fully explained to participants in order that they value the time spent on the project. Designers should also consider appropriate ways of rewarding participants for their time. In cases where participants receive paid salaries, thanks and appreciation may be sufficient. In some cases, Simprints provided gifts in kind, such as providing lunch for participants. More generally it is recommended to discuss incentives with project partners in order to make sure that they are culturally appropriate.

Finally, time constraints are also noted from the perspective of the designers, as they may have limited time in the field. As well as keeping tests concise and simple, designers should bear in mind some of the additional time requirements for particular exercises e.g. the time taken to travel between different locations for shadowing visits.

Staying safe and comfortable

As well as potentially working in an unfamiliar context, designers should be aware that the context may be unpredictable and volatile. Most importantly, designers should create a risk assessment strategy with input from the local partner. It is also recommended that the consent and involvement of all participants should be included (Ambole et al. 2016).

It should be noted that some communities may be concerned about the participation of vulnerable groups, particularly women and children. In this case, it is important to ensure that all engagement with vulnerable groups takes place in an environment where they are visible to communities. It is possible to arrange this such that participants are safe, but also that supervision does not influence power dynamics.

Designers should also be mindful of how poor working environments may affect participant engagement, including heat, light and other comfort factors. Simprints described trying to create comfortable environments for participants e.g. ensure they were not exposed to direct sunlight.

Getting access to users

Remote design is naturally difficult. The distance between users and designers poses challenges that are not only geographical, but also economic and technical. Such challenges were faced by Simprints, who have their head offices in UK and their users in Africa and Asia. Simprints, however, learned to cope with these challenges through the different field visits they conducted and other strategies. Planning and allocating enough resources for field testing is key for getting access to the user, ideally multiple trips. When they are not in the field, Simprints receive support from user champions. At the same time, they recognise that this may have certain limitations. For example, inexperienced user champions may inadvertently bias responses.

"Flying out is very expensive and timely and we've tried to counter that by having local champions to do testing for us... It's up to us to train them on how to get clear unbiased answers. Some people will intuitively be very good at getting the information from end users and communicating back to us and some people will clearly incorporate their own biases into that." (Daniel)

Finally, Simprints has realised that many of their design activities required time in the field. As their product has developed, the need for an in-country office became apparent. In 2018, the organisation decided to set up a local office in Bangladesh and are considering opening representative offices in other locations.

Conclusions and further research

This study explores the application of PD methods in LRSs. The research was prompted by the experiences of Simprints, who found that there was a general lack of information for designers using PD in technology-related Development projects. Our work responds to these concerns, by synthesising fragmented knowledge to identify eleven key challenges for PD in LRSs. We build on this knowledge to provide a detailed case study of Simprints, revealing recommendations that can be taken in order to overcome commonly-faced challenges when using PD in LRSs. We believe this is particularly valuable for designers who are planning to use a PD approach and who are not familiar with working in LRSs. Specifically, it offers insights for designers who may come from a science or engineering background. The authors also believe that this paper provides a valuable resource for academia. It highlights particularly challenging areas, such as power imbalances, cultural barriers and unequal understanding of design methods, for which future PD methods need to be specifically developed.

As interest in DfD projects increases, there is a more urgent need to disseminate this research to designers. As a next step, the authors plan to develop the findings into an actionable tool for designers, to assist with the planning stage of PD for DfD projects. Future plans include the organisation of DfD workshops in Cambridge (UK), using the planning tool for novice designers with a technical or science background.

Acknowledgements

The authors are grateful to Alexandra Grigore, Daniel Storisteanu and Toby Norman for participating in this research. Their experiences provided the inspiration for conducting this research.

Research Perspectives IN THE ERA OF Transformations

The Journey of Local Knowledge Toward Designing Neighbourhood Regeneration

WOO Eunji; KIM Chorong and NAM Ki-Young*

KAIST, Republic of Korea
* corresponding author e-mail: knam@kaist.ac.kr
doi: 10.33114/adim.2019.03.177

This research explored design opportunities and new challenges with a paradigm shift toward participatory processes in neighbourhood regeneration. Further, it emphasized the significance of local businesses and their local knowledge to overcome the challenges faced by designers. Three types of local knowledge *Handler* was established based on the Literature Review: *Possessor*, *Processor*, and *Implementer*. Through content analysis on 30 practical cases, 18 types of *Actors* in the process of participatory neighbourhood regeneration were identified. Based on these findings, two ways of local businesses' contributing to neighbourhood regeneration projects were proposed: as a *knowledge reservoir*, and as a neighbourhood *guide*. As future studies, the authors suggest 1) understanding the types and forms of local knowledge possessed by local businesses and how to motivate them to share their knowledge; and 2) devising new methods of participation for local businesses that can enhance designers' capabilities in neighbourhood contexts.

Keywords: Participatory design, neighbourhood regeneration, local knowledge, local business

Introduction

Recently, public participation in urban planning has been highlighted to reflect people's diverse and complex needs. These can be referred to as *local knowledge* (Sanoff, 2005; Berman, 2015; Mueller, Lu, Chirkin, Klein & Schmitt, 2018; Moore & Elliott, 2016; Al-Kodmany, 2001). Local knowledge is defined as the contextual intelligence that only locals possess (Fischer, 2000) and includes needs, perceptions, desires, or information on local contexts (Berman, 2015; Corburn, 2003).

This knowledge poses as key challenges in *participatory neighbourhood regeneration* which means endeavours to involve residents in revitalizing neighbourhoods with their voluntary activities (Tallon, 2013; Yamazaki, 2012). One challenge is that urban planners have trouble rendering local knowledge acquired from residents and incorporating it into planning processes (Mueller *et al.*, 2018; Moore & Elliott, 2016; Berman, 2015). The other challenge is that urban planners have a lack of tools and methods to involve residents who hold local knowledge in participatory neighbourhood regeneration (Sanoff, 1990; Towers, 2003; Burke, 1979).

Both these challenges can be successfully dealt with design as demonstrated in the emerging cases. First, design can render such implicit knowledge into useful resources to solve urban issues. For example, Baibarac & Petrescu (2017) introduced a new co-design process for enabling diverse interest groups to solve urban development issues by sharing knowledge and mutual support. Second, design can develop tools and methods to involve residents and even moderate conflicts among diverse stakeholders. Dalsgaard (2012) conducted a

series of participatory design workshops involving citizens, architects, and others, in developing a public library in Denmark. Pahk, Self, & Baek (2018) developed a novel design method to moderate conflicts among multiple stakeholder groups dealing with neighbourhood problems. These examples show how design can address the aforementioned urban planners' challenges caused by local knowledge. In this context, design can act as an effective means to involve people and mitigate complexity of handling local knowledge in participatory neighbourhood regeneration.

Nevertheless, scholars of design have reported existing difficulties in incorporating comprehensive local knowledge into participatory neighbourhood regeneration (Pahk *et al.*, 2018; Lee, 2008). This is because the urban planning context is different from the typical design context, in which a particular product or service has a homogeneous target user group (Dalsgaard, 2012). Whereas, participatory neighbourhood regeneration projects include heterogeneous stakeholders such as residents, local businesses, technical experts, and government. As such, design has difficulties in mining local knowledge and mediating cooperation within a multidisciplinary team. In other words, the heterogeneity of stakeholders makes it difficult for designers to handle local knowledge in participatory neighbourhood regeneration.

To overcome these difficulties, it is necessary to discover the roles of participants and strategically design projects, but most of the researches focus on involving *general* residents (Toker, 2007). Local businesses, especially, can take critical roles in participatory neighbourhood regeneration for the following reasons. First, local business owners can play multiple roles in their neighbourhoods, including resident, producer, seller, and consumer. They can represent diverse stakeholder groups. Second, local business owners possess both of first- and second-hand experiences (Sánchez-Jankowski, 2008). They frequently socialize with other residents at their own shops, and making them well-informed of other residents' experiences. Finally, local business owners are interested in and have a strong will to discover other residents' needs, preferences, and opinions because such knowledge can influence their businesses (Chapple & Jacobus, 2009). To summarize, local businesses have the potential for providing abundant knowledge and moderating other locals. Therefore, local businesses may complement the designers' challenges in handling local knowledge.

Despite their potentials, there is a lack of design research on the modes of local businesses' participation in neighbourhood regeneration. This research accordingly attempts to explore how designers can involve and utilize local businesses to overcome the designers' challenges.

Three research aims have been formulated:

1. To establish the significance of local businesses and its local knowledge in participatory neighbourhood regeneration and identify knowledge *Handlers'* types;
2. To identify and characterize *Actors* within each *Handler*'s type and identify the *Actors'* roles in participatory neighbourhood regeneration;
3. To propose the ways in which local businesses can contribute to participatory neighbourhood regeneration projects.

To achieve these aims, the research methodology includes 1) Literature Review in urban planning and participatory design to define key research concepts and construct an analytical framework and 2) content analysis with practical cases on participatory neighbourhood regeneration to identify the *Actors* and their roles in the *journey of local knowledge*.

Literature Review

This section reviews the current challenges of participatory design approach for neighbourhood regeneration. Furthermore, it emphasizes the role of local businesses in participatory neighbourhood regeneration. Based on the conclusions of the Literature Review, a conceptual framework including *Handlers* of local knowledge is built. The framework will be used to analyse practical cases during content analysis.

Design Opportunities and New Challenges in Participatory Neighbourhood Regeneration

Participatory neighbourhood regeneration refers to endeavours to revitalize neighbourhoods with residents' voluntary activities (Tallon, 2013; Yamazaki, 2012). It is necessary to explain why the authors set the scope of participatory urban regeneration as a *neighbourhood*. A neighbourhood, the smallest local unit, is regarded as a more effective testbed for experimental projects that require residents' participation than a mega-city.

Within a neighbourhood, residents naturally meet each other and share their experiences (i.e., local knowledge). Consequently, people can have shared goals and challenges associated with individual well-being that improve their neighbourhood environments (Manzo & Perkins, 2006). This enables residents to be more engaged in neighbourhood projects. Through participation in such projects, people become spontaneously tackling complex and *wicked* local problems, and it makes their neighbourhoods more sustainable and resilient (Watkins *et al.*, 2018; Zautra, Hall, & Murray, 2008). Because of residents' willingness for and immediate effect of experiments, many endeavours occur in neighbourhoods. Therefore, the authors selected neighbourhoods where the participatory design approaches to solve urban issue are frequently taking place for reviewing cases.

Scholars of urban planning have trouble handling local knowledge and involving locals in participatory neighbourhood regeneration (Mueller *et al.*, 2018; Moore & Elliott, 2016; Berman, 2015; Sanoff, 1990; Towers, 2003; Burke, 1979) and design can be an effective tool for their challenges. A review of the previous research suggests four roles of design in this context. First, design can make people be engaged in participatory projects even if the topic is unfamiliar (e.g., backward region development) or seems difficult to them (e.g., local housing policies) by using visualization or storytelling techniques (Hanington & Martin, 2012; Kim, Woo, & Nam, 2018). Second, design can facilitate people's expression by using toolkits such as visual aids, cards, or well-planned questions (Manzini & Rizzo, 2011; Baptista & Sampaio, 2015). Third, design can translate invisible and intangible ideas into communicable forms by using visualization and prototyping (Lee, 2008; Manzini & Rizzo, 2011). Finally, design can mediate conflicts among different interest groups and coordinate multi-disciplinary cooperation (Mueller *et al.*, 2018; Manzini & Rizzo, 2011) by translating both expert's and non-expert's language and creating a shared language (Mueller et al., 2018; Lee, 2008). With the recognition of these design specialities, many attempts have emerged to bring participatory design to urban planning projects with the purpose of making locals active players in the process of local problem-solving (Baibarac & Petrescu, 2017; Dalsgaard, 2012; Pahk *et al.*, 2018;).

Despite this potential of participatory design, neighbourhoods provide designers with new challenges caused by the following differences. The first difference is the heterogeneity of neighbourhood stakeholders. Typical design projects conducted in lab environments typically include homogeneous user group who could be clearly identified and have common goals (Dalsgaard, 2012; Schuler & Namioka, 1993). However, stakeholder groups are much more heterogeneous in neighbourhood regeneration (Dalsgaard, 2012). A participatory neighbourhood regeneration project generally includes residents, local businesses, architects, administrators, designers, and others. High levels of heterogeneity among stakeholders induce complicated and even conflicting relationships, which makes it difficult for designers to handle local knowledge. The second difference is that a designer is no longer the sole expert. In typical participatory design projects, designers have the authority to plan workshops, make or devise toolkits for workshops, recruit appropriate participants, moderate sessions, and analyse outcomes (Lee, 2008). In participatory neighbourhood regeneration, however, there are other technical experts, such as administrators, urban planners, architects, as well as designer (Al-Kodmany, 2001). Moreover, residents are not just research subjects, but *local experts* who have local knowledge. This fact makes it difficult for designers to mediate and coordinate communication among multidisciplinary teams.

To summarize, design can be a powerful tool in participatory neighbourhood regeneration and it provides research opportunities for the design community. However, due to heterogeneous participants with their own expertise, it is necessary for designers to deeply understand the context of participatory neighbourhood regeneration and develop the better way to handle local knowledge.

Significance of Local Businesses in Participatory Neighbourhood Regeneration

To complement the aforementioned designers' challenges, it is worth noting that local businesses can affect neighbourhoods. From the perspective of local knowledge, local business owners have richer knowledge than other neighbourhood stakeholders. One reason is that their workplaces (i.e., local shops) are the places where residents naturally gather (Sánchez-Jankowski, 2008). Consequently, shop owners acquire local knowledge including perceptions, opinions, and grievances raised by residents, and hence, Sutton (2010) suggests that a local shop can be the key base for social interaction, inclusion, and social organization. The other reason is that local business owners are willing to acquire local knowledge because such knowledge can affect their businesses (e.g., residents' food tastes, preferences, and dining culture can affect local restaurants) (Noble, Griffith, & Adjei, 2006). For these reasons, local businesses can play a crucial role in discovering local

knowledge, processing it into useful design resources, and incorporating it into participatory neighbourhood regeneration.

Despite their potentials, local business owners often cannot participate in most of neighbourhood projects. The reason is that existing participation channels are not suitable for their circumstances. The most popular channel in participatory neighbourhood regeneration is a workshop (Sanoff, 2000; Toker, 2007). A workshop is a typical participatory design format because it helps diverse stakeholders communicate and set shared goals, strategies, and outcomes through the introduction of novel procedure (Muller, 2003). A workshop invites people to spend hours doing activities in a dedicated place and it is a burden for local business owners to make time to attend workshops away from their workplaces. They need to be present at their workplaces during business hours.

To overcome the limitations of current participation channels for local businesses, Woo & Nam (2018) suggested that local business owners participate in neighbourhood regeneration by providing or sharing their business resources. For example, one supermarket set up a bench in front of the shop to increase revenue. It made pedestrians gather and stay there and triggered the public conversation on their neighbourhood issues. This case shows that local business owners can participate in neighbourhood regeneration even if they do not attend workshops.

The aforementioned case implies that there exist alternative modes of participation for local businesses in neighbourhood regeneration. However, existing participatory design research has little focused on the roles of local businesses in there. Participatory design methods for neighbourhood regeneration should be further developed so that local business owners can fully contribute to projects with their expertise and resources. Therefore, it aims to propose how designers strategically deploy local businesses in participatory neighbourhood regeneration by analysing the current practical cases which involved local businesses.

Conceptual Framework: Handlers of Local Knowledge

To achieve the aims, the authors established three *Handlers* of local knowledge in neighbourhood projects based on the Literature Review. Berman (2015) proposed five stages of participatory process in urban planning: determining project motives, planning the procedures, extracting local knowledge, processing local knowledge, and incorporating local knowledge into planning. From the perspective of local knowledge, this process can be classified into extracting hidden knowledge (tacit knowledge), processing it into explicit insights and workable concepts (refined knowledge), and implementing those concepts on the neighbourhood environment (realized knowledge). Accordingly, the authors redefined three stages of participatory neighbourhood regeneration, and labelled each stage as a role describing a way of handling local knowledge: 1) *Possessor*, 2) *Processor* and 3) *Implementer* (Figure 1). Hereafter, these are referred to as *Handlers* of local knowledge.

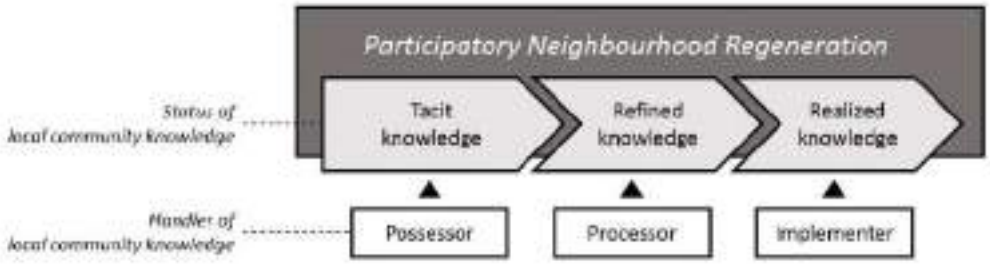

Figure 1: Journey of local knowledge and its Handlers.

First, *Possessor* holds local knowledge, ingredients of a participatory regeneration project. Local knowledge is usually embedded in locals, so it is also called a "local way of knowing" (Corburn, 2003). Accordingly, *Possessor*'s participation can provide not only latent needs of neighbourhood but also useful information on local context. Hence, *Possessor* can be sub-classified according to the types of local knowledge.

Second, *Processor* renders or enables other participants to render tacit local knowledge applicable. Local knowledge is usually too implicit, immature, and abstract to incorporate into the neighbourhood (Berman,

2015). Thus, it should be extracted from *Possessor* and refined by *Processor*. Hence, *Processor* can be sub-classified according to the ways of processing knowledge.

Third, *Implementer* actualizes concepts from the refined knowledge. Usually, the proposed concepts in urban context require construction or permission from the government, because concepts for neighbourhood regeneration need the use of public facilities or public spaces. *Implementer* can be sub-classified according to the ways of implementing the proposed concepts.

This framework 1) provides overall stages of incorporating local knowledge in participatory neighbourhood regeneration at a holistic level and 2) can be utilized to identify the specific role of participants in neighbourhood regeneration projects.

Methodology

To specifically identify types of *Actors*, which is a sub-category of *Handlers*, *content analysis* on practical cases was conducted. The *content analysis* method aims to obtain a systematic understanding of new phenomena using an analytical framework established by existing knowledge (Elo & Kyngäs, 2008). As the analytical framework, three priori codes (e.g., *Handlers*) were established in the Literature Review, which are *Possessor*, *Processor*, and *Implementer*. Two experienced design researchers were participated in the whole analysis process.

Case Collection

Practical cases were collected in advance of the analysis, and case selection criteria were set as follows.

First, within each case, researchers or practitioners should take a participatory approach with the purpose of neighbourhood regeneration. A participatory neighbourhood regeneration project aims to empower people and deals with topics affecting neighbourhood physical environments (Toker, 2007). Hence, it should involve locals (e.g., resident, local business owner, student) in planning process, and its aim can be divided into three: 1) *community building* to enhance relationships between locals (e.g., social dining events) as a prerequisite for planning neighbourhood experiment (Sanoff, 2005; Mason, 2010); 2) *community experiment* to apply a novel participatory approach for urban problem solving (e.g., workshop for identifying neighbourhood problems); and 3) *community business* to take an entrepreneurial process (e.g., job creation or start-up support) by utilizing local knowledge to pursue community goals (Johnstone & Lionais, 2004). Therefore, cases were selected that met at least one of these purposes.

Second, each case should contain a detailed description of its participatory process, the stakeholders' activities, and the outcome implemented in a neighbourhood. The researchers collected cases not only from academic papers, but from white papers, books, brochures, websites, and blogs. The search keyword includes 'community-led regeneration', 'neighbourhood planning', and 'participatory urban planning'.

Lastly, each case should involve at least one local business as local knowledge's holder (i.e., *Possessor*, *Processor*, and *Implementer*) in its process. As this research aims to highlight the role of local businesses in participatory neighbourhood regeneration, local businesses should be involved in each case. A local business is defined as a neighbourhood small-scale enterprise, and such enterprise is generally independently owned and operated (e.g., grocery stores, hardware stores, or restaurant) (Sutton, 2010). The researchers hence looked through each case report and excluded it if there was no depiction of local businesses' participation.

The cases are not confined in the design field in order to impartially analyse the practical cases and characterize *Actors* handling local knowledge at holistically. Ultimately, 30 cases were collected as the sources of content analysis (see Table 1).

Table 1: Cases collected for content analysis.

Case No.	*Project Aim*	*A brief description*
01	Community experiment	To promote an island by preserving the unique value of the neighbourhood without disturbing residents' lives
02	Community experiment	To redesign a public road by involving diverse road users to suit their needs
03	Community experiment	To design specific solutions for improving liveability in the neighbourhood by involving local communities
04	Community business	To encourage the youth to settle down in a neighbourhood by discovering local specialities and growing local talents
05	Community business	To promote local industries by discovering local specialities and growing local craftsmen
06	Community building	To activate conversation among people in a depressed shopping district by sharing local business owners' stories
07	Community building	To strengthen relationships between residents and local businesses by planning local festival together
08	Community business	To revitalize a neighbourhood by making residents encounter each other and investing local start-ups
09	Community experiment	To enable the youth to settle down in a neighbourhood by sharing residents' lives and supporting their local experiments
10	Community building	To strengthen relationships between university students and local businesses by learning cooking skills from local chefs
11	Community building	To design programs for a public park by applying residents' daily community activities
12	Community experiment	To design a playground by involving children in a planning process
13	Community experiment	To design educational programs at a playground by involving children in a planning process
14	Community experiment	To make proposals for the future neighbourhood planning by involving residents
15	Community experiment	To discover the values of a neighbourhood by publishing magazines containing residents' daily lives
16	Community business	To promote local industry by discovering local specialties and branding
17	Community experiment	To make policy for local revitalization by involving residents in writing proposals
18	Community experiment	To make policy for local revitalization by involving children in interviews with local seniors
19	Community building	To moderate conflicts on dam construction between residents and government by designing a deliberative workshop
20	Community building	To build community for revitalizing public park
21	Community business	To support community activities by a shopping mall's providing places for residents
22	Community experiment	To hold a local festival by involving residents in a planning process
23	Community experiment	To renovate a place with historical values by involving residents in a planning process
24	Community experiment	To discover latent problems in a neighbourhood by children's participation
25	Community business	To revitalize a traditional market by utilizing local business owners' stories
26	Community experiment	To promote a neighbourhood by discovering local specialties and branding local identity
27	Community experiment	To promote a neighbourhood by storytelling residents' and places' knowledge
28	Community experiment	To revitalize a neighbourhood by the elderly' art activities
29	Community building	To promote traditional market by publishing a newspaper containing local business owners' stories
30	Community experiment	To discover local problems by involving residents in process of community development

Content Analysis

The collected cases were analysed through priori coding and affinity diagramming (see Figure 2).

First, all corpus describing stakeholders and their activities were extracted. Then, each activity was categorized by the priori codes (i.e., *Possessor*, *Processor*, and *Implementer*) based on how each stakeholder handled local knowledge. For example, Cowley road project aims to redesign a public road by involving diverse road users (Symonds, 2005). In this case, a team of locals conducted interviews of pedestrians and encouraged them to drop by the exhibition site for collecting feedback. The team induced road users to express their implicit local knowledge, and thus they were coded with *Processor*. Another stakeholder group, road designers in the same case developed the final design based on pedestrians' comments, so they were coded with *Implementer*. At the end of priori coding, 48 activities were coded as *Possessor*, 138 activities as *Processor*, and 104 activities as *Implementer*.

Subsequently, the coded activities were grouped with *affinity diagramming* (Beyer & Holtzblatt, 1999), and each group was labelled as a sub-code describing activities precisely. For example, 'to conduct an interview' and 'to encourage people to join' were coded with *Processor*. However, the priori code, *Processor*, cannot concretely describe the way of processing, hence the researchers sub-classified each priori code. Accordingly, each priori code (i.e., *Handler*) is further divided into sub-codes (i.e., *Actor*). The final codes characterize specific *Actors* within each knowledge *Handler* in participatory neighbourhood regeneration (see Figure 3). A total of 18 *Actors* were identified through content analysis.

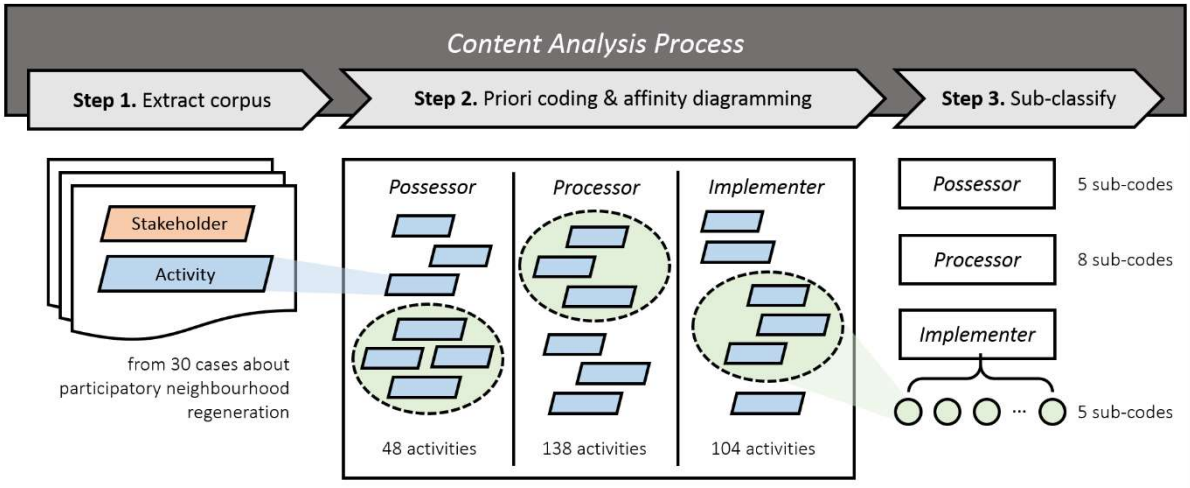

Figure 2: Content analysis process.

After the content analysis, the authors classified the *Actors* within each *Handler*'s by typical design activities. This step aims to identify common or distinctive activity between two contexts, which are participatory design and participatory neighbourhood regeneration. With reference to books published in design field, the *Actors* within each *Handler* were grouped again using affinity diagram method and labelled as a design activity. As a result, seven categories were identified (see Figure 3).

Finally, the frequency of each stakeholder's (e.g., designer, local business, and other stakeholders) performing each *Actor's* role was counted from the collected cases, and its proportion was calculated (see Figure 4). Based on the results, the authors could propose new ways in which local businesses can contribute to neighbourhood regeneration projects.

Results and Findings

Figure 3 shows *Actors* within each *Handler*'s type and the *Actors'* roles in participatory neighbourhood regeneration. There are three types of *Handlers*: *Possessor*, *Processor*, and *Implementer*. Within those categories, there are five *Actors* in *Possessor*, eight *Actors* in *Processor*, and five *Actors* in *Implementer*. *Actors* within each *Handler* are classified by design activity. Each *Actors* and design activity is described below.

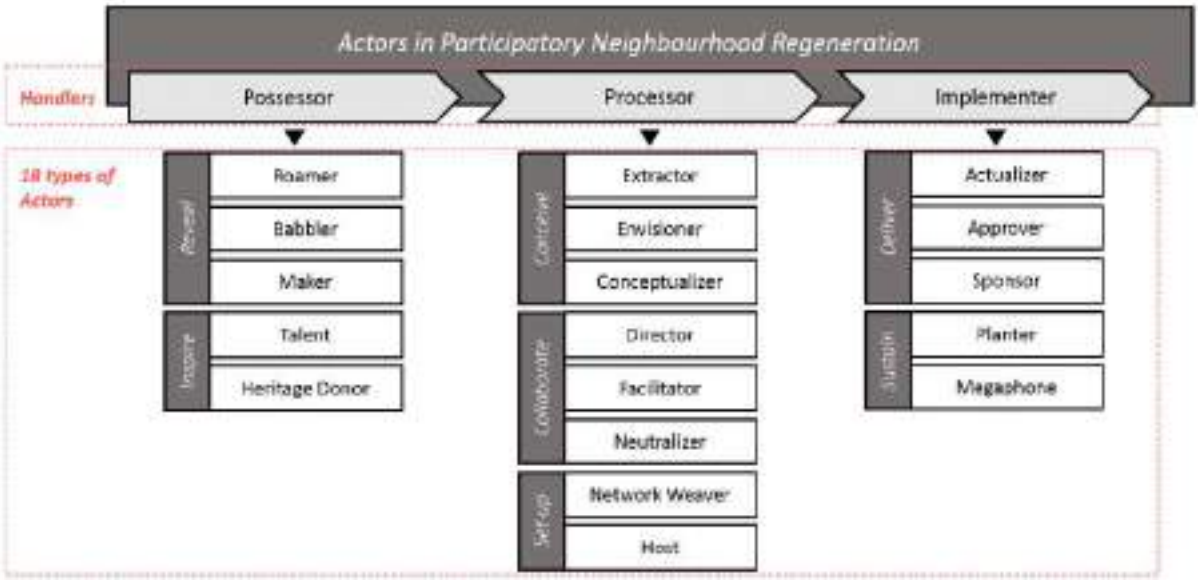

Figure 3: Final codes.

Possessor

Five sub-codes were found under *Possessor,* one of the three priori codes. The sub-codes represent five *Actors*, labelled according to the way in which they express local knowledge:

- *Roamer* displays local lifestyle or local culture just by roaming around the neighbourhood;
- *Babbler* says personal thoughts, opinions, grievances, needs, and information out loud;
- *Maker* creates artefacts reflecting local feelings, dreams, fears, and aspirations;
- *Talent* shares his or her skills relevant to local context (e.g., craft, cooking);
- *Heritage Donor* donates his or her spaces of historical or cultural value.

As seen in the definitions above, *Possessors* hold local knowledge within their lives. To collect such knowledge and incorporate it into a planning process is the aim of participatory neighbourhood regeneration (Al-Kodmany, 2001; Berman, 2015). Accordingly, it is necessary for designers who lead participatory neighbourhood regeneration projects to understand what makes *Possessors* actively express local knowledge. There are two ways through which *Possessors* express local knowledge: revealing and inspiring.

First, *Possessors* **reveal** undetermined and flexible local knowledge as evidenced by the definitions of *Roamer*, *Babbler*, and *Maker*. For example, in Case 15 (see Table 1), residents' daily lives, especially their use of public space, were captured by designers and revealed via a lifestyle magazine. This magazine triggered interaction between residents and promoted the neighbourhood. In this sense, the residents acted as *Roamer*s. In Case 6, designers produced a series of posters containing short excerpts from local merchants' interviews (e.g., their pride and joy, news, and stories) and displayed them in a stagnant shopping district to attract pedestrians. Here, local knowledge was revealed by merchants acting as *Babblers*. In Case 1, children drew pictures of the island where they were born and raised. Their drawings became unique local souvenirs by designers and artists. The children as *Makers* unintentionally and implicitly revealed their perceptions of, desires for, and information on their neighbourhood via creations.

Roamers' knowledge is acquired via observation, *Babblers*' knowledge is acquired via interview, and *Makers*' knowledge is acquired via creation. These correspond with the ways in which designers can learn from users in participatory design, that is, through what users do, what users say and what users make (Sanders, 2003). This fact implies that this area, participatory neighbourhood regeneration, can utilize design methods to collect local knowledge. How, then, can designers facilitate these *Actors* to express their own knowledge? First, *Possessors* who reveal local knowledge express it through natural activities, and hence designers should devise a medium by using *Possessors'* natural interactions, which can encourage them express knowledge more actively. Second, *Possessors'* knowledge can be anything based on the format of projects. Accordingly, to act as useful resources for projects, designers should help *Possessors* express knowledge in a guided way.

Possessors also **inspire** designers by voluntarily providing their own local knowledge, as evident in the definitions of *Talent* and *Heritage Donor*. These *Actors* are newly identified in the neighbourhood regeneration context. For example, in Case 10, restaurant owners acting as *Talents* taught university students who lived alone how to cook. While spending time together, the owners and students shared their stories naturally and developed emotional intimacy with each other. Here, the owners' cooking skills were the trigger for these social dining events. In Case 23, one local business owner acting as a *Heritage Donor* donated his closed sawmill and asked designers to utilize the space for neighbourhood regeneration. The designer extracted the local knowledge (e.g., stories of residents, spatial narrative) embedded in the sawmill and transformed it into a workshop where residents could learn woodworking skills from local craftspeople and make furniture on their own.

In these cases, the skills of the *Talent*s and the places belonging to the *Heritage Donor* triggered neighbourhood regeneration projects. Both cases show that the aim and outcome of the project are aligned with the given local knowledge. *Talent* and *Heritage Donor* provide their knowledge when the aim of a project aligns with community or business value they pursue. Accordingly, designers should plan projects in ways that persuade local businesses to participate, thereby encouraging these *Possessors* to provide their knowledge.

With *Possessor*s expressing local knowledge, the *Processor*s' role begins in earnest.

Processor

Eight *Actors* were coded under *Processor* and labelled according to the way in which they process local knowledge:

- *Extractor* extracts local knowledge from *possessors*;
- *Envisioner* provides vision regarding neighbourhood development that is based on local knowledge;
- *Conceptualizer* creates workable concepts for neighbourhood development that are derived from *Envisioners'* visions;
- *Director* leads and manages the processing of local knowledge;
- *Facilitator* encourages and facilitates the processing of local knowledge;
- *Neutralizer* mitigates conflicts among participants during the processing of local knowledge;
- *Network Weaver* builds human networks for processing local knowledge;
- *Host* stages events or provides spaces for the *Possessors* of local knowledge gather together.

Processing is not only the phase of participatory neighbourhood regeneration in which designers demonstrate traditional design skills but also the phase in which participation and cooperation begin. Based on the results, the authors identified three types of design activities that *Processors* perform: conceiving, collaborating, and setting-up.

First, *Processors* **conceive** possible solutions for neighbourhood development based on *Possessors*' local knowledge. *Extractor*, *Envisioner*, and *Conceptualizer* are the *Actors* involved in this activity. Designers conceive the design matter, define non-existing problems, and plan solutions even in unfamiliar fields (Buchanan, 1992; Lawson & Dorst, 2013). In this way, designers involved in participatory neighbourhood regeneration produce workable concepts for neighbourhood development by conceptualizing *Possessors*' local knowledge. For example, in Case 25, designers as *Extractors* and *Envisioners* discovered the uniqueness and competitiveness of the traditional market, unnoticed by locals, and established a branding strategy to revitalize the neighbourhood. In Case 17, a designer as *Conceptualizer* collected residents' future visions for the neighbourhood and, based on those visions, made a proposal to persuade the local municipality.

However, in neighbourhood regeneration situations, locals often become active *Processors* with an increased emphasis on public participation. For example, in Case 18, children acting as *Extractors* discovered local issues by interviewing elderly residents, and the data was utilized for developing a neighbourhood regeneration policy. In Case 23, local university students acting as *Envisioners* generated concepts for renovating an old workshop.

As the roles of locals in conceiving solutions become more important, *Processors*' roles are expanding to enable **collaboration** among participants. *Director*, *Facilitator*, and *Neutralizer* are under this activity. These *Actors* help encourage collaboration among participants and ensure the participatory nature of processes during projects. Here, participatory design is applied to enable users to easily and voluntarily participate in projects. For example, in Case 2 and Case 3, designers acting as *Directors* and *Facilitators* devised novel

participatory processes to increase residents' engagement in civic public interest and to enable multidisciplinary collaboration in urban development. In Cases 14, 17, and 18, designers planned and organized generative workshops where local stakeholders devised solutions for neighbourhood development.

During these projects, conflicts can be exacerbated due to political conflicts, which can lead to heightened emotions. In such situations, it becomes difficult to properly reflect people's opinions. A new finding in this research was the observation of *Neutralizer* role in which residents ease unnecessary conflicts among people. For example, in Case 15, a vendor selling milk communicated with local elderly people while selling her products. The elderly gathered around the vendor to confide their stories. Case 19 was a participatory process to mediate a dispute over dam construction between residents and the municipality. University students heard both sides and expressed opinions based on their own judgement, and their activity neutralized the conflicts.

The last design activity under Processors is performed by *Network Weaver* and *Host*, who **set up** a project. The processes of setting up the environment and recruiting participants affect the results of the project and, therefore, these processes should be planned out such that they align with the project goals (Kuniavsky, 2003). Symonds (2005) reported that a local shop was a neutral space where many people felt more comfortable than at the municipal office. This suggests that spatial conditions can impact public participation. For example, in Case 22, a designer put together a team to plan a local festival and recruited artists relevant to the festival's theme. The designer in this case acted as *Network Weaver* who had the vision, energy, and social skills to connect with diverse individuals (Krebs & Holley, 2006). Harmonious team composition helps the effective processing and implementation of local knowledge. As such, designers should be skilled at understanding participants' capabilities and capable of managing the team in such a way as to optimize team harmony while engaged in projects. However, designers who are non-locals usually have not developed the local human networks and do not have access to the local facilities needed to set up a project. In these circumstances, local businesses are powerful *Actors* when it comes to supporting project set-up. For example, in Case 28, a café was utilized as the place where the elderly learnt paper-based crafts and exhibited their craftworks. In Case 10, a diner was utilized as the place where youth learnt cooking from a chef. As such, local businesses can provide gathering places for people and indirectly support the processing of local knowledge.

Implementer

Five *Actors* were coded under *Implementer* and labelled according to the way in which they implement proposed concepts:

- *Actualizer* designs and realizes concepts proposed by *Conceptualizer*;
- *Approver* grants permission for the actualization of neighbourhood regeneration projects;
- *Sponsor* provides funds or places necessary for project implementation;
- *Planter* establishes organizations to maintain and safeguard implemented regeneration solutions;
- *Megaphone* promotes the implemented solutions.

After the roles of *Possessors* and *Processors* are carried out, local knowledge is implemented in the neighbourhood. The authors identified two types of design activities that *Implementers* perform: delivering and sustaining.

First, *Actualizer*, *Approver*, and *Sponsor* under *Implementer* **deliver** the final outcome of a project. 'Deliver' is the last phase of the Double Diamond model from the British Design council in which the resulting project is finalized, produced and launched. Designers take a leading role in the actualization phase. However, actualization in urban planning appears in various forms, such as products, services, architectures, organizations, businesses, or even relationship building (Sanoff, 2005), and most of these forms require public goods. Accordingly, *Actualizer* requires permission from *Approver* and funds from *Sponsor*. For example, in Case 2, urban designers acting as *Actualizers* designed and realized concepts that were proposed by residents at workshops. The city council acting as *Approver* and *Sponsor* then permitted the plan and provided subsidies. As seen in this case, implementation of neighbourhood planning requires cooperation from the government. The government or municipality has the authority to approve decision-making, and without their permission, it is difficult to implement ideas in the neighbourhood, meaning local knowledge cannot be manifested. Accordingly, designers acting as *Conceptualizers* and *Actualizers* must take into consideration the need to persuade the government to approve the project in order to carry out implementation.

Sustainability is one reason for emphasizing public participation in urban planning (Amado, Santos, Moura, & Silva, 2010; Manzini, & Rizzo, 2011) Thus, care must be taken to ensure this implemented solution a not one-off event.

In this context, *Planter* and *Megaphone* under *Implementer* **sustain** the final outcome. Participatory neighbourhood regeneration is generally conducted as a pilot study. Designers as a project leader are typically non-locals and, thus, cannot monitor the implemented solution continuously. In the beginning, locals are more likely to actively participate due to curiosity or expectation, but it can be difficult to sustain their interests once the project has been implemented. Accordingly, some designers attempt to *plant* the system and culture of the implemented solutions. For example, in Case 4, the project team developed local specialities based on the neighbourhood's agriculture and fishery using a participatory approach. They established organizations to grow local talents and preserve local specialities. In Case 14 and Case 26, the designer's role was to help locals acclimate to the participatory process and help such culture settle down after the pilot project.

In addition to *Planter*, *Megaphone* contributes to sustaining the implemented solutions by promoting projects. For example, in Case 1, the project team held exhibitions and published brochures explaining their process, achievements, and value. In Case 9, a local municipality promoted the achievement of their project, and this promotion led to an increase in the number of participants as well as subsides from the central government. *Megaphone* thus gives wider publicity to a project's achievements in order to 1) give residents pride and motivation, 2) attract others to join in, and 3) showcase their potentials to investors.

Discussion & Conclusion

Figure 4 shows the proportion of local businesses, designers, and other stakeholders in each *Actor's* role. The figure supports the argument that local businesses can mitigate the designers' challenges discussed in the Introduction section. How, then, can designers strategically deploy local businesses in participatory neighbourhood regeneration? Based on the findings of the research, two ways in which local businesses can contribute are proposed: 1) knowledge reservoir and 2) neighbourhood guide.

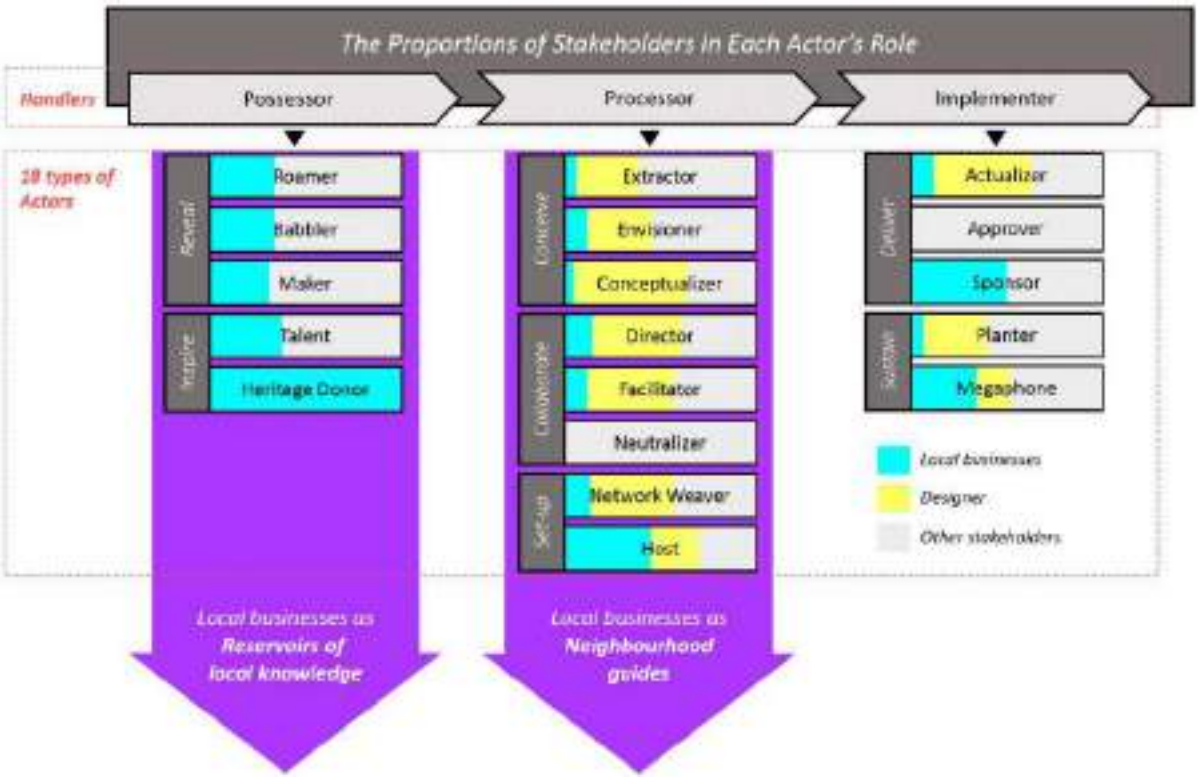

Figure 4: Two ways of local businesses' contribution.

Knowledge Reservoir

The first contribution is local businesses as *reservoirs of local knowledge*, from which designers can acquire abundant and unique local knowledge. As found from the content analysis (see Figure 4), local businesses hold rich and diverse local knowledge including the history (Cases 6, 7, 9, 25, and 29), heritage, neighbourhood locales (Cases 23 and 27), and expertise (Cases 1, 10, and 21) relevant to their businesses, as well as the needs of the local economy (Case 3). Furthermore, they possess stories containing their views not only as merchants but also as residents. Therefore, designers should utilize local businesses as key *Possessors* of local knowledge in participatory neighbourhood regeneration. However, designers often find collecting local knowledge difficult, as previously discussed.

In order to address such a difficulty and strategically utilize local businesses' knowledge, designers should first understand what types of knowledge they have, in what form it is provided, and how to engage them in sharing their specific local knowledge. The research found that local businesses, particularly, the *Talent* and *Heritage Donor* (new and original role types identified through this research) types of merchants, were willing to voluntarily offer their knowledge such as their skills and spaces, if their vision aligned with the goal of the project. Further, Woo & Nam (2018) maintained that the alignment of businesses' vision with the community vision is a potent driver for local businesses' participation in neighbourhood regeneration. As such, designers need to tap into local businesses' vision in order to make effective use of their local knowledge.

Neighbourhood Guide

The second way in which local businesses can contribute is as *neighbourhood guides*, allowing designers to enhance their capabilities to mediate diverse local stakeholders. Collaboration among diverse stakeholders actively occurs during participatory neighbourhood regeneration projects, and thus a designer's role as an expert in moderation and facilitation becomes all the more important. The Literature Review, however, showed that the complex heterogeneity of stakeholders makes it difficult for designers to handle local knowledge and projects. In this context, the authors suggest that local businesses could mitigate such challenges of designers in a way that they lead designers toward the neighbourhoods.

As found in the content analysis (see Figure 4), local merchants are usually 'people-in-the-know' who are well aware of local situations including local issues, culture, talents, and resources. For example, local businesses can envision possible solutions (Case 3) or articulate the future vision of neighbourhoods (Case 8) based on their understanding of the neighbourhood. They can also guide 'the right man in the right place' in their local context. For example, they can discover or persuade people to engage in projects by using their personal connections and social skills (Cases 5, 15, and 21), and provide natural gathering places for locals (Cases 27, 28, and 30). These examples unveil research opportunities for developing alternative modes of participation for local businesses beyond just the workshop format. Although designers have the potential to play more active roles in participatory neighbourhood regeneration, they are often unable to demonstrate their capabilities well due to a lack of infrastructure. By involving local businesses, however, designers can more efficiently and effectively engage in participatory neighbourhood regeneration.

Conclusion

This research explored design opportunities and new challenges in a context which the paradigm of neighbourhood regeneration has been shifted toward a participatory approach. Further, the research emphasized the significance of local businesses and their local knowledge to overcome the challenges faced by designers. This research established three types of local knowledge *Handler* within the framework of participatory neighbourhood regeneration based on the Literature Review: *Possessor*, *Processor*, and *Implementer*. Through content analysis on 30 practical cases, 18 types of *Actors* involved in the process of deploying local knowledge for neighbourhood regeneration were then identified. Based on these findings, two ways in which local businesses can contribute to participatory neighbourhood regeneration projects were identified: as *knowledge reservoirs*, and as a *neighbourhood guides*. The significance of this research is in that it provides evidence suggesting that local businesses can help address the challenges faced by designers. Furthermore, there may be new ways of local businesses' participation for neighbourhood regeneration projects. There are two possible directions for future research to be suggested based on this research. First, it is necessary to understand the types and forms of local knowledge possessed by local businesses and how to motivate them to share their knowledge. Second, it is necessary to devise new methods of participation for local businesses that can enhance designers' capabilities in neighbourhood contexts.

Making the difference through design: Possibilities for the re-production of Social Capital

SEDINI Carla

Politecnico di Milano, Italy
carla.sedini@polimi.it
doi: 10.33114/adim.2019.04.389

Contemporary societies have been strongly characterized by the emersion of hybrid economies, which in several cases, through *making,* pursue goals of urban regeneration and social engagement. Recently, the Municipality of Milan has started to be interested in several hybrid and collaborative experiences, focused on: 1) the creation of local markets; 2) the revitalization of peripheral areas; 3) the engagement and its inhabitants. This paper presents the first step of a collaborative study developed by the School of Design of Politecnico di Milano and the Institute of Design of IIT of Chicago within the Sister Cities policy program. The results of preliminary research activities, which wanted to investigate the relationship between design, manufacturing and social inclusion will be presented. The main focus will be on the actual and potential role of design within these hybrid activities with a particular attention to its capabilities to support the creation/acquisition of Social Capital both at individuals and territorial levels.

Keywords: hybrid enterprises, making, Social Capital, urban regeneration, civic design

Introduction

This paper presents the first step of the collaborative study developed by the School of Design of Politecnico di Milano and the Institute of Design of Illinois Institute of Technology of Chicago within the Sister Cities Policy Program. Civic Design has been the topic chosen for this collaboration, and the Italian team decided to analyze it through a focus on the local economy (in particular manufacturing), innovation, and social inclusion. This report summarizes the results of a specific section of the field research activities, in order to investigate the relationship between design, manufacturing and social inclusion. Companies and associations which work in these - apparently diverse -sectors, actually mix different characteristics: innovation, social entrepreneurship, (new) craftsmanship, design, storytelling, meanings, a strong focus on territorial development and the relationships.

Then Milanese context, which is the one I am focusing on, has recently been strongly characterized by the emersion of these hybrid economies, which also the Municipality has started to recognize and to be interested in.

The systemic approach, which we propose to use, was initially applied in the environmental field of urban management. This approach focuses on the articulation of the different elements which compose a city and the connection between them (Friedmann, 1987; Taylor, 1998). In more recent years, the ecosystemic approach was extended also to knowledge and creative fields (Becattini, 1989; Harrington, 1990; Landry, 2000; Santagata, 2007). The European Union, as well, has been more and more careful about the development and

the study of creative and innovative ecosystems, which are seen as levers for sustainable growth, because of their focus on co-creation and coopetition among different groups of stakeholders.

This paper focuses on selected case studies, whose spokespeople were interviewed. After the interviewing phase, we organized a co-design workshop called "Let's make room for innovation!" which was held at POLIFACTORY (fablab of Politecnico di Milano) and involved both the group of our interviewees,students, and experts from several fields (e.g. design, architecture, psychology, etc.). The brief of the workshop was co-designing an urban living lab in the Milanese suburb of Bovisa. The workshop was attended by 30 people, divided into 5 working tables; it lasted 4 hours and provided a series of specific questions, which were answered by participants using specifically designed tools. The final output was an idea proposal for an urban living lab were making and culture encountered.

In this paper, I am going to present the interviews results according to the role which design (and making as well) can have in the development of network and in the creation/acquisition of Social Capital both at territorial and people levels.

For a definition of Social Capital

The concept of Social Capital has been used by several disciplines in order to study, discuss and analyze the creation of community networks, the achievement of economic success, and the support to local development. Its definition has been changing over time and often has been taken for granted; however, a unique definition of the concept is not possible and also a complete overview of it cannot be the main focus of this paper. Therefore, in this first paragraph, a possible composed definition which could be useful and effective for the present argumentation is going to be delineated.

The definition proposed by Jane Jacobs (1961) was related to two main levels of manifestation and impact: the individual/personal level and the territorial/urban level. She stated that Social Capital is created and reproduced thanks to the presence of informal relationships, local self-government networks, neighbourhood associations.

The importance of factors such as proximity, on the one hand, and informal networks, on the other, are already present in Jacobs dissertation. By proximity I do not mean only a physical-geographical proximity, which is a condition, but not a guarantee, for the presence and the development of cognitive, organizational, social and institutional proximity (Boschma, 2005); while, for informal networks, the concept of *weak ties* proposed by Mark Granovetter (1973) identified a relationship which is nor of kinship or friendship, but which is expressed in a combination of trust, (non-economic) exchange and reciprocity. These two elements (networks and proximity) are very much connected, indeed networks have a variable length: they can be very local, but they can also extend to the whole city.

The most well-known scholar who theorized the concept of Social Capital, is probably Pierre Bourdieu (1980) who analyzed it in connection and interaction with other types of capital (economic and cultural) and defined it as the set of real or potential resources that depend on the possession of a lasting network (of relationships) and of more or less institutionalized relations founded on high levels of respect and reciprocity.

Therefore, as mentioned before, the utility of Social Capital is recognized at two levels, which are simultaneously separated and connected: the personal and the collective. Social Capital supports individuals in solving everyday problems, such as finding a job; at the same time, by doing so, it can generate broader positive effects on the city and beyond. According to Enzo Rullani (2006) Social Capital is embedded and rooted, often implicitly, in territories. This approach clearly states the shared and collective nature of this resource, which is particularly useful for the attainment of economic and social improvement of places. As far as the economic competitiveness is concerned, for example, the importance of Social Capital has been widely discussed in the constitution of districts, first industrial, then cultural and creative (Becattini, 2000; Scott, 2006).

As the shared value of Social Capital is concerned, Arnaldo Bagnasco (1999) analyzes what Robert Putnam called *civicness*, that is a fabric of values, norms, institutions and associations that permit and support civic engagement, mutual trust, and widespread tolerance, where the interest is no longer (only) private and personal but becomes public. The possibility that a culture of *civicness* found fertile ground is directly influenced by the presence of high levels of Social Capital. According to Putnam (1993), the possession of Social Capital can directly have a positive impact on a territory (nation, region, city) and on the functioning of

its democratic institutions; therefore, territories need strong social participation to attain certain levels of efficiency. Putnam developed this statement thanks to Tocqueville's work on civic participation in America in the 1830s; however, as Ferragina (2012) highlighted, Putnam did not consider Tocqueville's main explanation about the conditions which allowed high levels of social participation at that time in America, which was the widespread condition of equality. At the same time, it might seem quite optimistic to talk about "widespread equality" in order to define the general environment of America in the 1830s. Surely, America was a more equal country compared to others but, if compared with 1993 (when Putnam wrote) or with the current situation, notwithstanding the permanence of social and inequality issues, we might say that at least basic rights have been conquered since then[1].

As said before, Bourdieu theorized that the different typologies of capital (Economic, Cultural and Social) are able to influence each other's and in particular the possession of high levels of Social Capital could favor the acquisition and accumulation of Economic Capital. In this paper, I want to highlight also a backwards process, which thanks to the participation in economic and cultural activities allow people to improve their levels of Social Capital. The (strategic) collaboration between governmental institutions, civil society, enterprises and academy (in our case represented by Politecnico di Milano) can be able to open their close networks. In line with what Rullani (2006) proposed, I am going to question if design can act as a facilitator in the production of new bonds and - therefore - new forms of Social Capital.

Making: from business to local development

"Making" and the Fourth Industrial Revolution has been extensively investigated in the last few years by academics, journalists, politicians, and have also raised the interest of many entrepreneurs and passionate people.

Several pieces of research have been developed on the topic of fab labs networks and makers movement; in many cases, these studies highlighted problems of economic sustainability of these activities, but a more cultural-related role of these places emerged (Wang, 2015; Taylor et al, 2016; van Holm, 2017). Indeed,

> *"For makerspaces to become similarly ubiquitous and sustainable platforms, they need to offer the kind of institutional stability that will support meaningful community programming, educational opportunity, and grassroots economic growth. A glance at the history of makerspaces illustrates both the challenges and opportunities of building communities, and businesses, around the ethos of shared making." (Holman, 2015)*

In order to theoretically frame our study, we took into consideration the social and cultural side of "making". "To make" (*fare*), in Italian, is often associated with the concept of capability, of "being able to make" (*saper fare*). These capabilities are both objects and contents of places such as makerspaces and fab labs, but also districts, regions and even nations are often recognized as repositories of specific making/artisanal cultures.

Makerspaces and fab labs, specifically, are not only connected with the physical production of goods, but also with the production of knowledge and relationships, which sometimes are expressed through the physical production/practice. Harvey Molotch (2003) stated that goods and social practices are directly connected and are able to sustain each other's. This means that the availability of a certain object is able to influence the endurance of people habits (e.g. what and how they eat); on the other way around, habits influence the consumers request of certain typologies of goods, and therefore their production.

In order to define our field of interest, we connected making with knowledge and social inclusion issues, identifying several pieces of evidence:

- production is an urban and cultural fact, which is able to re-signify places;
- in many cases, makerspaces and fab labs are located in peripheral areas because of the availability of empty and large spaces, and because there are more accessible areas compared to city centers. The

[1] "Every boy knew that he might be the governor of the State, or a member of Congress. There was nothing to hinder him from being President; all he had to do was to learn. No position was beyond his reach if he chose to work for it. Franklin was a printer's boy and Andrew Jackson a poor boy who worked his way up from the humblest position." In this caption from the article "A Portrait of America, 1830" (EyeWitness to History, www.eyewitnesstohistory.com, 2008) for example, it is very clear that the equality was at that time extended to white boys, excluding women and Afro-American people.

localization in the suburbs often contributes to the physical and cultural regeneration of these areas. This aspect is particularly evident in Italy and especially in Milan (Armondi & Bruzzese, 2017);
- rediscovering craftsmanship means to uncover a deeper relationship between people and their work (Friedmann, 1987). We assist nowadays to a new idea of craftsmanship, which owns a renovate dignity and value (Sennett, 2008);
- craft knowledge is based on mutual, learning, cooperative, collaborative connections, and development of dialogic competences (Sennett, 2008);

In line with Molotch view, there could be then the chance that also the production of goods (and I am not referring to GDP production) might be able to sustain positive and innovative social practices, looking in particular at inclusivity.

In the following paragraph, I am going to focus the attention on Milano, making a rapid overview of research and activities which were particularly useful to frame our study.

Milano: theoretical framework and reference research

Makerspaces and fab labs, even if take back on the production working activities, are clearly part of the panorama of so-called Post-Industrial societies (Touraine, 1969; Bell, 1973) defined by:

- Closing down of several factories and the consequent need to re-define the identity of cities whose economy was based on manufacturing industry.
- Flexibility of workers, products (customizable), production quantities, etc.;
- Growth of the service sector: people working in commerce, tourism, health, education, entertainment, transport, etc. sectors become more numerous than the workers in the industrial sector;
- Increase of the importance recognized to knowledge (scientific and theoretical);
- Global networks of interaction (Castells, 1989).

As Antony Giddens (1990) highlighted, globalized societies and the working sectors which characterized it, are defined by dynamics of time-space compression. This last aspect is represented also by the faded boundaries of traditional urban functions: different tasks co-exist in the same places (work, consumption, leisure, etc.) "and new functionalities emerge as people take spaces into new uses" (Di Marino & Lapintie, 2017: 1). Di Marino & Lapintie (2017) talk about Post-Functionalist cities, which are characterized by hybrid forms of work, enterprises, and spaces, in general. For this reason, as I am going to deepen later, we decided to take into consideration for our research, not only makerspaces and fab labs but also other kind of spaces where sharing, encounter, production, socialization, etc. happened in order to delineate a complex ecosystem which characterizes also the directions taken by the municipal administration of Milano.

In the last few years, many Milano-focused research studies, and projects have been developed on the topic of "making". I quickly summarize those which were useful to theoretically frame our research.

Studies and research developed within the Design Department of the Politecnico di Milano by Stefano Maffei & Massimo Bianchini, directors and founder of POLIFACTORY, were particularly interesting for their analysis and reflections on the urban dimension of the phenomenon. They developed the idea of micro-urban manufacturing applying to it the concept of ecosystem (Maffei & Bianchini, 2013; Bianchini et al., 2014). At a national level, in 2015, with other scholars, they produced the "Maker's inquiry" (Bianchini et al., 2015), with the purpose of studying and analyzing the makers phenomenon in the Italian context. They investigated also the economic sustainability of the sector discovering that the majority of makers (54.4%), who participated in the survey, confirmed that making was a secondary and complementary economic activity; in addition to that, the majority of respondents (36.5%) declared an income range between 10,000 and 25,000 euros per year, and on the other hand, 23.1% of them declare an income between 0 and 10,000 euros.

Inside the Department of Architecture and Urban Studies (DAstU) of the Politecnico di Milano a research group, coordinated by Ilaria Mariotti (Armondi & Di Vita, 2018), carried out a FARB project called "New Working Spaces. Promises of Innovations, Effects on the Economic and Urban Context". The importance of the political framework, in which the investigated phenomena takes place, was particularly relevant in this research; indeed, one of the main focus and result is about the regenerative capabilities of these new working spaces, which often substituted old typologies of production. The research used the interesting interpretative category of proximity, proposed by Ron Boschma (2005), who analysed different typologies of proximity

(cognitive, organizational, social, institutional and geographical) and how they might influence learning and innovation processes.

Professors and researchers in Sociology (mainly from The Sociology and Social Research Department of the Università degli Studi di Milano Bicocca) stressed the current re-specification and re-signification of the manual and productive work focusing also on the cultural value of makerspaces and fab labs, which actually seems to be the most important value if compared with the economic one (Colleoni, Vicari Haddock & d'Ovidio, 2015; d'Ovidio & Rabbiosi, 2017). In addition to that, a research carried out in collaboration with *cheFare* and Fondazione Feltrinelli, "broke" the wall which separated culture and production, developing an analysis of 6 different case studies which involved both cultural and art spaces, makerspaces and fab labs (Giuliani, 2018).

To conclude, I want to mention a project which wasn't developed within academy: *SUPER - Il Festival delle Periferie* (The festival of the suburbs). We had the opportunity to discuss and involve their initiators and researchers in order to compare our projects since they had several points of contact. In particular, we were interested in their idea that peripheral neighborhoods of Milano are important pieces of the whole Milanese ecosystem, and, in the strong connection between culture, making and social innovation, which they wanted to highlight thanks to the organization of workshops and events around the city.

In light of the core concepts, which emerged from the research listed above, we decided to look at "making" in a wider way or in an "open" way as Sennett suggested (2018). Indeed, making is not only oriented towards utilitarian purposes but also towards sociality goals (Sennett calls it "limited fraternity" relationships) favoured by processes of co-creation, collaboration or even by the possibility to meet and interact with other people in the same (physical) place (Fassi & Sedini, 2018).

In the following pages, the study that we carried out starting from February 2018 to September 2018 in collaboration with the IIT of Chicago will be presented.

Made in Milano: a collaborative research

The idea of considering all those activities able to bring together people both for economic and leisure purposes as making was quite "extreme". However, it has been thought that it would have been an interesting point where to start from and then eventually focus our attention on more specific and coherent issues. However, using an ecosystemic approach and having as a research goal the identification of a possible definition of Civic Design, we thought that this was the right path.

In collaboration with the IIT of Chicago, we identified our common research questions and 10 key concepts which would have been driving our research.

In this paper is going to present only the work developed on the Milanese territory by the School of Design of Politecnico di Milano. Not all the steps and results of the study will be taken into consideration, but only some specific research activities, focusing mainly on the following research questions: How can the goals of social innovation and inclusion be achieved through making? What's the role of Design in these processes?

The initial mapping activity involved places and initiatives of (and for) (new) work, creativity and aggregation:

- coworking spaces;
- fab labs & makerspaces;
- service centers and hubs;
- incubators;
- cultural centers;
- spontaneous engagement spaces;
- cafés;
- events.

Then, our first group of case studies was selected among the 180 mapped activities. The selection was based on three main factors:

1. their mission: more or less focused on social innovation
2. their location: peripheral
3. their originality: they had not already been investigated by other recent research (in particular by those mentioned in the previous paragraph).

Figure 1: Matrix of the selected case studies. source: Vanessa Monna.

We interviewed also some key informants from the Public Administration (the Municipality of Milan and the Metropolitan Area of Milan). Additionally, we decided to interview some artisan entrepreneurs, because they had been suggested to us from the previous interviewees or because their activity was particularly interesting for us; indeed, all of these spaces owned crucial characteristics of innovativeness (e.g. integration of traditional and 4.0 tools and technology), openness to a wider public, connection with the design field (in terms of competences, strategy, collaborations, etc.), suburban localization. We involved in the interviewees' group the following sectors: jewellery design, lute manufacturing, typography, bakery, bicycle manufacturing, brewing.

In total, we interviewed 19 people. The interviews lasted on average 45 minutes; they were recorded and fully transcribed.

Made in Milano ecosystem: vision and mission

Some of our case studies were actually born from previous spontaneous experiences of political and social activism, then they associated themselves and, after a while, they decided to become enterprises or associations. Others were initiated thanks to the Municipality or the Academy with the purpose of regenerating places/spaces, and with the purpose to involve specific marginalized populations or to favour the encounter between citizens. Others were already mainly business-oriented.

Social issues were often at the core of our interviewees' mission. Even if social innovation is harder to pursue by artisans, many of them pay specific attention to sustainability.

Several activities are focused on empowering marginalized people, such as immigrants and refugees. In addition to that, sometimes, they were able to help people who lost their jobs (or just wanted to change it) to reinvent themselves, thanks to the participation in their courses or activities.

> *"The isolation issue is very strong; being an unoccupied woman or with bad conditions of work in a period of general crisis is a very strong weakness." Piano C*

In general, a common characteristic of these case studies is that they try to promote *social mixité* (Wirth, 1938; Sennett, 2008) in the composition of their workers, collaborators, users, and clients' groups. *Social mixité* is also obtained thanks to the design of new products and new hybrid spaces, which for example are capable of trigger a change into the average target by diversifying it.

Figure 2: Noor, nato con la camicia banner. source: Serpica Naro.

I can mention here the activity "Noor nato con la Camicia" (*Noor born with a shirt on)*[2] carried out by Serpica Naro association. This initiative was started in February 2016 to promote the work of Noor Zaman, an Afghan tailor who was waiting for the approval of his request for political asylum in Italy.

> *"Anyone could come here to get custom made shirts or a kurta (a traditional vest), upon payment of a deposit. Now Noor continues to have his private customers who contact him via Facebook. He also teaches in some courses here about shirt and vest tailoring, we also went to Pavia to organize an ethical fashion show with his collection. We tried to create some opportunities for him." Serpica Naro*

He has now obtained the status of refugee and works as a tailor. Sometimes he still goes to SerpicaLab to make the tailored shirts committed to him.

Made in Milano ecosystem: localization and relationship with the territory

Figure 3: Localization of case studies and artisans-entrepreneurs (pinpoints) selected. source: Carla Sedini, with snazzymaps.com.

[2] The name of this activity in Italian is actually a wordplay, since "being born with a shirt on" means "to be lucky".

The reason for being in Milan was always identified as quite strong for our interviewees. Milan was recognized as the right place where to invest because of the presence of several *soft* factors, together with the *hard* ones.

The localization in a specific neighbourhood, though, while in some cases was a choice in other cases happened by chance. Indeed, some interviewees declared that the localization in a specific area of the city was part of their entrepreneurial project, not only because of accessibility but also for reasons of cognitive proximity. The connection with the territory was often stressed as a win-win element both for the enterprise and for the area, which underwent a social, economic, and territorial revitalization also thanks to the localization of these new businesses.

In other cases, the location was mostly due to the availability of a space with the right economic and structural characteristics.

Sometimes the peripheral localization represents a weakness and a challenge in attracting users and clients. This difficulty seems to be much more related to a mental prejudice than to actual problems connected with safety or accessibility.

> *"The location does not help. There's a wrong perception of suburbs. But the policy helps (Suburbs delegation in the municipality of Milan). It's not that easy to reach us, there's no subway lines, for example. But it is more a mental constraint." FabriQ*

The impact of these spaces is not measurable yet. However, in some cases, just the fact of regenerating an abandoned area was able to make it accessible and to attract people.

In addition to that, several initiatives were also able to change the perception of places which were once felt as private and closed from the outside, turning them into spaces open to the community (local or not). Indeed, the relationship with the city emerged also from events and activities aimed at opening these spaces and connecting the inner community with the external one.

> *"Cavriano [an area of Milan] has a forgotten identity. The action of making a place accessible to different targets is something that you can measure in terms of presences. Farms and vegetable gardens make a place an important social device." CasciNet*

FabriQ, for example, is the first incubator of the Municipality of Milan specifically dedicated to promoting social innovation. The launch of FabriQ in 2014 is part of a wider long-term plan of the Municipality to relaunch the North-West area of the city and a wider policy of recovery of empty or abandoned spaces. FabriQ is located in a suburban area of the city, called Quarto Oggiaro, which does not own a very good reputation. FabriQ is located in a regenerated 650 square meter space.

One example of initiatives developed for and with the neighbourhood was "The Street Art week" which was one of the activities composing the wider project "Mettiamoci in gioco" (*Let's get involved*)[3] focused on the social regeneration of a small playing field close by FabriQ. In particular, during "The Street Art Week" painting and street art activities were developed at the playing field, under the conduction of the well-known Milanese street artist, Bros. Involving people from inside and outside the neighbourhood, this marginal and residual space was given new life thanks to co-drawing activities.

[3] It was a project carried out by a local partnership - created thanks to a tender promoted by Timberland and King Baudouin Foundation - made up of FabriQ, Save the Children, ASD Futura, and Ambiente Acqua Onlus, acting in the Quarto Oggiaro.

Figure 4: The playing field in Valsassina street (Quarto Oggiaro) before and after. source: FabriQ.

As it is possible to understand from this example, our case studies were characterized by a multiplicity of activities and purposes.

Made in Milano ecosystem: design role

Several managers and entrepreneurs, who were interviewed, studied in a Design School. They stressed how the role of designers have changed over time: there has been a return to analogic processes and tools, often (but not always) connected and integrated with digital fabrication and, in general, new technologies. This clearly has an effect on productions which are composed of small quantities and high-quality goods in opposition to large-scale distribution processes.

The contribution of design in our case studies happened both on tangible and intangible aspects. Therefore, design was helpful both in the ideation of specific tools, in the design of the space and its interior, and also in the activation of networks and good practices.

In general, there is wide recognition of the value of a design approach and where design is not immediately at the core of the entrepreneurial or associative strategy or it is not an "in house" resource, our interviewees declared that they try to collaborate with designers and design schools.

According to the answers collected, it is possible to identify three main roles that design can play for these spaces:

1. The first two can be combined. Design has an **envisioning** role to imagine good practices and project opportunities; and it has a **facilitating** role able to activate relationships (which will be discussed in the following section).

"In 2007, we looked for external [from the company] product design for our guitars. A young designer came in, bringing the idea of a shape linked to gestures. That same year, Giulio Iacchetti proposed bringing the topic of music to the Milano Design Week. Each designer was linked to a company in order to make a musical product. So, we also made an instrument for this event." Noah Guitars

2. Design has a **strategic** role within enterprises from other fields, allowing the reinvention of traditional businesses, expanding their offer, developing a communication plan, and attracting new types of clients.

"We use a method which we called 'work design'; it tries to connect already existing resources. Your job is a project. This method is based on the design thinking approach." Piano C

Coltivando, a community garden within the Bovisa Campus of Politecnico di Milano, is another interesting case study to be mentioned. Coltivando was ideated in 2011 and developed in 2012-2013 and it is addressed to two main purposes: allow the local community to discover a public place which they usually do not attend, and create connection between people from different communities, such as students, citizens, scholars, etc. with - it is possible to say - the pretext of growing their own food. Service design combined with a community-centered design and a spatial design approach were used to develop Coltivando.

"In the preliminary work, we had spent a lot of time figuring out how to divide the harvest among people. Unexpectedly, we realized that people did not care: they came regardless of the collection, it was more for meeting people. For this reason, we have also organized harvest days." Coltivando

Figure 5: (left) first Coltivando Happy hour; (right) a usual saturday at Coltivando. source: Coltivando

Today Coltivando is managed by a team of 15-20 people plus some "supporters" who pass by sporadically or on special occasions. Indeed, the permanent people who take care of the garden meet there every Saturday but Coltivando organizes and hosts also workshops and convivial events which are able to attract people who usually do not participate in it as well.

Made in Milano ecosystem: network

Some of our case studies were born thanks to the connection between different actors and stakeholders: Academy, Government, Civil Society, and Enterprises, according to a Quadruple Helix approach (Carayannis & Campbell, 2009). In other cases, this network was created after their constitution. In others more, institutions have taken an active part in the project, through specific offices.

The creation of networks, in most of the cases, is not limited to the business activity or association, but it is also extended to their workers, users, clients, "friends" as it was mentioned also in the previous pages. These spaces are indeed platforms for encounter where the creation and accumulation of Social Capital is made possible. This goal can be already declared in the mission of the space or it can be a (positive) side effect. Design plays an important role for this purpose; the creation of networks can be achieved by design or with design, where in the first case design is the content and-or the agent and in the second it is a tool and-or a strategy.

"Our vision was to create a place where people could work supported by adequate spaces and equipment. Above all, a place where there is a real exchange, sharing, putting aside the competition, and embracing the idea of internationality (because we believe in it)." About Officina Orafa (About Goldsmith Lab)

A good example of network creation at different levels is the MakersHub Design Hostel initiative: during the Milano Design Week, the spaces of MakersHub were transformed into a hybrid hostel and exhibition space.

The creation of networks works both at the organizational and territorial level (e.g. among institutions) and at the users' level; in addition to that, in this case, design worked both as content and as a tool for the ideation, realization and the experience itself.

Figure 6: Design Hostel, day (left) and night (right). source: MakersHub

Starting from the idea of Davide Crippa, founder of the Ghigos architecture studio, MakersHub offered the space, realized the technical project and the set-up, and coordinated the whole operation. The collaboration with the Design Department of Politecnico di Milano and POLI.design was crucial, in order to internationally spread the call. This was the first level of creation of networks, which during its second year in 2018 actually started the Bovisa Design District.

> *"We understood that playing 'solo' was not sustainable. We had to think in a wider way. It was a win-win partnership with the territory: the birth of the Bovisa Design District has brought to light Bovisa potentialities, which we only had imagined years before." MakersHub*

The second level is represented by the fact that several young designers (and design lovers) from all over the world slept and lived together for several days, knowing each other both personally and professionally, since they could use their accommodations also as showrooms.

Making the difference through design: first conclusions

In these first conclusions of the collaborative study here presented, I want to highlight the main roles played by design with a particular focus on the topic of social inclusion and Social Capital improvement.

First of all, apart from the results collected by the research, design had a wide **political** role. Indeed, in light of the general concept of Civic Design, which is based on the central role of citizens in the creation and diffusion of civic visions (Saunders, 2008), two Universities (School of Design of Politecnico di Milano and the IIT of Chicago) started a collaboration after being involved in the policy Milano-Chicago Sister cities program.

Looking specifically at what emerged from our study in Milano, design served as a **content**. Indeed, the topic of making is strictly connected both with traditional and advanced design and this is pretty evident in artisans, maker spaces, and fablabs case studies.

Design was also a **strategic** lever for innovation and development processes inside other hybrid enterprises, such as co-working spaces, incubators, social gardens.

A transversal role of design and making was the creation of **networks** and - as a consequence - the support given for the development of Social Capital.

Indeed, making, manual, artisanal, and design activities:

- are perceived as more inclusive than intellectual ones, and therefore able to create a *social mixité* and favor the dialogue between different people and stakeholders;
- can positively influence social redemption, because they also offer opportunities for excluded and weak population groups.

In this sense, design can have a positive impact on the creation of more suitable and sustainable working environments.

Milano, as an ecosystem, is an interesting case study because it seems that the role of making and design has been recognized at several levels from the political to the entrepreneurial and the social side.

A dense environment is already empowering and stimulating by itself; in addition to that, the continuous support for the creation of new initiatives to connect different stakeholders is a way to create a legacy, a reputation, and an environment defined by values of openness and empowerment. Richard Sennett in his most recent book (2018) talked about the Open Smart City, a city which support non-required encounters. Indeed, cooperation has not necessarily be driven by consent, but can also be supported by different stakeholders, collaborating in the accomplishment of impersonal tasks (such as growing tomatoes or co-design a hostel). The creation of such social environment which does not only answer to utilitaristic purposes is made clearly possible by the personal commitment of people but, in order to become a consistent /persistent practice, needs institutional and political support, which could be mediated by the strategic role of design.

Research Perspectives IN THE ERA OF Transformations

A Story of Journeys: Contemporary Design Facilitation

MYSORE Vinay Kumar* and GADY Isabella

Parsons School of Design
* corresponding author e-mail: mysov916@newschool.edu
doi: 10.33114/adim.2019.05.394

How is design itself transitioning and transforming as it moves into more complex domains of organizational and social change. In many of these contexts, designers now play roles as facilitators, working in complex systems and dynamic environments. Design facilitation itself is moving from being a vessel for participation and becoming a vehicle for organizational transformation and change. The authors use a case study of a multi-stakeholder international design facilitation project with UN Women's Fund for Gender Equality to highlight some of the critical features of a design facilitation process, from mediation and navigation of systems of power and hierarchy within organizations to an expansion of designerly duties 'before' and 'after' a design intervention. Reflecting on this experience the authors propose possible models for design facilitation to further develop its approach, and offer future questions for the nascent field as it develops into a critical component of contemporary design practice.

Keywords: design facilitation, social innovation, social field, transformation, strategic design

Introduction

A key point in a discussion of design is its own process of transition and transformation as it moves into more complex domains of organizational and social change. Design has expanded into new fields, from visual communication to industrial design to now a focus on the non-physical. Designers now work on problems of organizational and social structure, on interpersonal interactions, service and experience design. (Norman, 2010). In many of these contexts, designers now play roles as facilitators, working in complex systems and dynamic environments.

While many, since and including Papanek and Simon have anticipated this transition of design to new realms of the non-physical and intangible, design education and practice have still fallen behind. Designers often fail to understand the complexity (see Fig. 1) they are dealing with, and lack the tools and models to approach the interlocking complexities of human and social behaviour, of business and culture, of privilege and power.

Correspondingly, there is a challenge and question about the role of the designer themselves, the role of expertise and the skills they provide and bring to processes described variously as "co-design" or "participatory-design" or perhaps even design facilitation. Sanders and Stappers identify the need for the inclusion of non-designers in such projects, and begin to explore how this inclusion blurs the lines traditionally held between roles in the design process. (Sanders & Stappers, 2008).

Manzini pushes forward with his provocation that an expert designer must be wary of merely fulfilling an administrative role. What, therefore is the role of expertise in these new design processes? Manzini expresses that the expert designer can select and develop design methods and tools for use in their practice, but also that their practice must be discerning and self-reflexive. For this reason, he argues, the expert designer must

also create artifacts, proposals, and provocations that can be used in tangible processes. Manzini argues that this understanding holds true for all levels of design from the local to the systemic and therefore whoever is classed as a design expert also carries within them a design methodology and design culture. (Manzini, 2016).

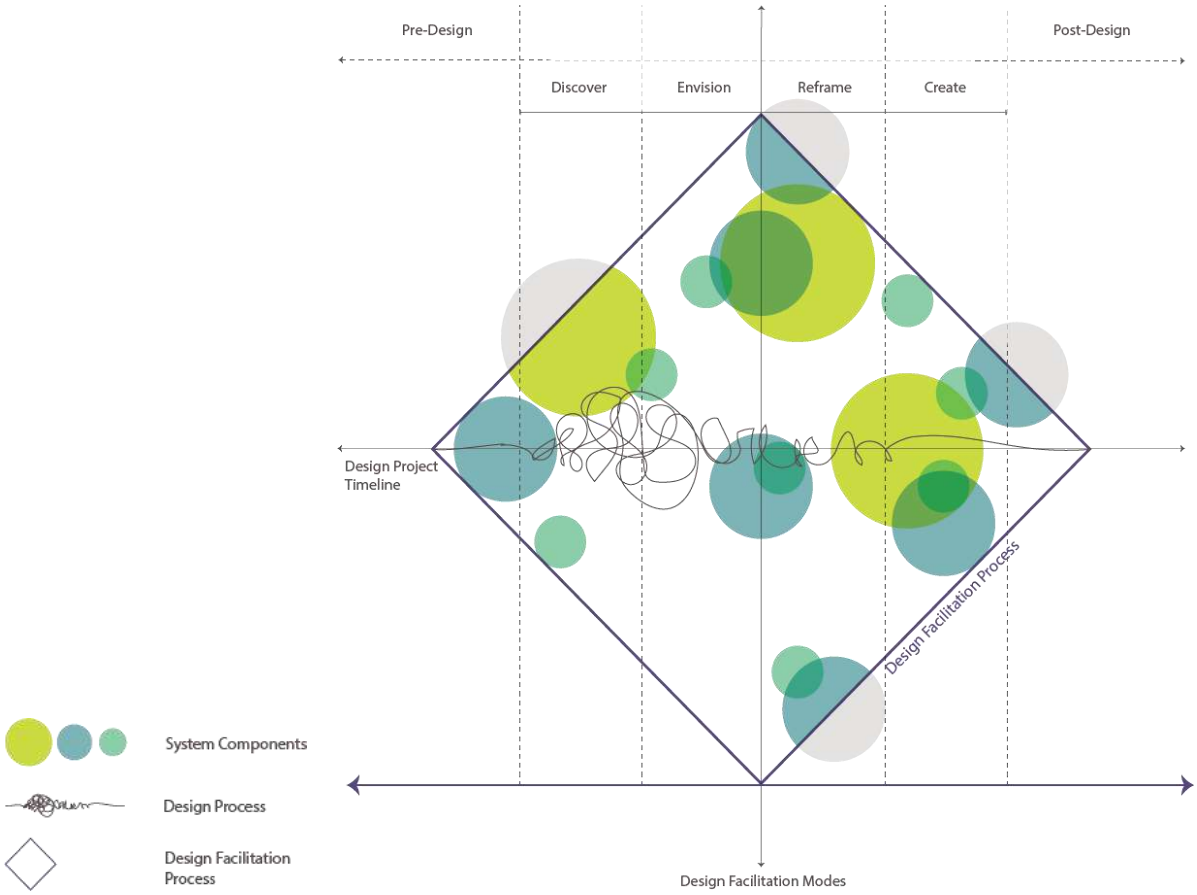

Fig. 1.: Design Facilitation. Facilitation Design.
As the design field moves into more socially complex domains of systems-wide change, new tools and practices are needed to suit new roles. In these complex adaptive systems, designers need to create contexts for distributed participation. In these living systems, designers must address the underlying conditions for spontaneous emergence, or creativity, in the generation of new forms, that drives self-organization and system evolution. Designers need to be stewards, coaches, and shepherds of the process, designers need to be facilitators for emergent transformation.

Along these lines, Sanders and Stappers underscore that the move from the traditional user-centered design process to a design process based on collective creativity. Whereas a traditional design process may have a designer translating between different user groups, a co-designed initiative turns the designer into a facilitator between participants, designing a process of guiding and supporting individuals of varying levels of inclusion and creative confidence, to participate within a process. (Sanders & al., 2008 and 2012).

However, is this too narrow a view of facilitation and the role of designers in this process? If the role of the designer is to operate as vessel does it not miss the role of the designer as participant? What happens to agency of designers facilitating such processes as roles increasingly start to blur? Yet, design, whether graphic, industrial, multimedia, interior or architecture, and whatever the intention, purpose or function, is a discipline that requires the shaping of form. (Wahl, 2008). Designers, therefore, bear responsibility to a future output; this also proves to be true when designing the invisible. Furthermore, the concept that co-design is inherently ethical because of the reciprocity that it entails also suggests a profoundly interactive and user-orientated aspect to design.

This paper explores the evolution of the design field and the rise of the practice of design facilitation as a significant component of contemporary design practice. Using a project co-implemented by the authors as an example of what this work looks like in action, we observe a mismatch between current literature and the needs of the design facilitation process. Arising from this, the paper offers criticisms as well as potential

pathways for design to further develop design facilitation, and begins investigating what such development would need to involve and include.

Contemporary Design Practice and New Design Methods

Design has developed dramatically over the last twenty years, and strategic design practices have matured into a real alternative to conventional problem-solving strategies.

This contemporary view of design not only encompasses the traditional alliance of design with market-based considerations and consumer culture, but also accounts for design as a locus for public and social innovation: design intended as a combination of ways of thinking, knowledge and skills to be applied to the most diverse kind of artifacts, provision of services, communication, organizations and policies. (Manzini, 2012). Increasingly, designers are facing these open-ended challenges head-on, and are called upon as uniquely effective translators and synthesizers of this class of societal problems that are not neatly bounded, but ill defined, ill structured and "wicked". (Rittel & Webber, 1973). Yet, as many scholars and practitioners have noted, most models of the design process fail to capture the new reality of contemporary design.

Designing for systems and social change is not the same thing as designing physical artifacts. It is more than a question about a linear increase in scope and scale. It is a qualitatively different act. Therefore, it needs its own theory and grounding to be successfully applied. Prior models of design while often necessary cannot be sufficient. *And when one is designing to catalyze social change through systemic reconfiguration, the problem grows even more complex. The process changes, the content changes, and outcomes change in ways that present unique and vexing challenges for traditionally trained designers.* (Hunt, 2014, p.14).

Papanek may have been masterful at rethinking the process of design, but the opportunity he missed was that process could also be designed. Too often, designers go through the motions of creating inclusive, participatory design projects that follow, with pious devotion, the rote clichés of participatory methods; they surrender all creative capacity to non-designers, as if it were the case that the only things those communities lacked were enough marker pens, sheets of paper, and Post-it notes to see their way out of the challenges they face. According to this playbook, the designer's role shifts to facilitator, as if this were a capacity inherent to designers (which it is not). (Hunt, 2018, p.187).

This suggests an evolution in how we think about the design process when it applies to these kinds of complex systems and organizational moments. Design research is now a participatory process, sense-making a dynamic facilitation, ideation part of a negotiation of vulnerability and power, and iteration becomes grounded in capacity-building. Yet even here, perhaps we can move further. As Scharmer argues, "the key for successful prototypes lies in creating generative holding spaces." (Scharmer, 2007, p. 204). Yet to what extent are design facilitation and its tools being developed to create these spaces? How are designers being trained to build and rise to these moments?

Design Facilitation

With design at times being closer to a social process than craft, the designer's role is changing. Often times, designers find themselves in roles mediating a consensus amongst participants who may have differing interests both within the design process and in terms of its outcomes.

Napier and Wada identify as design facilitation a process of including individuals with differing decision-making capacities and areas of expertise in order to develop more desirable, viable and feasible design outcomes. (Napier & Wada, 2016, p.156). Embedded in the understanding of design as tool for strategy and innovation, Martin describes the term as a process that has been shown "to aid and abet innovative practices within and between organizations and organizational cultures, and, in some cases, to help them gain competitive advantage in particular markets." (Martin, 2009, p.57). Design facilitation moves our focus as designers from products and artifacts, from apps and brand architecture, to process; in surfacing the needs and goals of participant populations and better understanding what is needed next for a design intervention to succeed. (Napier & al., 2016).

For designers to be successful facilitators, it entails development and competency in skill sets focused on participatory practices. Qualities of listening, consensus and relationship building between individuals and organizations, a social and inclusive understanding of a community and its diverse constituents all emerge as critical skill sets for designers acting as facilitators. (AIGA, 2017).

Thus a question must be asked in how might one differentiate design facilitation from more general facilitation practices. Body, Terrey and Tergas, through this contrasting, argue that design facilitation entails a focus on creation, a human-centered and user-centered design research process, and one that embodies design attitudes, competencies and capacities: to be deeply empathetic, iterative, oriented towards abduction and anchored within a design methodology. (Body, Terry & Tergas, 2010)

From this review, when taking on the role of a design facilitator, the authors recognize the development and enhancement of the collective capacity of the group crucial to the achievement of transformative design processes considering the high involvement of participants throughout the process. It is apparent that such a process entails distinct instantiations of designerly skills from other areas of design practice. It is also embedded within a design strategy process; and successful, participatory social innovation design often necessitates design facilitation within the context of a particular project or practice.

Design Facilitation in Practice

Drawing from our shared experience and research, what follows is an attempt to reanalyze key elements of a design process in terms of a design facilitation practice. To do so, we will be introducing a pilot initiative - *Rethink.Experiment* - launched by the Fund for Gender Equality (FGE), a grant-making mechanism of the United Nations Fund for Gender Equality and the Empowerment of Women, that aimed at exploring the potential for design to serve as a tool for innovation in women's rights programming by involving partners and beneficiaries in the construction and implementation of programs. (UN Fund for Gender Equality, 2018)

In doing so, the project team saw an opportunity "to do international development differently" with the objective of creating positive and more lasting impact while at the same time, putting into practice much of what the FGE had been advocating for - placing beneficiaries at the heart of the work, flexible and adaptive processes, addressing root causes using systems thinking, and co-creative approaches that allow for inclusive and participatory development. Furthermore, the project team also meant to encourage women civil society organizations (WCSOs) to explore, generate and test design as a tool for their own social innovation in a safe-to-fail environment.

We, therefore, use this initiative as an example of contemporary design practice and design facilitation, and through this example reveal some of the deeper considerations and complexities at play within the design process that current models are insufficiently addressing or missing entirely. Summarizing the previous discussion, that process currently entails (1) develop a collaborative design process, (2) utilize appropriate design research methodologies and (3) channel results into stakeholder appropriate action.

The Rethink.Experiment

Over the past nine years, the UN Women's global grantmaking mechanism, the Fund for Gender Equality (FGE) has directly impacted the lives of over 580,000 women and girls from the most marginalized groups across 80 countries, and reached millions through policies and public campaigns. Its strategy combines the provision of grants for high-quality projects supporting women's economic and political empowerment and strengthening the capabilities of women's organizations through technical assistance and training has been validated by independent evaluations. Its projects have demonstratively advanced gender equality, especially affecting changes around social norms, the creation of women's collective structures and development of their skills on the local level.

However, following its first independent evaluation and a self-reflection exercise, the FGE realized that its projects were not tapping into the full potential of the organizations driving them, that much more could be achieved with the same of even fewer resources: Are we grant-makers and project implementers working in the most efficient and effective ways? Are our projects designed to respond to the real needs of the furthest behind? What alternative approaches and tools can lead to more transformative results?

These questions were the starting point of the Fund's *Rethink.Experiment* initiative, launched in 2018, through which nine women-led civil society organizations operating in eleven countries, over a period of nine months were introduced and trained in key principles of the design process to address a specific project challenge using a beneficiary-centered design approach reaching from "how might rural women from disadvantaged communities transition from small-scale producers to profitable entrepreneurs" to "how can we find creative solutions to keep women's rights in the political agenda in a conflict setting".

As the Fund supports women's organizations that can reach end beneficiaries – especially the most marginalized communities – and have the capacity to influence at a national level, investing in their innovation capabilities has a powerful catalytic potential hoped to result in positive changes in the lives of marginalized women and girls. (UN Women, 2018).

While structured into six main phases of iterative character: 1) Identify a challenge, 2) Understand and Emphasize, 3) Redefine the challenge, 4) Ideation, 5) Prototyping, and 6) Testing, the process was designed with the intention of creating participants with a safe-to-fail environment that encourages participants to explore, generate and test design as a tool for social innovation.

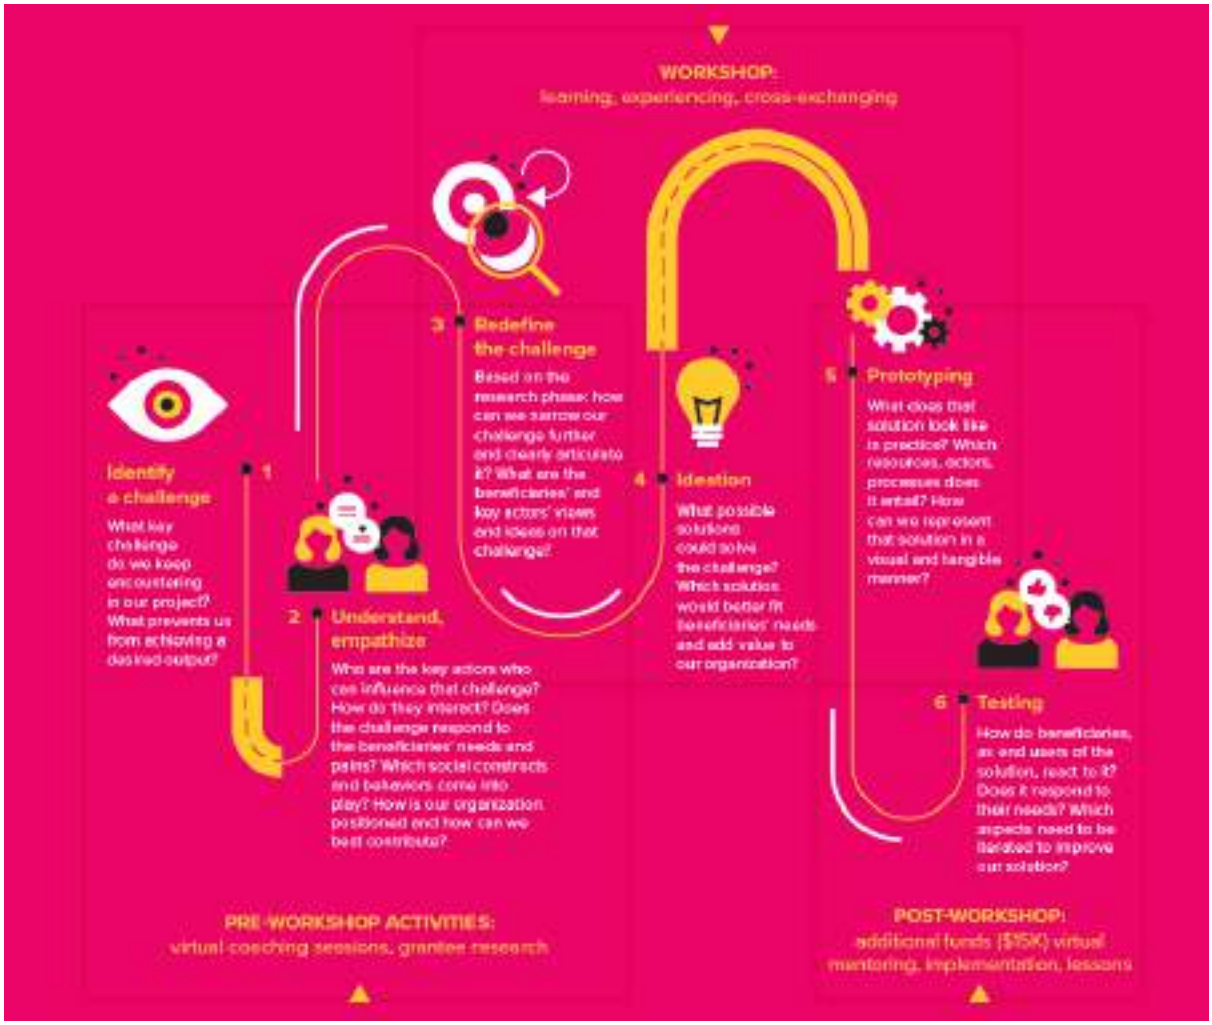

Fig. 2: The Rethink.Experiment Process*: Nine FGE grantees with capacity to absorb additional funds, potential for larger scale impact, and strong reporting skills were selected. With the support of social innovation experts and the FGE team, they are learning about and experiencing the stages and loops of innovation processes thanks to virtual coaching, one face-to-face training, peer exchanges and $15,000 to test their solutions. Source: Fund for Gender Equality*

Given the current literature, a designer looking to facilitate such a process, would most likely follow similar steps, and might even consult the literature cited earlier for a framework of design facilitation. However, as many practitioners might attest, there is a mismatch between current literature and the needs of the design facilitation process: designers working in such context are required to use their designerly expertise and skills to design individualized processes using contextual-design tools.

In the case of the *Rethink.Experiment*, as this was the first time for the Fund and its grantees to explore the potential benefits of applying design methodologies to gender equality programming, the project followed a multi-phased approach that included an expanded phase of coaching on design and research methods in the early phase of the project as well as allowed for testing of tools and adjustment of working methods in real

time. The extended focus on research also aimed at deepening understanding and building empathy with the multitude of constituents involved in each context.

Considering that the participating organizations were located in nine countries taking into consideration the specific complex context of each one not only seemed crucial to the success but also ethically appropriate considering the nature of interventions. All research activities were, therefore, co-created taking into careful consideration the specific reality of each context, leading to to different research activities for each organization. For example, while in conversation with grantee partners in the Philippines, observation was considered to be an apt method, others, such as the Paraguayan partners, were encouraged to engage in in-depth interviews or mapping exercises, or - as in most cases - a combination of multiple methods.

Furthermore, through acknowledgement of the unique, complex environment of each organization and a strong emphasis on co-creation and capacity building, the team hoped to fabricate the condition that allowed partners to adopt broad and general design principles to their very specific contexts. Additionally, "exporting" particular design practices - which might be seen as political as they often come value systems attached - might lead to unintended consequences and hinder pluralism in design practices.

Using this specific context to raise more general concerns, the authors observe that models design facilitation neglect critical areas of practice in the field and raise the following questions of the design facilitation process.

What is the role of the designer in mediation within a design facilitation context?

This kind of multistakeholder process involves multiple actors co-creating with multiple interests and multiple dynamics and processes at play. This includes navigation of systemic power biases and structures within the organizations and participant social structures. Through the construction and activation of a design facilitation process, how are designers successfully identifying and managing these mediatory considerations? If facilitation is a designed process more than a crafted artifact, and therefore if the success of a design initiative is to be impacted by the success of that social process, what are the skills and techniques to be employed by designers? How are designers providing value as mediators?

In the FGE example, how do designers mediate a process between various international and local organizations, mediate an intersectional process, mediate a collaboration between those funding the funders, the grantees and the funding organizations - each with their own concerns, vulnerabilities, anxieties and interrelated power imbalances?

How is design facilitation developing and connected to strategic vision?

A critical piece of all design practice is the articulation and formulation of the design problem. That itself is a process of discovery, introspection and transformation. How does design take this deeply internal process embedded in design expertise, and enable its exploration in collective, collaborative processes by multiple stakeholders? How is vision, and the design problem at play, turned into a dynamic investigation as opposed to a static destination?

In the FGE example, the complexity and diversity of challenges faced meant that identifying the design problem was a critical collective competency to be developed. Designers could not come and provide the frame of the problem, and instead had to help participants develop intuitions and insight into their own evolving situations. Yet simultaneously, and paradoxically, vision, structure, purpose and strategy, needed to be developed out for participation to occur. The process had to both provide form and help generate form simultaneously for vision to emerge.

What is the role of the designer before and after the “design process”?

What are the considerations designers need to manage and maintain in the introductory phase of this work? When building space for co-creation and building a culture through a project for a design mindset and orientation? How are designers practicing preparation of their participants in this kind of transformative process? Furthermore, what are the roles, responsibilities and expectations for designers at the culmination of a design sprint or project? In a systems context, there is continuing work that must be planned for and accounted for in helping build solutions that possess resiliency and sustainability in their scale of impact and endurance of effect.

In the FGE example, how does design prepare participants who are not otherwise exposed to design processes, encourage vulnerability and risk-taking, and prepare participants to engage with discomfort? How

do we prepare participants to be open to the new, and move beyond the cynicism of failed initiatives past? How do designers help participants understand and approach future prototyping and development of design competencies and approaches after the end of the workshop, and help participants as they face challenges previously unanticipated?

How are we creating space for reflection and transformation within the facilitation process?

Co-creative approaches rely on participants coming to new kinds of approaches and embodying that newness in their work moving forward. Such processes are by definition transformative, yet how are designers trained and practicing personal and organizational transformation?

In the FGE example, how do designers make space and provide form for participants to become anew, and create the opportunity for new initiatives to take shape. How are we designing for embodiment, designing for resonance and designing for new futures and possibilities to take flight?

Social Models to Underpin Design Facilitation

These questions suggest a much more fundamental need for models to apply in design facilitation. When and what is design operating on within the context of a team, within the context of an organization? What are we focusing on when design acts through facilitation upon a social dimension?

One answer may lie in the work of Scharmer and the social field. In Peter Senge's description "...in every setting, from working teams to organizations to larger social systems, there is much more going on that meets the eye. Many of us have known firsthand the excitement and energy of a team that is deeply engaged in its work, where there are trust, openness, and a pervasive sense of possibility. Conversely, we have also seen the opposite…where each statement has thick political overtones of defending one's position or attacking others'. Scharmer calls this the 'social field'". (Scharmer, 2007, p. liii.).

To us this immediately calls upon a quality, or dynamic that a design facilitation seeks to develop and embody. Scharmer, in his work on a theory of organizational change, theory u, argues that fundamentally, a key aspect of facilitation and transformation comes from an attention paid to a "blind spot" (ibid), "From a structural point of view, the blind spot concerns the fact that most of the key issues of institutional development cannot be solved at the level of the organization. Today's organizations are often too big to deal with the small problems that are better solved locally, and too small to adequately address the big problems that must be considered in the context of the larger ecosystem of value creation". (ibid).

What is critical in our context as design facilitators is then understanding that beneath the veneer of a facilitated group process is a complex social dynamic that must be charged and cultivated, redirected and opened. And immediately lays bare a paucity of design training in the underlying transformational issues at play, Adding to this complexity, is the inherent need for translation of and between disciplines, contexts, communities, and organisations that designers are required to fulfill.

Using such a model leads to questions and considerations that are provocative additions to the practice of facilitation. One such example is the creation, use, development and nature of "vision" and strategic intent within the facilitation process. This model suggests that the concepts of vision and intent are dynamic, and their interpretations are both temporally and socially bounded by the individuals connecting to them at any given point in time. Building on Scharmers' work and Senge's *creative tensions*, Stroh emphasizes: "If people hold to the vision of what they want and are simultaneously clear and candid about where they are, then the tension will tend to resolve in favor of what they want. This principle applies both at the individual level and the collective level. Translated to the collective level, when people have a common aspiration - as expressed by a shared vision, mission, and set of values - and a shared understanding of not only where they are now but also why - then they establish a creative tension, which they are drawn to resolve in favor of their aspirations". (Stroh, 2015, p.73).

Designers therefore need new models of facilitation and even of what their participation entails and requires of them. It would involve new models of training to see and preparing to do.

Such models of design practice would involve an articulation of and an understanding of collective intelligence, of shared and built capacity and the ways by which art and form give these conceptions shape and direction. It would be impossible, in such a practice of collectivity and awareness to ignore the hermeneutic element in such a process. "The hermeneutical dimension of the process [of experience] is inescapable: every

examination is an interpretation, and all interpretation reveals and conceals at the same time". (Depraz, Varela, & Vermersch, 2003, p.9).

In such facilitation practices, there is a goal or moment of transformation. How are designers being trained to identify and help coalesce participants around these critical moments? We have discussed them in terms of *crystalizing moments* and in terms of *blind spots* within a social field. Capra offers another model to approach the same moment in terms of critical junctures within living systems. There is a spontaneous emergence of order at critical points of instability - emergence or self organization; "in other words, creativity - the generation of new forms - is a key property of all living systems. And since emergence is an integral part of the dynamics of open systems, we reach the important conclusion that open systems develop and evolve". (Capra, 2002, p.13).

This has yet to entail and involve a clarified and critical discussion of power and privilege, of the role of the designer within participatory processes. Design as a discipline has always been vulnerable to a charge of irresponsibility, of creating and designing artifacts with consequences, often dire, beyond the initial intent and predictions of their designers. Through his work and writing, Papanek repeatedly emphasized that "the designer must be conscious of his social and moral responsibility" based on his underlying understanding of design as "the most powerful tool yet given man with which to shape his products, his environments, and, by extension, himself". Designers, he warned, "must analyse the past as well as the foreseeable future consequences of his acts". (Papanek, 1985, p.103). This dynamically comes to the fore within facilitation practices, wherein a designer's actions as facilitator, their wielding of power to enable and disable participants within a process is a significant act of franchisement and disenfranchisement.

Towards New Models of Design Facilitation

As design facilitation evolves and emerges as a form of design practice in response to a need to develop systems-level design interventions, we must continue to build our understanding of its process and impact. And through these mechanisms develop a deeper understanding of the critical inflection points and key skills of designerly facilitation. As with every discipline and practice of design, some of these skills are a resuscitation of design practice through the ages, albeit through a different lens, and some are the appropriation of other traditions and practices now within a context of design praxis.

To remain relevant in these new professional realities, a sought-after, and, more to the point, effective designer will need to be able to formulate, conduct, analyze and synthesize the results of research that informs design processes and design decision-making beyond the traditional, cursory client interview and a narrowly framed, shallowly plumbed survey of secondary resources. Rather, the contemporary designer will need to possess the ability to cultivate and effectively utilize meaningful input from the varieties of people who both affect and will be affected by the design processes that guide the development of these projects and their outcomes. Failing to broadly account for the social, economic and technological biases of eventual users and audiences will limit the designers' abilities to create useful, usable and meaningful artifacts, services and experiences with, rather than for, these groups.

As we begin to understand this dynamic of design as social practice, design facilitation as intervention, we will need to develop more robust models of design facilitation in practice. This paper proposes but a few critical pathways to address. We will need to draw from schools of mediation and build a designerly practice of mediation within participatory processes. We will need to draw from schools of organizational dynamics and change to build better practices of shared vision development and the collective development of high quality design problems. We will need to expand our view of the design process itself and build new forms and approaches to form for an wider area of design intervention. And we will need to integrate a more collectively reflexive and reflective process to facilitate the underlying social transformation, to better identify the right questions to ground intervention and to even understand our role and impact as designers embedded within and active contributors to a system's change process.

We would speculate that such a process may also involve a return to the artistic, to develop methods and approaches that inspire and are evocative. Design must still delight as well as inform, and operate in a space beyond and between scientist and artist. It could also question the use of the term facilitation itself and whether it is appropriate for the lexicon of contemporary design practice.

Our research into design facilitation questions where and how a designer must carry expertise, and what are they approaching when designing the non-physical? How are designers approaching the design of and for the

social field? Current definitions of the design facilitation process outline a series of steps and checklists. Yet as we are finding, when design is a social process, it is a story of journeys and no longer an inventory of destinations. How might we move towards a more plentiful model of design facilitation?

The Role of Design in Policy Making: A Wicked Problems Perspective

HOLIERHOEK Sophie Elisa* and PRICE Rebecca Anne

Delft University of Technology, The Netherlands
* corresponding author e-mail: sophie.holierhoek@gmail.com
doi: 10.33114/adim.2019.06.313

The design discipline is of increasing appeal to a public sector confronted with ill-defined problems consistent with the socially-embedded. This paper explores the role of design in policy making projects, by means of two case empirical case studies. We establish and apply a wicked problems perspective to analyse data from; (1) MindLab and (2) Helsinki Design Lab. Findings reveal that design is specifically useful in the mitigation of wicked policy problems when harnessed by a strategically composed multidisciplinary team including designers. The characteristics of design that are identified as essential are an interactive approach to problems, a holistic perspective, and a user-centred way of working. This paper contributes empirical evidence toward the role of design in policy making, drawing the two domains together via wicked problems theory.

Keywords: social design, social innovation, public sector, co-evolution of problem and solution, problem framing

Introduction

A powerful convergence is underway. Problems that affect society are increasingly being acknowledged to be interrelated – crossing borders, cultures and falling into the portfolio of the collective (Tromp & Hekkert, 2018). Public trust in political leaders is low, with the immediacy of social media encouraging if not amplifying extreme ideological views (Im, Cho, Porumbescu, & Park, 2014). Citizens are increasingly critical of government institutions and political partisanship that plays out via inaction or counterproductive policy directions, ("let's build a wall"; "let's exit Europe") ibid)). The fourth converging factor is associated with the design discipline. The design discipline has been elevated from the realms of project and operational subject matter associated with artefacts, products, services and processes - to areas of strategy, culture and organisational reform (Sharma & Poole, 2009; Muratovski, 2015). Buchanan describes this change in subject matter as an evolution – the *design movement* (2015).

While the last ten years strongly heralded a view of design as powerful business capability, attention regarding the power of design when unleashed into socio-embedded problems is also garnering interest. Methodological developments demonstrate a discipline undergoing maturity yet retaining a sense of deep responsibility for social matters. Methodological developments include but are not limited to:

- **Vision in Product Design** (Hekkert & Van Dijk, 2011), future focused, designers taking responsibility for the impact of their design;
- **Transformation Design** (Jonas, Zerwas & von Anshelm, 2016), with the goal to drive positive change within organisations via design;
- **Transition Design** (Irwin et al., 2015), designing transitions for "more sustainable futures" and;

- **Designing for Society** (Tromp & Hekkert, 2018), designing with the social implications in mind, or even *for* certain social implications.

Yet achieving policy reform requires overcoming political plurality which is inherent in democracy. The construction of a policy must work to the interests of multiple stakeholders in order to surpass the rigours of political negotiation. Policy makers rarely succeed in making the change they envisioned, which means that policies are not as effective as they should and could be (Bason, 2014). Yet how to design necessary policy reform required to capture system-level and social change remains an area for further exploration.

This paper explores the role of design in policy making projects, by means of two empirical case studies. The greater purpose of this paper is to contribute toward a growing body of literature associated with the role of design in policy making. We apply wicked problems theory to analyse two case studies; (1) Helsinki Design Lab (Finland) and, (2) MindLab (Denmark) in order to evaluate how design as an approach assists policy making. The paper responds to two research questions:

> RQ1: In what way do dedicated design labs aid governments in the mitigation of wicked policy problems?
>
> RQ2: What methods, tools and techniques of design are effective in design lab projects where policy planning and design are combined?

The paper proceeds in the following manner; beginning with a review of relevant literature; detailing a case study methodology; describing results related to the two individual case studies; a discussion of the comparative findings before concluding. This paper contributes empirical evidence toward the role of design in policy making, drawing the two domains together via wicked problems theory.

Establishing a Wicked Problems Perspective

Complex problems in policy making are common. In 1973, Rittel and Webber attempted to understand the nature of these kinds of problems, assigning the title 'the wicked problem'. Wicked problems are characterised as, "a class of social system problems which are ill-formulated, where the information is confusing, and where there are many clients and decision makers with conflicting values" (West Churchman, 1967, p. B-141). In more recent research, wicked problems have been described as problems with high levels of complexity, uncertainty, and divergence of values between different stakeholders (Head, 2008). In isolation, these factors do not make a problem wicked. However, once present simultaneously, they reinforce one another (ibid).

The wicked problem theory is resurgent today, due to the increasingly complex challenges society faces on a day-to-day basis (Buchanan, 2015; Norman & Stappers, 2015). These arise not only in the policy making field, but in other fields as well. Since its introduction, the theory has eagerly been adopted by scientists in the fields of business strategy (Camillus, 2008), design (Buchanan, 1992), and knowledge management (Courtney, Merali, Paradice & Wynn, 2008). Despite the attention 'wickedness' is attracting, there is no academic consensus on an approach to negotiating such problems, merely that traditional approaches (i.e. technical solutions and routine administrative solutions) fail to deliver sustainable outcomes (Rittel & Webber, 1973; Roberts, 2000; Head, 2008). Perhaps the main reason for this weakness can be found in the general point made by Rittel & Webber (1973) and Schön & Rein (1994), that the definition of a problem discretely suggests an approach for resolution as well. As each wicked problem is unique, an approach is likewise unique. As Head (2008, p. 103) puts it: "It is not clear that labelling a project as 'wicked' will readily assist in solving it." Approaches that are advocated by policy scientists lie among the lines of (stakeholder) collaboration and consultation, incrementalism, and iteration. These approaches share theoretical and practical affinity with design as an activity.

The Design Activity

Design as a discipline of practice is historically defined as the process of planning and creating ideas, then implementing these ideas to improve the artificial environment (Simon, 1969). Cross (2006) defines design thinking as a type of problem-solving cognitive process utilising a unique type of intelligence based on reasoning and logical inference. The cognitive process allows the central activities of design to extend beyond problem solving to describe problem identification, solution generation and strategy (Cross, 2006). The presence of creativity within the design process, and within design thinking as the intangible articulation of the

design activity, is considered central to the designer's ability to frame and reframe the problem at hand (Dorst & Cross, 2001). Creativity is often associated with the fine arts but also drives an important component of design — the ability to imagine what could be, not just what is. Creativity rests within the design process as an imaginative ability that links ideas. Cross (2006) refers to the 'creative leap' as a vital moment within the design process where novel concepts emerge. Schön (1983) had earlier described the notion of 'surprise' that prevented designers from routine behaviour; the type of behaviour that might inhibit original thoughts.

Dorst (2015) further explores the approach of framing and reframing problems, which is enabled by design thinking. Dorst (2015) describes design thinking as a paradigm for problem solving. Problem-solution framing is critical in determining different kinds of design reasoning, design processes and design skills that are utilised within a design approach (Dorst, 2011). Designers' are reflective practitioners, who engage in reflection-in-action during their work. This means that they search for problem and solution pairs, also identified as an activity named framing (Schön, 1983; Dorst, 2011). The activity of framing results in the co-evolution of problem and solution is a fundamental component of the design activity, see Figure 1 (Maher et al., 1996; Dorst & Cross, 2001).

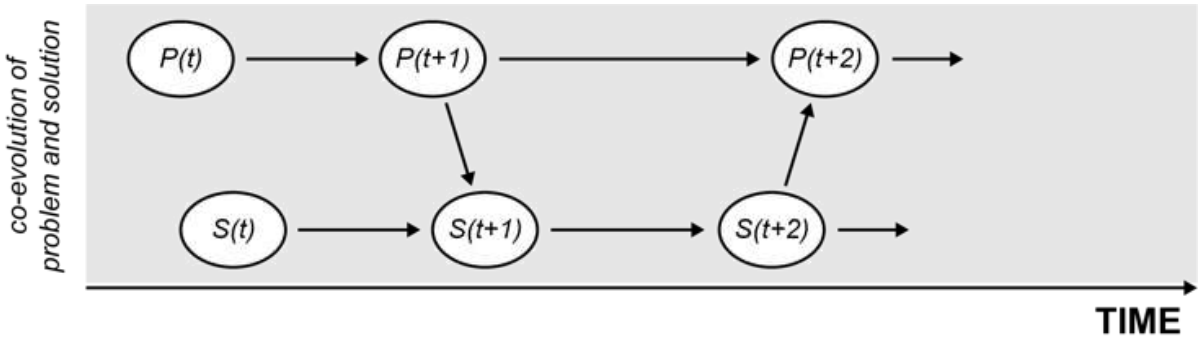

Figure 1: The co-evolution of problem and solution model (Maher et al., 1996; Dorst & Cross, 2001)

Policy Making and Design

Wicked Problems and Public Institutions

When looking at examples of wicked problems (climate change, obesity, racial discrimination, etc.), the origins seem to lie outside of public organisations—the institutions we generally point at to solve these problems. However, the very way in which governments are organised often sustains or even reinforces the prevalence of wicked problems. (APSC, 2012; Carstensen & Bason, 2012; Head & Alford, 2015). For example, politicians generally have a preference to address highly visible or tangible parts of the problem, which they do by proposing concrete and simple solutions ("Let's build a wall"). Politicians are not alone in this preference. The (financial and political) accountability systems that are in place in public organisations tend to favour discrete and finite solutions over complex, interconnected solutions. Such solutions don't necessarily have the potential to solve a problem as they are often short-term fixes, and don't approach the problem comprehensively (Head, 2008).

Additionally, public institutions remain highly hierarchical and bureaucratic, having different sectors both vertically between administrative levels, and horizontally between policy domains (Carstensen & Bason, 2012). Hierarchical bureaucracies have not yet been successful in grappling wicked problems (Head & Alford, 2015), as they tend to be risk-averse, are intolerant of messy processes, perform better when issues have clear boundaries, and hinder collaboration across domains. The opposites of these characteristics have been labelled as useful for the mitigation of wicked problems (APSC, 2012; Carstensen & Bason, 2012).

Policy Problems as Design Problems

Buchanan (1992) compares design problems to wicked problems and states that the two are similar. He also points out that a linear approach to such problems is rarely effective, as this approach derives from definite conditions, whereas wicked problems are characterised by the indefiniteness of conditions. This implies that putting together a team of designers and having them follow an iterative design process will result in a

successful solution, but this is not necessarily the case. Norman (2014) argues that complex problems require complex solutions. In order to resolve a complex problem, a multi-disciplinary team needs to be put together, in which all the disciplines relevant for the problem are united, including the design discipline and the user. In a follow-up paper (Norman and Stappers, 2015) the point is made that the complexity in a complex problem is not so much about the solution, but more about the implementation. They propose an approach much alike Lindblom's 'muddling through' approach (1959): an incremental approach that makes for a satisfactory result, rather than an optimal result. In general, the problems that are addressed by the design discipline have been increasing in complexity (Sanders & Stappers, 2014). Moderately and highly complex problems in the meso and macro level are now the subject matter of designers (Figure 2). Examples of projects that apply design in public innovation are 'Future of Fish', a non-profit social incubator aimed to end overfishing ("About Future of Fish | Future of Fish", 2017); and InWithForward, a social design organisation mainly active in Canada (Van der Bijl-Brouwer & Malcolm, 2018).

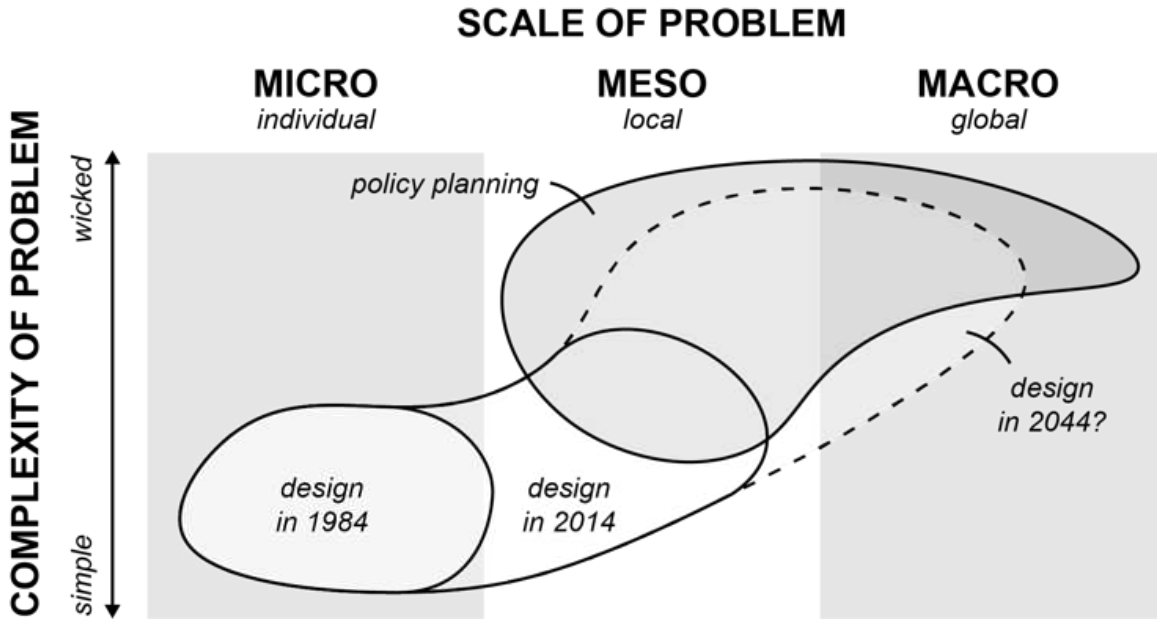

Figure 2: The field of policy planning, the expanding field of design, and the complexity they address, adopted from Sanders & Stappers (2014)

Research gap

That applying design principles to wicked policy problems is considered a good fit, is reflected in the growing number of government design units and external design agencies that assist governments in policy making. The names these units often go by— "labs" —imply a certain openness to experimentation and iteration that is not necessarily present in governmental organisations *themselves*, but that is natural to design. Even though there are a lot of examples of successful design interventions, and there are numerous examples of government design labs, academic knowledge on the topic of policy making via design remains limited. There is no unified view yet on what the specific role of design in policy making can and should be. This paper aims to explore what aspects of design are helpful in the mitigation of wicked problems, by studying the activities performed by design labs for governments.

Research Design and Methodology

Case Study Method

Considering that the aim of this explorative study is to clarify the role that design can play in the mitigation of wicked problems, it is necessary to study the actual contribution of design to existing addressing wicked problems. The unclear boundary between phenomenon and context in this case, make experimental settings with any form of manipulation a nonviable option. Creating a representative simulation of reality would be

nearly impossible. As such, case study is considered the most suitable approach for this study (Yin, 2009; Gray, 2014).

This study takes a multi-perspective approach by implementing methodological triangulation (Ravitch & Mittenfeller, 2015). The phenomenon and accompanying data are viewed from multiple perspectives, increasing rigour in the study. Between-method triangulation was achieved by using primary, public and third-party information as data sources.

Two Cases

There is a large number of design institutions (i.e. labs) in Europe that assist governments in policy making. Two of the more significant ones—because of their lasting influence on governing and the example they have set for other labs—are MindLab (Denmark) and Helsinki Design Lab (Finland). Both labs are among the first design labs in Europe, and both have made available a considerable amount of information on the way design has helped mitigate complex problems for their government. This available information has been largely self-reported and not critiqued by a third party. This makes the cases very suitable for a comparative case study.

Helsinki Design Lab

One of the more significant and earlier design units is *Helsinki Design Lab (HDL).* HDL was a platform set up by SITRA (the Finnish Innovation Fund) with the aim to advance strategic design within the Finnish government. It consisted of a small team of about three or four trained strategic designers. The initiative ran from 2009 till 2013. Helsinki Design Lab performed several pilots, with two formats. The first format was to set up one-week 'studios', in which multidisciplinary teams try to tackle policy problems suggested by local governments. The other format was to place designers in-house at city governments, where they participate in a policy making team. HDL has extensively and openly recorded the progress of their projects through project pages and blogs. Next to working on government projects, HDL performed research themselves, and published books and articles on the topic. These documents will also be studied. An overview of the case data used can be found in table 1.

MindLab

MindLab is a cross-governmental, internal innovation unit for the Danish government. Running from 2002 till 2018, it was one of the longest running government design units. It was originally set up to find new ways to craft policy, as approaches used at the time were not delivering successfully. MindLab's responsibilities and corresponding composition have varied over time, ranging from creative facilitation to informative support in high-level strategic decisions. Due to its lengthy operation, MindLab has a vast amount of high-quality information concerning its responsibilities and activities. An overview of the case data used can be found in table 2.

Qualitative Data Analysis

A thematic analysis was performed on all material from each case separately with major predefined codes established based on literature. Predefined codes included the design process, policy making challenges and elements of wicked problems. Codes were also expanded during an open-analysis where data repetitively pointed toward new themes; both major and minor. The results of the two cases were then compared and contrasted. The results are presented in the results chapter, with the findings from the comparative analysis forming the basis for the discussion.

Results

Helsinki Design Lab

Grappling complexity through supporting multidisciplinary teams in design

One of the ways in which Helsinki Design Lab aims to grapple the interconnectedness that characterises the complex problems they are facing, is by forming multidisciplinary teams with people both closely and distantly related to the problem. As a result, the composition of the teams is similar to the problems the teams have been created for, in that they are both multifaceted. Having these multiple perspectives helps in creating a rounded view of the problem. Similarly, as each complex problem is different, each team has a different composition, representing the most relevant disciplines.

> *We tried to construct a 360° perspective around the problem, so Lai came from Singapore, she runs one of the top secondary schools; Juha works in the Ministry of Health on health policy but also as a practising physician […]; Ann is an educational software specialist; and then Darryl and Maja were the two designers. The designers are in a clear minority and their role is to help bring synthesis to the conversation.*

Within the multidisciplinary team, there are two designers. Their main role is to steer the team towards synthesis when this is needed, but they are a core part of the team, and act as such: "They are expected to bring their expertise and experience to the table by actively contributing like everyone else." Of the two designers, one acts as *design lead*, the other remains in the background but can jump in for "back-up".

During the one-week project the multidisciplinary team is led through a typical design process, of which this inclination towards synthesis is but one of the relevant characteristics. In the next paragraphs, the design characteristics that were considered relevant for this multidisciplinary approach to mitigating wicked policy problems will be discussed.

Synthesis mind-set

One of the core capabilities of designers that Helsinki Design Lab identified as valuable in designing for wicked policy problems, is the ability to think in solutions rather than problems, even if the problem is not completely framed yet. This is important, because the complexity of these kinds of problems makes it almost impossible to fully comprehend the problem before moving on to solutions.

> *The machinery of government in general in the West has been designed to consider objective facts and make decisions based on those facts. […] There are areas where we just don't know enough yet, so there are decisions that we're being forced to make without having complete data…That's a design challenge; that's what a designer does on a daily basis.*

As having a synthesis mind-set is not a skill commonly present within the multidisciplinary teams, it was the task of the design lead to steer towards synthesis when needed. Sometimes that meant having to make tough decisions to move the process along, but other times a synthesis-mindset was achieved early on in the process through the creation of a strong shared vision.

Synthesizing the various inputs and needs of all partners was not that hard, in the end, because we had invested a lot of time up front in aligning everyone behind a shared vision.

Facilitating participative governance

When studying the activities HDL performed to design for policy problems, it became clear that one of their main objectives was to bring user-centeredness to both policy making projects and the Finnish government in general. This was meant to reduce the gap between the government and its citizens, which eventually could lead to the delivery of better services.

We are putting designers in different ministerial and municipal positions to help create a better interface between public and private.

Policy makers rarely have contact with the 'users' of their policy, mostly making estimations on citizen interests based on their own experiences. By putting the team or policy maker in contact with the people they're working for, HDL is making sure that the user is incorporated earlier on in the process, so that user interests are treated with equal weight as other stakeholders' interests. Considering the complexity of the problems, there are often stakeholders whose voice is not represented because they are hidden within a system. These stakeholders carry no political weight under a conventional system. They have no capital or room to negotiate. When using design, stakeholders see their needs represented the best.

On day two they visited a school and spoke to as many people there as possible, including the principal, teachers, pupils and caretaker. In the afternoon they got to know the wider context, visiting places like family counselling centres and sports clubs.

Interactive approach

In all their projects, HDL adopts the interactive (i.e. iterative) approach that is characteristic to the design process. In their experience, a linear approach does not help in tackling complex problems, whereas an iterative approach can. This is where designers come in.

Industrial society is predicated on the idea that you can look at the world, identify a problem, think about it really hard to identify an answer, make a plan, and then execute on that plan, all in a linear manner from beginning to end. That linear approach worked when human society more or less agreed that the world was simple. […] Human economies, and perhaps human societies, were oversimplified.

Working on a problem iteratively is useful for complex challenges as it enables constant evaluation of the problem and its solutions, learning more about both in the process. This behaviour can be recognized in the way the teams begin to think of solutions and themes *during* problem analysis.

We end Monday with a lightning quick summarizing discussion just to get some ideas on the whiteboard. Tuesday ends with a download session back in the Studio where everyone shares their insights from the day and the group begins to assess emerging themes and questions.

Another important aspect of design iteration is the 'doing' element. By visualizing and prototyping solutions, themes, etc. intangible objects become tangible, making them a subject for discussion and experimentation. This tendency is known to greatly help in steering towards synthesis – which is essential in design.

Pairing a complex web of problems with a holistic set of solutions

The problems that are given to Helsinki Design Lab are perceived by them as "a complex web of factors creating the problem", in which the factors don't function independently and are instead interconnected. The problem is multi-layered, for the factors that create the problem are situated on the micro, meso and macro levels.

In education, this is about the individuals and their lifestyles; it's about the teaching methodologies; it's about the classrooms; it's about how you educate teachers; it's about health; it's about mental health, it's about after school; it's about early child education; about jobs.

Top-down government responses to problems tend to be reactive, addressing symptoms in isolation rather than engaging with the often complex web of factors that create a problem.

While governments often tend to address symptoms of the problem, Helsinki Design Lab respects this complexity and aims to understand and reframe the problem without needlessly oversimplifying—in their own words: "developing the architecture of the problem". This is done with synthesis in mind. Linked to this acceptance of complexity in the problem, is the acceptance of a complex solution, or rather a holistic *set* of solutions.

> *Amid this inherent complexity, the challenge is to find the right dependencies and to avoid oversimplifying things.*
>
> *Propose an architecture of solutions that highlights the top ten opportunities to help move closer to the vision.*

HDL sees design as a very suitable approach for dealing with this complexity, but at the same time it recognizes that it still has to evolve in order to truly mitigate complex problems. In the policy making field, designers are out of their comfort zone.

> *Sitting around the table with world-leading experts from other fields, working in abstract systems, strategy and policy recommendations is something that designers often aren't used to doing.*
>
> *To really contribute in the public sector, designers need to become better at juggling data and engaging broader communities of stakeholders.*

MindLab

Needing new ways to approach challenges

At the time when MindLab was set up (2002), the Danish government was in need of new approaches to successfully develop and implement new policies and address wicked problems. Even though small policy changes could be successfully implemented, bigger policy changes or complete policy reforms often weren't completed. At the time, most of the public organisation's innovation efforts were inwardly focused, and innovation was not an activity that came naturally to the organisation.

> *How do you work with innovation in government, when the whole institutional setup of our public organisations is to emphasize stability over change; predictability; mass production of services; application of law in an equal way, and so forth. That's why a lot of people would say that innovation in government is an oxymoron.*

When the Danish government set up MindLab, it showed that they had the desire to change this status quo. It became MindLab's responsibility to disrupt the Danish government in their current way of policy making, by cutting through silos and aiding them in innovating *outwardly.* This need for disruption was reflected in the initial (unofficial) goal set by MindLab's new director:

> *Mindlab is the equivalent of throwing a hand grenade at bureaucracy.*

This was to be done by finding and creating new strategies for policy making—adding new tools to the policy maker's toolbox (Table 3). One of the primary ways this was done was by introducing aspects of design to policy makers. Design was considered a good fit because of its user-centred way of working, which could increase empathy and serve as inspiration during the policy making process.

> *The pursuit of a more contextual and fine-grained appreciation [by civil servants] of how people experience public services and regulation is at the heart of the approach.*

Design was also beneficial because of its proactive nature, having the tendency to both *do* and *think*, and keeping the future in mind at all times. This is also reflected in its ability to work visually and physically, enabling effective communication between civilians and policy makers, but also among policy makers.

> *Through [tangible & intangible] prototyping, they could produce more workable solutions and communicate them to decision-makers so as to have a good chance of implementation.*

Lastly, design's iterative approach was estimated to be beneficial for the complexity of wicked problems, as it enables the evaluation of solutions and using this knowledge for the development of new ones.

A systematic approach for design in the public sector

MindLab functions as a link between policy and services, "combining the high-level macro calendars of policy, with the nuanced details of qualitative research." In order to do this effectively, it had the objective to create a systematic approach for user-centred design within the public sector.

> *Working effectively with user-centred innovation requires a systematic approach to what needs to be investigated, underpinned by a wide variety of methodologies.*

This systematic approach takes the user-centred and iterative way of working of designers as a basis, but expands it by working with multidisciplinary teams and introducing design tools suitable or adapted to the public sector (Table 3).

User-centric way of working

By design's ability to "make problems experientially available", the policy maker comes closer to the people who are experiencing a problem, which can serve as inspiration during the policy making process and increases empathy.

> *By enabling the civil servant to 'see' the world differently and with empathy, and understand that things could be done differently.*

Partly because of its user centric way of working, design was able to help identify problems earlier in the policy making process, because you operate 'on site'.

> *I got some really nasty statistics about this implementation process, and then my staff came up and told me that they knew already it was coming, because three months ago they ventured into the field with MindLab and took a look at what people are experiencing. And that is just now showing up in the statistics, but we could see that in the behaviour and experience already.*

Iterative way of working

As Figure 3 shows, the systematic approach MindLab has created for design in the public sector is iterative, building in room to go back to implemented policies and adjust them. Next to this large iteration loop, smaller loops can be recognized. In its way of working, MindLab is taking an evaluative stance, constantly evaluating problem frames, ideas and solutions and consequently adjusting. This is also reflected in the tools it adopted in their processes (Table 3), where most of the tools are means to generate, prioritise and evaluate ideas.

> *MindLab was to take a longer-term, project-based focus by: Developing new ideas based on user needs, analysing, qualifying, and possibly testing ideas, and – after a deployment and operational phase – evaluate and measure the impact of new action.*

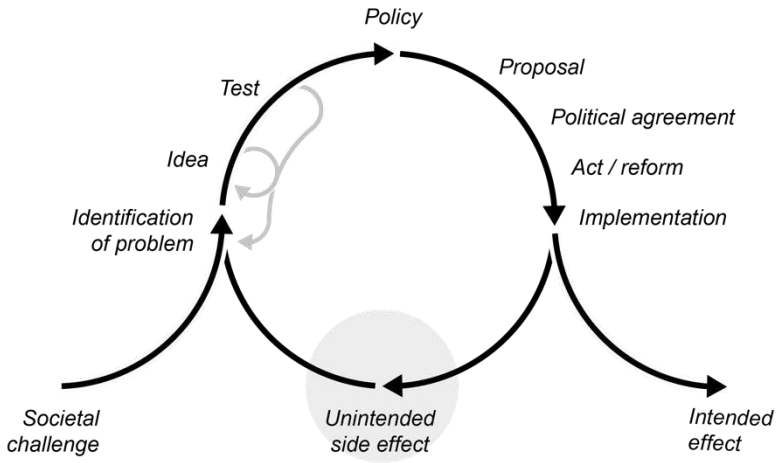

Figure 3. MindLab's systematic approach for user-centred design in the public sector (Carstensen & Bason, 2012), with extra iteration loops added by the author

Working with multidisciplinary teams

MindLab attends to the policy making projects of three different ministries that normally operate separately, even though their policy domains overlap at places. An example is school reform, which affects more than just schools.

> *How do you create school reform if you realize that it does not happen just by getting the law through parliament? It is ultimately powerless, unless it finds a way to work with school principals, teachers' unions, parents, local governments, other ministries.*

> *We're working on an intersection of so many different fields.*

In an attempt to mimic the problems their ministries are facing, MindLab not only performs user-centred design, it also facilitates short- and long-term team work with people from across ministries and departments, to create situations in which overlapping problems could be explored, e.g. by exploring joint solutions.

> *MindLab management and team developed the layout of the lab so as to facilitate design activities such as multidisciplinary teamwork. […] To help cut across disciplinary and departmental silos.*

Major themes identified for each case have been presented. Findings from a comparative analysis will be discussed in the following chapter.

Discussion

The key problem of policy making that comes forward in both case studies, is that there is a big gap between the original intent of a policy, and the way it is eventually implemented in society. There are three main barriers that cause this problem. Firstly, it is rarely the case that the problem addressed in a policy making project is rightly understood; secondly the policy making process is a linear, evidence-based process, which is passed on to different parties in different stages, causing for a lot of leakages in the project; thirdly, projects are placed within single policy and knowledge domains. The designers working in the labs attempt to address all these barriers with their processes, which will be described in more detail in the next sections.

Designing with non-designers

One of the more striking similarities between Helsinki Design Lab and MindLab was that they both opted to let their teams of professionals go through a design process, albeit in unique forms. In both cases, following a design process was key in addressing the complex policy problems they were facing. The holistic perspective and the interactive way of framing and solving problems are most important here. Designers are trained in these capabilities, and therefore support and participate in the team throughout the process.

Co-evolution of Problem and Solution as a Challenge to Mind-set and Procedure

The policy making process as described in the case studies is a linear process, in which problem, solution and implementation are handled subsequently and in isolation. Moreover, in the process of defining a policy or social problem, policy makers often take an evidence-based approach, in which a policy is based on (quantitative) evidence. This is done by doing desk research and talking to (a limited amount of) stakeholders in the system. Both strategies have been argued to be ineffective in dealing with wicked problems. Taking a linear, rigid and rational approach to wicked problems is believed to be ineffective (Lindblom, 1959; Buchanan, 1992; Schön & Rein, 1994). Lindblom proposes a different approach: 'muddling through' (i.e. the 'Branch method'). In this approach, the problem solver tries to reach his goal by making incremental decisions and solutions, and evaluating the effect.

By exploring problems through creating provisional solutions, design when used in both labs eliminated a linear approach, and instead applied a process of co-evolution of problem and solution. Both co-evolution of problem and solution and 'muddling through' are approaches in which the final problem and final solution co-evolve. Schön and Rein (1994) offer an alternative, albeit similar, approach, called 'frame reflection': a reflection-in-action activity in which the frame of problem and possible solution, but also the value perspective of the project, is continuously evaluated and reframed (Head & Alford, 2015). As established earlier in this paper reflection-in-action and framing are key design activities, however Schön and Rein's proposed approach hints to another key design characteristic as well; understanding and keeping in mind the *value* of a project. The user-centric thinking mechanisms of design and the empathy for the needs and interests of stakeholders this generates, provide one way to achieve this.

Inciting empathy and decreasing the distance from the problem

Another characteristic of design that played a substantial role in the design lab's activities was its human-centric point of view. The link between a human-centric way of working and the mitigation of wicked problems is not strikingly evident. It gets clearer when considering that most of major system failures can be dedicated to the disregard of human-factors (i.e. human behaviour) (Norman & Stappers, 2015), and that it is with the addition of human-beings to a system, that it becomes unpredictable (Van der Bijl-Brouwer, 2018). A human-centric point of view allows for solutions that fit within the user's world view and behaviour, as such increasing their conformance to the system. Moreover, human-centeredness allows for empathic and culture-specific decisions, aspects that are generally missing from decision-making mechanisms in public organisations (Bosch, 2016). An additional benefit is that policies suited to its users can aid public organisations in regaining trust of its subjects (Bosch, 2016). The simple activity of taking policy makers into the 'field' to interact with the environment they were writing policy for, had profound consequences. The HDL quote;

> *On day two they visited a school and spoke to as many people there as possible, including the principal, teachers, pupils and caretaker. In the afternoon they got to know the wider context, visiting places like family counselling centres and sports clubs.*

Not only did it allow for quicker insight building, (where waiting for statistical data may take months to be gathered and fully analysed), it also aided policy makers to connect the abstract nature of strategy and policy to a set of concrete experiences.

Multidisciplinary design work

When crafting teams to work with, both Helsinki Design Lab and MindLab chose to put multiple disciplines together in one team. MindLab sought these different disciplines within the government but across policy domains, HDL sought them across the world. Their objective was the same: to create a well-rounded view on the problem. This is supported by Norman & Stappers (2015). An indirect, but probably even more important consequence of multi-disciplinary team work, was that it enabled the design labs to break through knowledge and policy domain silos. If wicked problems fall beyond the parameters of one discipline alone, then the convergence of disciplines will be effective in approaching problem framing. Important to note is that, even though the design characteristics discussed in the previous paragraph show to be essential in the mitigation of complex problems, its benefits truly come to fruition when combined with multidisciplinary teamwork.

The problems addressed by designers when dealing with wicked subject matter seldom fell within the boundaries of *one* domain of knowledge. The very nature of design might force the breaking of silos (Buchanan, 1992). The notion of 'throwing a hand grenade at bureaucracy' (MindLab) is just one illustrative example. Norman and Stappers (2015) suggest that "In the best of cases, these different participants combine their expertise in creative, effective ways, often compromising goals and principles for the greater good. In the worst of cases, there can be strong ideological and political arguments behind the scenes that disrupt collaboration." Observed in the material of both cases is the role of designer, and function of design as an underpinning process, as connector across silos to set up collaboration as a purposeful activity. One of the challenges here is encouraging non-designers to harness the design process in their work.

Conclusion

Today, the majority of policy making processes do not reach conclusion or are deemed to fail even if their implementation is completed. Being a consequence of the social systems in which they are situated, the challenges public organisations face can be characterised as 'wicked'. Considering its failure rate, the strategies public organisations do adopt to craft policies for these challenges are not always successful, which means that policies are not as effective as initially intended (Bason, 2014).

This paper shows that the way in which designers think and do can be very valuable to the solution of wicked policy problems. We applied a wicked problems perspective to analyse two cases in order to reflect a holistic view of the challenges of development through new policy frameworks. Findings point toward the future role of designers' not specifically crafting policies alone, but as facilitators of multidisciplinary teams who are 'designing'. Multidisciplinary teams are needed for policy making because it ensures multiple perspectives on the problem are established and that breaking through knowledge and policy domain silos occurs daily. Design labs have taken on the role of stewards or guides, aiding public organisations in developing characteristics that are inherent in design, valuable to the mitigation of wicked policy problems, but not naturally present in public organisations: a holistic perspective, an interactive approach, and human-centeredness.

Motivating Growth in Low-tech Manufacturing Industries: A Case Study of the Israeli Footwear Industry

HERTZ Naomi

Bezalel Academy of Art and Design, Israel
hertznaomi@gmail.com
doi: 10.33114/adim.2019.07.315

Intensive manual labor enterprises in the developed world face challenges competing with products imported from countries where manufacturing costs are low. This reduces the volume of domestic production and leads to rapid loss of knowledge and experience in production processes. This study focuses on the Israeli footwear industry as a case study. Qualitative methodologies were applied, including in-depth interviews and field observations. A literature review on previous research, and contemporary trends was conducted .The field research examines challenges along the value chain in small factories. It finds that mass production paradigms impose a decentralized process between designers and manufacturers and therefore do not leverage local potential into a sustainable competitive advantage for small factories .The proposed solution is a digital and technological platform for small manufacturing plants. The platform mediates and designs the connections between production, technology, and design and enables the creation of a joint R&D system.

Keywords: New Product Development Innovation, Design Management, Sustainable Development, Open Innovation, System Design

Introduction

Over my ten years as a designer, developer and teacher of footwear, I noticed that the local market was showing a growth in designers opening a local brand. On the other hand, the producers I was working with where not growing as a result and were struggling for survival.

looking at the problem through a wider lens, I realized that in fact many low-tech traditional industries in the mature economies are now facing a similar challenge. This challenge affects levels of low-skilled employment and deepens social gaps. It also causes a loss of opportunities for the development of new innovative knowledge, which relies on manufacturing 'know how' of producers who: "actively pursue strategies to maintain competitiveness and increase the value added of products and processes" (Hansen & Winther 2015)

Returning to my local case study of footwear in Israel, I began my research by asking, how might we sustain growth in local manufacturing industry? The research plan followed the value chain of footwear production: design, development, production and market.

Traditional production of footwear relies on manual labor and is considered a low- tech industry.

Changes in global and local market conditions have led to a reduction in local footwear manufacturing. In Israel today, there are only a handful of functioning industrial footwear factories. There are also a few dozen

micro-factories, reduced by market conditions to small-scale production, and an almost complete reliance on manual labor. These are on the cusp between factory and workshop. They maintain production relations with the local design industry and thus, in practice, enable organic growth in the industry. And yet, mapping of the local footwear market indicates that products developed by small manufacturers for local designers are not competitive in the saturated domestic market. This threatens local knowledge and capabilities. As a result of the research insights, the research question was rephrased for the process of developing a solution: How might we preserve knowledge in the footwear manufacturing industry in Israel, and leverage it to create new knowledge and a sustainable economic practice that can compete in the global market?

As a designer I began to wonder how might we design the system of production instead of the product it makes.

The proposed solution is a digital and technological platform for small manufacturing plants. The platform mediates and shapes the connection between production, technology and design. It therefor enables the creation of a joint R&D system with the potential to develop strategies, production methods and innovative products, while overcoming the barriers of the global market and leveraging the advantages of personal contact with the consumer.

Literature Review

Local industry does not exist in a vacuum. It is influenced by and reacts to large and complex systems globally and locally. In this review, the impact of market conditions on local production was examined to identify issues that could serve as a basis for creating opportunities for intervention, as defined in the research question.

The following is a list of the topics reviewed:

1. Recent changes in global market conditions.
   This includes how innovation and creating new knowledge has become a currency companies use to compete with countries with low manufacturing costs.
2. Changes in global production trends.
   This includes changes in the relationship between producers and consumers, as well as economic strategies that have been developed to suit these changes, while maintaining a sustainable economic practice.
3. Innovation in low-tech manufacturing industries.
   This includes practices of creating new knowledge in the low-tech industry and dealing with barriers to leverage it for innovative practice.
4. Reciprocal relations in the fields of production and design.
   This includes the relationships that exist between participants in the Israeli footwear industry and points out to the potential for innovation in production skills.

Recent changes in global market conditions

Globalization and the information revolution affect the global production market. In recent decades, there has been a dramatic shift of production from places where production costs are high to places they are low. This was driven by the fall of trade barriers and the opening of previously closed markets. (Buciuni & Pisano, 2015). The communication revolution reduced communication costs between geographic regions to almost nothing and led to the creation of a knowledge society (Audretsch & Thurik, 2000). In the “knowledge economy” the acquisition, creation, and utilization of knowledge provide a competitive advantage between companies (Hansen & Winther 2015). This had changed production clusters and the structure of companies’ supply chains. The surge in global production enables R&D to be carried out in one place while products are manufactured elsewhere. This now-common practice creates value in sectors that deal primarily with intangible assets such as intellectual property. The textile, clothing, and leather production sectors were significantly affected by the opening of trade borders (Buciuni & Pisano 2015) since they are traditionally based on manual labor and therefor easier to transport.

Changes in global production trends

Changes in the production model

According to Hegel & Brown (2008), there are two models for resource mobilization: *Push*, created by the Industrial Revolution, and *Pull*, created by the Knowledge processes, and predicting consumer behavior. Push-type production is characterized by: forecasting demand, high economic investment, production of surplus stock, and work with intermediaries that weaken consumer attachment (Deloitte, 2015). The Push model is less competitive in contemporary changing market conditions (Hegel & Brown, 2008). The Pull model of on-demand production allows for reduced investment and inventory costs. It relies on technology enabling direct access to consumers (Deloitte, 2015). Future models of production will have to consider new market trends (Deloitte, 2015):
A. Increased consumer power. Unwillingness to compromise on standards of mass production. Growing desire for authenticity, customization, and niche markets.

B. "Smart" products with new technological capabilities. Transition from material products to those that enable access to services.

C. Technologies enabling rapid, small, and local production.

D. Elimination of mediation between manufacturer and customer.

Business strategies in the PULL model

Mass Customization (MC) is a business strategy that aims to sell products that are mass-produced but are adapted to the needs of customers, at a near-standard production cost (Bruneo & Nielsen 2016). Together with the benefit of inviting customer input and responsiveness, as a business model, this offers significant cost advantages by eliminating inventory costs resulting from forecasting and purchasing (Anderson 2011).

Koren, Shpitalni, Gu & Hu (2015), propose an advanced Pull model, an open platform enabling individualized mass production. They suggest that using individually optimized production and open platform principles will lead to a sustainable industry and innovation. They note customized production is enabled by modular architecture and flexible production systems, such as Additive Manufacturing.

Innovation in low-tech manufacturing industries

Innovation has been defined as the effort invested by companies in research and development (R&D) (Cardoso & Torkkeli, 2014). Indices for measuring innovation include the number of R&D studies and the number of people committed to R&D in a company.

Patents are a primary product of innovation and create opportunities. However, while patents are compatible with technology and science-oriented industries, they are not commercially viable for sectors characterized by rapid change. Design, training, consulting, and practical knowledge are key resources for innovation, particularly in low-tech industries (Cardoso & Torkkeli, 2014).

Knowledge resources of low-tech industries

Hansen & Winther (2015) distinguish between two types of innovation: cumulative and radical. Cumulative innovation refers to ongoing improvement of a product or process ("to do what we already do better"). Radical innovation is a complete change of the product or process in the market ("to do something we did not do before"). Norman & Verganti (2012) note two major drivers of radical innovation: technological invention and changing the meanings of existing technology.

Hansen & Winther (2015) further differentiate between analytical and synthetic bases of knowledge. In an analytical knowledge base, scientific data coding is the input and output of the knowledge creation process. In a synthetic knowledge base, existing and tacit knowledge acquired through practice and use are used in new product development.

A synthetic knowledge base can help companies shift from standard products towards customized products (Hansen & Winther, 2015). Most low-tech companies rely on synthetic knowledge, which is globally available and context-specific. They innovate through collaboration, redesign, and tapping into knowledge repositories (Bender & Leastadius, 2005, as cited in Hansen & Winther, 2015).

The inherent innovative potential of low-tech industries

Innovation creates potential for growth, but involves risk (Bougrain & Haudeville, 2002, as cited in Cardoso & Torkkeli, 2009). In small or medium-sized companies, it is difficult to allocate resources to high-risk projects. Several strategies have been proposed to address this. First, internal and extra-sectoral networks and co-operative structures can minimize risks to individual companies from the insecurities inherent in innovation (Cardoso & Torkkeli, 2009). Second, inter-sector collaboration among craft industries can drive innovation and growth through evolution of techniques, discovery of new materials, and application of new tools, which can be applied to multiple industries (British Craft Council, 2016). Third, a case study of managerial innovation and collaboration in the footwear industry in northern Italy finds that a "Knowledge Integrator" enables sharing knowledge related to production, ideas, design, and global markets (Buciuni & Pisano, 2015). This led to an integrative supply chain, development of original knowledge, and a competitive advantage for all partners.

Reciprocal relations in the fields of production and design.

Production skills

Pye (1995) distinguishes between "the workmanship of certainty" - mechanized production, and "the workmanship of risk" - manual production. Manual production depends on manufacturers' skill and familiarity with materials and relevant processes. Risk and skillful manipulation of materials enable unplanned breakthroughs.

According to Sennet (2009), craftsmanship adds quality to the world around us. The quality of work is embedded in an ethic to do a good job for its own sake. The development of skills becomes implicit knowledge, enabling discovery of new techniques and achievement of different results. Knowledge-building is a circular, operational process that transforms implicit knowledge into explicit knowledge. This process requires many iterations of trial and error. Niderer (2009) points out that craftwork can express values that transcend time, space, and social boundaries. Its strength is based on an authenticity and intimacy with the object, which is absent from mass-produced products.

Design-production relations in the development of a new product

The combination of design, craft, and manufacturing has the potential to create innovation (Tomeltas, 2017; Wolley, 2011; Yair, Press & Tomes, 2001). Craftsmanship enables the selection of appropriate materials, structures, and technologies (Wolley, 2011). Ongoing involvement of design throughout the new product development process has a high potential for radical innovation (Roper, Micheli, Love & Vahter, 2016) The designer's contribution to the production process may be expressed in various stages of knowledge creation (Temeltaş, 2017). In craft industries, product development tends to be cumulative rather than collaborative. Products are derived from predefined capabilities.

Research Methodology

The research methodology included interviews with 11 informants from the industry and three experts. The interviews were recorded, analyzed, and categorized. A literature review was conducted on relevant issues in the field and global market trends. The study sought to deepen understanding of the various users and their relationships in the footwear industry in Israel. While developing the proposed solution at the final part of this paper, design thinking methodologies where applied including ideation meetings, prototyping and co-design.

The system is divided into five main axes corresponding to the stages of footwear production: market, design, technical development, production, and design training. These axes enable a broad perspective within the short research time. Informants represent different points of contact with various delegates in terms of enterprise size, place of production, and seniority.

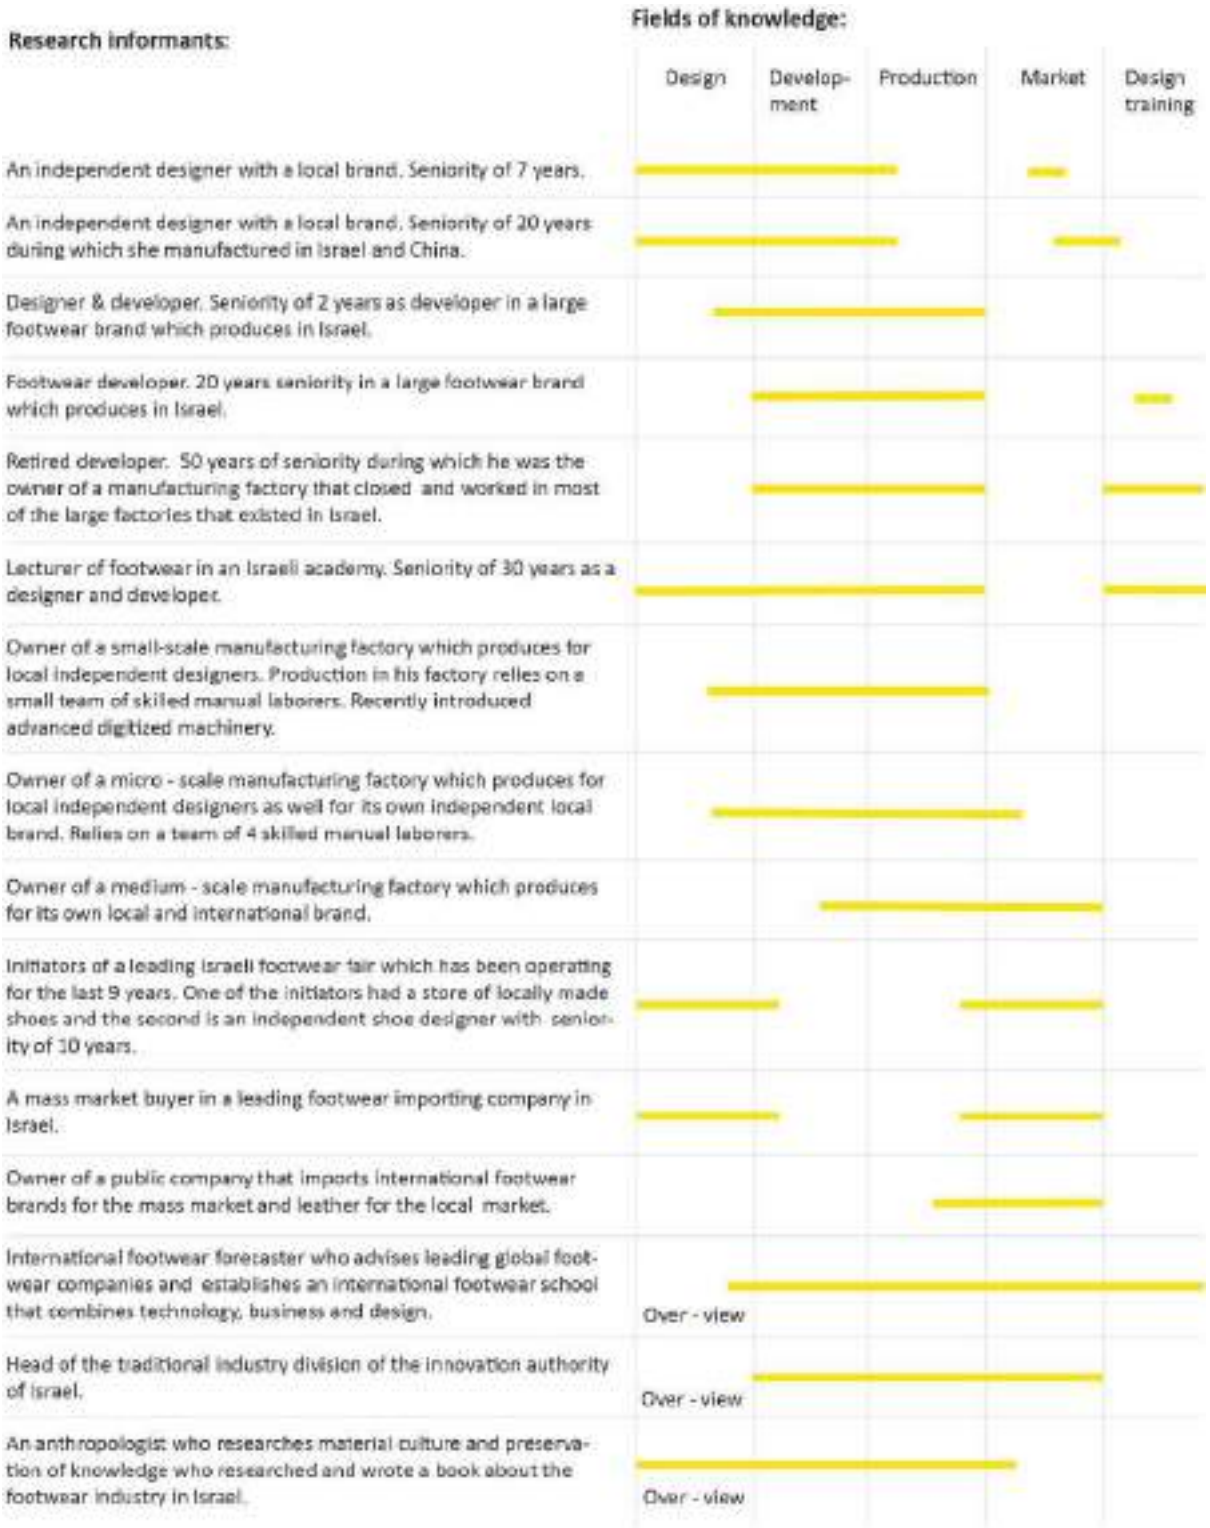

Figure 1: Research informants rationa

Variables prior to field research

This short-term study (four months) did not enable representation of all participants in the field. The researcher's professional experience in the field enabled access. However, some informants might have viewed the researcher as a potential competitor. The proximity of the researcher to the field is liable to distort the data due to prior assumptions.

Approval was received for recording each interview. Factory managers granted prior approval for interviews with workers. The purpose of the study was explained prior to the interviews. There was a request not to disclose details of confidential business information.

Research findings and insights

General background: The effect of opening trade borders on the local ecosystem.

Until the 1980's, footwear factories in Israel were family enterprises based on professional knowledge brought from the owners' countries of origin. They were protected from a competitive environment. In the 1980's, the Israeli government began to open the domestic market to foreign competition, in response to inflation. The local market was flooded with previously unavailable products, which varied in quality and price.

Background finding: The high production costs channel local production to medium- high-priced niche products

At present, there are three medium-sized factories and 30-40 small-scale factories in Israel. Footwear production costs in Israel are four times higher than imported footwear. The average expenditure on footwear in Israel in the mass market is around $62 US. Footwear produced in small factories in Israel costs between $110-350 to the final consumer. Operating in a niche segment reduces the target audience. The local market is small, as Israel is country of 8.5 million inhabitants.

> *"It doesn't pay off to produce here, it is suicidal - unless you have something very special." (importer of leather and footwear in a leading company in the market)*

> *"The biggest challenge in the local market is to get people to buy from me, there is a lot of competition and the market is small." (independent local designer)*

Differences in strategy between large and small producers

Insight: Medium -large factories emphasize professional management. Small factories specialize in professional knowledge of footwear.

Since the 1980's, many factories closed due to competition with global markets. The remaining enterprises have taken various approaches to survive in the new conditions. Large factories introduced professional management and strategic knowledge external to the field of footwear. Their products are of a functional nature aimed at a niche market such as comfort and outdoor. In contrast, small factories specialize in professional knowledge of footwear and are service providers for local designers who design stylish boutique footwear.

Secondary insight: The nature of the product affects planning, development, and production.

The findings show that large factories produce independent brands of functional character, which meet physiological needs (convenience and outdoor use) of customers in local and global niche markets. Small factories usually do not have an independent brand. They provide their services to local designers and produce fashionable products. The Israeli fashionable footwear market has a diverse price range and has been flooded in recent years by global retailers.

The literature indicates different processes of design and development for functional versus fashionable products. Functional products remain relevant long-term. Their development is a process of improving existing products and streamlining production. Fashionable products have a short shelf life. The pace of their development process is high and most of the production line changes every season.

Secondary insight: The factory's work practices change production costs and, accordingly, the factory's profitability.

Large enterprises produce in large quantities; they can therefore lower the cost of production through mechanized production. On the other hand, small factories that work with a variety of designers fail to maintain production lines that are broad enough to operate machinery; they therefore produce manually at a higher cost.

Secondary insight: The work practices of the enterprise impact the employees' knowledge base *and its ability to adapt flexibly to changes.*

Large production lines can be divided into many workstations. Thus, workers do not need to have professional skills for all steps in the manufacturing chain, and they are sometimes only familiar with a few specific workstations.

In contrast, small factories that rely on a varied but small customer base have small-scale, diverse production lines that require skilled workers who have a broad, flexible, professional knowledge base.

A large plant relies on mechanized and complex production lines. Therefore, creating a change in the production system requires heavy financial and logistical investment. On the other hand, a small plant is capable of changing the type of product produced and the production system relatively easily while relying on the knowledge of its employees.

This insight has helped identify the potential ability of small factories to adapt and implement faster, radical changes. The rest of the insights presented will therefore focus on small factories.

Disconnected manufacturers

Key insight: Service providers have lost the ability to respond appropriately to market conditions.

Small-scale manufacturers and service providers are alienated from the distribution system and end users. They remain dependent on the marketing and distribution capabilities of local designers.

Secondary insight: The development process replicates manufacturers' capabilities and does not encourage innovation.[1]

Designers are in direct contact with consumers. They mediate knowledge about customers for the factory, in the form of product design. The literature suggests that collaboration between craft and design encourages innovation. A continuous, rather than collaborative, product development process tends to replicate known capabilities. The development process adjusts the design to the production line, but designers are not involved in the production process itself.

> *"People do not think creatively about the production process because they are not exposed to it ... If a designer understood how things were made he could make better designs and if he felt the system was limiting he could redesign the production process." (trend forecaster)*

> *"When production and design were a single department, the designer brought a design that had a technological change in the performance and composition of the shoe. The approach to the shoe was completely different … and required a new production line and new equipment. This line became so successful that gradually most of the production changed to this method." (senior development expert)*

The distance between producers and consumers prevents them from identifying needs and offering a new value proposition. Manufacturers lack tools that allow them to offer an independent identity to customers.

Secondary insight: Designers' distribution challenges affect their ability to increase production. This prevents growth of small enterprises.

Most local designers use the same suppliers, distribution methods, and production methods, resulting in similar products. This congests the local market, preventing growth without additional resource investment.

Independent designers in Israel lack sufficient time and money to create efficient distribution networks and reach beyond the local market. Their distribution and marketing are often not based on professional business knowledge. Distribution depends on their ability to invest in development of an online shop, work with distributors, maintain a physical store, and sell at local fairs. Their distribution is mainly to local markets.

[1] *The creation of new knowledge that is the basic condition for innovation.*

"What designers need is help with advertising. 'Shuphuni' (the largest fair of Israeli shoes) gives them a big opportunity as a window display." (small manufacturer).

"The main obstacle to growth is lack of market. Going abroad is a much more complex operation" (entrepreneur of local shoe fair)

Inability to reach a wide market prevents designers from increasing production. The reliance of footwear manufacturers on the distribution capabilities of designers prevents them from influencing factories' production quantities.

Secondary insight: Identifying commercial and market realities is necessary for cooperation and innovation.

Small factory managers lack business and professional knowledge, leading to nonprofitable investment decisions and preventing return on investment.

Example 1: Manufacturer A invested in an advanced cutting machine and software. This increased product quality and improved the development process but did not return the investment due to lack of sufficient production.

Example 2: Manufacturer B invested in creating a website for direct sale to customers but did not consider the costs of digital marketing necessary for promoting it.

From a factory to a workshop

Key insight: The mass production model is not economically feasible for a workshop that produces in small series.

Most small factories were formerly medium-large family enterprises with independent brands and a mass production model.

"It's like producing just samples all the time. It does not permit for a flowing production line that can allow a sale or a production line to earn." (a senior development woman and a lecturer for footwear)

Manual production requires fewer employees, but each must have a broad skill set and responsibility for the final product. Therefore, manual production is a "work of risk".

Small factories operate more like workshops than like industrial mass production plants. Their small series production line is not profitable and traps them in survival mode. However, the literature indicates producing in small series presents an opportunity to move from a PUSH (build to stock) model to a PULL (made to order) model. To stimulate the innovative potential inherent in craft work, it must be combined with elements from other disciplines.

Survival mode

Key insight: Survival mode does not enable development of long-term strategies and differentiation from competitors.

A long-term strategy requires investment of time and economic resources. When the owner is struggling to maintain the business, investment of resources constitutes an existential risk.

"It's hard to manage a factory when you manage the nuts and bolts." (senior developer in a medium-large scale factory, former manufacturer)

Secondary insight: Differentiation and competitive advantage result from new knowledge or a new value offered to the customer.

In open markets in a competitive global capitalist economy, knowledge building is an indispensable resource enabling innovation.

"Traditional industry is defined as an industry whose knowledge is known. There is no change of knowledge here." (owner of a medium-large factory)

Creation as identity

Key Insights: Many factories in Israel were originally family enterprises, and the threat of losing their identity leads small manufacturers to perform radical changes in order to survive. Even when the enterprise is unprofitable, they try to maintain it.

> *"Whoever knows how to do, has to do. When I closed my factory, it was as if I was frozen. I was like a bird that had its wings cut off." (a small manufacturer)*

Decentralization versus union

Key insight: Creating partnerships in the footwear industry may reduce risk in development of knowledge and innovative products.

The reports of the Israeli Association of Craftsmen and the Israeli Association of Industry and Trade have not covered the footwear industry since 2007, due to its minimal contribution to the economy. This reflects the political attitude to the field.

Decentralization of the industry isolates each participant in their daily challenges and with limited resources. For small manufacturers, designers, and suppliers, unsafe investments endanger survival. Decentralization eliminates potential power and the ability to manage it systemically in current market conditions.

Risk of innovation can be minimized through internal and extra-sectoral cooperative networks, use of a knowledge coordinator (KI), and combining resources. This enables each network member to reach its potential and a competitive advantage.

Summary of findings and insights

The above insights were aimed to identify challenges and barriers in the industry which prevent its growth and threaten its existence.

The first major insight differentiated between two types of factories in the Israeli footwear industry: medium-large and micro-small. These differ in management, strategy, product character, distribution, product development, production quantities, job character, and employee skill. A comparison of these enterprises highlighted their strengths and weaknesses and led to the identification of opportunities for intervention specifically with small producers. From this point onwards, the research focused solely on these small factories/workshops.

Four *areas of opportunity* were observed:

Motivation - Small producers are willing to make radical changes in order to survive and maintain their identity.

Knowledge - The labor force in the small enterprises is more skilled and has broad responsibilities and therefore a broad knowledge of the entire production process.

Flexibility - Working with a variety of small producing clients in a market where the product turnover is high (fashionable shoes), established a working paradigm on small series that requires flexibility in planning and manufacturing.

Cost of changes - Small plants rely on skilled manual labor with relatively simple machinery. In contrast, the automation infrastructure in large enterprises is complex and extensive. It follows that change in small enterprises would mean retraining a well-skilled workforce and introducing new technology, and this would be considerably cheaper than the replacement of large existing automation infrastructures and the training of a new workforce.

Along with the opportunity zones, *barriers* were observed that prevent small enterprises from realizing their potential:

Disconnection - manufacturers have lost their ability to sense their environment and therefore respond appropriately to market conditions. This is reflected in the lack of independent distribution capabilities and working for customers that limit their knowledge of their end users. This detachment usually leads to the conservation of previously known abilities, and therefore does not encourage the creation of new knowledge.

Survival practice - the designers' distribution challenges influence the factory's ability to increase its production. The practice of mass production is not economic for a workshop which produces small quantities and leads to a state of continuous survival. This survival mode does not allow the mental and economic well-being needed to develop long-term strategies and differentiation from competitors.

A scattered industry - The Israeli footwear industry does not provide a significant profitable economic return, and therefore is not integrated by government agencies. There is no independent industrial association. This means that the industry is not valued, has no systemic vision, and has no collective power.

Drawing from the insights, the following *principles* led towards the proposed solution:

Additional perspectives from different disciplines must be introduced to the industry. This could serve as a basis for the development of strategies, production methods, and innovative products. *Collaboration* could help facilitate investments for innovative products and reduce the risk that comes with innovation.

Project Outputs

The insights helped reframe the research question as follows: *How might we preserve knowledge in the footwear manufacturing industry in Israel, and leverage it to create new knowledge and sustainable economic practice that can compete in the global market?*

The RQ formulated the basis for proposing a solution:

1. "Preserve existing knowledge by leveraging" - a mixture of existing knowledge with new disciplines.
2. "Sustainable" - beneficial for the producer, consumer and the social and ecological environment.
3. "Competitive economic practice" - creation of knowledge enabling a competitive advantage, differentiation, and added value to the consumer.

This preliminary research and ideation session yielded two outcomes. The first is the collaborative design of a product and its manufacturing process. The second, a derivative of the first, is a technological digital platform to be used by small manufacturers.

First outcome – Design of a product and its manufacturing process

First, since the research identified the manufacturers' disconnection as one of their main challenges, a new model of a shoe and its production process were co-designed with a local manufacturer. During this process the researcher served as a knowledge integrator (KI), mediating knowledge on market trends, consumers, and advanced production technologies.

This led to the selection of a triple bottom line business strategy which allows for sustainable innovation.

Following by are the characteristics and decisions that compound the design of the product and its manufacturing process:

Consumer trends: The rise of online consumption has changed consumer expectations from service providers and products: Consumer power increased, niche markets expanded, and consumers began to express a growing desire to be involved in product design and its adaptation to their lifestyle. An example of this trend in footwear is the steep drop in sales of tailored products and the growth of a new segment, *Athleisure*, indicating a leisurely and sportive lifestyle.

Production and distribution trends: New technologies enable lean production, such as Additive Manufacturing, and enable small-scale, rapid, local production and personalized products. For example, smartphone applications assist in the collection, transfer, and analysis of consumer physiological data. These trends change the value chain of products, and the need to mediate between producer and customer. Inventory costs related to forecasting and purchasing are reduced.

Product Characterization: The strategy focused on one main product that would offer personal value through 3D foot scanning and manufacturing of a footbed and 3D printed soles. This enabled a lean and uniform production process to be developed. Product development drew from a sustainable "design for disassembly" perspective. The market segment is unisex, everyday wear, and leisure. Distribution and marketing are online.

Figure 2: The shoe design – made from 3 materials that are attached to each other only by sewing. The insole - sole is a one-piece 3D printed according to a specific foot.

Product Value Chain Mapping*: Following the characterization of the product, a process of in-depth research was initiated. Meetings were held with experts[2] in fields related to the value chain of the product as a system. The experts helped map out the steps required for development[3].*

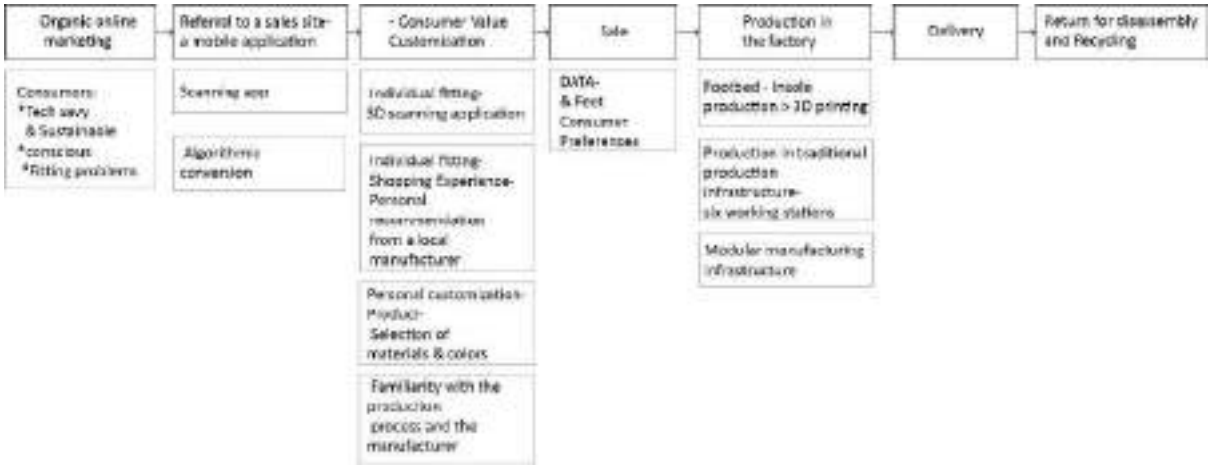

Figure 3: Value chain of the product as a system.

Sustainable product development: Recyclable materials are used. The shoe is connected by sewing, without adhesives. This allows for simple disassembly of the product at the end of its life cycle.

Development of the production process: Intervention in the existing production line with the assistance of the manufacturer has allowed for reduction of the number of workstations from 12 to 6. The manufacturing process allows for connecting shoe parts only by sewing.

3D scanning and printing technology enable employees to respond to new production capabilities and needs in planning the production line. This enables production of a single model with endless modes of expression adapted to the consumer's foot structure, style, and values. This model can be executed within a single, uniform, and continuous assembly line. It therefore reduces the production cost of the shoe.

Consumer Value Proposition - Product: Durable footwear customized to physiological data.

Consumer value proposition: purchasing experience: Personal recommendation from a professional, personal acquaintance. An illustration of the product and the consumers' shopping experience can be seen in the Know-Me Video. [4]

[2] *A senior development man in a large footwear factory, two entrepreneurs in the field of additive manufacturing, materials specialist, e-commerce, digital marketing, programmer of orthopedic software for three-dimensional.*

[3] *Some of the meetings with experts were conducted with the manufacturer and at his initiative, and the researcher mediated some meetings.*

Second (following) outcome - Development of the Know-Me platform

Cost calculations of the value chain of the product introduced in the prior chapter revealed an economic barrier to manufacturers. Gaps were found between the shoe production costs at the plant and the costs of operating the digital site, marketing, and data analysis. This led to a shift from a system serving a single enterprise to one serving multiple enterprises and offering a variety of products to consumers.

The proposed solution, Know-Me, is a technological digital platform that designs:

- Direct contact between manufacturer and consumer
- Lean and modular production processes
- A database that can be converted into business opportunities

The platform model is based on an open platform linking online shopping opportunities to strengthen the connection between manufacturer and consumer. Three design values were defined as guiding principles for the platform value proposition to the end consumer: personalization, personal connection, and environmental impact (locally and globally).

Value proposition to consumers: Artisanal approach to a digital relationship

A review of the changes in production processes between pre-industrial craft production and global mass production identified values that could be leveraged as a new value proposition to consumers. These include the nature of the consumer-producer relationship, generic versus personalized products, and implications of the production process.

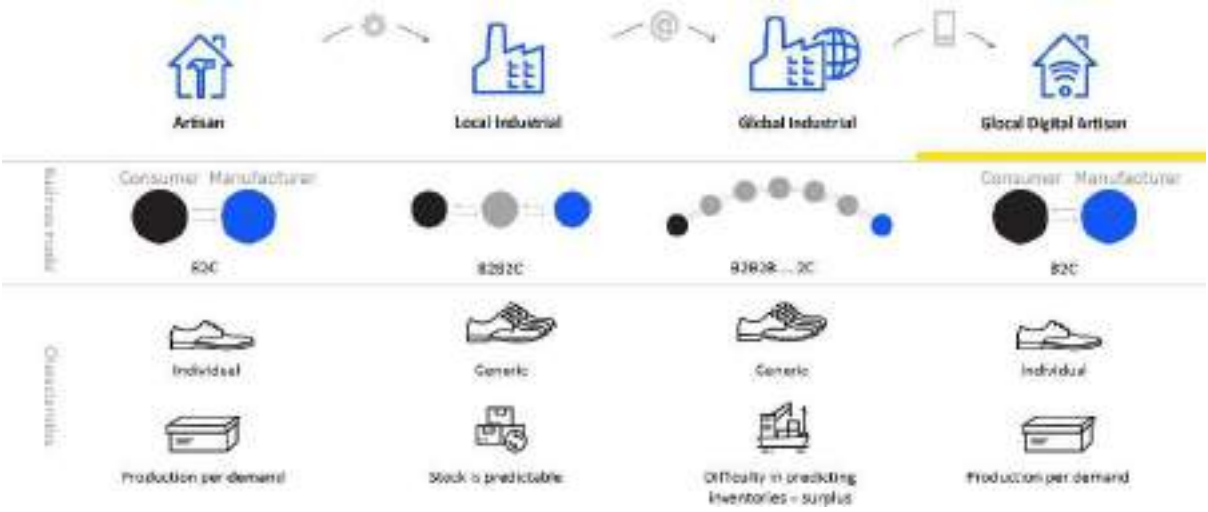

Figure 4: Production overview. New technologies facilitate the return to artisanal production values (craft) in a new digital configuration in the glocal (global/local) system.

The primary value offered and marketed to the consumer*: Personalized product and communication. The online selling site enables reception of physiological and other data from the consumer. In turn, the consumer receives personal and professional recommendations from the manufacturer.*

The added value to the consumer: The possibility of buying a product with sustainable value and responsibility for the end of the product's life. During the buying process, consumers can select the material, reflecting their worldview. Also, they have an opportunity to get acquainted with the manufacturing process and the manufacturer.

The value of sustainability is expressed in a product designed for disassembly. It can be collected from the customer at the end of its use, easily disassembled, and the materials recycled and/or reused. This enables the following sequence of production on demand: designing modules and production infrastructure > customer personalizes & customizes the design > purchase > manufacture.

Values to manufacturers

The platform offers the manufacturer accompaniment on three levels:

A. Product development process and production process

On-Boarding - The platform assists in co-developing a product and manufacturing process prior to the start of work. This is designed to adapt the product to a relevant target audience with a clear marketing value while maintaining an economically feasible production process and developing existing knowledge in the plant. The platform is used as a knowledge integrator.

Development of the production process - Development and design of the product takes place together with creation of a production infrastructure based on principles of minimal modules and workstations. This minimizes inventory of raw materials and eliminates excess stocks. It introduces technology to the plant that enables personal production on demand. This holistic process simultaneously considers product design, production, employee skills, and customer experience.

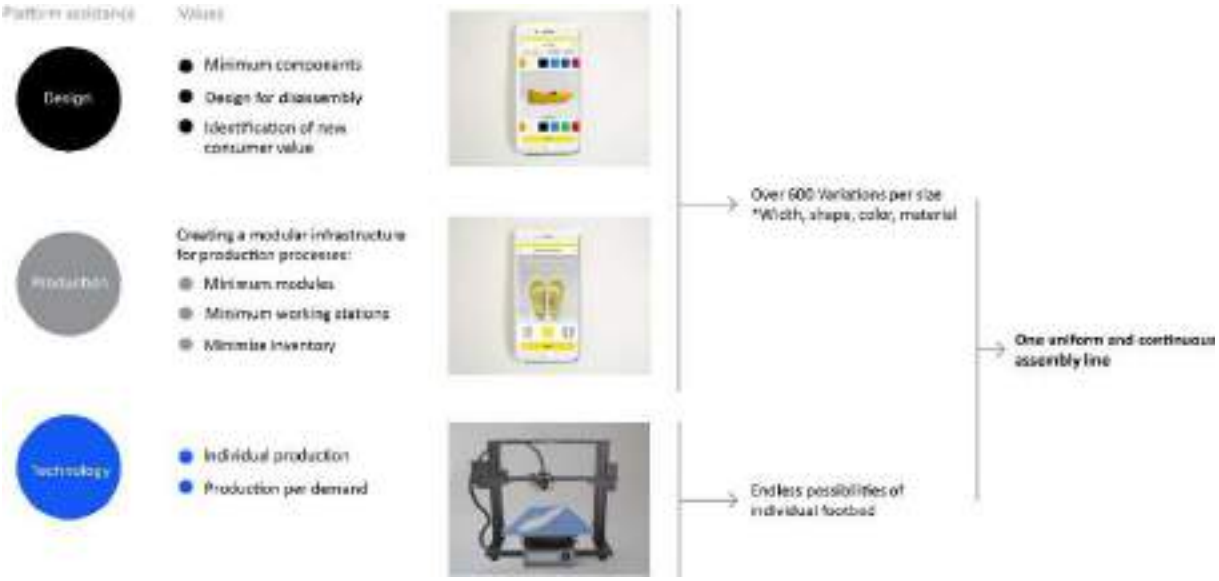

Figure 5: Product development and manufacturing process with a local manufacturer.

B. Support for ongoing activities

In daily operations, the platform manages the sale site, digital marketing, customer service, digital operation of the site and its applications, and transferring files needed for technological production (for instance 3D printing). The platform collects data and makes it accessible to the manufacturer. This is reflected in digital inventory management, production instructions for workstations, and communication with suppliers.

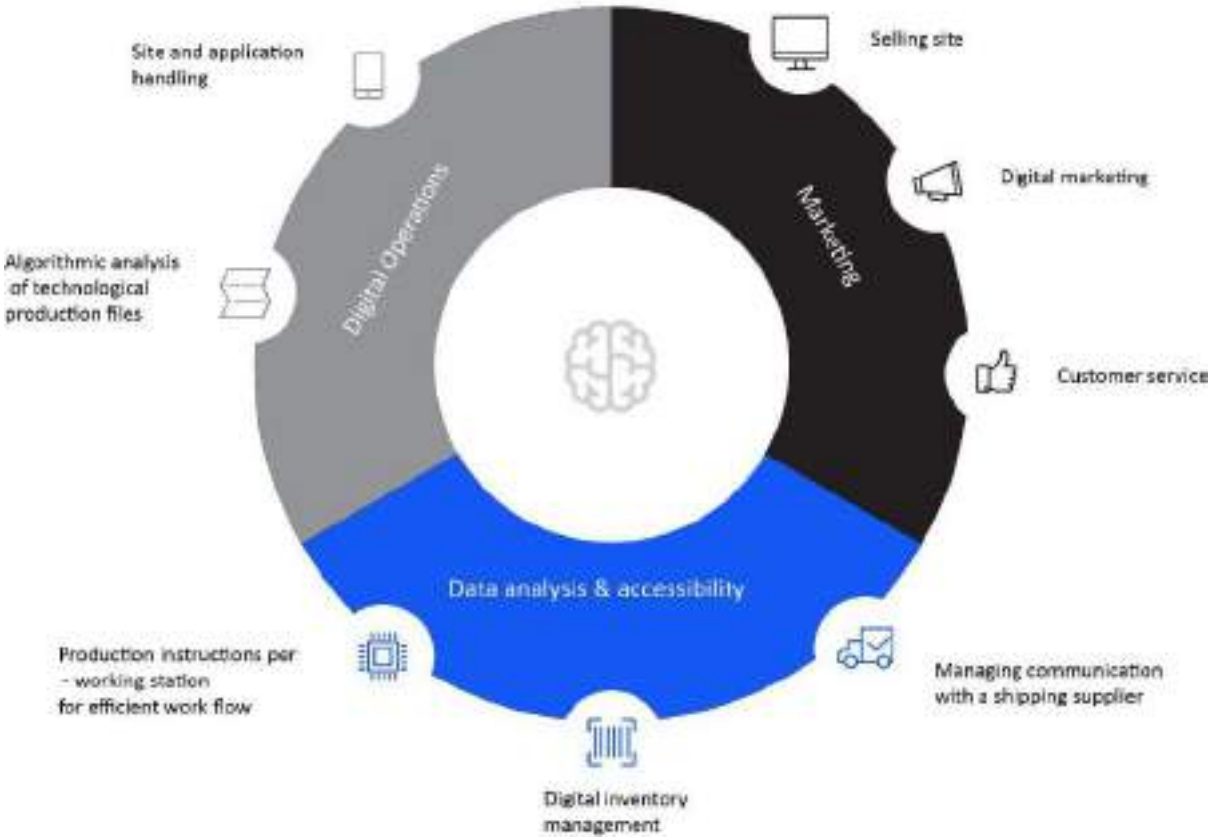

Figure 6: Platform support for ongoing activities.

C. Database and future R&D processes

Digitization can revitalize local production. New technology in the production process enables development of manufacturing capabilities. Data on customers' behavior and foot physiology will help identify opportunities for further development. This combination enables an interconnected and sustainable production process that can be continually updated and improved.

In the long term, the platform will enable creation of a unified network of an updatable and decentralized production process, which can be connected to additional workshops and industries to create new opportunities. The platform will unite plants in the collection and analysis of data, logistics, marketing, and distribution. It will allow for individualized production processes for different manufacturers, enabling a wide range of products for customers on the selling platform.

Environmental and ecological values

Short-term: Design for disassembly enables recycling or reusing materials. Eliminating final product inventory by producing on demand and reducing raw materials inventory.

Long term: Products will be offered to a local and global clientele. After identifying consumers outside the original production location, the platform will locate local producers in the new geographic location and initiate local production of the product near that customer.

Summary

The research presented in this paper finds that improving the connection between production and design within the footwear industry and with other industries may enable the creation of new knowledge regarding the product and the consumers. This can lead to a competitive advantage for the Israeli footwear industry and serve as a potential growth engine for local production.

The proposed solution is a platform used as a digital and technological platform for micro-small manufacturing plants. The platform mediates and shapes the connection between production, technology, and design. It

enables creation of a joint R&D system with the potential to develop strategies, production methods, and innovative products. It overcomes barriers of the global market and leverages the advantages of personal contact with the consumer.

The platform can serve as an infrastructure for developing a system that creates innovation. It could minimize the inherent risk of investing in innovation by creating a co-production and co-R&D network for manufacturers.

Track 5.b Introduction: Strengthening the Design Capabilities of Professional Organisations in a Complex World

VAN DER BIJL-BROUWER Mieke; PRICE Rebecca; WEGENER Frithjof and SMULDERS Frido

Delft University of Technology, Netherlands
doi: 10.33114/adim.2019.5b

Introduction

In Hong Kong of the year 2017, a new academic community convened to attend to pressing issues regarding design as source of innovation. The inaugural Academy for Design Innovation Management Conference (nee Design Management Academy) attended to a sense of urgency regarding the adoption of design capabilities within organisations as source of innovation. The title of the conference, *Research perspectives on creative intersections* was therefore pertinent, with papers exploring how design and designers were intersecting with new business challenges. Two years later in London (2019), rhetoric has notably shifted from matters of adoption to strengthening design capabilities within organisations, thereby enabling those organisations to unlock the possibilities and subsequent benefits of design. These possibilities include but are not limited to strategic and cultural renewal, design of new processes and meaningful engagement with hard-to-reach stakeholders.

To address the complex nature of today's societal and economic problems, professional organisations now recognize that traditional tools and approaches may not provide the required solutions. To address complex challenges, many managers and business leaders have consciously turned to design approaches over the past decade, including both public and private sectors (Bason, 2010; Dorst, 2015b; Irwin, 2015). To increase design capabilities, these organisations have established innovation labs with designers, have recruited designers in strategic positions, and/or have started building the design competence of existing staff through educational programs, often provided by design consultancies. Yet to date, describing the resultant impact of teaching. Individual design competencies on organisational design capabilities (Salvato & Rerup, 2010) has proven elusive.

There is limited evidence of the impact of design capability building within private and public sectors, although many seem to agree that workshops and short courses in design thinking do not lead to the required change. We identify that ubiquitous post-it-note workshops have become the associated image of designing shared by many practitioners. Yet this simplistic association reduces design to undisciplined brainstorming – an association that may be counterproductive to greater elevation of design as means to address complex societal challenges. Furthermore, capability building programs do not always build on contemporary educational and social theories of workplace learning which highlight the social and complex nature of how professionals learn (Hager, 2011; Orlikowski, 2002). This situation is further complicated by the fact that design for complex societal problems differs from traditional design practices, and should be *adapted* to the needs of this 'target field' (Buchanan, 2015; Dorst, 2015a; Smulders, Dorst & Vermaas, 2014; Van der Bijl-Brouwer, Kaldor, Watson, & Hillen, 2015). This means that design practices need to be adapted to deal with the complexity inherent to societal problems and organizations, and the political nature of dealing with divergent stakeholder needs. Happily, we observe that the scope of this Academic for Design Innovation Management

Conference in London (2019) has broadened to reflect the rich array of contexts in which designers now find themselves with contributions spanning across the public and private organisational spectrum.

Introducing the contributions to this session

The applications of design in complex contexts are diverse, as demonstrated by the wide variety of application areas represented in the papers that were submitted to this track session, ranging from the government, the financial sector, a supreme audit institution, an academic library, the science community to an airline. Each of these organisations has unique structures, processes, and histories which require customized adaptations of design and of the way it is introduced.

In the first paper of the session, Kim & Van der Bijl-Brouwer present an explorative study of the introduction of design practice within governments and conclude that embedding these practices is not just about developing skill-sets, but also requires organisational change. Rothkotter, Garner & Vanja present a literature review of the application of design in a science-based innovation context. Their results show a range of different types of design capabilities apparent in science-based innovation. They discuss the challenges at the creative intersection of science and design. Meijer-Wassenaar and Van Est work for the Netherlands Court of Audit and present a study of their work of introducing design practice to their organisation. They discuss how design practice needs to be adapted for use in supreme audit institutions. A second application of design in an academic context is presented by Gasparini who shows how design capabilities can be built within academic libraries, and how that brings (and requires) openness and dialogical spaces. Close-Debais & Matthews present an evaluation of the perceptions of design capability by staff from a financial service organisation. A critical discussion of what design competency is and how it can be built follows. Finally, Stoimenova, Stomph and de Lille present their action-research study in which they used design to develop 'organisational prototypes' for the ways of working, infrastructure and culture of an airline. Stoimenova and colleagues argue for continuous prototyping so organisations can adapt to a complex and dynamic context.

We have learned from our track that implementing design capabilities is not just a matter of exchanging one way of working for another. Design capabilities are novel and unprecedented in most of the present application areas we have witnessed in our track. Design capabilities in performative state could bring specific contributions that are believed to shed new light on existing (complex) challenges, unlocking solution spaces, in most cases unfamiliar to the actors involved. Based on the papers in our session we have identified three organisational subjects that are important to consider when building design capabilities. First, the topic of organisational learning that is undoubtedly related to implementing design capabilities must be more closely attended to. Second, developing design-rhetoric to better reflect organisational contexts in which capabilities are being built. Lastly, and very much interrelated to one and two, the need to acknowledge organisational changes that occur as collateral effects of implementing design capabilities.

Individual, collective and organisational learning

Two key questions to consider when approaching the task of strengthening design capability are; (1) how we learn, and (2) how we learn collectively in the context of professional organisations. From an individual learning perspective, theories such as experiential learning (Kolb, 1984; Moon, 2004) and practice-based or situated learning (Lave & Wenger, 1991) are commonly applied when teaching design skills in a professional context. Learning programs were proposed and/or discussed in five papers in this track session, all with an experiential 'learn-by-doing' element. Three of the papers showed cases of situated and practice-based learning where non-designers were actively engaged in 'design experiments' to introduce designerly approaches to their own organisation. For example, Stoimenova et al describe how airline staff were actively engaged in 'prototyping' ways of working and how that created noticeable change in the capability of the team. In this way design capabilities are built from 'within' the organisation with non-designers by demonstrating the possibilities of design, much akin to the work of Price, Wrigley and Matthews (2018).

While theories of individual learning have a long history, and organisational & team learning came up as a concept in the nineties (Argyris & Schon, 1996; Senge, 1990). More recent theories of professional learning focus on the complexity of organisations, and acknowledge that learning needed for successful performance in an occupation cannot be specified in advance or imparted in a formal course (Hager, 2011). Instead these theories conceive of knowledge as situated, negotiated, emergent, and embedded (Gherardi, 2009), and acknowledge that learning is not independent from context. Instead workplace learning and performance are

considered to be significantly shaped by social, organisational, cultural and other contextual factors (Hager, 2011). With the shift from collective and professional learning to a situated understanding of organisational learning, building design capability shifts from predefined context-independent design programs, to building learning spaces that allow design capability to evolve to allow adaptability of design practice (Elkjaer, 2004). A nice example of this is shown in the paper of Gasparini, who presents a range of different capability building interventions for public libraries, resulting in the design of 'dialogical spaces' where participants could feel safe, share knowledge, stances, and ideas freely.

A design language and vocabulary

A reoccurring topic that came up in the paper presentations was the language that was used to articulate what design is. The language impacts both the understanding of what design is (and what it is not), as well as the more emotional acceptance of new ways of working.

The first goal is about explaining to staff or colleagues how the act of designing has the potential to contribute to the purpose of the organisation in different ways. Gasparini described in this track session how building a design and project vocabulary are of paramount importance for building and sustaining design capability. For example, part of the design vocabulary discussed in the session was Buchanan's four orders model, which was used in both the Court of Audit study (Meijer-Wassenaar and Van Est) and the Science based innovation study (Rothkotter, Garner & Vanja) to explain the how and what can be designed (Buchanan, 2015).

The second goal of design language is related to the emotions involved in the discomfort that can often be experienced when new ideas presented that do not align with current views (Frese, Wegener & Smulders, 2018) and ways of working (Smulders, Dorst & Vermaas, 2014; Wegener & Smulders, 2019). The researchers from the Court of Audits for example explained how they developed a 'customised' language with terms that are related to elements of design, but are explained in terms of the language used within the organisation. The conference track session raised discussion of the 'Trojan horse' as a means to introduce design practice without explicitly calling it design. Applying design related activities like experimenting and visualising need not be referred to as 'design' as these activities are grounded in many disciplines. We see this distinction as a way to prevent entanglement in ambiguous discussions on what design is and what it can bring. An emphasis on action, demonstrating and experiencing design, is what engages stakeholders and overcomes hesitancies to a novel way of working (Price et al. 2018).

The development of a vocabulary and language are important elements of designing (Dong, 2007). Boland, Collopy, Lyytinen, and Yoo (2008) explain how "the design attitude includes an expectation that an organisation's familiar language will be subject to scrutiny" and, "that new vocabulary elements are expected as an emergent outcome of seeking to create a more desirable state of affairs" (p.22). They further argue that a critical awareness of vocabulary might also benefit organisation design. The discussions in this track session further contribute to this claim and suggest that building a new and customized vocabulary that draws on a linguistic perspective of designing as learning can strengthen design capabilities.

Organisational change

When addressing design capabilities in organisations, designers and design scholars are faced with an organisational-level phenomenon. Organisational capabilities are firm-level assemblages of lower-level routines (Nelson & Winter, 1982) and go beyond individual competencies (Salvato & Rerup, 2010). Therefore, to understand strengthening design capabilities of organisations, a sophisticated understanding of organisational change is needed for building organisational capabilities and underlying routines. The different papers within this track conceptualise organisational changes required to strengthen organisational capabilities for design as changing *practices*, changing *processes* and the *process of inquiry* inherent to organisational change.

Changing practices in organisations as a way to strengthen organisational design capabilities was a focus in several papers. For example, Meijer-Wassenaar et al. draw on Sparrow (2000) to conceptualize organisational change as requiring a change in practices instead of just changing regulations.

Changing processes, as bundle of practices, was another way of conceptualizing the organisational changes needed to strengthen organisational design capabilities. Close-Debais & Matthews highlight that building design capabilities in organisations requires changes in methodologies and practices (p.2). Similarly, Gasparini

conceptualized organisational change as “repeated interventions (each having a different design goal), and over time, led to integration of these ways of thinking and working with daily routines, transforming the work practices in the library” (p.2). Interestingly they link organisational change with organisational learning through referring to the process of inquiry by Dewey (1938) , as previous scholars in design have done (Junginger, 2008; Melles, 2008).

The process of inquiry inherent to organisational change is exemplified by Stoimenova et al. Their work highlighted the processual nature of organisational change as, "emergence of an adaptive organisational structure by tracing its evolution from the introduction of methods and tools to the full adoption of a new way of working" (p.2). Interestingly in their work they change organisational processes as stepping stones toward the process of organisational change. This reflects discussions in organisational change literature, highlighting that the changes of organisational processes (conceptualized as organisational routines) is an analytically fruitful way to study organisational change (Becker, Lazaric, Nelson & Winter, 2005; Feldman & Pentland, 2003). In line with this processual perspective on organisational change, Kim & van der Bijl-Brouwer problematize the very concept of 'embedding design'. Their discussion drawing on design and organisational development literature conceptualizes embedding design as "combined effort of introducing design practice and sustaining and amplifying design-led change energy until it transforms the public organisation" (p.3). Their work highlights the need to change practices, the processual nature and the requirement to transform the whole organisation toward a preferred state.

Together these studies highlight the required organisational changes when building a capability for design in an organization. Design often results in new concepts that not necessarily comply with existing ways of working (Smulders et al., 2014). An organisational design capability requires bringing new concepts from design to realisation, needing changes to existing practices, processes and engage in more fundamental organisational change (Junginger, 2008; Wegener & Smulders, 2019).

A research agenda for design capability building

When addressing design capabilities in organisations in a complex world, designers and design scholars increasingly are faced with pedagogical and organisational considerations. In this introductory paper we have highlighted topics such as educational models for individual learning and collective learning, the language and vocabulary used, and an understanding of organisational change. The different papers within this track reflect these different ways of conceptualising learning and the organisational changes required to strengthen capabilities for design. These discussions and papers are important stepping stones toward a fuller grasp of what it means to strengthen design capabilities in professional organisations in a complex world.

To further advance the field of design capability building, we propose a future research agenda that combines building a more expanded empirical base of effective capability building strategies, with a grounding of these strategies in relevant disciplines, including organisational learning and pedagogy, linguistics, and organisational management. Questions include for example:

- What does a ‘mature level’ of design capability in organisations look like to achieve their organisational purpose and goals? How can we measure that?
- How can we develop design and project vocabularies that strengthen design capability building?
- How can we ensure organisations are able to reap the benefits of deploying design capabilities?
- How do we build effective learning spaces to collectively reflect and organise dialogues that promote an ongoing practice of (organisational) learning?
- In line with the above, how do we organise for experiments based on these learnings that result in an evolving adaptive practice?

We argue that addressing these questions requires an interdisciplinary approach, bringing together theories and insights from design with those from for example learning, language and organisational studies. This requires us to move beyond our mono-disciplinary academic design community and engage with academics from these other fields. It also requires an engagement with practice, by actively experimenting with new approaches to strengthen design capabilities. Indeed, this diversity of disciplines and professional backgrounds was clearly represented in the audience and participants of the track session. We hope the session contributes to building a connected community of practitioners and academics to advance the body of knowledge on how we build, strengthen and sustain design capabilities in professional organisations in a complex world.

Acknowledgements

We would like to thank the authors in this track for their paper contributions and for their engagement in the track discussions.

doi: 10.33114/adim.2019.01.301

Design is today suggested as an alternative way of working in government contexts. Many developed nations are trying to embed design in their public organizations. Yet recent studies have shown that design is not easily permeating into everyday practice of public organizations. This research therefore aims to understand what the current practice of design-embedding in government is like and its limitations by interviewing six experts in the design for government field. The research findings reveal that the changes created by the current design-embedding practice in government are not being actively sustained or amplified. Based on an understanding of organisations as complex systems, we suggest a further practice of design-embedding in which designers steward and stimulate design-led change energy within public organizations. This study shows that embedding design capability in professional organizations is more about design-led organizational change than passing on a design skillset to the organizational members.

Keywords: Embedding design in government, design for policy, complex systems, design-led organizational change, design capability building

Introduction

We are living in a hyper-networked society that generates wicked problems – the ones defined as “complex, unpredictable, open-ended or intractable” (Head & Alford, 2015, p.712). As governments cannot properly handle these problems in their old ways, they are trying to make changes in their ways of working. Design in this situation has risen as an alternative way of working in government contexts. The experimental, human-centered and co-creating approach of design is praised as opposed to government’s bureaucratic, risk-averse, hierarchical and siloed ways of working (Bason, 2010). As a result, in recent years hundreds of public innovation labs using design as their core methodology have been created worldwide (Fuller & Lochard, 2016; Mortati, Christiansen, & Maffei, 2018).

Design has engaged in complex problems of business and service areas before, but in the unique context of government design is faced with many challenges. Firstly, designers are criticized for the lack of policy-relevant skillset and knowledge and the lack of commitment to implementation (Mulgan, 2014). Secondly, recent studies have revealed that the aforementioned design-led public innovation labs are having a hard time entering mainstream policy practice (McGann, Blomkamp, & Lewis, 2018; Mintrom & Luetjens, 2016). Lastly but not least, the closing of leading public innovation labs such as Helsinki Design Lab and Mindlab seems to suggest some challenges in the current approach of embedding design in government. Overall, despite its merits in government context, design is not easily permeating into the day to day practice of public

organizations. Designers and public leaders interested in the design-led public sector innovation have not yet fully grasped how to embed design in government.

Therefore, this research aims to understand the current practice of embedding design in government and its limitations, by interviewing six experts who are working inside and outside of governments in the design for government sector. This preliminary study for a doctoral thesis will serve as a starting point for further development of practical knowledges for design practitioners and public leaders who are interested in the design-led public innovation and especially those who are in the stage of scaling design-led change in public organizations.

* *Explanation of the term 'design/ designer' in this paper*

In this paper, the term 'design' refers to the design practice (or its approach) conducted in solving societal problems by the public sector. It is often used interchangeably with design thinking or designerly ways of working. Design as an approach to problem solving is characterized by abductive thinking and act of framing (Dorst, 2011). Design in the public sector deals with problematic situations where the desired values are known but what causes the situations and how to achieve the values are unknown. Thus, the design process involves co-evolution of the problem and the solution as well as the act of adopting certain "working principles" to describe the problematic situations (Ibid, p.525). This designerly way of problem solving is considered to be fundamentally different from the deductive thinking processes commonly preferred in public organizations. 'Designer' in this paper concerns both design-trained and non-design-trained people who practise design in the public sector.

Literature review

In this section we will briefly explain why design is desired in government contexts. Then, it is examined how design literature illustrates what 'embedding design in government' means and how to practise it. Lastly, we define the concept of embedding design in government based on the understanding of organizational change and development theories.

Why design is desired in government context

Policy can be defined as a course of actions that a government takes to solve societal problems while governing the state (Colebatch, 2009). If policy is the act of problem-solving, the making of a policy entails operations similar to designing such as defining the given problem, setting a preferred goal, and deliberately attempting to achieve the goal (Ibid). In fact, the concept of policy design has existed since 1950 in policy context (Clarke & Craft, 2017). However, today's policy design is more about co-designing a policy with multiple actors in open and networked systems as opposed to the closed and siloed ways of policy designing by a few actors in the past.

The reason why the co-designing ways of policymaking receive attention today has to do with a change in governance paradigm. In the current governments of developed countries, there are three paradigms of governance - traditional public administration, new public management, and networked governance. Hartley (2005, p.29) explains that all the three paradigms coexist as "layered realities," but it is reported that "significant elements of networked governance are seen in countries such as the UK, the USA and Australia" (Bason, 2010, p.10). Furthermore, it is known that the wicked societal problems of today are best dealt with in the networked and collaborative ways of policy-making, as involvement of multiple actors improves the understanding of a problem and ensures that needs of citizens are taken into consideration (Sørensen & Torfing, 2016). Thus, public servants and policymakers are asked to have the design capability that helps them understand the given problematic situation, find a real problem, and co-design its solution with other policy actors.

Design is also favoured for the sake of government innovation. Mulgan and Albury (2003, p.3) point out that current "practices, structures, cultures and modes of operation of public services, government departments and agencies" are shaped in the time when the needs of citizens were homogeneous. For the systems of public organizations are no longer suited for the diverse needs of citizens and wicked societal problems of today, the public sector is urged to change (Ibid; Hartley 2014). In this context, design is proposed as a major driver to the public sector transformation. Design is believed to help government not only design public service and policy but also "achieve wider long-term aims of growth and quality of life for its citizens" (Design Council, 2013, p.4).

What 'embedding design in government' means and how to practise it

Despite the increasing interest in 'embedding design in government,' what the concept means is not sufficiently discussed yet. How we define the concept is important since its definition can influence how to practise it. We firstly examine how current design literature explains what embedding design in government means and how to practice it, and secondly propose how the concept can be newly defined based on organizational change and development theories, as design in a government context is a change or innovation.

The British Design Council (2013, p.8) (BDC) made a model called the public sector design ladder to describe different levels of design used in public organizations. In this progressive three-step ladder model, embedding design is explained in the second step "design as capability," where, as BDC explains, design "becomes part of the culture of public bodies and the way they operate and make decisions." In this model, embedding design is a step below "design for policy," the stage where design is used by policymakers. However, in reality design can be used by policymakers before design becomes embedded in public organizations. This model is therefore rather confusing to explain the concept of embedding design in government properly.

The Scottish service design firm Snook and Design Managers Australia (2014) describe embedding design in government by three different embedding activities: embedding design capability and skillset, embedding design thinking, and embedding a lasting environment for design practice. This understanding seems to be more comprehensive than the design ladder model as it interprets embedding design as building not only design capability but also an environment for the sustainable practice of design. Nonetheless, a limitation of this explanation, as well as of the design ladder, is that it does not acknowledge the complexity in the design-led organizational change process in the design-embedding practice.

Design literature has paid less attention to the complex organizational change process also in explaining how to practise design-embedding in government, how public employees and organizations are transformed through design experiences. Sangiorgi (2011, p.29) claimed that the design process – the co-design process, precisely speaking, as co-designing is the norm in the public sector – "necessitates the concomitant development of staff, the public and the organization." It is also asserted that design process is not necessarily a change management process and "leaving the participants with the tools and capacity to continue to adapt and innovate means […] that organisational change will continue to happen" (Burns, Cottam, Vanstone, & Winhall, 2006).

However, such optimistic prospects about organizational change contrasts with the general opinion of organizational change experts. Roehrig, Schwendenwein and Bushe (2018) claim that "without an amplification strategy in place, chances are the energy and momentum [of a change] will dwindle." Only few design scholars such as Deserti and Rizzo (2014, p.86) criticized the pervasive idea that introducing design practice in public organizations will work "per se." They warned that designers' lack of concern for managing and fostering a design-led change process could "lead to the rejection of the new practices or confinement of them to a cosmetic role"(Ibid, p.87).

According to the theories of organizational change and development, 'embedding' of any change or innovation is the last stage of a change process (Hayes, 2018; Roehrig et al., 2018). It is a state where the change is sustained so that people in the organization no longer go back to their old ways of working. Behavioural changes are observed in leadership and people's roles, and cultural and structural changes are followed (Hayes, 2018). Most importantly, embedding design in this understanding means not only introducing and implementing design practices in government but also "encouraging and growing the energy, inspiration, and networks" of design-led change that will eventually make changes in every aspect of government- mindset, culture, practice, leadership, decision-making, and structure (Roehrig et al., 2018, p.325). In sum, embedding design in government based on the organizational theories can be defined as a combined effort of introducing design practice and sustaining and amplifying design-led change energy until it transforms the public organization.

Research methodology

Out of the literature study, we drew a preliminary conclusion that the current practice of embedding design in government may lack the practice of sustaining and amplifying design-led change within the public organization. To further explore this topic we set up a study that aimed to answer the following research questions:

1. What is the current practice of embedding design in government?
2. What kinds of changes are being made by the current design-embedding practice in government?
3. How are these design-led changes being managed (sustained or amplified)?

This research is based on the worldview of social constructionism. Social constructionism believes that the meaning of reality depends on social interactions and agreements between members of society, and thus communication and interaction shape the reality (Barrett, 2018). In this epistemological stance, this research aims to understand the practice of embedding design in government by interviewing six experts who are practicing design in the public sector.

Interview participants are recruited through networks of the researchers as well as using the snowball method. Out of the total six participants, three were experts working outside of government, and the rest were experts working inside government. Their work experience was limited to more than and equal to two years, and three of them were in senior positions in their organizations. Their geographic base varied such as Singapore, Australia, Finland, Canada, and the U.K. Please note that selecting participants from developed countries only limits the generalisability of this study, and we acknowledge that the results discussed in this paper might not apply to governments in other parts of the world.

The interviews lasted approximately thirty minutes to one hour in a semi-structured way through Skype. The interviews were recorded under the consent agreement of participants. We examined the data through thematic analysis and interpreted the results through the theoretical lens of complex systems. Interview questions included for example: Do you perceive change in terms of the adoption of design in the way government works? How do you ensure the change will be ongoing? In an ideal future, what would design in policy context look like?

Table 1: information about interview participants

Experts no.	*Type of organization they worked/ work for*	*Design training*	*Type of activities with government*	*Overarching view on design-embedding practice in gov.**
1	Senior designer in design research center of university	Yes	Design capability building, design projects for policy	It is a very slow process, but design-led change is happening in government.
2	Researcher in university	Yes	Design projects for policy	One big challenge for design to enter government is designers' tenure - how to make a team of permanent nature that can pull strings over the long period of policy projects.
3	Designer in social innovation lab	Yes	Design capability building, design projects for policy	Government is a significant lever in social change but should be regarded much like other stakeholder groups who are part of a system.
4	Senior public manager in ministry's innovation team	Yes	Design capability building, design projects for policy, strategic design for policy	If we develop design leaders who understand the matters and needs of senior leaders and policymakers, design-led change can scale.
5	Senior public manager in state government's innovation team	No	Design capability building, design projects for policy, strategic design for policy, innovation management	We're still figuring out how to scale but we think it is more of how you set off networks to work so that change and momentum become viral.
6	Public manager in central government's innovation team	No	Design capability building, design projects for policy, strategic design for policy	Bureaucratic funding model and governance (of a project) are big barriers of design practice in government.

* These are not direct quotes but edited by the authors.

Results

The interviews revealed some limitations of the current practice of design-embedding in government but also suggested possible directions to overcome them. The first and second themes answer the three research questions of this study: what the current practice of design-embedding is like, what changes are being made by the practice, and whether the changes are being managed. The third and fourth themes explain the directions that may improve the current practice of design-embedding in government. The last one is an ancillary theme about the design practice in government.

1 The current practice of embedding design in government

The aforementioned design ladder model divides the general activities of design-embedding practice in government into design capability building, design project for policy, and strategic design for policy (Design Council, 2013). Most experts interviewed were engaging in the two activities of design capability building and design project for policy. Three out of the six experts were involved in the policy designing at a strategic level. One interesting thing was that while other experts are practising these activities on their own, one expert reported that her team is outsourcing the practice of design capability building and design project for policy. Her team seemed to be more concerned with innovation management as she described below. As we will see later, this is a very rare practice in the current design-embedding in government.

> *Our goal isn't to do the innovation. We're not innovators per se. Our role is to try and bring the good things that are happening in and help leverage them and grow them in government. (expert no.5)*

2 No practice to sustain or amplify the design-led change

All the experts confirmed that design is creating some changes in government. The changes are of different levels - individual, team, or organizational – and in different features – awareness, skillset, attitude, mindset, practice, culture, leadership, or structure, though it is not always clear to classify them. The most observed changes were in individual or team level in awareness, skillset, attitude, or mindset. Changes in practice were also reported but they were in singular projects, not in everyday practice.

Changes were often better-observed in long term design projects. Experts emphasized the long term is an essential condition to make a substantial impact in the mindset of participating public officers, as well as in the project success.

> *over the course of eight months, the impact was felt there, where there was definitely buy-in from different levels and different parts of government. Once they saw the outcomes to invest more into it, you could see the team change and become the team who was actually working alongside of us change to be confident in the thinking and the mindsets and the implementation and the leadership. (expert no.3)*

> *[A] really exciting thing is that through the process all of the participants have been exposed to a different way of working and it created a relationship and appetite for ongoing working together around how it can have a continued development together. (expert no.5)*

However, many times changes were seen in individuals who participated in the projects, and most experts did not have clear strategies to sustain the individual changes or to amplify the individual changes to a group or organizational changes. Only one expert seemed to be explicitly engaging in change management practice in her organization. Experts working outside of government were not given the opportunities to steward the changes when their contracts with government ended.

> *I think that the main impact we can point to right now is more the one on one change like the first degree of change that we can see [with] the immediate people that we worked with. I think what will take a lot more time is to see how much further that change goes outside of the immediate team that we engaged with. (expert no.3)*

> *I guess you could say yes there is an influence. But how much they are prepared to let that influence to change all the ways they work, you know, I don't know. It's hard to know. (expert no.1)*

Besides, two experts reported some difficulties in design capability building practice. The challenges were that public organization's rather tokenistic approach to the design training – short term or one-off training – and new design knowledge not integrated within the organization after the training, the phenomenon expressed as "tissue rejection."

> *over 20 weeks we ran that program to help cycle people through and get experience of what was so kind of experience and that was good. The challenge was that the project … because it was built in our environment in terms of the space and the ways of working, they just simply couldn't reintegrate back into the department they come from because it was like tissue rejection. (expert no.6)*

Nonetheless, design capability building is considered important in terms of raising design awareness in government. Three experts expressed their concern that design being regarded as exogenous and inessential to policy context is a major barrier of design-embedding. The expert who experienced the tissue rejection also suggested not to underestimate the "creative energy smoke, even if there's no fire." Additionally, one expert emphasized that design capability training should be as much about attitude and mindset such as agility, resilience, action orientation, courage, and resilience as about skillset.

3 Understanding the organizational context of government

Government as an organization is unique and different from private organizations. Four out of the six experts had work experience in both private and public sectors, and we asked them how their design practice in public organizations was different from that in private organizations. One expert who had a long career history in diverse organizations replied that government is the most complex operating system that she has ever seen. She explained further as below. Her point was that government has its own system of "culture, rhythm, process, and structure."

> *Australian government lasted for how many… Westminster government as a form of organization for 300 years. The average corporates peak at 60 at max at the moment, and those are the exceptions. So, you know, there's something about it. (expert no.5)*

Other experts described the distinctive ways of working in government as political, risk-averse, and bureaucratic. One expert called it a paradox that governments are "bloody careful not to do anything wrong" despite desiring innovations so much. Another paradox seemed to be that despite the governments' risk-averse culture, some aspects of their system are prone to failure.

> *Government has tended always deliver software the way they deliver bridges in that you spec everything at front and you deliver it on a fixed schedule and you assume it's all going well as you planned. […] It means by all that is this cultural aversion to failure. People are scared to throw the hands up and say, hey- this didn't work. (expert no.6)*

> *They genuinely feel that they want to make change for the good. So, their hearts are in the right place. It's just the structure that doesn't allow them to be as positive and courageous. (expert no.1)*

While the bureaucracy of government was criticized the most, one person inside government showed a neutral opinion about it. She explained that "bureaucracy is all about standardization, compliance and risk management" that only contrasts with design, which is "all about exploration, iteration and change." It reminded us what policy scholars explain about the "ambidextrous" approach in public sector innovation – "running business as usual" at the same time as supporting innovation (Hartley, 2014, p.228). Another expert inside government made a similar comment,

> *if you were to build the government from scratch today and you had a completely blank slate starting fresh, you'd build it in the way that Google builds Google or Amazon builds Amazon. […] The challenge is when transitioning a huge behemoth machine to work that way while keeping the lights on because it [has]is a lot of moving parts. (expert no.6)*

Overall, embedding design in government is about transitioning large organizations with long history and their own distinctive systems of culture, rhythm, process and structure. To successfully work on this transition, as in the ambidextrous approach, designers should be able to understand the organizational context of government

well enough. Designers' understanding of the organizational context of government can influence the practice of design-embedding in government.

Understanding organizational change dynamics and nurturing design-led change energy

Then, how can we diffuse design practice and embed it in government? Three experts answered that we need more designers in government. One of them argued that we need a clear designer career track to encourage more designers to enter the public sector.

> *[The] Finnish public sector is big and that's what they call [the] Nordic model. The public sector produces a lot of GDP. And they do very much with little. […] compared to that, the number of designers they have and the number of design project they hire is miniscule. (expert no.2)*

> *designers have got to be infiltrated. They've got to be in there in the government as part of the hierarchy, part of the important… (expert no.1)*

> *I think maybe with things like a career pathway you signal to designers that it is a core specialization that is valued in government. Cause we have career pathways for things like economist or legal or engineering like that. But we don't have a career path for designer as yet. (expert no.4)*

However, it is to be careful that simply hiring more designers in government may not have as much impact as expected since organizational change in complex systems does not happen by few powerful individuals but emerges from multiple local interactions of organizational members (Stacey, 2018). In this respect, we were drawn to some other comments made by the three experts inside government describing internal organizational change dynamics. Consciously or not, they were talking about the local interactions in the design-led organizational change process.

> *When you're not inside government, I don't think you completely understand the tensions that the decision-makers face. (expert no.4)*

> *You need to change the way people work and interact and that's hard. You can't do that from outside. For it's own sake, it needs to be owned and lived by the participants in the culture and that's a self-reflecting change. […] It's not developed out of the great seething cauldron that we're working. (expert no.5)*

> *You could only slowly do that before we start [to] bang [our] head so much that you can't do anymore and that's really hard. (expert no.6)*

Another interesting remark was one expert talking about a 'burning platform'- the term used in change management literature arguing that a desperate need like setting a fire in a platform is required for people to change. She hypothesized that policymakers are not willing to adopt design because there is no absolute need for them as they for long had no trouble of making policies without the help of design. However, some scholars of complex systems theory disagree with the extremity of the burning platform idea and contend that encouraging the system's "creative and curative power" works better in changing the organization (Roehrig et al., 2018, p.327).

In conclusion, embedding design in government is about design-led public organizational change that needs to be owned and lived by the members of the organization. In this change process, the designer's role is to understand the organizational change dynamics and to nurture the system's creative change energy until the energy transforms the organization thoroughly.

It is often not clear what design practice in government means

During the interview, we found it interesting that four experts were hesitant to call their ways of working 'design.' One of them even told us that her team had been practising design principles for long without recognizing it as design.

> *It would have people with a process which is similar to design. Let's not say it's a design process but it's... it has many of the aspects of the way designers work… (expert no.1)*

> *do we actually have to call it design or can we just call it more integrative working, or can you call it more democratic way of involving participants or citizens into the process? (expert no.2)*

It is known that in public innovation sector, many non-design trained people are practicing design. Designers, on the contrary, are reflecting their own practices and questioning what other disciplines are needed to better comprehend complex societal problems. This ambiguous state of who to include as designers and what to include in design practice must be natural as design has expanded to a new territory of public innovation. Dorst (2015, p.31) claimed that "contradictions" in design field are what continuously "feed(s) discussion in the field" and what defines the culture of design.

What is clear though is that more experiments, reflections, and researches are required about the design practice in government context as one expert pointed out,

> *It's kind of like a method design exercise in the government contexts. Instead of going this is what design looks like and you should be doing this, it needs to go more to, this is the operating system that you're moving, how can we integrate as much of the good things and the good outcome of design […] how we can fit in it, how we can start to bring these principles and new ways of thinking. (expert no.5)*

Discussion

In the literature study we redefined the concept of 'embedding design in government' as a combined effort of introducing design practice and sustaining and amplifying the design-led change energy within public organizations. Based on this understanding, we concluded that the current practice of design-embedding in government may lack the practice to sustain and amplify the design-led change in public organizations.

In the interviews with six experts, these literature-based conclusions were further confirmed. The changes reported were mostly individual or team changes in skillset, awareness, attitude, or mindset, and no experts mentioned changes in everyday practice, culture, and structure on an organizational level. It showed that the 'concomitant development of participating individual and organization' in the co-design process is not always guaranteed. For the individual changes to become group or organizational changes or for the changes in skillset and mindset to become changes in everyday practice and culture, there should be some strategies and practices to amplify the change energies. However, five out of the six experts did not have such strategies and practices in place.

In addition, it was found that designers' understanding of the organizational context of government can influence the practice of design-embedding. It means that for designers who work with government as external consultants, their relatively low understanding of the culture, rhythm, process and structure of government can be a barrier to their practice of embedding design in government. Another finding in the interviews was that three experts inside government were more sensitive to internal organizational dynamics than other three experts outside of government. This also confirmed the disadvantage of being an external designer in the practice of design-embedding.

The common activities of current practice of embedding design in government are: design capability building, design project for policy, and strategic design for policy. If the goal of embedding design in government is the transformation of public organizations, the current activities may not be enough to make the transformation. Embedding design in government is about design-led public organizational change that needs to be owned and lived by the members of the organization. The designer's role in the change process is to understand the organizational change dynamics and to sustain and amplify the system's creative change energy. It might be a new role for designers, but we cannot confine the design practice in government as it is practiced now. This role, of course, will not apply only to designers inside government. Designers outside of government should be able to find ways to engage in the design-led organizational change process too.

More studies are required on how the designers can sustain or amplify the design-led change energy in practice. At this point, we find the clues in literature of complex systems theory. Stacey (2018, p.152) says that an organization is shaped by the "interplay of all the choices, intentions, and strategies of all the group and individuals both in organization and in all other organizations," and thus the organizational future is inherently unpredictable. Nonetheless, aggregated intentions of people in the organization make some patterns to emerge so that designer can plan certain "attractors" to stimulate or support certain activities (Hasan, 2014, p.51). Thus, there is a possibility that designers can stimulate design-led change energy using various attractors.

So-far-known attractor factors based on our literature study are conversation, power, and learning. Conversation is how we make sense of our experience and how we construct our social reality: in this sense, changing conversation in an organization could change the organizational reality (Marshak, Grant, & Floris, 2018). Power is itself an important part of organizational reality since everyone is interdependent and thus constrained and enabled by the relationships (Stacey, 2018). Lastly, learning is important in a workplace because to work means to learn practice as the "shared way of doing things" (Gherardi, 2009, p.356). For a new practice is always challenged to be institutionalized, it should be proactively facilitated and nurtured through "inter-organizational networks of sharing and comparing" by designers like gardeners (Hartley, 2016, p.101).

Summarising, designers might be able to sustain and amplify the design-led organizational change by following conversations of people in the organizations, understanding power dynamics in-between individuals and groups, paying attention to the learnings of people in the organization as well as those of themselves, and eventually figuring out what to design and what to expect to emerge in the design-led public organizational change process.

This research does not intend to provide any concrete answers to how to embed design in public organizations. However, we would like to propose that paying more attention to organizational change dynamics and attractor factors in the change process may provide designers with opportunities to sustain and amplify the design-led change energy and eventually succeed to embed design in public organizations. To further explore these opportunities, our future research will be aimed at investigating how the attractors may work in real contexts, what are known and unknown attractors, what are context-free and context-specific attractors, and how designers can monitor the organizational change.

Conclusion

This study aimed to understand the current practice of embedding design in government and its limitations. The study results showed that the current practice of design-embedding in government are generally the three activities of design capability building, design project for policy, and strategic design for policy, and change management is rarely practised. Thus, the changes created by the current design practice mostly remain on an individual level and do not touch the deeper parts such as everyday practice, culture, and structure of the public organizations. The practice of sustaining and amplifying the design-led changes in public organizations is largely missing.

Study findings also showed that embedding design in government is about design-led public organizational change, and the designer's role in the change process is to understand the organizational context and change dynamics and nurture design-led change energy within the organization. We therefore suggested a new practice of design-embedding in which designers steward and stimulate design-led change energy within public organizations as well as future research directions on design-led change amplification strategies.

In light of a growing research interest in the innovation potential that lies at the intersection of design, technology, and science, this paper offers a literature review of design initiatives centered on scientific discovery and invention. The focus of this paper is on evidence of design capabilities in the academic research environment. The results are structured along the Four Orders of Design, with examples of design-in-science initiatives ranging from (1) the design of scientific figures and (2) laboratory devices using new technology to (3) interactions in design workshops for scientists and (4) interdisciplinary design labs. While design capabilities have appeared in all four orders of design, there are barriers and cultural constraints that have to be taken into account for working at or researching these creative intersections. Modes of design integration and potentially necessary adaptations of design practice are therefore also highlighted.

Keywords: Design–technology–science, Four Orders of Design, interdisciplinarity, literature review

Introduction

Two parallel trends mark the research landscape on the future of design: in one lane of research, there is increasing recognition that design (in the sense of creating and modeling any kind of physical and virtual artefacts) plays an important role in innovation. In this lane, one finds studies on design-driven organizations and the value of design for business. In the parallel lane, the academic research environment is itself under study as a source of innovation: from the difficulties academic innovators face in translating discoveries from the laboratory bench to the user, to breakthrough technologies that could lead to solutions for global challenges such as climate change.

At the crossing of these two research streams, the design community is exploring the interplay between design, technology, and science in relation to the changing role of design in the context of innovation (Cautela, Dell'Era, Magistretti, Öberg, & Verganti, 2017). The design–technology–science (DTS) intersection is developing into a research field with an uptick in studies and published materials over the past years, including the launch of the Journal of Design and Science in 2016 (MIT Press, 2016).

This paper is a literature review centering on the DTS intersection and shows initiatives, collaborations, and studies that introduced design capability, either temporarily or permanently, into the academic research environment or strengthened existing capabilities. Collaborative work taking place between designers, scientists, design schools, study programs, and scientific laboratories is currently highly relevant, since both scientific studies (e.g., Acklin & Wanner, 2017) and government-issued reports (e.g., Sainsbury of Turville,

2007) have arrived at the conclusion that significant benefits can be expected from collaboration between design and science, although the specific contribution of the two aspects remains to be elucidated.

Before delving into the evidence from the literature, a brief definition of terms is warranted, as both of the key concepts in this paper, *design* and *science*, encompass vast areas of application and may differ in meaning depending on the exact context of usage. A detailed comparison of the similarities and differences between design and science can be found in a review on the subject by Peralta and Moultrie (2010).

Science is concerned with producing knowledge and testable assertions (Bonsiepe, 1995), with the generated knowledge from systematic study being expressed in a variety of forms such as models and theories, thus creating intellectual value (Simeone, 2016). These activities are typically, but not necessarily, based in scientific institutes. The focus of this review is the academic research environment at universities and research centers as opposed to commercial industrial operations. Scientific discoveries, inventions, and new technologies can form the basis of emerging business operations as shown in Figure 1.

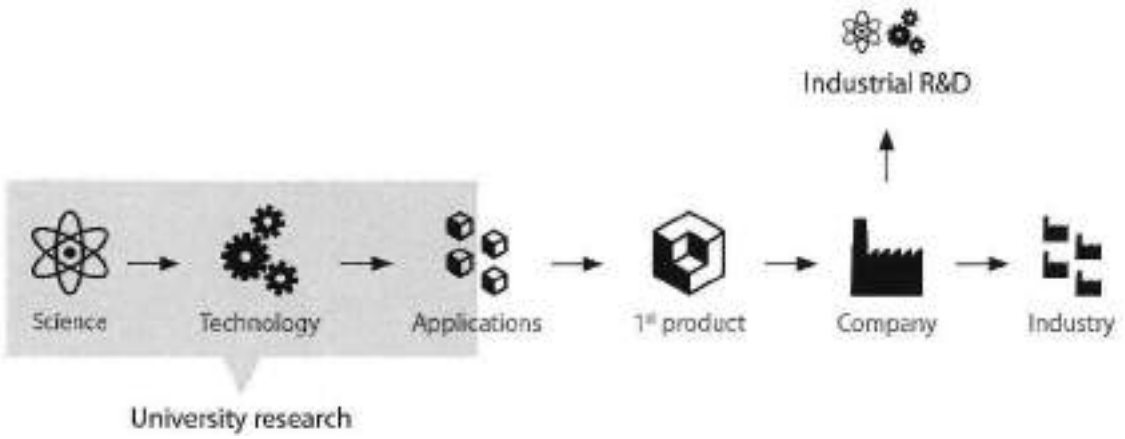

Figure 1: Positioning of the academic research environment (Driver, Peralta, & Moultrie, 2012, p. 20). Although this figure suitably shows the focus of this review (gray box), the original authors of the figure note that the true complexity of this process is not captured in a simplified linear depiction. Other authors echo this ecosystem view (Hudson & Khazragui, 2013).

In business, the value of design and designers is recognized (Hernandez, Cooper, Tether, & Murphy, 2017). Organizations are expanding their understanding of design beyond concerns of aesthetics and function, with investigations into the impact of design indicating that design-centric organizations show above-average economic performance (Westcott et al., 2013). This effect has been investigated especially in relation to the development of new products, where companies with a high design intensity, as expressed by their investment in industrial design, experience significantly better company performance (Gemser & Leenders, 2001). In contrast, the potential impact of design in academia has scarcely been explored (Moultrie, 2015).

Design itself is an ambiguous term with many definitions ranging from general to discipline-specific. In order to make sense of the various meanings under the umbrella of design, scholars have identified ways of grouping or classifying types of design. This paper follows Richard Buchanan's (1992, 2001) model of the Four Orders of Design (FOD) and uses it as a means of categorizing examples from the literature on design-in-science initiatives. The FOD model was selected because it offers definitions and a suitable number of design subtypes, unlike broader differentiations that are e.g. based on a goods-dominant vs. service-dominant logic of design (Eneberg & Holm, 2015). Additionally, the FOD model has already been employed by design scholars as the basis for design conceptualizations and as a tool for the analysis of design processes, as will be described in the following.

In the FOD model, design outcomes both by professional designers and those not necessarily considering themselves to be designers can be any of the following: (1) symbols, (2) material objects, (3) activities and services, and (4) systems and environments (Buchanan, 1992). Initially, the FOD were not called *orders*. Rather, Buchanan wrote about the placement of design in these four *areas* or *places of invention* and cautioned against equating one area with one major design field such as graphic design or product design (Buchanan, 1992). In practice, all orders are interconnected and have an impact on each other. For example, a system may be made up of objects that are connected through activities. In analyzing the history of design, Buchanan

argues that a progression through the FOD can be seen, with designers' focus appearing to shift from the first and second orders in the 20th century to the third and fourth orders in the 21st century (Buchanan, 2001). Eneberg and Holm (2015) highlight the immaterial aspect of the higher orders, where "Buchanan describes an offering that is becoming increasingly intangible" (Eneberg & Holm, 2015, p. 12).

The approach of looking through the lens of the four orders can be found, for instance, in the case study of a fashion magazine by Nylén, Holmström, and Lyytinen (2014), where the transformation from print to digital magazine design is described as *oscillating* between the FOD and posing challenges on several orders in parallel. The authors use a timeline of design decisions categorized into the FOD to trace the design process. This approach allows them to then analyze the relationships between the FOD in digital design and to identify co-dependencies between orders. In a design process spanning multiple orders, *ripple effects* can occur since a design decision in one order may set constraints and entail related design decisions in another higher or lower order (Nylén et al., 2014).

A second example of the FOD lens being used is a case study on improving the Australian Income Tax Act (Golsby-Smith, 1996), in which the author describes how third-order design was employed: in this case study, the design approach went beyond the delivery of the product, namely a redesigned, rewritten piece of tax legislation. Instead, the design team recognized that with complex, perpetually changing legislation "the value to be delivered […] is ongoing capability to handle the designing process" (Golsby-Smith, 1996, p. 12). The author additionally reflects on aspects that can be considered fourth-order design, for instance the design team's discussion of the wider purpose of the Tax Act project (Golsby-Smith, 1996). A further study focusing on the third and fourth orders is Breslin's (2008) perspective on the design of retail centers of a postal service.

Similar to the approach of the above-cited authors, this paper is centered on applying the FOD model to a specific area, in this case design-in-science initiatives, in order to address the question to what extent design capabilities are integrated into professional operations in the academic research environment.

The four orders of design in science

The previous section introduced the FOD and explained how they can be used as an analysis tool in studying design. In this section, examples are given of design-in-science initiatives as they can be found in the literature to date. One section is dedicated to each of the four orders. Some of the examples appear multiple times in different orders of design, underlining how several aspects of design can be found within one project and stressing Buchanan's point that each order is interconnected with the others (Buchanan, 1992).

First order

First-order design is firmly placed in a world of visual communication through signs and symbols. It is thus closely related to graphic design, yet it does not overlap fully with this design profession (Buchanan, 1992). Examples of the connection between visual design and science are numerous, often relating to the need to communicate the results of scientific research or to visualize and analyze data in the first place. As researchers produce an abundance of posters, figures, data plots, etc., many opportunities for graphic design are given. New symbols and other forms of expression have to be found for phenomena on micro and nano scales, inside living organisms or even on distant planets.

The importance of visual literacy in science has a long-standing tradition: more than three centuries ago, René Descartes declared that "[i]magination or visualization, and in particular the use of diagrams, has a crucial part to play in scientific investigation" (in: Trumbo, 1999, p. 409). Recent academic interest has resulted in a volume of work published throughout the 2010s, starting with a guide to designing scientific figures (Rolandi, Cheng, & Perez-Kriz, 2011) and continuing with studies of visual science communication (Chen, O'Mahony, Ostergren, Perez-Kriz, & Rolandi, 2014; Rodriguez Estrada & Davis, 2015). With the Design Help Desk, the University of Washington offered graphic design support to scientists and engineers. In parallel, a study by the same team found that a redesign of scientific figures according to graphic design principles had a positive impact on the reader's perception (Cheng & Rolandi, 2015).

Design drawings and renderings are useful tools to illustrate how new technologies developed in an academic environment could be used in products of the future. This application was explored in the Design in Science (Driver et al., 2012, 2011) and DesignSeed (Acklin & Wanner, 2016, 2017) initiatives, in which designers created materials such as renderings of potential applications for a biophotovoltaic device (Driver et al., 2012) and a gynecological measuring device (Acklin & Wanner, 2017), thus supporting the imagination of

stakeholders for these science-based products and creating means of engagement with audiences outside academia through symbolic depictions of the artificial.

Second order

Second-order design is the design of physical objects, which is often associated with product design and engineering design, but not exclusively so (Buchanan, 1992). Collaboration between scientists and designers has been carried out in the field of bio-design, which offers opportunities for designers to work with and create new materials and methods for manufacturing. An example of the outcome of such a collaboration is algal bio-ink, a liquid containing algal cells that can be printed using an inkjet printer, after which the cells will grow in the patterns in which they were deposited (Sawa, 2016).

Two major initiatives linking product design and science have been written about recently, namely the Design in Science and the DesignSeed studies (see section on first-order design above), in which teams of designers worked with academic inventors and groups. Design here is understood in the sense of what makes a product become tangible and usable. Many definitions have been attempted, and one that captures this meaning is "'Design' is what links creativity and innovation. It shapes ideas to become practical and attractive propositions for users or customers. Design may be described as creativity deployed to a specific end" (Cox, 2005, p. 2).

On the practice side, the design teams of both initiatives produced tangible outcomes including models and fully functional prototypes of science-based new products such as a novel fluid handling device. In the Design in Science project, the researchers were motivated to explore how designers might contribute to early-stage scientific research (Driver et al., 2011). DesignSeed, on the other hand, laid focus on startup ventures based on technologies stemming from scientific research (Acklin & Wanner, 2017). On the research side of these studies, the authors created models of processes in design–science interaction that may give clues for third- and fourth-order integration, e.g. through an overview of stakeholders and their relationships (Acklin & Wanner, 2016).

Third order

Third-order design can be understood in different ways: in one sense, it is service design (Buchanan, 1992). This meaning was adopted in the DesignSeed study and touched upon in one of its practice cases, where a group of bio-technicians were trying to decide whether to use their technology of culturing cells in biopolymer scaffolds as the basis of a product or a service (Acklin & Wanner, 2016). Beyond the service design definition, the third order also spans other processes, activities, and actions as per Buchanan's (1992) original delineation. For instance, Cheng and Rolandi's (2015) Design Help Desk for graphic design resulted in first-order outcomes while additionally creating third-order opportunities for designer–scientist interaction.

The process of scientific research itself can become the subject of design activities: in a collaboration between design consultancy IDEO and a biology laboratory at the University of California – San Francisco, Design Thinking was used to generate new ideas for research avenues in synthetic biology and to create a "safe space for uncertainty" (Bernstein, 2011, p. 497) that supports scientific exploration. This collaboration was one out of several within the Synthetic Aesthetics project, in which short-term residencies shared between designers and synthetic biologists across the world were formed. For a duration of two weeks each, the designer would take up residence in the laboratory, and the biologist would later also spend time in the designer's studio while working on a joint project (Ginsberg, Calvert, Schyfter, Elfick, & Endy, 2014).

Golsby-Smith (1996) suggests that "[i]n the third order, the designer decides that the client will benefit from an earlier intervention of design thinking, at a more strategic and crucial time" (Golsby-Smith, 1996, p. 12). For instance, these early interventions take place in the United Kingdom as part of the Design Council's 'Design support for science and technology innovation' initiative, where scientists can benefit from support sessions through design associates, i.e. design management experts who coach academics on product design (Design Council, 2014). Participatory workshops on design were also among the collaboration formats facilitated by the DesignSeed initiative (Acklin & Wanner, 2017). These services touch upon the strategic aspect of design in science and additionally move towards the fourth order, which can be considered to apply once a transfer of skills is involved (Golsby-Smith, 1996).

Fourth order

Fourth-order design deals with systems and environments, and how human beings integrate into these (Buchanan, 1992). Design of this highest order is evident when skills are being transferred (Golsby-Smith, 1996), examples of which can be found in design and engineering education. Programs e.g. in the fields of human-centered product development (Vajna, 2014) and biomedical engineering (Yock et al., 2015) rely on multidisciplinary teams working together on current real-life challenges.

Design labs existing at several universities may also be considered to fall into the fourth order, since they are a lasting system or infrastructure connecting design and science. These labs are spaces for creative exploration connected to major universities such as Massachusetts Institute of Technology (MIT) with its long-running Media Lab (Simeone, 2016) and Harvard University with the Biodesign Lab, which has a multidisciplinary team of designers, engineers, and medical researchers working on wearable robotic devices, among others (Biodesign Lab, 2018). These labs and the translational activities undertaken by their participants provide a glimpse at the potential of interweaving design and science.

Similar to Bason (2010) calling for an *innovation ecosystem* in the public sector, the conceptual move from a design-in-science system to an ecosystem is easily made. The biological image is used by Sawa (2016), who refers to the interaction of designers and scientists by saying that "the role of a designer in scientific research should be more endosymbiotic with the designer physically located within the laboratory" (Sawa, 2016, p. 71). Analogously to endosymbiosis, where one organism lives within another with possible mutual benefits, win-win situations could be created with designers embedded in the scientific research environment. As Rust (2007) notes, designers' ideas can spring from simply being present and "dwelling in the situation" (Rust, 2007, p. 72). However, such a cultural shift depends on the building of a community that is interested in translating design practices to scientific applications (Yajima, 2015).

Placement of research activities

This section outlined initiatives at the DTS intersection from a variety of sources, including anecdotal reports of collaborative projects to account for the challenge that few studies have been conducted on the impact of design in academic research (Moultrie 2015). In the field of industrial design, Peralta and Moultrie (2010) stress that despite there being few literature sources, practice examples of design–science interaction can be found. However, information on these is not easily accessible (Peralta & Moultrie, 2010). Based on materials that are accessible, this section demonstrated that initiatives at the DTS intersection span all four orders of design. Out of the projects introduced in each section of the FOD, Table 1 summarizes initiatives that include a design research component, e.g. with respect to designer–scientist interaction.

Table 1: Overview of instances of designer–scientist collaboration with a contribution to design research. Personal perspectives and accounts of experience by individual designers are not included. Circles (●) indicate the corresponding orders of design, with larger circles for the focus of the study and smaller circles for further relevant areas.

Name of study (alphabetical order)	*Key publication*	*Scientific focus*	*Orders of design*			
			I	*II*	*III*	*IV*
Design Help Desk	Cheng and Rolandi (2015), University of Washington	Contribution of graphic design to science communication	●		●	
Design in Science	Driver et al. (2012), University of Cambridge	Contribution of industrial design to scientific research	●	●	●	
Design Moves	Simeone (2016), Malmö University	Contribution of design to academic entrepreneurship in design labs	●	●	●	●
DesignSeed	Acklin and Wanner (2016), Lucerne University of Applied Sciences and Arts	Contribution of design and design management to academic entrepreneurship	●	●	●	●

Synthetic Aesthetics	Ginsberg et al. (2014), University of Edinburgh and Stanford University	Contribution of design and designer–scientist interaction to synthetic biology	

As Table 1 shows, research on design in science covers the FOD spectrum. In addition, further results are to be expected from a pilot study on the impact of designers in academic high-tech startup teams, which was supported by the German Federal Ministry of Education and Research and concluded in 2018 (Fraunhofer IAO, 2019; Sinell, Brodack, & Denef, 2017). By observing Buchanan's theory of a progression through the four orders in the history of design, one may anticipate a trend for the design field to move more firmly towards the third and fourth orders not only in industrial organizations, but also within academia. This status quo gives the design community the opportunity of expanding this niche in the creation of an innovation ecosystem that draws upon the wealth of scientific discoveries, and to move towards a more strategic understanding of design in science. By translating approaches such as human centeredness (e.g., Vajna, 2014) and participatory design (e.g., Bogers & Horst, 2014) to scientific design applications, design management across the FOD can help break out discoveries and inventions to users inside and outside of academia.

Towards fourth-order integration of design in science

Design management "embeds design or design processes in companies in order to create added value in products, services, experiences, processes, and structures" (Acklin & Wanner, 2017, p. S471). In this section, directions for further design research and areas of interest for design management are outlined, including investigating designers' roles in the academic research environment and addressing prerequisites for collaboration at the DTS intersection. Some of these factors, being particular to the scientific enterprise, provide examples of contexts in which design integration starts touching organizational values. As Golsby-Smith (1996) explains, values and culture are an expression of the fourth order of design.

Opportunities for design integration in an academic innovation ecosystem

In their analysis of future avenues for design in science, Driver et al. (2012) suggest three options for creating design support: firstly, there could be a centralized design service at universities to match the centralized technology transfer office (TTO, also known as technology licensing or valorization office). Secondly, funding proposals could specifically include design work and be filed jointly by scientists and designers. Thirdly, research councils could provide allowances for design contractors to work on scientific research projects (Driver et al., 2012). Design thus has the potential to integrate both as a design service and as co-design.

An initial suggestion for designers' roles is the engagement as a *design supplier*, a *design consultant*, and a *team researcher*, where the design supplier has the lowest level of integration into scientific research, while on the opposite end of the spectrum, the team researcher is firmly integrated starting from a stage as early as the conception of research questions (Peralta, 2013). Future research could add new insights on this subject and consider additional roles such as the *individual researcher* who is motivated by an own research question.

An example of an individual researcher is bio-designer Sawa (2016), who explored the option of working from within a scientific team on an independent, long-term project of designing an application for printable algae (see section *Second order*). Conversations with the collaborating scientists allowed her to acquire biological and technical knowledge as well as advance her research work in unexpected directions (Sawa, 2016). Other options besides being embedded in the academic environment in a spatial sense could be discussed by the design community, e.g. a co-design approach around shared solutions. Such a systemic perspective could ultimately *catalyze* science-based innovation (Yajima, 2015).

At a level beyond designers and scientists as individuals, professional design and design management societies can facilitate the interaction. The Design Council demonstrated the feasibility of this pathway in its training program 'Design support for science and technology innovation' (see section *Third order*) by working with universities in the UK to coach scientific teams to apply divergent thinking approaches and to develop prototypes employing new technologies from their research (Design Council, 2014).

A strategic position for designers and design managers could be in technology transfer offices and the multitude of incubators, accelerators and mentoring programs helping to drive innovation stemming from academia. Currently, these programs offer support in entrepreneurial aspects such as financing, intellectual

property and project management (Gehr & Garner, 2016), but design is rarely found on the curriculum. Here, upstream design integration has the potential to enable easier interfacing with stakeholders, e.g. by making boundary objects available early on in entrepreneurial processes (Simeone, 2016), as well as pursuing a highly user-centric approach to technology transfer while still in the academic environment rather than an industrial environment. Another beneficial consequence of early design integration would be access to knowledge and knowledge transfer. For example, the design community can benefit from cutting-edge technologies, materials and methods for manufacturing, including nanotechnology and bio-printing. As designers get to know technological boundaries, they can start translating new technologies into use and pave the way for them to become more widely known.

Prerequisites for design integration

As the DTS intersection is a crossing of disciplines, perceptions both of oneself and of one another may stand in the way of collaboration. On the topic of self-perception, Driver, Peralta, and Moultrie (2010) find that scientists consider themselves to be doing certain types of design as their work routinely involves designing experiments, circuits, surveys, and clinical trials, among others. Regarding the topic of perception of the other, the view of designers as stylists may still be prevalent, with a low awareness on the science side of the added value that design can bring (Driver et al., 2010). While these observations are the result of an early exploratory study and require more detailed investigation on a quantitative basis, they highlight the importance of perceptions as a potential factor influencing collaboration. On the one hand, projects at the DTS intersection are at a risk of appearing to draw attention away from the dissemination of knowledge and may thus encounter an ethical challenge, especially if they are geared towards the commercialization of research (Hudson & Khazragui, 2013). On the other hand, a positive impact on scientific practice is possible, since the envisioning of research applications by designers can serve as a source of motivation for scientists (Sawa, 2016).

On the design side, designers may not yet be aware of the untapped potential for design work in the academic environment and for different levels of involvement that are possible as outlined above. Here, design education itself is a potential enabler of new ways of design integration. Besides having multidisciplinary teams and working on practice applications in the academic research environment, design programs could also benefit from communicating particular needs regarding the scientific publishing and funding system to future designers who may encounter these in their work.

Funding to enable collaborative projects and workspaces at the intersection between design and science is a key prerequisite and “the critical barrier to be overcome” (Driver et al., 2012, p. 127). Once design potential has been demonstrated e.g. through prototypes, these can help secure further funding and investment (Sinell et al., 2017). In the absence of joint funding, designers have to be prepared to be the drivers of the collaboration (Sawa, 2016).

In terms of adapting design practices for the DTS intersection, Driver et al. (2012) find that for projects conducted with the involvement of both designers and scientists, the design process should include a phase of clarifying technical scientific terms in advance of the definition of a design brief. This stage is introduced as a *translation* phase to develop a shared language and understand abstract concepts (Driver et al., 2012). It is debatable, however, whether this stage needs to be defined as an add-on to the design process or whether it is implied that any phase of design concerned with understanding the design problem requires a clarification of technical terms. The nature of the translation phase could thus be a subject of interest for further investigation. Design itself presents a solution to questions of communication in the academic research environment through prototypes and other forms of creating tangibility (Moultrie, 2015; Simeone, 2016; Sinell et al., 2017).

Conclusions

The important role of the DTS intersection in fostering innovation has been recognized by the design research community and has been the subject of various studies that formed the basis of this literature review (e.g., Acklin & Wanner, 2017; Simeone, Secundo, & Schiuma, 2017). This paper contributes to an overview of current activities at the DTS intersection by including new studies that took shape since the most recent literature review on collaboration between designers and scientists (Peralta & Moultrie, 2010). These new materials include a stronger focus on academic entrepreneurship and driving innovation through design

(Acklin & Wanner, 2017; Simeone et al., 2017) while spanning further design professions such as graphic and service design.

By linking existing initiatives to each of the four orders of design in the first part of this paper, it was shown that design is able to contribute to the scientific world on all four orders. The communication and materialization skills required in the first and second order can improve the understanding of highly technical scientific results and support user-centered development of new science-based products, while the higher orders may offer motivation to those studying elusive phenomena and build a creative environment supporting open-ended research.

Despite this evidence that the DTS intersection holds opportunities for designers and design researchers alike, reported initiatives are often exploratory and first-of-their-kind at a particular research institution. This status may reflect what Bason (2010) refers to as *random incrementalism* in public-sector innovation. For a more strategic and integrated view of design, further research is required on how to initiate and sustain collaboration on all four orders of design. Topics of interest include the roles of designers, awareness and perceptions, financing and institutional support as well as a design process based on mutual understanding. If there is a progression along Buchanan's orders as it is happening in the design field at large, then more widespread initiatives with respect to third- and fourth-order design should be expected in the future.

In order to gain knowledge on practice projects that are hidden from the outsider's view and currently inaccessible in the scientific literature, ethnographic and action-based research strategies can be used. For instance, Simeone et al. (2017) conducted an ethnography-inspired investigation of MIT's Senseable City Lab, one of the above-mentioned design labs, as part of the Design Moves study (see section *Fourth order*). Action research (e.g., Ottosson, Björk, Holmdahl, & Vajna, 2006), which was chosen as a research strategy in the DesignSeed project by Acklin and Wanner (2017) (see section *Second order*), is valuable in two ways: firstly, it enables the researcher to gather relevant information from within an organization to place design integration on solid foundations. Secondly, in the process, the action researcher may him- or herself act as a catalyst for design innovation (Price, Wrigley, & Matthews, 2018), leading to direct consequences in practice.

Certain prerequisites for successful DTS projects have already been identified, as outlined in the second part of this paper, resulting from designers' and scientists' endeavors to establish interdisciplinary projects. These insights pave the way to move from an ad-hoc use of design at an unmanaged level, which Westcott et al. (2013) call *heroic efforts*, to strategic integration of design capabilities supported by design management. In doing so, there is access to a multitude of design challenges that are highly relevant to society. These challenges include environmental sustainability, the development of novel therapeutics and other wicked problems (Yajima, 2015). In new collaborations, the design community can thus support scientists in making the impact of their work directly visible and envision symbols, products, interactions, and systems of the future based on academic discovery and invention.

The adaptation of design thinking in auditing

MEIJER-WASSENAAR Linda* and VAN EST Diny

The Netherlands Court of Audit, The Netherlands
* corresponding author e-mail: l.meijer-wassenaar@rekenkamer.nl
doi: 10.33114/adim.2019.03.362

How can a supreme audit institution (SAI) use design thinking in auditing? SAIs audit the way taxpayers' money is collected and spent. Adding design thinking to their activities is not to be taken lightly. SAIs independently check whether public organizations have done the right things in the right way, but the organizations might not be willing to act upon a SAI's recommendations. Can you imagine the role of design in audits? In this paper we share our experiences of some design approaches in the work of one SAI: the Netherlands Court of Audit (NCA). Design thinking needs to be adapted (Dorst, 2015a) before it can be used by SAIs such as the NCA in order to reflect their independent, autonomous status. To dive deeper into design thinking, Buchanan's design framework (2015) and different ways of reasoning (Dorst, 2015b) are used to explore how design thinking can be adapted for audits.

Keywords: adaptation, Supreme Audit Institutions, design thinking, design research, co-creation

Introduction

Public organizations have to be accountable. As 'actors', they have to explain and justify their conduct to the 'forum', the forum judges (Bovens, 2007). In the end, it is about taxpayers' money. Supreme audit institutions help parliament – the 'forum' – understand how the government – the 'actor' – spends public money and how it performs. A minister, as a principal, has to be held accountable for the use of public funds.

The Netherlands Court of Audit (NCA) is a supreme audit institution. Based in the Netherlands, it checks whether the Dutch government spends public funds economically, efficiently and effectively. Its statutory task is to audit the revenue, expenditure and performance of central government and the institutions associated with it (NCA, 2016). Dutch law mandates the NCA to conduct audits using all the information it needs to check whether government did the right things in the right way. The NCA then reports to parliament and publishes its audit reports. The NCA is an independent and autonomous organization – no one can order it to audit a certain subject or to audit in a specific manner.

About 150 auditors work at the NCA; most of them are economists, chartered accountants, social scientists, data analysts or come from another academic background. Auditors 'form an opinion on a matter in an independent, expert and systematic way, based on acceptable criteria and sound evidence, within a certain institutional and accountability context', according to Dees's definition of public sector auditing (2010, p. 13, in Dutch). The audits are carried out systematically in an 'audit circle' designed by the NCA, in order to arrive at quality and impact. It comprises five compulsory phases the auditors have to follow: strategic audit proposal, audit design, collecting data, memorandum of findings and audit report.

The NCA's auditors inevitably have a preference for content-centred working environments, where people are expected to make improvements (positive change) based upon knowledge. This expectation that objective

knowledge will lead to changes can be understood as a particular style of change management. André Schaminée (2018) identifies five different styles of change management, based on management theory developed by Hans Vermaak and Leon de Caluwé, as summarized in table 1.

Table 1: Five styles of change management (Caluwé, 1998, p. 11), selection of characteristics from Schaminée (2018, pp. 46-47)

Change management style	*Things change when you*	*Focussed on*
1. Negotiation (yellow)	Align interests	Positions and context
2. Empirical understanding (blue)	First think and then act systematically	Knowledge and results
3. Learning (green)	Introduce people to a learning situation	Shared meaning, setting and communication
4. Motivating (red)	Stimulate people in the right way	Procedures, inspiration, atmosphere
5. Organic (white)	Make space for spontaneous evolution	Complexity and meanings

Auditors, though, are skilled in the second style of change management – empirical understanding. The first style of change management is based on negotiation. In the context of the NCA it is used mainly by parliament. Schaminée observes that the first two styles are dominant in the public sector (pp. 45 & 48). He proposes adding 'design thinking' as a new style. Design thinking is a combination of the third (learning) and fifth (organic) style 'where giving meaning is paramount' (p. 48). Design thinking 'refers to methods and techniques that designers use to achieve innovative solutions' (p. 22) and covers a wide range of design approaches. That is why this term is used in this paper.

Design thinking is a new concept in auditing

'Design thinking' is an interesting concept as a means for supreme audit institutions such as the NCA to stay relevant in a world of information overload. For an audit to have an impact, more needs to be done than simply writing down the findings in a report. Diny van Est and Linda Meijer-Wassenaar have been working at the NCA for more than ten years. In this paper they share their most recent experiences with the use of design thinking in the NCA's audits. Diny was audit manager of one of the two cases described in this paper and is an expert in innovative methods; Linda was involved in both cases as a design researcher.

Design thinking is a relatively new audit phenomenon. It can add value to audits and help auditors think more human-centred (Bijl, 2017), work iteratively and unravel complexity and abstract topics by making them tangible (visual, tactile) – and thus help create more impact. Yet, the first step to enable design to add value to an audit is to adapt the understanding of design (Dorst, 2015a). As Dorst explains, when adapting design principles in a new context it is important 'to delve deeply into the practices' (p. 23). In this paper we explore the different ways of reasoning between audit and design (Dorst, 2015b) and the design perspectives that can be used in audits (Buchanan, 2015).

One important distinction between auditing and design thinking is the way of reasoning. Most auditors start with deductive reasoning: they know the what (standards) and they compare this with the how (reality) to discover the unknown outcome (does reality comply with the standards?). When auditors want to know what patterns lead to the outcome (why doesn't reality comply with the standards?), they use inductive reasoning: they discover unknown patterns that, together with known elements, lead to a known outcome (Dorst, 2015b, p. 46). Designers, however, discover unknown elements and unknown patterns that lead to a known outcome: design abduction (p. 49). This is what makes the combination of designing and auditing quite challenging.

To explore the use of design in auditing the NCA carried out a series of experiments. The experiments can be put into perspective using Buchanan's framework (2015). Buchanan (pp. 13-14) differentiates between four

orders of design. They are derived from the evolution of design practices, as Buchanan explains (p. 11), and are 'an art comprised of four dialectical moments in the sequence of thought and action – moments of questioning and reflection as well as action', (p. 15). Figure 1 shows Buchanan's four orders.

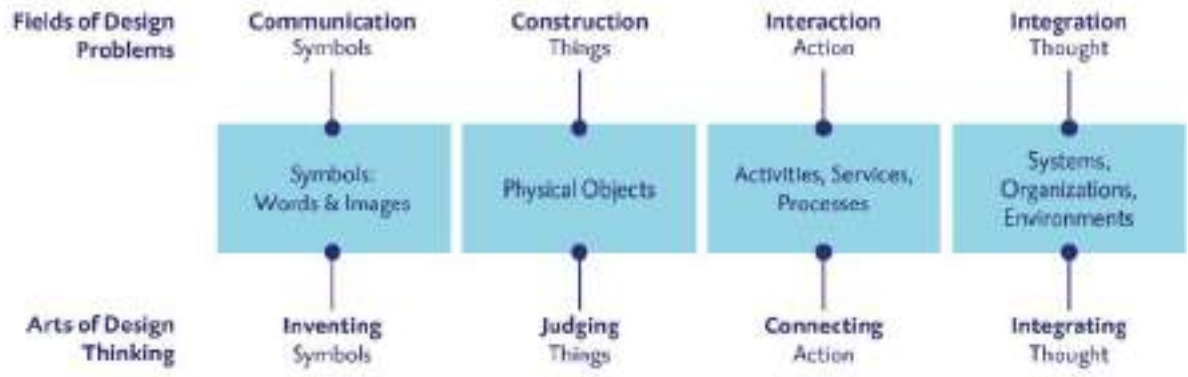

Figure 1. Based upon Buchanan's four orders of design (2015, p. 14).

We used this framework to reflect on our audit work and applied the four orders to understand what design can do for audits. The first order, 'symbols', can be found in our reports in the form of words and images. The second order, 'objects', is the report or publication as a whole, so this exceeds the individual words and images. The third order, 'interaction', is concerned with how we engage with our stakeholders. The fourth and final order is 'thought'. In this order all disciplines have to work together to improve the system. Yet various interests, values and methods stand in the way of improvement, especially in complex systems such as the examples we give in this paper.

Examples of design approaches in two audits

This paper describes two audits that we selected to explore and analyse how we applied design approaches using the different ways of reasoning identified by Dorst and Buchanan's framework. The first example is an audit of the EU system of CE marking. The audit asked: why is it that products that do not meet EU health, safety and environmental protection standards are nonetheless sold on the EU market? And what is the government doing about the problem? The audit commenced in autumn 2015 and the audit report was published in January 2017. The second example is an audit on the provision of information in the social domain. This audit started in January 2018 and publication followed in September of the same year. In this audit the NCA wanted to provide advice on how more coherent and more structured information could strengthen the information position of the House of Representatives.

First example: CE marking

Everyone in the European Economic Area, of which the Netherlands is a member, encounters products bearing a CE marking every day – at home or at work. Electrical appliances, toys, packaging, sticking plasters, supermarket scales, roadside petrol pumps, ladders used by window cleaners and bread slicers used by bakers are all examples of products that are subject to CE marking. Dozens of products in the EU are withdrawn from the market every month because they pose a grave risk to the users' health and safety. Curiously, many of these products carry a CE marking.

CE stands for 'Conformité Européenne', meaning 'in compliance with EU law'. By affixing a CE marking in the form of a logo to a product, the manufacturer declares that it complies with all applicable EU health, safety and environmental protection requirements. This logo is compulsory in all 33 countries of the European Economic Area.

Figure 2. CE marking as a logo (European Commission, n.d.)

The CE marking system is complex and hard to audit for several reasons. Firstly, as a system of the European Economic Area it involves many stakeholders. Secondly, it is a mixed public-private system in which both private sector parties (such as manufacturers) and public sector parties (such as market surveillance authorities) have their own responsibilities and need to interact with each other. Thirdly, it is a technical issue, specific expertise is needed to judge whether or not a product complies with the standards. And finally, the implementation of the CE system in the Netherlands involves a large number of public sector actors that are involved in policymaking for the CE system and its implementation: six ministers, five national inspectorates and a number of autonomous administrative authorities. This is probably also the case in the other EEA countries.

As an audit team we were challenged to 1) determine to whom we should address our recommendations, 2) formulate helpful recommendations for parliament in a transnational, public-private system and complete our audit knowing that we were stretching our mandate (the NCA may not audit the private sector), 3) command the same expertise as our stakeholders, and 4) make government 'care' when none of the six ministries felt responsible. The team consisted of three auditors (with legal and surveillance expertise), a data analyst and the two authors of this paper: a design researcher and an audit manager.

Our first goal was to provide the Dutch House of Representatives with an understanding of how the CE system works and the principles underlying it. By sharing this knowledge we wanted to focus on the opportunities available to the Dutch parliament to perform its role as a watchdog and thus help safeguard such interests as health, safety and environmental protection. We used inductive reasoning – finding patterns – to reach our first goal. The team carried out a statistical analysis of the database used by the inspectorates of the 33 European countries to inform the European Commission about dangerous products, analysed various documents and held a wide range of interviews. We then discussed our findings with Dutch stakeholders from both the public and the private sector. And finally, we discussed the most important challenges in an international EU workshop on market surveillance.

Our second goal was to 'make people care', but we did not know how to. So we experimented without knowing in advance whether or not we would succeed. The way we worked to reach our second goal can be classified as design abduction – searching for elements (what) that would work (how) to reach our desired outcome (making people care so they want to take over our recommendations). We experimented with various infographics (first order), methodologies to make our product more engaging (second order), approaches to interact with our stakeholders (third order) and searched for ways to improve and be meaningful as an SAI in a complex system (fourth order). To illustrate these experiments we will share a few of our experiences, presented in the same sequence as Buchanan's four orders of design.

Using 'symbols' (first order)

Since 2015 the NCA has used more infographics and data visualizations in its audit reports to tell stories visually. Yet the added value of using visuals *during* audits, in terms of new and different insights, was still being discovered at the time of this audit. The involvement of a design researcher helped the team discover a diverse range of visual stories which were used in the audit report to unravel the system and to get the message across (Meijer, 2018).

One of the elements the audit team wanted to explain visually concerned the 27 product groups that had to bear a CE logo. To produce the infographic (figure 3) the design researcher worked closely with a member of the audit team with a background in the law. Based upon the legal information on the product groups, 27 pictograms were selected to help readers better understand the audit subject. The process that led to the infographic helped the team sharpen its understanding of the product groups. The team also discovered that

the information about the product groups was not as clear as initially thought. The team did not realise this until it tried to present the information visually.

Figure 3. An infographic of 27 CE product groups (NCA, 2017)

In complex settings, such as the CE system, it is particularly important to start visualizing at an early stage in order to unravel the complexity and show it in an accessible way to laymen, such as members of parliament and journalists, without losing the nuances needed to understand the issues relating to the topic. The legal basis of the CE system can be found in a Blue Guide, a 122-page document on the implementation of EU products rules (European Commission, 2016). It took months for the team to understand its contents and produce an infographic that explains the system in a nutshell (see figure 4). It was used in various presentations as a framework to contextualize our recommendations.

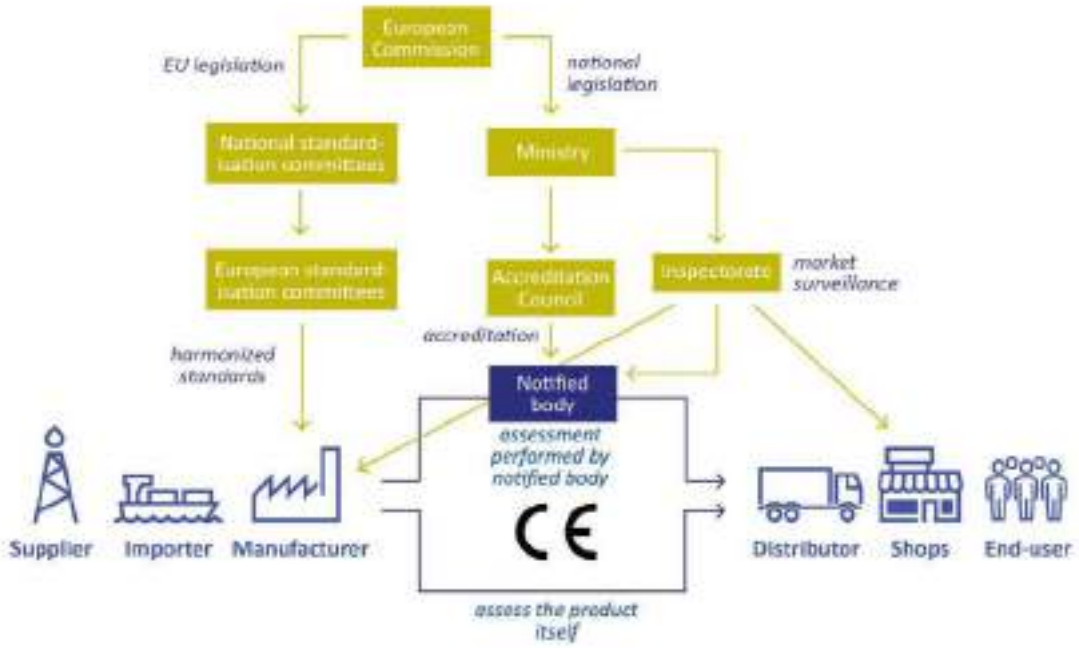

Figure 4. An infographic explaining the essence of the CE system (not published, NCA)

Using 'objects' (second order)

To deal with the complex environment, the audit team needed to think about how the audit report could make an impact. Publishing a thorough report with good infographics (first order) alone would not do the trick, they had to design the report as a whole, an entire story that would engage a broader audience. That meant that writing the story down and using good infographics would not be enough, we had to use methods that would form the building blocks of the audit story. In the team discussions we would talk about how the report could become more engaging, e.g. how CE marking affected our own lives and the lives of our children. As at least four of the auditors had young children and they had to admit that most of the time they noticed recalls of toys in newspapers. Simply visualizing the data was not enough to address the concerns of young parents, so how could the team catch that urgency without compromising the supreme audit institution's standing? How could they give the data more meaning?

The team decided to select one specific item in the 'toys' product group from the list of notifications and follow it from supplier to consumer. The reason they selected this product group was twofold: it was the product group with the most notifications in the Netherlands, and toys was a product group which the team felt the most concerned about in view of its impact on the lives of vulnerable users. The key question was: how can an item that does not comply with health and safety standards bear a CE mark and still be on sale in stores? The team started by looking for items in the data that were still available in shops, and bought one. They then asked the responsible inspectorate to provide the notification file. The file identified the stakeholders (supplier, distributor, manufacturer) and stated whether a notified body had been designated for the product group. The team contacted the manufacturer and asked it to help reconstruct the 'journey' taken by the item. The reconstruction of the journey was based on interviews with both private and public stakeholders and on desk research. During the interviews the item functioned as a conversation piece (Gaver, 1999) which sharpened the team's focus and prevented the conversation from getting bogged down in a discussion of the entire CE system.

The team experimented with many different ways to visualize the product journey and discovered that it was not possible to capture the journey in one visual alone. Based on the available information they discovered that the best way to visualize the journey was to show three journeys the product made: its first time on the market, the rejected product and the current product. Figure 5 shows the final infographic of the toy's three journeys.

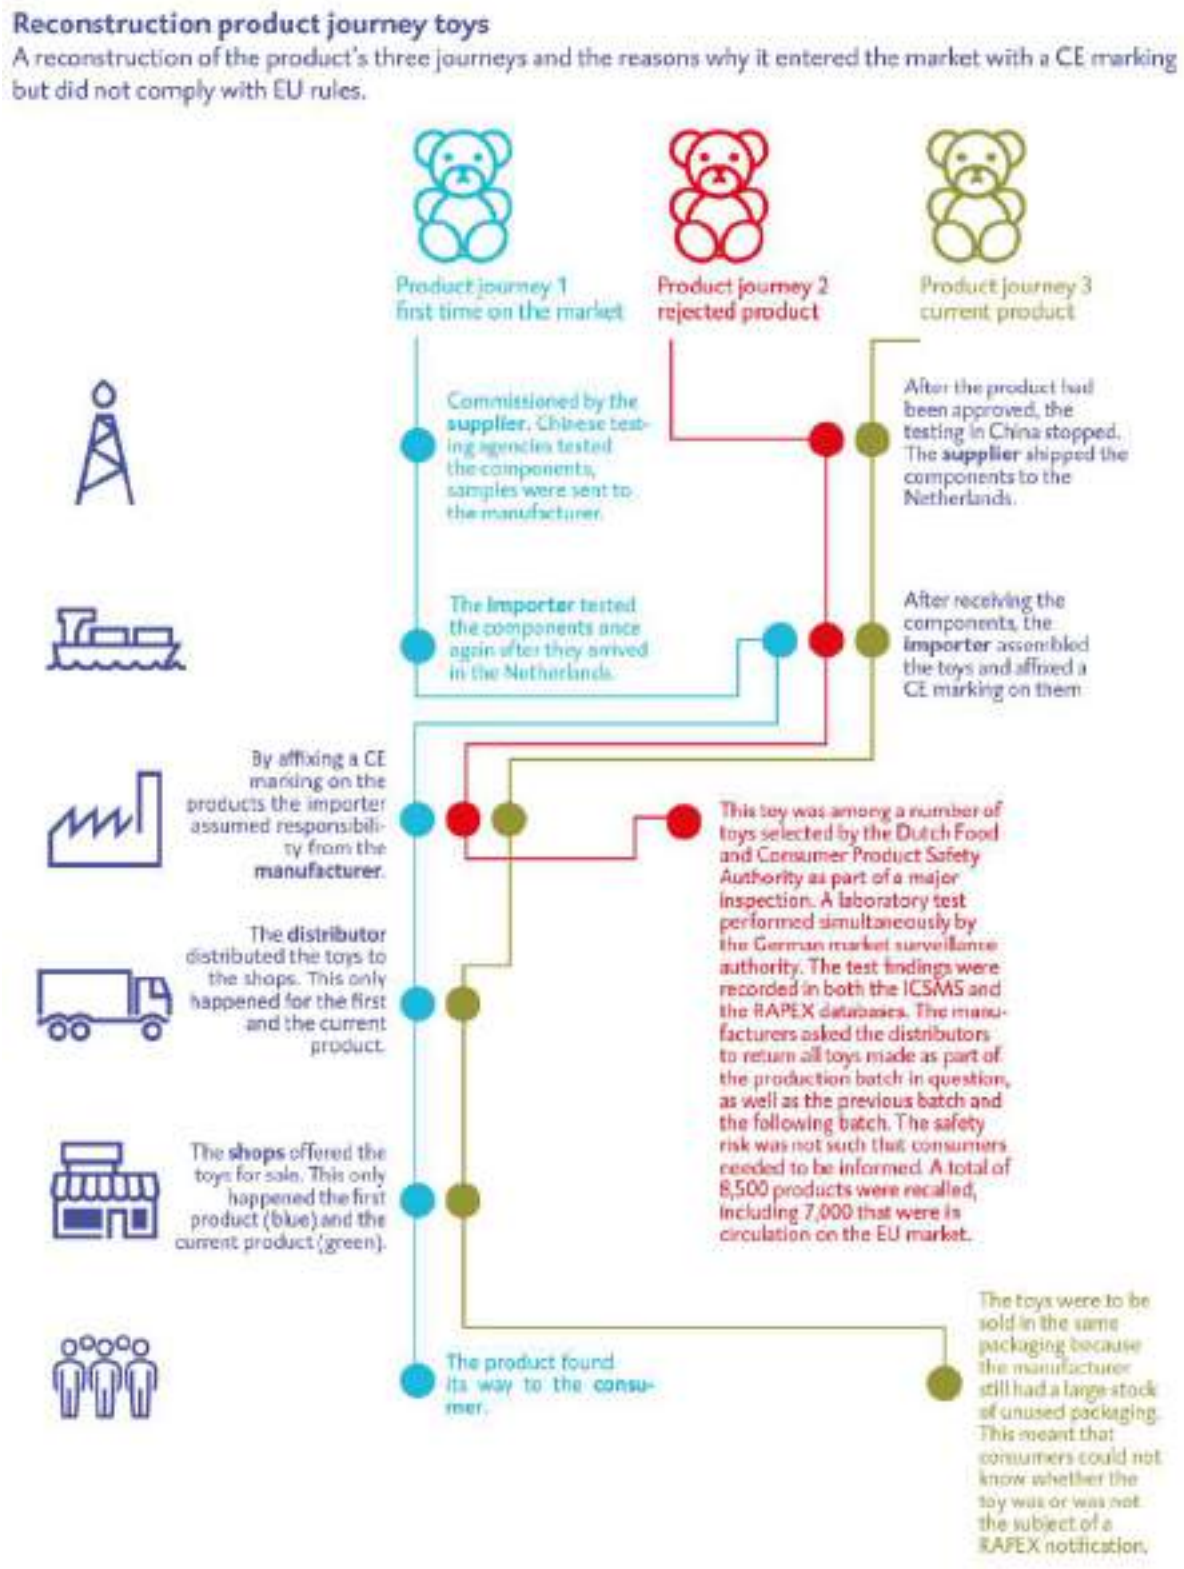

Figure 5. An infographic of a product journey (NCA, 2017)

After discovering which visual story could tell the story best, the team selected another product group. The top 3 notified product groups were: toys, pyrotechnics, and appliances burning gaseous fuels. Dutch law on the use of pyrotechnics is very different from laws in other countries in the European Economic Area, so the team decided to choose the third product group. Again they mapped out the selected item's journey, and again discovered insights about the system the team could use in the audit, e.g. the fact that ongoing technical

safety discussions could be the reason why items that were considered unsafe by the inspectorate were still on sale. These insights into the weaknesses of the system (and the infographics) were used in the final audit report.

The team named this self-developed design research method a 'product journey'. It not only helped the team gain more and different insights than data analysis and interviews would, it also helped design a more engaging product – our audit report. The data and the CE system were given more meaning, and it satisfied the team's personal wishes to have some pressing questions answered. Moreover, the audit was picked up by several journalists and their articles had many similarities with the way the audit story was presented in our report.

This approach differs from the first order because you have to look at the report as a whole: the report was 'directed' by the team. They added 'design abductive reasoning' to 'inductive reasoning', while they searched for ways to make people care (outcome – abductive reasoning) about the patterns they found in their audit (how – inductive reasoning).

Using 'interaction' (third order)

One of the complexities of the CE system is its transnational nature: 33 countries use CE marking as a passport for products to be sold in their markets. One of the audit report's recommendations was to improve the existing database and its use by the member states. But as the SAI of just one of the member states, the NCA was just a voice in the wind. In order to have an impact, the NCA needed to collaborate with other members of the audit community. It reached out to other SAIs in the 33 countries and hoped that they would pick up the same audit topic.

Knowing from experience that joint or collaborative audits would take a lot of time to coordinate, the NCA wanted to try something else. It came up with the idea of CODEA: COoperative Data Exchange and Analysis. The aim was to enable other auditors to audit CE marking in their own country, without coordination by or interference from the NCA in the form of data sharing. Four data visualisation students at Utrecht University of Applied Science were asked to design a tool that would help auditors from different SAIs understand and analyse CE marking data. The tool would address the problem that not all auditors were data experts, or were used to working with data. A two-day workshop in The Hague taught eight SAIs that were interested in carrying out a similar audit how to use the web-based tool. The team also presented six audit building blocks to help the other SAIs investigate the audit subject. Two SAIs that attended the CODEA workshop indicated that they would consider auditing this subject in their own country. In the end, you need one follower to bring these innovative plans further.

Again, this is an example of adding 'design abductive reasoning' to 'inductive reasoning'. We did not know what would work to find the collaboration that this audit needed. We tried to understand the needs of the CODEA participants (what do they need to execute the audit?), we designed a workshop and building blocks in order to get started with the results of the inductive part of the audit.

Using 'systems' (fourth order)

In 2000 Malcolm Sparrow argued to reform the practice of regulatory and law enforcement which, he wrote, "has more to do with changing the behaviour of regulators than with changing regulations" (p.1). It is not their job "to catch smugglers, it's to stop smuggling.", he said (2011). According to Aken and Andriessen (2011, p. 1, translated from Dutch) design-oriented research differs from explanatory research because it aims not only to describe and explain problems, but also to develop and test generic solutions to those problems. So, in order to find alternative strategies for inspectorates more attention should be devoted to problem- and risk-based solutions.

In our audit on CE marking we did not notice any problems in the regulations – the Blue Guide. The Blue Guide contained a well-defined system. But we also saw that unsafe products bearing a CE mark kept entering the market. That is why we recommended that the data and the database should prioritise *smarter* surveillance rather than *more* surveillance, and that 'the eyes of the consumer' should be used in that surveillance. It is important to notice that our recommendations asked for adding actions next to classical regulatory approaches.

Besides finding alternative strategies on CE marking, we tried to find alternative ways to increase our own impact. To strengthen our recommendations to make better use of the database, the team held workshops and presentations to share insights and data analysis methods. In face-to-face contacts with the inspectorates

they formed a DOE coalition (Dutch for a 'doing' coalition, in keeping with the inspectorates' aim of changing 'thinking about cooperation into cooperating' (Rijksoverheid, 2018, translated from Dutch)) in order to establish a smarter inspectorate for CE marking.

At the moment the inspectorates are improving their working methods by using data analysis and cooperating more frequently and more effectively with the various data owners. In their working plans they state that they want to change their way of inspection in accordance with our recommendations. This means that what we designed – an alternative strategy in a complex system – was picked up by the inspectorates. If we had just followed inductive reasoning, we probably would have recommended to improve the information position of parliament because the data was not adequate. Now we took it a step further: what would really work to improve the system? The data was not adequate but what could we do to convince the inspectorate that the solution was in the data? And in the end, we did everything to 'make people care': we made engaging infographics, we followed a product journey to give the data more meaning, we searched for collaboration on the topic and we added our report with workshops about our analysis of the data in order to help inspectorates learn.

Second example: Information provision in the social domain

In the Netherlands various tasks to provide care to people in need have been transferred from national and provincial government to local government. Examples of care that were decentralized include care for children and adolescents, care for the elderly and informal care. This transfer in the social domain took place in 2015, and since then parliament has struggled with the way it is informed about the provision of care by local government. Parliament asked the NCA for advice on how the information it receives about the social domain by law could be improved (Algemene Rekenkamer, 2018, in Dutch).

The team decided not only to honour this specific request but also to address a related problem. Parliament receives a lot of information via websites and databases that is not always accessible. The team engaged a design researcher (author of this paper) to investigate this unwritten question.

The audit's first goal was to explain to parliament what information it should receive by law, so this part of the audit was approached by means of deductive reasoning. The second audit goal was to show how the information could be presented in a more accessible and more useful way.

Using 'objects' (second order)

Besides sending the audit report to parliament, the team wanted to present a tool that would function as a signpost in the labyrinth of information. To design a tool that would meet parliament's needs, the design researcher made a prototype which she tested with the MPs' support staff. These staff members gather and analyse information to support the MPs' work. The tool was designed as an interface for the database containing government information produced for parliament.

The first prototype was tested with the MPs' support staff, and adjustments were made based on their feedback. The next iteration was tested with another part of the staff and the feedback was again incorporated in the interface. Finally, the tool, known as the Social Domain Signpost, was released together with the report. To offer other stakeholders a means to develop the tool, the NCA presented it as 'open design' and all the government information produced for parliament as 'open data', free for everyone to use and to design their own tool.

Using 'interaction' (third order)

The prototype developed by the audit team's design researcher was used to promote interaction among the stakeholders. The team didn't want to be the product owner but encouraged stakeholders to develop their own interface by integrating the tool into their own information services. The team deliberately focused more on the tool's design and testing than on its technical features. The prototype was used as a conversation piece in order to test its accessibility and raise awareness that parliament's problem involved more than just receiving enough information: it was also about the information's accessibility and presentation so that it met the users' needs.

Adapting design in the world of audits

The two examples described in the previous paragraph can be placed in Buchanan's framework as shown in table 2.

Table 2: Design approaches used in two NCA audits, placed in Buchanan's framework (2015).

Audits	*Symbols*	*Objects*	*Interaction*	*Thoughts*
Products sold on the European market: unravelling the CE marking system	X (discover and tell visual stories)	X (giving the data meaning, product journey)	X (design a tool from perspective of target groups (SAIs))	X (help inspectorates carry out data and risk-based surveillance)
Information provision social domain		X (tool, open design and open data)	X (interaction through the Social Domain Signpost)	

Table 2 suggests that the four orders of design are quite distinct from each other but in reality they are interdependent. A compilation of visual stories (first order) creates an engaging, directed publication (second order), and a tool to promote interaction between groups (third order) overcomes the groups' reluctance to cooperate and therefore challenges the system (fourth order). We also discovered that the results of the design approach used in an audit can both overlap each other and differ from each other. But the main characteristics of a design approach – human-centeredness, iterations, tangibility – are found in the examples. Human-centeredness was strongly represented in the product journey. The auditors wanted the data to have a stronger impact because dozens of products bearing a CE marking posed serious health and safety risks and were having to be withdrawn or recalled from the EU market every month. This was a very design-oriented approach to the issue. The iterative approach was most apparent in the prototyping of the Social Domain Signpost. This was an example of innovation, as auditors normally do not share information that still has to be signed off. Visualising the legal information on product groups helped the team understand the topic better and heightened their need to gain more information.

The NCA's first encounter with design thinking lies in the first order. The NCA was persuaded to use more infographics, data visualizations and animations to get our message across. We first hired designers to make infographics when the audit was completed, but the complexity of the audits was difficult to portray and the infographics would go through many revisions. As the auditors did not feel that they owned the visuals, this was a side issue. Fortunately, the auditors themselves began to use information design and visual design, and in 2017 a pool of external designers was set up to co-create infographics while reports were being written. Nowadays, every audit contains infographics made with input from the auditors to portray the complexity of the audits and explain the nuances. Auditors tell their stories in words and images, and designers work with auditors to co-create visual stories, not just to fulfil an engagement.

As noted above, the four orders of design are interdependent. An audit that does not address certain system values can have effective infographics, but it will have a low impact. Designers working at the NCA should understand this, and the importance of asking relevant questions. This is when the use of different kinds of reasoning (Dorst, 2015b) can help.

The audit process is based on auditors taking a deductive and/or inductive approach to objective knowledge. All steps in the NCA's audit process are geared to collecting data based on exacting standards of research. That is why the audit process contains many steps to safeguard quality, including fact checking with the auditee and internal and external quality control. A design process uses iteration to allow for new information and to understand the user's needs. Designers use a design abductive approach to strengthen audit significance and impact. For design thinking to add value to audits the NCA should integrate the audit process with the design process, the knowledge-centred approach with the impact-centred approach. Although concerned mainly with the use of visual and information design in audits, Meijer (2018) suggests how the NCA could integrate the two processes, as shown in figure 6.

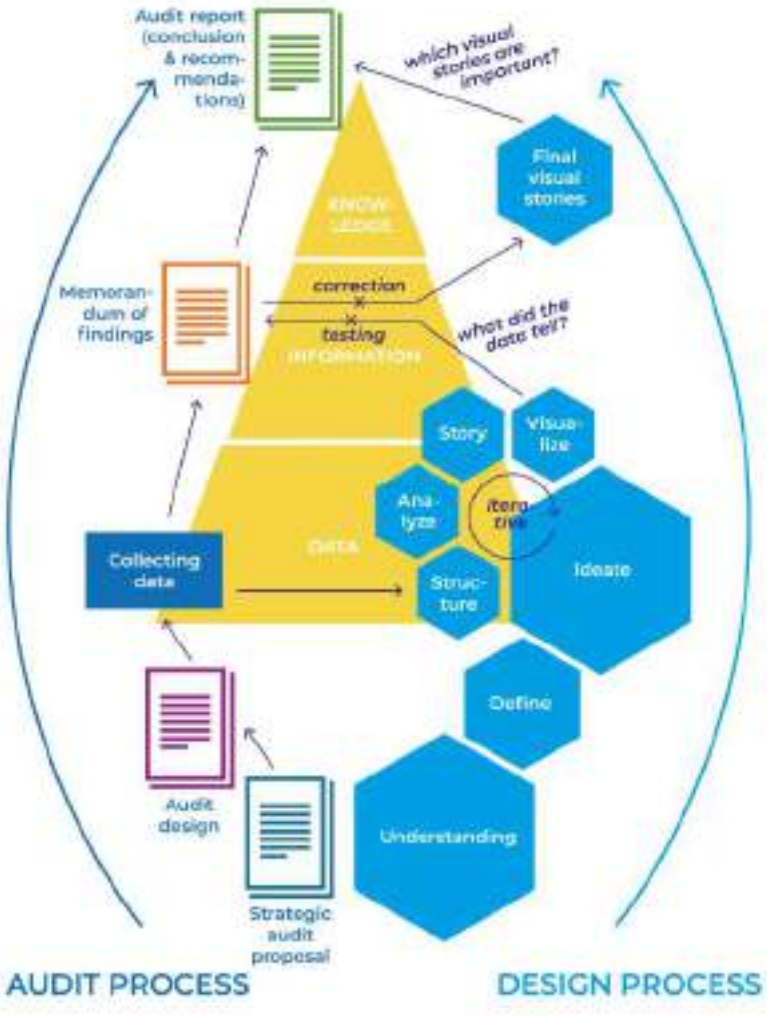

Figure 6. Suggested integration of the NCA's audit process and the design process (Meijer, 2018, p. 78)

These working strategies stimulate the adoption of design thinking in audits. Nevertheless, there is an important element in the world of audits that impedes the adoption of design thinking. The users of an audit are 'users' in a complex world. The users of the NCA's audits, the minister and House of Representatives, have different interests. Ministers want to prolong their political term and avoid any risks that challenge that term. The House of Representatives wants to put the screws on the minister in order to represent the interests of voters. INTOSAI (2018) warns SAIs about this risk:

> *When engaging with external stakeholders, a SAI needs to be mindful of potential risks such as being exploited for political purposes or being seen to be too dependent on international partners. Such risks need to be carefully managed, for example, through ensuring that the purposes of meetings are made clear to all involved in a transparent and accountable manner and the outcomes are documented and agreed. (INTOSAI, 2018, p. 18)*

That is why the independence and autonomy of SAIs is the highest good and also increases the impact of audits. As Van der Bijl (2017) notes, human-centred design is about 'how to gain and apply knowledge about human beings and their interaction with the environment, to design products or services that meet their needs and aspirations.' (p. 2). There is a thin line between 'being exploited for political purposes' and 'meeting needs and aspirations'. Auditors cannot just meet the needs of their auditees in order not to be exploited. Yet, stakeholder engagement is an emerging audit issue. The SAI of Estonia (Asari, 2019, pp. 18-21) recently took stock of the engagement of stakeholders by SAIs. As one might expect the most common way to engage with stakeholders is through 'consultation', which presents the least risk to the SAIs' independence. And SAIs, of course, are very risk averse.

In view of the environment in which auditors work – fundamental differences in reasoning, independence while engaging with users and co-creating with designers who understand the interdependency of design orders and embrace the complexity of the audit topics – adapting design thinking to auditing is quite challenging. But like regulatory agencies, auditors are beginning to realize 'that complex societal problems cannot be managed using traditional […] tools' (Malcolm & van der Bijl, 2016, p. 1). The NCA is convinced of the added value of the first order of design, but the other three orders of design are not yet daily practice. That is why the NCA is investing in a new community of practice: the Design Audit Studio. This community will aim on the further adaptation of design thinking in order to us it in the audit work and the audit process.

Building Design Capabilities in Academic Libraries

GASPARINI Andrea Alessandro

University of Oslo, Norway
andreg@ifi.uio.no
doi: 10.33114/adim.2019.04.376

While design-led innovation may have huge potential to change both tangible outcomes of design, such as products and services, and the intangible ones such as values, mindsets and organizational cultures, the approach has not been broadly investigated in the organizational settings, especially when it comes to building in-house design capabilities. The paper reflects on both practical and theoretical concerns around building of design capabilities in academic libraries. The making and sustaining design capabilities was supported by design interventions in the form of design workshops and other design activities, and repeated re-enforcements of constructivist and experiential organizational learning leading to integration of design proto practices with daily routines and established work practices. The findings are articulated as a set of guidelines toward building design capabilities in academic libraries through design thinking. At the conceptual level, the work highlights the importance of openness, dialogical spaces and temporal aspects of such processes.

Keywords: Design capabilities, research through design, design thinking, knowledge brokers, design interventions

Introduction

In the past decade, we have witnessed extensive changes in the roles of libraries in general, and academic libraries in particular. Academic libraries have been challenged, on the one hand, by the emergence of new technologies and devices (e.g., e-book readers, smart phones), digitalization (e.g., Google Scholar) and new ways of research and knowledge management (e.g., Research Gate) (Saunders, L. 2015). On the other hand, academic library users are often competent and are early adopters of new technologies and digital tools. They also have ever increasing demands for good user experiences and services and solutions that support their dynamic work patterns, both in physical and digital environments (Sennyey, Ross, & Mills, 2009). This situation requires paying continuous attention to the role of the library in an academic community, including consideration of the services on offer. In other words, academic libraries must be ongoingly concerned with institutional visions and strategies for the future, and develop innovative practices that allow them to be active and agile forces within the academic communities they serve. One approach to tackle this challenge is based on adoption of designerly ways of thinking in an organization, and building design capabilities toward sustained innovation and strategic reflection efforts.

We make a distinction between designerly ways of thinking and working and design thinking as commonly appropriated in business management. The former has been tied to design research and understanding of how designers think, reflect and act, see for example, (Buchanan, 1992; Krippendorff, 2006; Margolin & Buchanan, 1996; Schön, 1983, 1992). The latter has been praised as one of the best approaches to innovation and organizational transformations, for both public and private sector. The literature here is extensive, but we

refer to early research such as (Brown, 2009; Brown & Wyatt, 2010; Kimbell, 2011; Martin, 2009; Stewart, 2011), emphasizing how design thinking creates opportunities for design to enter new fields like business management and strategy, or education. The main 'active' ingredient in design-led approaches is creativity (Kimbell, 2011). Design thinking in business has been criticized for suppressing this ingredient by streamlining the process into a procedure consisting of four main phases: empathize (with users), define (the problem), ideate (consider and rapidly prototype a broad range of ideas), prototype (one or two of the most promising ideas from the previous stage), and evaluate (to what extent the proposed solutions solve the problem and how well they work for users), see (Nussbaum, 2011, 2013). Even so, just how to implement and sustain design thinking efforts in organizations without the presence of professional designers or design consultancies becomes a crucial question, and represents an identified research gap (Carlgren, Elmquist, & Rauth, 2014, 2016). Furthermore, if an organization opts for hiring designers or consultancies for specific tasks, the issue of how to continue working on these tasks after the work of a professional design is done (ibid.), presents a continued challenge.

Later examples in entrepreneurial and managerial discourse around design in institutional settings (Malmberg & Wetter Etterman, 2016; Malmberg, 2017) point in the direction of building institutional design capabilities.

Given their need to innovate, libraries have also turned toward design thinking. Consultancies like IDEO (IDEO, 2014) developed a set of methods for working specifically with library's visions, strategies and responsiveness to external challenges. However, these tools were useful when professional designers guided the work. When their work was done, the design thinking and innovation efforts would often stop.

Thus, in this paper, we propose an approach that aims to provide for sustained (over time) abilities to work with design-led innovation by building *in-house design capabilities*, so that academic libraries can respond to both external and internal challenges more appropriately. This does not imply that professional designers and design consultancies cannot play a role in innovation any longer; it just scaffolds forces within the organization to understand design and be able to work with or without professional guidance more effectively.

The research presented in this paper is of an explorative and experimental nature, aiming to inquire into how to approach developing in-house design capabilities at an academic library. Research through Design (RtD), see (Bowers, 2012; Dalsgaard, 2010; Fallman, 2008; Gaver, 2012; Höök et al., 2015; Koskinen, Zimmerman, Binder, Redstrom, & Wensveen, 2011; P.J. Stappers & Giaccardi, 2012; Zimmerman & Forlizzi, 2014) was chosen, inspired particularly by the work of Fallman (2008), as it focuses on how design practice, design explorations and design studies combine to address the research positioning towards discovery of best practices, tools and methods that support emergence of design capabilities within an academic library. Other approaches, such as action research could have been a good alternative. However, experimental quality, flexibility and openness of RtD, as well as continued insistence on reflection, were characteristics that led to choosing the RtD for this work.

The library as an organization had no prior orientation towards design or design thinking. Methodologically, we use designerly ways of thinking and working to introduce design thinking processes and enable library employees to gain design capabilities that can, in turn, sustain the use of design-led organizational transformations and innovation of products and services. The research was carried out through design of a series of sixteen design interventions, in the form of design workshops or other design activities. The interpretation of the design practice, exploration and studies in the context is presented in detail in the methodology section of this paper. Constructivist and experiential organizational learning were used to gain design capabilities and establish designerly practices. This learning was re-enforced by repeated interventions (each having a different design goal), and over time, led to integration of these ways of thinking and working with daily routines, transforming the work practices in the library (Pandey, 2015). The contribution of this paper is a detailed presentation of how design capabilities were introduced and incorporated into everyday practices, with general guidelines as a starting point for knowledge transfer to other settings.

The paper is organized as follows: the next section presents a selection of literature focusing on design capabilities and tools for building them. We proceed by presenting sections on the methodology, the case, and the findings, which led to the set of guidelines.

Background

In this section, we first provide a brief reflection on previous work regarding building of design capabilities. Then frequently used tools that support design thinking, such as cards or mappings, are outlined.

Building design capabilities has been a recent topic of interest and described by, for example, Malmberg & Wetter Edman (2016) and Malmberg (2017). They put emphasis on how design capabilities are sustained within the organization, after project activities end. Malmberg (2017, p. 218) has observed that participants of design projects are often, after the project ends, not followed any further, and no attention is paid to strategies that enable them to spread design capabilities in the organization. This led to the conclusion that projects where skilled designers have learning-by-doing-based design workshops does not support "sustained innovation capability through design knowledge" (Wetter Edman & Malmberg, 2016). As pointed out in Malmberg & Wetter Etterman (2016), there is a gap to be addressed: "…and we see issues when it comes to structures that support diffusing and upholding new knowledge, for example, a lack of managerial activities that can support assimilation".

Service designers, along the same lines, found that the design tools and methods they try to use in organizations do not produce "the kind-of high-level transformational thinking in managers" they hoped for (Junginger, 2015). These findings were also true for libraries as organizations, and some researchers, e.g., Bell (Bell, 2011) argues in favor of including design thinking as a subject in librarianship education, and a way to gain design competence. In (Booth, Schofield, & Tiffen, 2012; Tiffen & England, 2011), the authors propose inclusion of design activities within the library through cooperation with the School of Design, which facilitated the use of design thinking approach on a more continuous basis. In (Luca & Narayan, 2016), design activities within the library were supported by an artist-in-residence, and in-house designers. A design thinking project at an academic library, described in Whang et al. (2017), explores its concrete applications to specific services, such as support of transfer students. The service focus is the one that is the most frequently reported on regarding library services innovation, see (Scupola & Nicolajsen, 2010), or (Trischler & Kelly, 2016). The latter used co-design with users at three different academic libraries in Australia. However, in line with findings from Malmberg & Wetter Edman (2016), when co-design activities stopped, so did the projects.

One of the largest design consultancies, IDEO (2014), focused on tools and methods for innovation in libraries. The toolset has been developed through a large project concerned with design for a Danish public library. The project is described in Dindler et al. (2016). Others have built on this work, e.g., (Zbiejczuk Suchá et al., 2015) or (Modern Human, 2017), both providing card sets inspired by those of IDEO, specifically to facilitate design thinking for libraries. However, it is difficult to use toolsets without the basic design knowledge, and it is easy to underestimate the importance of designer's tacit knowledge and sensibility for the positive outcomes of processes supported by the toolkits.

Diverse forms of mapping are also frequently used in conjunction with design thinking. We find Giga-mapping (Sevaldson, 2011) to be particularly useful. It aims to facilitate thinking and communication by visualization, inviting participation and collective negotiation of understandings related to the design context, usually by providing a large physical work space for these efforts. Furthermore, it allows for mapping out the context in layers (e.g., from the perspectives of different stakeholders), fostering further understanding of complexity and relatedness of problems.

From this background work, we find that in order to sustain design capabilities, diverse tools can be effectively employed, but also, attention needs to be paid to develop structures that support diffusing and upholding new designerly knowledge.

Methodological approach

Research through Design (RtD)

Research and design have been long regarded as separate endeavors, in particular within interaction design and human-computer interaction. Research through design (RtD) is a recent effort within those fields to merge the two, building on designerly ways of thinking and working (see Bowers, 2012; Dalsgaard, 2010; W. Gaver, 2012; Höök, Dalsgaard et al., 2015; Koskinen, Zimmerman, Binder, Redstrom & Wensveen, 2011; P.J. Stappers & Giaccardi, 2012; Zimmerman & Forlizzi, 2014), using design research, its theories and practices, as the main vehicle to generate new knowledge, often engaging users to validate, evolve and evaluate the work.
As articulated in Höök et al. (2015, p. 2), one of the main issues that RtD faces is how to articulate the gained design knowledge, and allow design researchers to engage with, and build on, one another's contributions. There are several proposals aiming to establish connections between theory, and practice, e.g. (Fallman, 2008; Gaver, 2012; Höök & Löwgren, 2012; Odom et al., 2016) and others. One of these approaches is Fallman's interaction design research triangle (Fallman, 2008), a tool to guide and describe research and design efforts.

The triangle frames the work by three main activities: design practice, design studies and design exploration. Each one of these "*has its own purpose and intended outcome and the rigor and relevance have to be defined and measured in relation to what the intention and outcome of the activity is"* (Fallman & Stolterman, 2010). Recognizing that research practices do not normally fall neatly into one of the three activities, but exists in the space between them, the triangle (see Figure 1) provides a way to address the research practice through *drifting* trajectories, looping or shifting dimensions, etc.

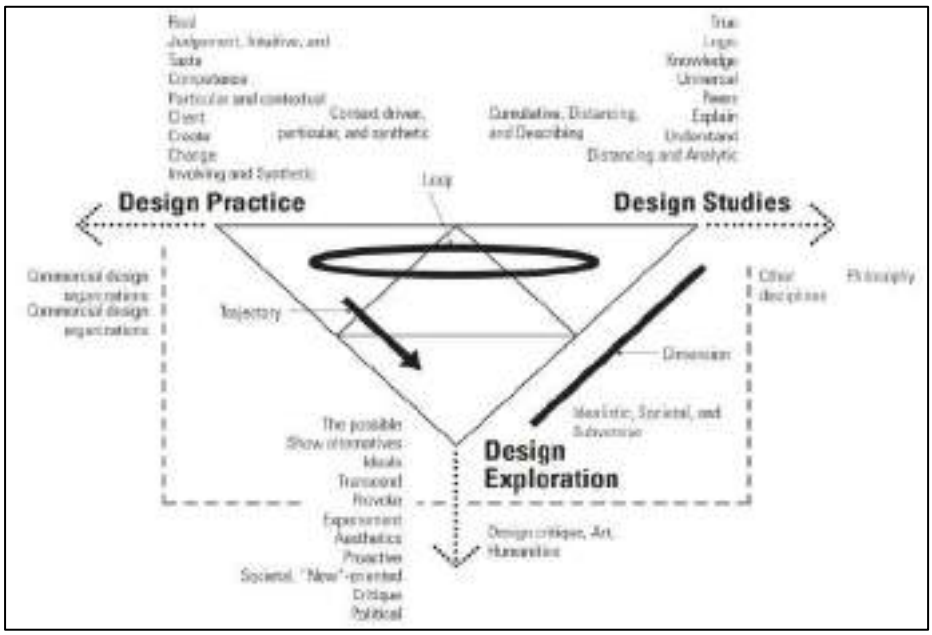

Figure 1: Design Research Triangle connects design practice, exploration and studies as researcher drifts in various ways (loops, trajectories, dimensions) through these activities. Figure adapted from Fallman (2008).

The main three activities are now briefly described.

Design practice can be described as a generative and synthetic research practice where the researcher becomes an integral part of a multidisciplinary design team working on a real-life library project, not primarily as a researcher or observer, but as a designer. This is to say, the researcher takes an active part in the hands-on design work of sketching, constructing and building artifacts and prototypes, dealing with time constraints and communicating and negotiating with fellow team members. Thus, the researcher, alongside library employees can build an appreciation and understanding of the tacit knowledge and competences involved in a professional design practice. However, unlike a professional designer, the researcher approaches the process "*with an explicit design research question in mind, or with the clear intent of forming such a question from their activities"* (Fallman, 2008, p. 6). It is important to mention that the research question does not have to align with the direction and goal of the design interventions, but can be formulated to focus on particular issues or themes that are relevant from a research perspective. In this case, for example, the intervention's goal may be to create a new service, but the research aim is to inquire into tools, meaning creation, ways of thinking etc., which support gain of design capabilities and understanding of design thinking.

Design exploration is synthetic and proactive, involving the researcher in a reflective, hands-on process of exploring designs and constructions of prototypes. These activities revolve around the researcher's own research interests, where "*the most important question is: What if?"* (Fallman, 2008, p. 7) Design exploration intends to experiment, question and provoke critical reflection on the current state of the world, and to imagine possible, alternative and preferred futures. "*[D]esign exploration is a way to comment on a phenomenon by bringing forth an artifact that often in itself, without overhead explanation, becomes a statement or a contribution to an ongoing societal discussion"* (Fallman, 2008, p. 8). In the context of this paper, the research explorations were centered on how design interventions should be designed so that the learning is re-enforced by tackling different real-life issues. Each intervention outcome was intended to serve as a road to becoming aware of larger, more complex issues, values and notions that the library can engage in through gained skills and understandings.

Design studies is the type of design research activity "that most closely resembles traditional academic disciplines" (Fallman, 2008, p. 9), where the goal is to build upon and contribute to a cumulative body of knowledge. This requires an analytical engagement with design theory, methods, history and philosophy, as well as theories and approaches from a variety of other disciplines. It also involves presenting and publishing research outcomes in academic conferences and journals. "*[U]nlike design practice, [design studies] seeks the general rather than the particular, aims to describe and understand rather than create and change, and because of that often appears as distancing to its character rather than involving."* (Fallman, 2008, p. 9) Design studies, in the context of this paper, highlight concepts that emerged through the process of implementing the interventions as the most important ones for gaining and maintaining design capabilities.

The role of the triangle is not so much about the positioning of a particular activity, but the way in which it enables reflection and discussion about how RtD researcher moves in between the three activity areas, thus providing concepts that describe movements, such as *trajectories*, *loops*, and *dimensions*. *Trajectories* are either intentional or unwanted drifting between research activities. They enable discussions about the perspectives and directions of a particular research activity, how the outcome of the activity may feed into another activity and *"what kind of quality measures, guarantors, and stakeholders we will face when moving in between different activity areas",* (Fallman, 2008, p. 11). *Loops* are trajectories without start and endpoints, signifying an ability to freely move back and forth between the two, and in some cases all three, activity areas. Thus, activities in different activity areas feed into each other, iteratively driving the research forward. Finally, *dimensions* infuse the triangle with meaning by creating conceptual continuums and tensions between the activity areas.

All these concepts have been useful in describing the research process regarding design capabilities within an academic library through interventions. The interventions were made with a clear intent of performing designerly work and allowing the challenges, both the learning ones and the ones related to appropriateness of methods and tools to emerge from activities and engagement of participants in any given intervention. Each intervention required engagement in design practice prior to the intervention (for example, designing and making context specific card sets, worksheets, or other objects to be used during the intervention to engage the participants in rapid prototyping), during the interventions (by participating in whatever design activities were a part of the intervention). Design explorations required a focus on research intent and exploring different ways in which design capabilities and practices could be supported through an intervention, as well as performing explorations under each intervention together with other participants. Design studies, in line with traditional understanding, served the purpose of generalizing findings from individual interventions and framing of research contribution to the body of knowledge that addresses how an organization, such as an academic library, develops design capabilities over time. Epistemologically, the triangle postulates that concepts and ideas have to be tried and explored to demonstrate their validity, in line with Dewey's position that knowledge and theories are active phenomena "that are formed and reformed" during an inquiry (Biskjaer & Dalsgaard, 2012).

Constructivist learning

Building design competences by applying design thinking in the library context had to do with ways of organizational learning. The approach to learning that was implemented in the context of the library was based on real-life problem solving, through an experiential and constructivist approach (Jonassen, 1999; Kolb, 1983). In fact, while articulating how learning was implemented, the Beckman & Barry's (2007) model that combines design thinking, innovation and learning styles (see Figure 2) was re-discovered.

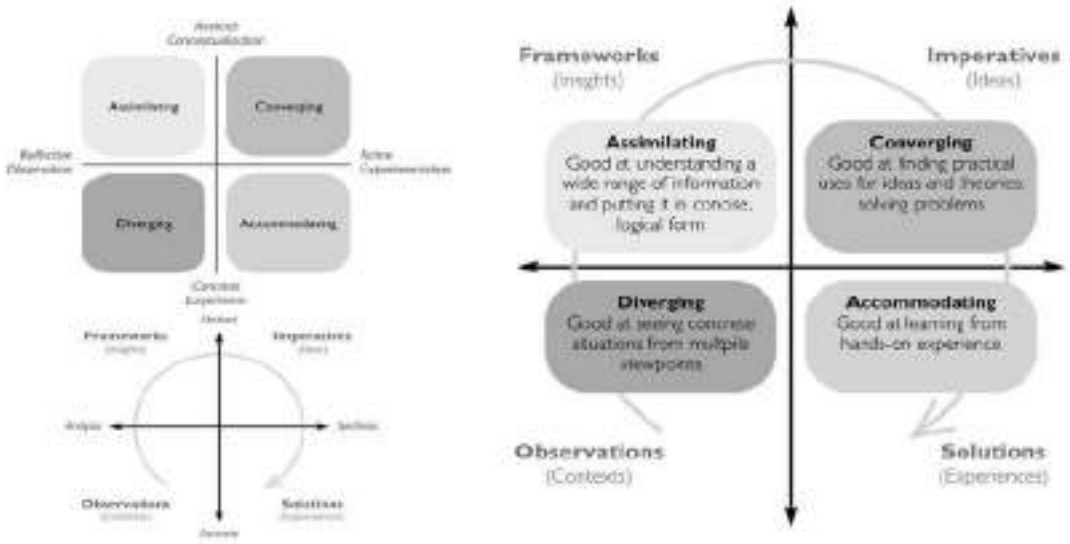

Figure 2 - Beckman and Barry's model that integrates design thinking, innovation and learning styles. Figure: from (Beckman&Barry, 2007).

Figure 2 is rather self-explanatory. Design thinking process is shown in the left bottom image, iterating between the synthesis and the analysis, the concrete and the abstract when moving from understanding the context towards solutions. The top image on the left shows different thinking styles. These are explained in relation to design thinking phases in the large image on the right, which depicts the integrated model.

While engaging participants in intervention activities in the library context, attention was paid to shift between divergent and convergent thinking, concrete and abstract, allowing the time for dialogues and assimilations, synthesis and learning from concrete experiences.

The case: design interventions in an academic library

During the course of this research, 16 design interventions were carried out. They grew increasingly complex over the period of four years that this research took. Interventions can be divided into three groups in accordance with what research aims were. The first set interventions (4) all focused on service design as the aim of the intervention (innovative services, or improvement of the old ones), as well as organizational learning (vocabulary for service design and design thinking) through experiential engagement in the intervention, exposing participants to different thinking styles and thinking through rapid prototyping. The mid-period interventions (9) also focused on services, but were tackling more complex issues that were of importance for the library at the time when they were performed. During this period, some library employees already got engaged with the approach, and it could be said that became knowledge-brokers for design thinking in the library (Pandey & Srivastava, 2016). The last set of interventions (3) was related to three large projects, two of which are still going on. These interventions were strategic, deeply engaged in envisioning of the role of the library in the future. To provide flavor of these workshops, one representative intervention from each group is presented.

An example of early interventions

The intervention presented here was a workshop with 25 participants. Seventeen participants were library employees, including leaders, librarians, digital service employees, and open access consultants. Four participants were graduate students in interaction design and four were researchers. The participants were divided into four multi-disciplinary groups to discuss searching for e-books, which was a real life issue at the library. The activities were hands-on. Each team got their deck of service design cards, and other typical workshop items, such as colored pens, dots, and a large sheet of paper (see Figure 3, left and center). The participants took some time to become familiar with service design concepts and tools, especially cards. Cards were quickly recognized as an excellent tool, facilitating the building of common understanding of the problem space. Soon, all groups started also using arrows and dots to reason by assigning importance to specific cards or processes, and mapping out present and future customer journeys while searching for e-books. Design

thinking was an approach, at least in the simplified format in which it was presented, that all could easily understand and use to solve the problem at hand.

Figure 3 - The images show some of the cards that were made to depict the local library spaces, use of cards during a workshop and a Giga-mapping session (Photo: Gasparini).

The outcome of the workshop was, for the library employees, the understanding that service design uses a design thinking approach and tools such as customer journeys and touch points between library users and the library. Alternative customer journeys (prototypes of future services) were easy to visualize using service design cards (touch points cards). One of the lessons was related to the understanding that through synthesis of experiences from diverse suggestions of future customer journeys, inferring and discussing the best solutions may lead to design of better services.

The research aim was how to best introduce design thinking and build interest, motivation, engagement among the library employees by considering the selection of the intervention aim (a small, manageable one at first, such as e-books search, yet related to the real organizational need) and the use of tools that are appropriate for the purpose. The team work facilitated fast learning and constructive dialogues. Attention was paid to the number of participants within the team (in this case, 6-7 per team) in relation to the engagement and equal opportunities for all to actively take part in the process. The level of openness of tools emerged also as central (Culén & Gasparini, 2016; Culén et al., 2016) already during this first intervention.

In the subsequent three interventions in this first group, we used different sets of cards, to explore the different effects on participants when tools were directing behaviors, were too open, somewhat structured, or fully structured. Other layers of *openness* also became visible, establishing openness in tools, processes and mindset and a main theoretical concept to be explored.

An example of mid-period interventions

This example is an intervention concerned with the use design thinking in order to improve web services for the library, as well as the coordination between different departments maintaining the web pages. The goal was also to envision a common strategy for dealing with web-services across all departments. The intervention comprised several workshops and was organized in collaboration with the Communication Department at the University of Oslo Library. All participants were web-editors and different workshops had different number of participants, ranging from 7 to 10, most participants took part in more than one workshop. Since participants by now were familiar with design thinking processes, the tools changed. Communication exercises, design thinking exercises, mind-mapping and Giga-mapping (see Figure 3, right image) became central, and were based on real library needs (apart from the communication exercises such as writing a break-up letter, and others that were picked up to support the processes). Materials such as large paper sheets, post-it notes and colored pens were provided.

The outcome of these web-service workshops (constituting a single intervention to improve processes around web-page maintenance) for the library was a draft of the common strategy that all could agree to. In the aftermath of the workshops, it became evident that the participants in this intervention managed to integrate the design thinking approach in their daily work practices, implying that they have indeed succeeded in developing some design capabilities. They demonstrated this this indeed is a case by using the new gained skills and ways of thinking to organize different events and services entirely on their own.

From the research perspective, exploration of how to support dialogues continued. This now became conceptualized as *dialogical spaces* and is described in more details in the discussion. The emergence of these spaces was fostered by using and shifting between different tools (again, in accordance to constructivist and experiential learning, Figure 2). The participants showed routinized behaviors when using tools, that is, familiarity with both processes and tools. Temporal aspects were now brought to the foreground of research inquiry into integration of design capabilities and designerly practice with everyday work in the library.

An example of the most recent interventions

A new department at the university, and the physical space to house it, was under planning since 2016. In the initial plans, the library was given only a small place to perform the traditional library functions. The intervention, comprised of two workshops was carried out to change this outcome strategically. The workshops were initiated by one of the library leaders, along line with other knowledge-brokers in the process of organizing the intervention. The first workshop had the aim to discover opportunities for the library that could be fronted, and through which the library could support the needs of the new department in new ways. The second workshop focused on an even broader question: "*What should the University do to be known as a place for convergence and innovation? How to create room for innovation, and innovative thinking in the new department?"*

Eleven participants took part in the first workshop, from different departments of the University, and one architect. The second one had 14 participants, all with different backgrounds, aiming to create truly multidisciplinary teams. Participants were in research leadership positions (6, in charge of research groups), a dean, a student representative, employees from different departments, interaction-design students and two library employees.

During the first workshop, people used ethnographic methods and tools (walking tours with photo-documenting). The second one used a whole range of tools – cards to make newcomers comfortable and open for dialogue, customer journeys and touch points to understand the approach to service design, Giga-mapping and other mappings to discuss the complexities and layers of needs in the new building, see Figure 4.

Figure 4 - Wall from the second workshop showing different design tools used, such as the affinity mapping, and customer journeys (Photo: Gasparini).

The outcomes for the library could be summarized by what the leader of the library who initiated the workshops said: design capabilities, skills and understandings of the processes gained during earlier design thinking interventions allowed her to envision how to use different design methods to position, in the difficult arena of political negotiations for the space and presence in the new department, the new values of the library. The design approach used during the two workshops helped the participants understand that the library could be a much larger stakeholder in the building than they previously realized. Using the design thinking approach in these two meetings, the library managed to change its position from being almost marginalized to be the party responsible for innovation and creative thinking spaces in the new department.

For the research, this represented the point at which the interventions could be stopped naturally. It confirmed very clearly that the understanding of design thinking at the organizational level was now deep enough and powerful enough to serve also the strategic purposes. The leadership and the knowledge-brokers have gained competences that they could use in complex contexts, and to meet new challenges. Temporal

aspects of the processes became of central interest, whilst different aspects of openness could not be clearly seen, as well as how it influenced creation of dialogical spaces that last within the organization.

Discussion

As common when engaged in research through design, the basic way of gaining new knowledge was through reflections in actions during each intervention, and reflections on actions post intervention. In practical terms, after careful planning, possibly design of cards or other tools, piloting the intervention, in action, every step was evaluated anew. For example, even if tasks were carefully timed, interesting processes and discussions were allowed to continue even if the allocated time was over. Also, many different aspects, such as team work, quality and quantity of ideas etc. were always ongoingly evaluated during interventions. Reflections on action allowed for establishment of new explorative pathways that were deemed optimal towards continuing to build in-house design capabilities. They also helped in recognizing important theoretical concepts that facilitate processes of adoption and integration of new practices in everyday work.

The three core concepts (openness, dialogical spaces and temporalities) that emerged as central through the research efforts are now discussed.

Openness

Several layers of openness became visible in these processes. *Openness to change* implies willingness to observe and identify opportunities for design in everyday work. It also requires the willingness to *periodically evaluate* the effects of using design thinking, as well as consider other ways in which it can be used, towards building of design capabilities. *Openness to learn* and acquire design skills and competences was also important, but did not necessarily apply to all employees. As long as some library employees were willing to become knowledge brokers, in-house competences could be maintained, and built further. However, it was remarkable that nearly all employees wanted to learn, and participated in at least one of the interventions to gain the understanding of design thinking processes. Keeping in mind Beckman & Barry's (2007) constructivist and experiential learning model, oscillation between the concrete and the abstract, as well as reflections and actions, was important to keep people engaged and open to learning. *Openness to proto-practices* relates to the willingness to integrate new ways of thinking and working with already established practices and processes. *Openness to be a part of a multidisciplinary team work*, where dialogical spaces and creation of truly shared knowledge, was important. It is directly related to individual's behavior and experiences in team-work settings and people's willingness to adjust personal behaviors and expectations from personal to project based ones, to take the full advantage of the diversity of competencies.

At a different level, *openness to research collaborations,* that is work with other researchers and designers engaged in similar research and practices, fostering positive collaboration to explore building of design competences, was of importance to increase competences of knowledge brokers and understanding of tools used to communicate design thinking processes.

When discussing tools, the understanding of *openness of tools* emerged as a very important one. Most of the tools, such as diverse card sets available on the market, have structured approaches so that novices can use them with some gain. Alternatively, they are open for interpretation and require facilitation by professional designers, to address their tacit knowledge and sensibility. One of the main findings from having been involved in the processes of building in-house competences has been that semi-open structure work best. In other words, using tools that allow creativity instead of limiting it, but that support well both divergent and convergent thinking and enable broader research and wider inquiries into the problem space were the best to use. In addition, such *semi-structured design tools* were found to support various forms of communication and emergence of dialogical spaces well.

Dialogical spaces

Developing dialogical spaces, design vocabulary, and the project vocabulary, in line with findings from (Krippendorff, 2006) and (Boland, Collopy, Lyytinen, & Yoo, 2008, p. 14), were shown through this work to be of paramount importance for building and sustaining design capabilities and understanding of design thinking processes in an organization such as the academic library. What we have seen is that the design thinking approach and the tools, different at different stages of assimilation and capabilities building, supports the creation of a dialogical space where a common understanding is created. The real-life solution-aimed activities supported well the reflective learning (Beckman & Barry, 2007; Schön, 1983). However, dialogical

spaces, both the physical ones (created for each intervention so that people could easily engage in creative activities, move and talk in different constellations was always facilitated) and the mental spaces in which participants could feel safe, and share knowledge, stances, and ideas freely were essential property of the process. Next, we found that playfulness was important in the dialogical space, as it supports team interaction and invites people to a more relaxed communication with each other. Often, tools to be used in an intervention were selected just for their power to support dialogues, speculations and criticism (where relevant) but through playfulness.

Regarding the physical aspects of dialogical spaces, the territory where they take place id important. Places chosen for interventions mediate the character of the event (for example formal or informal), level of care for the event (careful preparations, availability of all needed materials, preparation of cases to work on and more), level of intimacy (the size, coziness and other properties) and so on. In the dialogical space physical proximity of participants, as well as activity spaces are both important and some personal routines may be challenged. To be in the same space for duration of the intervention is important for dialogical spaces. When appropriate, informal spaces for dialogues could also be created, such as during lunch or coffee breaks.

In summary, the term "*dialogical spaces*", reflects the concept of both physical and mental spaces (supporting possibly multiple dialogues within the same space) in which a cross-disciplinary design projects take place. Dialogical spaces shape the project language and introduce the design vocabulary to newcomers to design processes. Through careful choice of physical spaces, using constructivist and experiential learning (sharing of concrete experiences, abstracting together, etc.), supported by adequate design tools, like Giga mapping (see Figure 3, right image), learning is speeded up, and new understandings of project-relevant knowledge emerge.

It is also important to note that, when concerned with building of design capabilities, knowledge brokers continue these dialogues by integrating them into their regular work-practices. They are thus always available to others, to engage in dialogues around possible new projects or areas of application for their design capabilities.

Temporal aspects of building design capabilities

As noted above, this part is rather mundane and part of the common practice when planning interventions, workshops or other activities involving people who dedicate their time to come to the activity. During the entire project, no participants were paid for their work extra (the library employees did the activities during the normal working hours, and had their regular pay, all others volunteered their time). Thus, the return on time investment needed to be thought of. It turned out that most participants, if novice, were happy with the learning process, and if experts, with sharing knowledge in a real-life and meaningful setting, usually with people who were quite engaged. Making sure that each intervention had some form of concrete outcome, even if not immediate, was an important return on time investment.

It can be said that the first group of interventions was an orientation phase, using the term as in Karapanos et al. (2009) that describe temporal aspects of processes, becoming familiar with design thinking and the ways of using it. The second group of interventions was corresponding to the incorporation phase, through prolonged use of the new practices. Finally, the last interventions can be said to represent the identification phase, demonstrating how designerly ways of thinking and working have become meaningful within the library.

Between interventions, especially the more complex ones, integration of gained knowledge, changes in the mindset, or in practices, needed to be allowed some time. This kind of temporal perspective are really little understood, because they can be subtle and unnoticeable for those who are not a part of the organization (connecting back to the importance of insiders and knowledge brokers for the development of design capabilities). How to support and how much time to dedicate to these processes? If new participants attend different events within an intervention, as was the case with later ones, how to save time related to establishing dialogical spaces, and the orientation phase? The findings here indicate that selecting knowledge brokers here too, is necessary (or, at the minimum, there should be some overlapping participants who can speed up the learning processes for the newcomers). Equally important, deciding what ideas and possible solutions should be discussed further, what solution trajectories to choose when implementing, was also interesting from the time perspective.

Remarks on learning and participation

Although the portfolio of interventions was diverse, they all focused on integrating design thinking and building of design capabilities in the library. Some have taken concrete, simple projects that, seen in isolation, are not of a large significance. However, seen jointly, as re-enforcements of learning how to act in designerly ways, they do address macro management of time. Distributing these smaller, manageable and possibly inspirational projects across the timeline of the overall project kept re-enforcing the learning.

In the light of previous research, especially the poor ability to sustain design capabilities (Malmberg, 2017), the creation of a design language based on the vocabulary used during projects was of paramount importance. There are many examples of how the library staff used their design capabilities. For instance, one subject librarian, long after this research was done, when working together with the faculty from another department at the university, used design methods to engage with the following questions: *What makes a research paper a good one?* and *What does a PhD student need to do to get to have a good one?* After mapping the problem area, they created a number of different user journeys, charting the territory from an assignment to a successful paper. This example shows that the subject librarian continued to be open to design methods, successfully remembered design vocabulary and explained the user journeys to others, creating a common dialogical space along the way. The subject librarian also could articulate the time perspective more clearly, leading to the better understanding and implementation of the collaboration on this particular case.

Since projects were diverse, people were always open for new learning and participation. As mentioned earlier, many library employees have participated in multiple interventions. Repetition and diversity of interventions were hugely important factors for building capabilities over time. There was no prescribed number of interventions that had to be done. Instead, the momentum built by one intervention and the interest it generated were used to organize the next one. In this process, the attention was paid to not have them too close to each other so that they do not become burdensome, but close enough that they can build on the outcomes of the previous ones. Between these, the library leadership could use the time to evaluate and appropriate the skills. With time, they developed the ability to notice the design opportunities. As described in the most recent intervention example, it was the leader who was the initiator of the intervention. This was a marker that incorporation has indeed taken place.

In summary: a practice-oriented approach, research through design, utilizing experiential learning, and a pragmatic approach and especially the Dewey's notion of *inquiry*, aiming to approach a non-defined situation and try make it *thinkable* (Dewey, 1909, p. 108), has been a suitable way of introducing design thinking and building of design competences for the academic library. Real-life problems, solved through design thinking and in the context of experiential and hands-on learning, were crucial. In addition to repetition, as a learning strategy, what motivated people to engage, and keep them engaged in design thinking processes, were dialogical spaces and openness. Allowing time for assimilation, integration, evaluation and emergence of proto-practices, also played an important role.

I close this section by providing guidelines, rather than recipes, on how to work with capability building and design thinking in complex organizational settings of academic libraries.

Guidelines

Based on the outcomes of this study, some simple guidelines are provided on how to work with design capability building and design thinking in complex organizational settings of academic libraries.

1) Start by providing introduction to design thinking and service design, using compelling examples of real-life library issues, to the leadership (have in the back of your mind the ways in which people learn (Kolb, 1983) and use concrete real-life library problems to so that people can relate them to experiences that they already have).
2) Systematically work on increasing and building design competences. This can be accomplished by using knowledge brokers, someone who has design competences to start with, or is willing to learn in order to facilitate systematic building of competences.
3) Use, at the very start, simple activation tools, such as cards. Then increase the complexity of both problems and tools used gradually. Changing tools, and choosing ones that are suitable for the issue at hand is important. Tools like cards, Giga-mapping, semi-open templates and workbooks are very helpful.
4) Use a lot of thought on how to facilitate emergence of proto-practices, but allow this organic process to unfold by itself. It may take time. After some time, people (as a collective) either pick up new practices and add to the old, or do not.
5) Pay attention to dialogical spaces, and keep them active even between interventions. When someone in the organization shows interest for the approach, take time to help (or design a help service for the approach).

6) Repeat and refresh whenever possible. Be very pragmatic about this. Nothing should be imposed, overdone, but also not underdone.
7) When engaging others in multidisciplinary process, pay attention to the choice of people that make up the team. Having positive and competent participants, who are communicating easily, is good. However, paying attention to thinking styles, the knowledge and competences that participants have is also important.
8) Knowledge brokers need to keep developing their own competences (exploring, experimenting and reading about the approach, tools, teams, practices, etc.). It is an advantage if someone in the leadership evolves into a knowledge broker.

Conclusion

Concluding, RtD offered a good, hands-on, exploratory, and reflective way to engage with the inquiry regarding development of design capabilities in the academic library. Engaging in a series of sixteen design interventions through practice – oriented approach that utilized real-life problems and experiential learning, gave insights into how design competences can be developed in an academic library. Some of these insights were articulated as guidelines that can be explored and followed when building design competencies is desired. At the more abstract level, concepts of openness, temporality and dialogical spaces emerged as foundational to understanding competence building.

Acknowledgments

Thanks are due to all participants in this research. In particular, deep gratitude is due to the University of Oslo Library for initiating the research project in the first place. National Library of Norway, for partially financing the project – thank you.

Applying design thinking in a hierarchical organisation

CLOSE-DEBAIS Sonya J.* and MATTHEWS Judy H.

Queensland University of Technology
*s.closedebais@gmail.com
doi: 10.33114/adim.2019.05.299

Many large financial services organisations are seeking to develop their employees' design capability to develop innovative customer solutions. Yet, there appears limited understanding on how individual employees (without a background in design) view the relationship of design thinking to innovation. This study investigates how employees perceive design thinking and its potential link to drive innovative practices within a large Australian multinational financial services organisation. An exploratory qualitative approach used face-to face semi-structured interviews with diverse participants from across the organisation. A modified existing design capability framework was used to map each individual's perspectives and illustrate the organisation's current DT and innovation capacity. Findings from this study contribute new insights regarding employee perceptions and design capability requirements.

Keywords: Design Thinking, Innovation, Financial Services Industry, Large Organisations

Introduction

As Design thinking (DT) has grown in popularity, organisations experiment with programs using DT principles to drive innovative practices (Bucolo & Matthews, 2011; Bucolo & Wrigley, 2013; Carlgren, Elmquist, & Rauth, 2011; Liedtka, King, & Bennett, 2013; Matthews, Bucolo & Wrigley, 2012). Large organisations generally recognise the need to innovate to achieve sustainable growth in today's economic marketplace (KPMG, 2015). Adopting design, DT, and design led approaches to innovation have been known to assist in this process (Brown, 2008; Brown & Martin, 2015; Johannsson-Skoldberg et all, 2013; Kolko, 2015;Liedtka, 2010; Liedtka and Ogilvie, 2011; Verganti, 2008 and Verganti, 2009). Hence, organisations are seeking to up-skill employees to develop their DT capabilities with the view to improve innovation processes and outputs.

With increasing numbers of people and organisations exploring DT methods, this empirical study presents findings from an investigation of how employees perceive the current DT capacity of their organisation and its ability to generate transformative innovation. Specifically, capturing and illustrating how employees of a large Australian financial services organisation recognise the possibilities of DT and its potential link to drive innovative practices. Applying a case study approach, the researcher interviewed 31 employees across various organisational levels, roles, geographical locations and departments within one large organisation, MFSCo. An existing design capability framework was modified for this context and used to map the participants' thoughts and views about DT and their capacity to drive innovation in current work contexts.

The aim is to investigate, discover and understand how employees without a background in design value and apply DT practices and the relationship to innovative outcomes. Building capability requires both knowledge and the ability to apply the learnings to provide real value generation.

The findings contribute practical evidence of the complexities associated with how individual employees understand and transfer DT learnings to innovative workable applications.

Current Understandings

Understanding what DT expertise actually is and how to establish it is crucial, in order to determine how to build DT capability. Despite the many views, definitions and interpretations of DT capability found in the literature, there is no single agreed consistent explanation of DT competency and how it can be acquired.

DT competency has multiple meanings (Barry & Beckman, 2008; Beverland and Farrelly 2007; Brown, 2008; Howard, 2012; Johansson et al. 2013; Kolko 2010; Lawson & Dorst, 2009; Liedtka & Bennett, 2013; Martin 2009; Martin 2010; Melles, Howard, & Thompson-Whiteside 2012; Sobel and Groeger, 2012). Melles, Howard, & Thompson-Whiteside (2012) discuss DT capability as the capacity to co-design and work together with end users at an organisational level in conjunction with developing skills and knowledge at the individual level, while Sobel & Groeger (2012) describe DT as effectively applying diversity of thought amongst users and internal stakeholders to uncover insights, identify the real problem and be adaptable whilst developing and testing prototypes to reveal the solution. According to Lawson & Dorst (2009) DT expertise is not defined as one way of thinking, it is a mixture of rational, analytical thinking and creativity. Barry & Beckman (2008) concur with this view, contending that the inherent capabilities differ within each DT cycle, where understanding and applying the right skill for the required element will produce better outcomes overall. Diversity of input across multidisciplinary stakeholders can enhance design, assist to define the problem and determine appropriate solutions, and is highly relevant in the context of a complex multidimensional organisation.

DT capabilities are much more than knowledge and skills and include intrinsic characteristics that accompany the application of DT. Martin (2009) stated 'the essential core capacity for designers is abductive reasoning, 'the logic of what might be' (Martin, 2009: p27). The ability to make 'a logical leap of the mind' without proof from past events or supporting validated data, differentiates the designer from the non-designer. This explanation offers further insight into what capabilities make up a designer, particularly in a business context and for employees without a background in design, where inductive and deductive reasoning is the norm (Kolko 2010). Martin (2010) proposed that consideration should be given to finding balance between analytical management and intuitive thinking, between 'exploration and exploitation.' Hence the necessary characteristics to apply a DT approach contain a mixture of feelings, empathy and intuition as well as systematic, rational expertise. These additional skills are often seen as foreign in a business context.

DT capabilities range from the tools and techniques required to follow the design methodology and the appropriate logical mindset or ability to apply abductive reasoning. By understanding what DT capabilities are, the next focus considers the integration of DT in large organisations.

Integration of DT in large organisations

Large, established organisations comprised of multifaceted frameworks contain traditional hierarchical structures and well-established management practices. Overcoming these obstacles to drive innovation through a design-led approach is challenging (Brown & Martin, 2015; Bucolo, Wrigley & Matthews, 2012; Carlgren, 2013; Carlgren, Elmquist, & Rauth, 2015; Howard, 2015; Liedtka, 2010; Liedtka, 2014; Martin, 2009; Sobel & Groeger, 2012). Large businesses today face a whole new level of challenges with rapid changes in the external environment and decreasing asymmetry between organisations and consumers (Kloeckner, 2018).

A study by (Carlgren, Elmquist, & Rauth, 2013) examined how employees perceive DT and its application across four industries (including software, product, services and healthcare). Findings note that many employees perceived design to be a mind set or culture rather than a practice or method, and the utilisation of design varied from early adoption in projects to alignment with strategic initiatives (Carlgren et al., 2013). In comparison, research conducted by Darden University examining the effect and impact of DT in large organisations, revealed difficulties and challenge in the application of DT. The challenges included complex structures; separate business departments; management ability and expertise and the language barrier between designers and non- designers (Carr, Halliday, King, Liedtka, & Lockwood, 2010). Both Carlgren et al. (2013) and Carr et al. (2010) noted that shifting individual and organisational existing competences to incorporate new and unfamiliar methodologies and practices, such as DT, requires considerable time, effort

and know-how, where both the environment and culture play a key role in applying the new learnings in an existing traditional organisational setting.

In contrast, large organisations such as Apple, Google Ventures and Nike have successfully applied DT to drive innovation (Berger, 2010) largely incorporating designers' skills successfully to solve problems and innovate. Developing core competences to understand your customers, build prototypes and iterate fast is essential to all designers and organisations (Kolko, 2015). This view supports Michlewski, (2008) who argues that the right design attitude is important to a designer's toolkit. Schweitzer, Groeger & Sobel (2016) suggest in order to build a design led approach to innovation, focusing on developing the mind-set is integral, as employees can adopt new processes quickly (Schweitzer et al., 2016). These studies indicate that developing the mind-set and learning how to think differently form an important part of a designer's core capability to transform solutions.

Understanding the operational environment and all the elements and characteristics of an effective designer will support large organisations to develop the design capability required to successful DT outputs.

Design thinking in the financial services industry

Many Australian businesses remain tied to traditional workplace practices and expertise that have successfully delivered predictable positive results (Bucolo et al., 2012). Financial services is a highly regulated industry comprising multiple sectors including banking, insurance, investment, superannuation and other financial services activities, where the support for DT as a lever for innovation is still in its early stages (Sobel & Groeger, 2012). Largely conservative in nature, the ability of these organisations to remain competitive in an environment of constant disruptive change is more important than ever (KPMG, 2015).

A study of an Australian division of a professional financial services firm providing consulting services, acknowledged the complexities associated with non-design trained employees learning DT (Howard, 2012). Both capability building and the practice of design were difficult due to the complexity surrounding highly analytical and logical environmental surroundings. Howard (2012) recommended the support of trained DT professionals to improve the quality and development of the employees. This research emphasises the complexity associated with transferring DT theory into practice, particularly to staff who are not trained designers, in the financial services industry.

Measuring and mapping application of design thinking

Understanding how design is understood, applied and delivered provides opportunity for further improvements. The Danish Design Ladder (Kretzschmar, 2003) was developed by the Danish Design Council, illustrates four steps towards design maturity, showing that the further up the ladder the more design is integrated into the strategic landscape of a company. The Danish Design Ladder represents the levels of design integration can have within a business and provides a basis for design integration, beginning with the absence of design in the organisation across projects or product development, through to design incorporated into the strategic arena of an organisation (Kretzschmar, 2003). The Design Management Staircase (DMS) (Best, Kootstra, & Murphy, 2010), an extension of Kretzschmar (2003) model, considers five factors: awareness of benefits; planning for design; resources for design; design management expertise and design management process. DMS provides for further consideration of design elements within an organisation and assumes a level of maturity within the establishment.
