The Design Capacity Model (DCM), defined as 'a framework for companies' design management capacity' (Storvang et al., 2014) builds on the two previous design frameworks. Inspired by the model established for the Chinese industry (Heskett and Liu, 2012), the DCM was designed for small to medium sized companies in a Danish context. The visual representation consisting of five (5) levers, is a spider web formation, focuses on design capability factors including: who is design valued by; how are customers engaged; who the design thinkers are; what are the innovation drivers, and design capabilities in the organisation as shown in Figure 1.

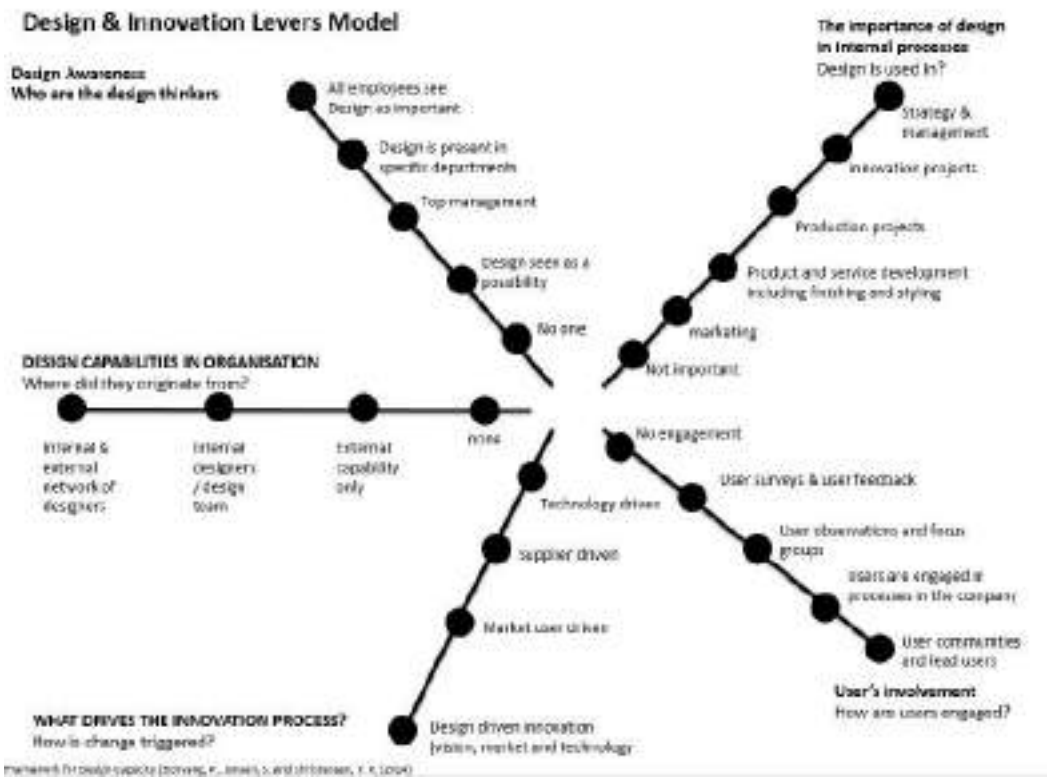

Figure 1: Design Capacity Model (DCM) (Storvang et al., 2014)

The DCM provides a practical tool for mapping an organisation's engagement with design and its design capacity, providing a basis for comparison over time and across organisations and provides the framework for this study. The next section considers the definition of innovation in the context of this study.

Defining innovation

While innovation has been defined in a range of ways (Amabile, 1988; Damanpour, 1991; Damanpour and Schneider, 2006; Frambach & Schillewaert, 2002; Rogers, 2010; Souto, 2015; Wisdom et al., 2014; Wolfe, 1994). For the purposes of this study, innovation is defined as the acceptance and adoptions of an idea or behaviour regarding a system, policy, program, device, process, product or service (Damanpour, 1991), with the focus on the perception of DT and its relationship to innovation.

Participating company

A large Australian publicly listed multifaceted multinational financial services organisation named 'MFSCo', was selected for the research project. The sheer size, complexity and the desire to utilise DT to deliver innovative outputs, is the motivating factor for selecting this firm as the case study for this research. While the company has over 10,000 employees, this case study examines employees within one sector within the Group, comprising 2000 employees, distributed in multiple geographical locations across Australia.

MFSCo's commitment to innovation exhibited an innovation framework incorporating varied DT based education and training programmes, ranging from a one-hour introductory workshop through to a tailored programme centering on knowledge based experimental DT practices aimed to drive innovation refer Table 1.

Program	*Purpose/Objective*	*Time*	*Program Content*
Program A	An introduction to design thinking	60 mins	High level overview of design thinking using D school model
Program B	Learn end to end Design Thinking through experimental application Introductory Course. Very fast, efficient course in busy business environment	90 mins	D School Model More emphasis on each step
Program C	Learners will describe the purpose, technique and skills used to generate creative ideas and demonstrate delivery of improved business results	90 mins	D school model in greater detail
Program D	Tailored individual program. Experiential learning through practical application of real problems or ideas	Timeframe is at the discretion of the team	The D school model was introduced and participants worked through each step to address an organisational problem

Table 1: Overview of internal design innovation training programs

Research Design

This exploratory qualitative approach applies a case study method (Yin, 2009), and provides deep exploration and understanding of an individual entity for the purpose of gathering insight into a larger group of similar types (Gerring, 2004). The study of MFSCo aims to provide greater comprehension of the dissemination and practical application of design capability to derive innovative results, considering the nuances of a complex multinational. The main purpose for selecting a qualitative case study method was to gain empirical data from individual participants regarding their experiences and the ability to contextualise employees' perceptions and applications regarding DT and innovation (Denzin & Lincoln, 2011).

To prevent any misgivings and demonstrate academic rigor, the researcher applied the six stage case study process developed by Yin (2009) and deepened guidelines outlined by Baškarada, (2014). The use of multiple approaches and data sources constructs validity in the research through data triangulation, as it utilises differing sources of information in contrast to investigative or environmental triangulation (Guion, Diehl, & McDonald, 2011).

Data collection and analysis featured the model inspired by the Design Capacity Model (DCM) (Storvang et al., 2014) in Figure 1 above. The original DCM was reframed and customised to reflect a large company structure and current organisational vernacular but the essence of the model remained unchanged. The majority of the customisations were name changes to existing nodes or removing /adding new nodes along the levers. Figure 2 illustrates the amendments.

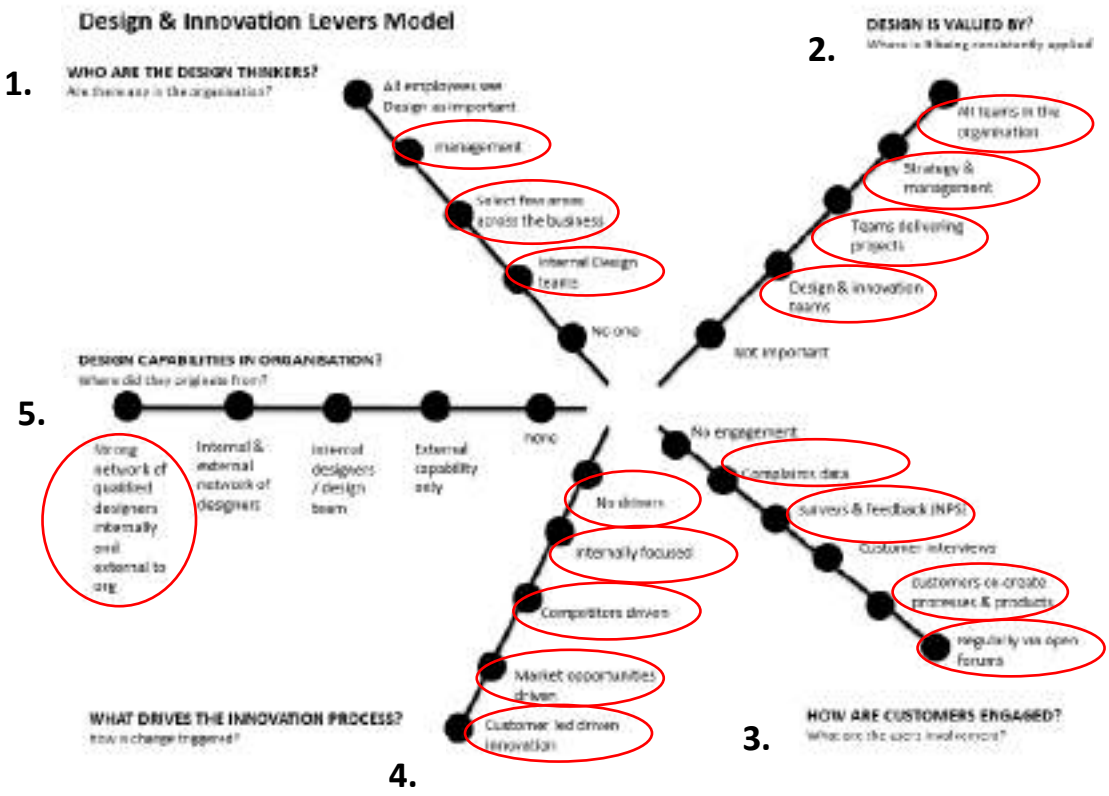

Figure 2: Modified Design Capacity Model (DCM) (Storvang et al., 2014)

Participating employees

Participating employees were selected from a range of diverse roles, primarily those in project, marketing, strategy and business improvement, rather than the functional or operational roles, where design capability may not be required. A diversity of participants were selected to acquire a broad appreciation of the dissemination of DT expertise from both bottom up and top down positions, incorporating both strategic and operational lenses. Participant sampling is shown in Table 2 and Table 3. Coding of responses referenced the role, location, and position of participants to identify patterns of responses and also ensured anonymity of the participants. An example of the coding is represented as (D-BNE-EGM).

Table 2: Participant selection (Departmental)

Department	***Distribution (D)***	***Claims (C)***	***Portfolio(P)***	***Operations (O)***	***Human Resources (HR)***	***Statutory (S)***
Participants	5	4	4	11	1	6

Table 3: Participant selection (Geographic and Managerial)

Location and Position	***Executive General Manager (EGM)***	***Manager (M)***	***Team Leader (TL)***	***Team member (TM)***
Sydney (SYD)	1	3	1	2
Brisbane (BNE)	2	4	7	8
Melbourne (MEL)	-	2	-	1

The researcher mapped the participant's beliefs about the organisation's position with regards to DT capability and its ability to deliver innovation, for each of the 31 participants. The five levers represent: who values design; customer engagement; drivers for innovation; design capabilities and design awareness. An example of the mapping and results is provided below in Table 4.

Table 4: Example of mapping the results in the modified DCM

	Who Values Design	***Customer engagement***	***Drivers for innovation***	***Design Capabilities***	***Design Awareness***
	Almost all of the organisation	Net promotor score (survey)	Internally focused	Mostly internal with help from design consultants	The design team with a few employees across firm
	Design & innovation team	Net promotor score (survey)	Internally focused	Mainly external consultants	The design team with a few employees across firm

Findings and Analysis

Individual maps were completed for each participant, collated in a table as demonstrated in Table 4, then each completed diagram compared, noting the key differences and similarities. The diagrams were divided into participants who did not attend any internal design innovation training programmes and participants who attended at least one of the programmes. This section provides a synopsis of the findings and then outlines three (3) broader themes identified from the findings: responsibility vs accountability; business centricity; and lack of integration and application.

Participants who did not attend any of the four-internal design innovation programmes

Six (6) of the thirty one (31) interviewee participants, who did not attend any of the four-internal design innovation programmes, were predominately senior strategic executives and managers. Two (2) of this 6 believed that all teams across the organisation valued design. 50% of participants highlighted 'employees delivering projects' valued DT more highly and one (1) participant stated *'a few outside of the design and innovation team'* valued DT. With regards to customer engagement, five (5) out of the six (6) participants focused on the long-standing net promotor survey (NPS) and feedback mechanisms as the primary way customers were engaged. The NPS is a national survey completed by a third party (such as a broker) on behalf of the customer, as the avenue for customer insights and engagement.

The innovation drivers for the organisation were evenly divided between external markets, internally focused or competitor driven. Perceptions regarding design capabilities currently in the organisation focused on the internal design and innovation team in conjunction with engaging external consultants to bring in design capability to the organisation. Lastly, design awareness was noted to be 50% 'a select few across the businesses' with two (2), of the participants highlighting design awareness is mostly contained to the internal design team with one (1) participant believing that management are aware of DT.

Participants who attended at least one internal design innovation programme

The remaining twenty-five (25) participants who attended at least one internal design innovation programme were predominantly front-line employees, first line leaders and managers from MFSCo. Many employees indicated that DT capability was concentrated in a few select areas across the business, and there was not a recognised DT capability in the management arena. Once again customer surveys were identified as the measure of customer's engagement.

16% of these program participants believed almost all of the organisation valued DT. 16% stated that the design and innovation team and those delivering projects valued DT and 12% of participants believed teams delivering projects valued DT. 52% participants nominated only the design and innovation team as the area that valued DT the most in the organisation. One (1) participant selected the node '*employees delivering projects with a positive shift towards a strategic focus*'. Employee (C-BNE-TL)

For Customer engagement, 13 of the 25 (52% of these participants) also selected the net promoter survey (NPS) as the main method for engaging with their customers.

Only eight (8) participants indicated that customer interviews had been undertaken to understand more about customers. Of those 8 participants, 6 had attended Program D of the internal design innovation programmes (See Table 1.), which promotes observations and conversations with customers to capture insights and identify patterns and themes based on the interview content.

With regards to the organisation's drivers for innovation, 17/25 (68%) stated the organisation was internally focused, primarily on internal efficiencies and improvements. One participant did select 'customer is the main driver' for innovation, outlining '*the customer is the primary reason we are in business and should be at the centre of everything we do*' Employee (O-BNE-TL).

For the dimensions of design capabilities recognised across the organisation, perhaps not surprisingly, the majority (13) of participants indicated that the design and innovation team, with assistance from external consultants held the design capabilities in the organisation. Five (5) participants noted that external consultants were brought in when design capabilities were required, for specific projects or needs. Interestingly, three (3) participants stated there was no DT capability in the organisation, adding that the design and innovation team were compiled of '*non-technically trained'* designers and "*they were the only ones who valued DT*" Employee (D-BNE-TM). This finding implies the employee may not require DT in their day to day role or has yet to see valid DT capability demonstrated across the organisation.

Lastly, 9/25 (36%) of participants believed design awareness was contained to mostly the internal design and innovation team with a select few across the organisation. 12/25 (48%) of participants noted that a 'few select teams' had an awareness of DT, indicating these employees were primarily related to those participating in projects, the design and innovation team and select managers responsible for change. Two (2) participants selected they believed only a 'few in the design team' held an awareness of design. Finally, one (1) participant selected that 'no-one' was aware of DT in the organisation.

Comparisons from all the completed participant diagrams

The overall participant diagrams were then compared and a thematic analysis applied to the data. The sub-themes identified in the data are represented as: responsibility vs accountability; business centricity and lack of integration and application.

Responsibility vs Accountability

The results show that senior management responsible for managing strategic decisions believed DT was valuable and important to delivering innovation. In addition, the notion that the design and innovation team contained design capability and were largely responsible for building and applying design capability was a popular view across the organisation. Unfortunately, there also appeared to be a distinct lack of investment in building these capabilities, or in encouraging wider application of any learnings undertaken.

One strategic leader expressed the value of DT at a strategic level, *"however we are not there yet".* Nevertheless, they did state *"there is an openness at that level to exploring possibilities and to challenge…."* Employee (C-BNE-EGM). This comment may imply that dialogue at the strategic level contains the notion of exploration and new possibilities, challenging existing approaches to solving problems. The concept of DT was acknowledged as a valuable tool for the organisation, and further education may be required to inform how strategic leaders can apply and drive design led innovation outcomes, without relying on one team to drive the expertise required to deliver change across the organisation. Describing their own limited investment in nurturing the DT capability required to enable innovative outcomes, also indicates an absence of responsibility and hence accountability for such outcomes.

Business centricity

An overwhelming emphasis on business centric thinking, in terms of the business forming a solution irrespective of customer insights was found. This distinct focus on internal drivers for innovation, with limited external inputs, particularly direct involvement from the customer or other external environmental factors, was a strong feature. This is not to say the employees were not aware of the importance of understanding the customer, however the ability to transfer those insights into tangible solutions was the challenge.

Harnessing and applying new concepts based on customer insights are difficult, particularly when they are in contrast to existing organisational methods, ways of working and tightly focused goals and objectives. Often in a business context, organisations develop a solution they believe a customer wants, based on their own projections, rather than capturing and applying the insights from the customer and developing solutions based on the wants and often unarticulated needs of the customer.

One participant stated that *"even going through the process (DT) the output didn't change…."* Employee (D-BNE-TM). This comment may indicate that the solution was developed before applying what they perceived as the DT process. Thus, customer insights were disregarded, and the solution was not necessarily based on what the customer was telling the organisation, but what met the immediate business needs and objectives.

Lack of integration and application

A disconnection between applying all the components of DT and the ability to generate the collective benefit of what design can bring, was found. For example, while design was valued highly by participants, limited customer insights were collected, mainly by front line staff in Claims and Operations. In addition, the drivers for innovation were often limited to internal drivers or exploring competitors' performance. The findings also noted that DT training was often brought in by external consultants, for often one teams requirement and not shared across the business. This team-based focus may indicate pockets where DT can be purposely applied throughout a team and extend beyond individual knowledge and skills.

One participant asked, *"how can you be innovative and add the design thinkers to a problem without the threat of slowing it down?"* Employee (D-BNE-M). This comment suggests their perception of DT as an activity carried out outside of the existing process to innovate, and perhaps a recognition that DT requires an added investment of time to achieve new value.

Discussion

The results reveal the difficulty encountered by the employees of MFSCo with regards to merging the mindset, skills and tools attributable to DT, with the celebrated structured analytical competence and the traditional, cultural environment found in a large established financial services organisation.

DT was valued most by the innovation and design team as well as with a few teams undertaking projects. The strategic leaders stated they valued DT as a method to deliver innovation. However there appears to be a distinct lack of investment in DT outside of the internal programmes which focused on foundational DT practices. The organisational change literature indicates that many developmental programmes build in ongoing projects, encouragement and support, mentoring and coaching to assist the implementation of new behaviours. These notions were not identified as present in the research interviews. In addition, limited time was allocated to practicing DT after attending the programmes. One consequence of limiting time for employees to properly apply or use the newly acquired DT capability is the restrained opportunity for integrating design with other practices performed across the organisation and generating new innovations. Many possible reasons why the value of DT and the relevant capabilities are not being valued and harnessed in entirety.

One possible reason for the absence of progress with design thinking capability is linked to the new knowledge and skill capabilities directly associated with DT. Consider Martin's (2010) description of DT as the balance of analytical excellence and intuitive ingenuity when applying design capabilities in a business context. Where DT takes the best of both traditional analytical thinking, including deductive and inductive logic, in conjunction with abductive reasoning. Kolko (2010) describes abduction as intuitive thinking or using gut instinct and allows for new ideas (innovation) to flourish, whereas inductive and deductive reasoning cannot deliver any new knowledge or discoveries, limiting innovative opportunities (Dorst, 2010; Kolko, 2010; Martin, 2009). In a highly conservative industry structured frameworks, technical expertise and analytical skills are often highly valued. These competences frequently utilise deductive, inductive logic and quantitative methods for problem solving not abduction, intuition or creative pursuits. Training employees to apply and adopt creative, messy techniques that encourage observed insights, an experimental mindset and iterative processes that include failure in order to learn, may require more significant time and expertise than was observed. Given tight timeframes, high expectations of financial benefits from invested projects, and hierarchical complex structures the ability to apply intuitive, creative solutions that may fail is challenging to traditional organisational management.

Traditionally for new projects to be funded, proposals for novel ideas require demonstrable evidence, substantiated by quantifiable and measurable metrics, often in the form of a business plan. This business approach seldom aligns to DT, where insights arise from abductive reasoning in the form of hypotheses and suggested solutions may be outside the organisational financial objective. Therefore, to improve the connection of DT to innovative outputs and establish value, MFSCo should focus on integrating new capabilities through implementing DT via experimentation, through minimal cost and resource as maturity and skills grows across the organisation (Dorst, 2010). Harnessing differing views and mindsets that allow for creative transformative innovations, will show the way design can integrate into the current knowledge and skills within the organisation by way of proven examples and applied techniques.

Through application of DT in small projects and building capability through experimentation, the value of DT could be enhanced and the shifts in management perspectives may embrace the designer's skill sets. As stories and case studies that demonstrate the usefulness of DT in this organisation and its context are developed and collected, the appetite for further engagement with DT mindset and methods is more likely to progress. In addition, longer and more extensive experience with DT in relevant, related projects, perhaps with ongoing coaching and mentoring may be more beneficial.

Limitations

The exploratory modification of the DCM used to extend this framework to large organisations is an experimental approach and has not yet been validated with further studies. However, such identification of levels and mapping changes for comparison over time may lead to new research on DT capability for improved performance in large corporations.

Research Perspectives IN THE ERA OF Transformations

The Organization as a Prototype

doi: 10.33114/adim.2019.06.327

Some of the most valuable companies in the world accumulated their fortunes as a result of a business model innovation built upon matured technologies. Now the majority of them are investing and shifting their focus to the development of new technologies such as AI, blockchain and genetic editing. If an organization is to remain profitable, it needs to be able to quickly adjust its structure to the rapidly changing context. We contend that a way to do so is to build an organizational structure that is conductive to both generative and evaluative prototypes. We report on our action research with a leading European airline following the transformation of a team of four into a new department, through the lenses of continuous prototyping. We then propose an initial framework that conceptualises organizational prototypes and provides a rational and systematic way of approaching the devising of such. Finally, we outline several directions for further research.

Keywords: prototypes, ways of working, emerging technologies, organizational design, generative prototyping

Introduction

The past 25 years brought us some of the most valuable companies in the world today – Google, Amazon, Uber, Facebook. Their rise became synonymous to unprecedented growth and business model innovations built upon matured technologies. However, we're entering a new era of technological development that becomes so enmeshed in users' everyday lives that it is difficult to judge the extend and kind of impact it will have on them. In the past few years we have witnessed the exponential investment and developments in new technologies such as Artificial Intelligence (AI), blockchain and genetic editing, largely due to the unprecedented computational abilities and the amounts of generated data daily. In fact, it is not uncommon to see all these companies who made their money off long-established technologies heavily investing in new ones. For instance, in their 2018 product launch, "Made by Google", Google announced its focus to be "software + hardware + AI" (Made by Google, 2018). Amazon, the most valuable company in the world that started as an online retailer, owns the biggest cloud service – Amazon Web Services (AWS). Historically Microsoft has been largely dependent on Windows. Yet in 2018 the product Windows ceased to be a separate business unit, so the focus could be shifted to cloud services that can provide other companies with the infrastructure on which they can run their data (Warren, 2018). Furthermore, the infamous startup unicorn Uber is investing billions in the development of self-driving technology (Somerville, 2018), competing with Tesla and Alphabet's Waymo.

The current pace of development of emergent technologies is defined by high degrees of uncertainty and companies built on agile principles that continuously adapt and work in fast iterations. It is precisely the desire

to reduce the adverse feelings of uncertainty caused by the rapidly changing context that serves as a strong motivator guiding organizational adaptation (Beckman et al., 2004; Akgün et al., 2012). Yet some organizations continue to be more agile than others (Panditi, (2018). However, if an organization is to not only survive but become/remain profitable, it needs to be able to rapidly deal with uncertainty by thoroughly understanding the different contexts in which such technologies can be implemented. Moreover, they need to have the capabilities to develop solutions employing them. This notion necessitates the establishing of methods and consequent organisational structures that allow for rapid development (also termed as organizational adaptiveness (Gibson & Birkinshaw, 2004) or ambidexterity (Tushman & O'Reilly, 1996)).

This paper presents our attempts to reduce the abstraction associated with theories on how such organizational structures are created and sustained by utilizing the design practice of prototyping. Prototyping is widely recognized as a means to deal with high levels of uncertainty (Buxton, 2007). Furthermore, it accelerates the learning by serving as a means of communication and validating hypotheses early in the development process. As such, we will present the emergence of an adaptive organizational structure by tracing its evolution from the introduction of methods and tools to the full adoption of a new way of working (WoW). While the notion of organizational WoW certainly does not exhaust the entirety of what constitutes an organization, it is our contention that it can serve as a first step in building a new organizational structure (Stoimenova & De Lille, 2017;2018).

This article is structured as follows. First, we elaborate on the nature of prototypes in design. Then we explicate the methodology behind the study and the generated insights as a result. We will report on our attempts in transforming a 4-person team within the operational department of a European airline, Air, into a division that is continuously re-inventing itself. Initially created to check ideas' feasibility and desirability early in the NPD and eventually accelerate the firm's pace of innovation, the team's new approach has grown to almost the entire operation of the airline. Based on principles of Lean Startup (Ries, 2011), Scrum (Schwaber & Beedle, 2002) and Design Thinking (Brown, 2008), its premise is to create ideas, prototype them in a matter of days (using MVPs) and test as soon as possible with real passengers and employees either at the Departure hall, one of the three dedicated gates at the airport or during flights. As such we helped them to establish a new WoW tailored to their context. This allowed them to involve internal and external stakeholders early in the process and then create, test and implement new ideas in live environments with real passengers, employees and flights. The generated insights are used as a foundation for the creation of an initial framework on how to conceptualise organizational prototypes that could be conductive to rapid exploration and development of emerging technologies and continuous re-invention of the firm itself. We conclude the paper with recommendations for further research.

The nature of prototypes in design

Prototypes are widely recognised as an important means to explore and communicate what it will be like to interact with future products, systems and services (Buxton, 2007; Lim, et al., 2008). As such, they can play different roles– evoke a focused discussion in a team, test hypotheses, confront theories, allow users to experience their world differently (Sanders & Stappers, 2014) and minimize design errors that may otherwise occur late in the process (Deininger et al., 2017). Many definitions of what constitutes a prototype exist complemented by a plethora of methods and tools serving each sub-field of design. Some of the most widely adopted types are summarized in Table1.

Table 1: An overview of the most popular types of prototypes

Type	*Description*
Minimum Viable Product (MVP)	*Contains the minimum number of features that allow companies to gain the maximum amount of insights and test their fundamental hypotheses on value and growth. As such, "an MVP is designed not just to answer product design or technical questions. Its goal is to test fundamental business hypotheses" (Reis, 2011).*
Experience prototype	*Aims to understand, explore or communicate what the experience of a solution might be. Its value lies in the prototyping attitude that requires the blending of multiple disciplines and a low-technology mindset (Buchenau & Suri, 2000).*
Boundary object	*Both designated (prototypes) or emergent objects can be used (Levina & Vaast 2005). It exhibits different meanings in different social/professional contexts. Yet, it has a structure that*

	is common enough to more than one community and thus it's able to transform knowledge in new product development (Carlile, 2002). This makes it a recognizable means of translation (Star & Griesemer, 1989; Eppler & Pfister, 2011).
Conscription device	*Enlists and engages participation of those who will later employ and/or build on it (Henderson, 1991; Roth & McGinn, 1998) to shape knowledge (Bendixen & Koch, 2007). It facilitates linkages between the meaning of the object and the knowledge of the network around it (Hölttä, 2013). It also aids with reasoning, reflection, and the linking of items in new ways to enable discoveries (Karsten et al. 2001).*

Prototypes are primarily seen as a tool to evaluate design's failure or success (Lim et al., 2008). For instance, to Sanders & Stappers, (2014), prototypes are usually put into action once the "design opportunity has been established". This view is complemented, among others, by Dong and colleagues (2016), Eekles and Roozenburg (1991) and Takeda (1994) to whom prototypes are to be used for evaluation and testing of hypotheses and requirements. This is in line with widely adopted approaches such as Agile, Lean Startup and Design Sprint (Knapp et al., 2016).

However, using prototypes in their evaluation capacity has its limitations due to the flexible, reflective and problem-setting nature of design (Schön, 1982). A design solution can never guarantee it is the best since there are many possible ways to tackle a (wicked) problem (Buchanan, 1992). Moreover, an examination of design practices shows that evaluative prototypes (i.e. during usability testing) are a relatively small part of the entire design process (Lim et al., 2008). Prototypes are also oftentimes used to help designers learn, discover, generate, and refine designs (Buxton, 2007) by stimulating framing, and discovering possibilities in a design space (Lim et al., 2008). In effect, becoming the means of a generative discovery that could play a pivotal role when new technologies and their impact on societies should be understood, as is the case with AI, for instance. The notion of externalisation of thought as an impetus for creativity (Clark, 2001; Magnani, 2007), a means to finding new aspects of a problem and generating new ideas to solve it is widely recognised in design (Suwa et al., 2000). By giving rise to new perceptual and cognitive operations that allow for reflection, critique, and iteration (Clark, 2001), externalisation helps designers develop and communicate their ideas through "physical" manifestations (Zucconi et al., 1990). These can take any form, shape, and appearance, based on the choice of material (Lim at al., 2008; Deininger et al., 2017) and provide help with the invention of important design requirements of a given problem (Schön & Wiggins, 1992).

To our knowledge, there are several attempts to define a taxonomy of prototypes (i.e. Lichter et al., 1993; Gutierrez, 1989) – all primarily based on different ways of using prototypes in a development and design process. However, developing generally applicable prototyping methods is not viable when faced with the complex variety of design (Lim et al., 2008). To understand how prototypes could be used in an organizational context, we will review the insights gleaned from our work with Air.

Methodology

This paper reports the result of an action research in Air. It was carried out in the span of 3 years and followed the transformation of a 4-person team into a new department. The first author carried out participant observations, complemented by more than 20 sessions and 10 semi-structured interviews with the growing team during the first year. Furthermore, she was involved in the creation, shaping and initial implementation of their new way of working (WoW). The study also followed the way the team tried to involve internal and external stakeholders and grow to the entire operational side of the firm. She was supported by a design MSc student, who helped her to facilitate some of the sessions. Subsequently 5 more interviews were carried out to gauge new developments in the last two years. All interviews were transcribed and cross-referenced with the accounts of participant observations and extensive literature review stemming from the areas of design cognition and methodology, and Participatory, Engineering and HCI design. As such, both inductive (Patton, 2014) and deductive (Crabtree & Miller, 1992) coding was used. The second author initiated and oversaw the transformation. The third author was regularly involved in the research through three MSc students performing research for the team.

The initial research is discussed in our previous work on implementing design principles and establishing the foundations for a new organizational structure in Air (Stoimenova et al., 2016; Stoimenova & De Lille, 2017) and cross-referenced with a study in a technology B2B company implementing the generated insights as discussed in (Stoimenova & De Lille, 2018). However, this research adopts a different frame of looking at the results – that of the role prototypes played in the change of the organizational design.

Results

In this section we will explicate the initial stages of how the team grew to an entire department through the lens of the different prototypes we used. The starting point was the new WoW the first author helped the team develop. As already mentioned, it's based on well-established principles from Lean Startup, Scrum and Design Thinking manifested in six main phases. Each new project starts with formulating a clear ambition (a purpose). This is followed by understanding of the problem using qualitative and quantitative data. Once such understanding is obtained, the team starts ideating on possible solutions. They then build an MVP (prototype) and test it in a live environment part of the airline's operations. The project ends with a thorough reflection and the making of a decision whether to adjust, kill or scale the solution. The WoW is carried out in increments of 2-week sprints.

The research employed a nested principle, in which MVPs and experience prototypes devised for user testing and hypotheses validation were used as a foundation around which prototypes of sessions, tools, templates and methods can be built. We started by understanding how the new WoW can be implemented in the Air's context. Such necessitated a better grasp on how to enable the team of non-designers to understand their context by using design principles and tools. The first step was to create a way to elicit insights from passengers waiting to board their planes quickly. To do so we used more than 10 sessions at the gates to prototype and test different tools, approaches and templates. This triggered the need to enable the team to work with such insights and involve stakeholders throughout their process. Thus, optimal ways to involve stakeholders had to be discovered by prototyping different sessions around on-going projects. These sessions were used as conscription devices, as not only stakeholders but also team members were involved to understand how to facilitate and organise such. They were also used as boundary objects allowing for the communication of the importance of such to other departments and new additions to the team.

These prototypes helped us reflect on the WoW and detail it for the context the team was in. This was enabled by vicarious learning and creating a shared understanding of the rationale behind each used method. The multiple sessions complemented by templates, explanations and modified to the context tools and methods created a noticeable change in the capabilities of the team. They also provided the foundation for a new (shared) mental model (Rouse & Morris, 1986) on how the WoW could be carried out. We label the changes in capability and mental model as culture. Finally, we observed changes in the infrastructure of team and subsequently the department regarding the needed resources (both human and monetary) and the extent of involvement of stakeholders. As such, our definition of infrastructure is similar to the one of Star and Ruhleder (1996). These three elements – WoW, culture and infrastructure – coincide with the factors crucial to design adoption discussed in Stoimenova and De Lille (2017; 2018).

In Table 2, an overview of the purpose of the prototypes we used, and their descriptions can be found. These initial attempts are also described in detail in Stoimenova and colleagues (2016; 2017; 2018). The table is structured as follows: the purpose of the used prototypes is stated paired with a short description. Then the form in which the prototype manifested itself is noted.

Table 2: An overview of the different types of prototypes used in building up a department

Purpose	*Description*	*Prototypes of*
Understand how to gain insights from passengers at the airport (in less than 15 minutes)	*Used over 10 sessions at the gates of the local airports to gauge how to involve passengers who are waiting to board their plane and usually have less than 15 minutes to spare. We went through several iterations of what set up to use, how much time should be spent per passenger, find tools and methods that are effective and efficient in the environment, how to elicit tacit insights and latent knowledge and overcome language barriers. In the process we worked with tools such as context mapping (Sleeswijk Visser et al., 2007), Lego, Brainwriting and Journey mapping. The sessions are described in detail in Stoimenova and colleagues (2016) and were later used as boundary objects to communicate the importance of involving passengers to the team.*	*Templates* *Generative methods* *Method setup* *Tools* *Passenger communication* *Sensitization*
Increase the amount of time team spends on exploring the	*Initially the team spent on average 2 hours during every 2-week sprint on exploring the context and coming up with new ideas. To increase the time spent, first the results from the passenger sessions were used as a boundary objects, then two four-hour ideation sessions were carried out*	*Templates* *Tools*

context and generating multiple solutions	*with the team and a few stakeholders. The duration of the sessions grew to 2 days of context exploration and ideation with stakeholders as part of a Design Sprint. The sessions were used as conscription devices.*	*Methods* *Sessions (duration)*
Create capabilities in non-designers to facilitate ideation sessions	*We carried out 6 different sessions to first understand the needed level of capability. Then, to create such, explanatory materials, templates and new methods were introduced to the team and used as conscription devices. The sessions were also used to train the team in facilitating such by sharing the process and creating a template and guidelines. These were paired with vicarious learning and explanation of the basic principles behind each activity. All prototypes were used as conscription devices.*	*Explanatory materials* *Templates* *Methods and tools* *Guidelines*
Understand how to create a sense of ownership among stakeholders	*Used the different sessions to involve operational employees in the ideation sessions, paired with regular involvement of operational employees in testing of on-going MVPs. Also, a dedicated moment in which stakeholders come together to ask difficult questions, called a "roast" became a standard procedure.*	*Team composition* *Involvement structure* *Tools* *Templates*
Understand how to test in live environments	*All MVPs during the first year of the research were used to gauge how to test and collect information from the users (both passengers and employees).*	*Solutions* *Test setup* *Communication* *Interviewing methods* *Result analysis* *Adjusting solutions in the field*
Understand how to prototype services in live environments	*A Design Sprint was carried out with the core team (6 people at the time) to prototype the structure of the sprint itself and adapt it to the context of Air. Further, ways to prototype a service in a live environment, the necessary time allocated for each day and the level of detail of a service MVP were explored. The sprint was used as a conscription device which was later further elaborated upon.*	*Team composition* *Design Sprint structure* *Test setup*
Understand how to involve a different department	*Prepared and facilitated a design sprint with another department of Air to understand who and when to involve, manage expectations, share insights, how elements of the way of working can be translated to the department and determine a possible way of communication. The sprint was used as a boundary object.*	*Communication* *Inter-departmental collaboration* *Method setup* *Test setup*
Understand when, how and what employees to involve	*A Design Sprint and the aforementioned sessions were used to understand what type of people need to be involved, when and in which manner to involve them. They were later used as a boundary object to communicate the importance of the WoW and ultimately help it spread to the entire operational side of the firm.*	*Employee involvement* *Team composition*
Understand how to combine and communicate qualitative and quantitative data	*Initial attempts were based on the research done with passengers. They were used during the design sprints and the sessions. However, they were mainly qualitative-oriented. This research is currently ongoing as the first author is involved in establishing a deeper understanding of how to combine and communicate thick and thin data.*	*Method* *Communication* *Templates*
Understand how to structure the newly-established department	*Two 1-day events were carried out once the newly department was established to understand the future of the department, the topics it needs to tackle, the culture and communication it needs to have through the means of multiple break-out sessions*	*Methods* *Communication* *Templates* *Tools*

The use of prototypes helped us explore the unusual context of the team and rapidly define an initial version of a WoW through the use of conscription devices, boundary objects, MVPs and experience prototypes.

However, using these generally applicable prototyping methods is not always viable when faced with the complex variety of design (Lim et al., 2008). Therefore, the creation of a rational and systematic way to approach the devising of prototypes in an organizational context is necessitated. A way that will provide the guidelines on how prototypes with evaluative and generative purposes can be devised on both project and organizational level.

Framework for Organisational Prototypes

To our knowledge, one of the most prominent works on conceptualising prototypes' dual nature by providing a systematic and rational way of devising them comes from Lim and colleagues (2008). Developed for the field of Human-Computer Interaction (HCI), their anatomy of prototypes is based on two dimensions that are interconnected and influenced by each other – filters and manifestations. The former identifies an initial set of design aspects a prototype might exhibit such as appearance (i.e. size, color, shape), data (i.e. size, type, privacy), functionality (i.e. system function), interactivity (i.e. input and output behavior), and spatial structure (i.e. arrangement of interface). The decision of what to filter is always based on the purpose of prototyping. Once a filtering dimension has been selected, choices should be made about the way the idea will be manifested. Lim and colleagues identify three manifestation dimensions – prototype's material, the resolution of its details (corresponding to the notion of fidelity), and the scope (whether the prototype covers one or several aspect of the design idea). These dimensions can be determined, they claim, by following the economic principle of prototyping: "the best prototype is one that, in the simplest and most efficient way, makes the possibilities and limitations of a design idea visible and measurable.".

Combining their anatomy with the gathered insights from Air on how a WoW is prototyped, we propose the following framework that can assist organizations in creating organizational prototypes. First, we start with the filtering dimensions. As already suggested in the Result section, the WoW influenced the culture and infrastructure of the department. Therefore, we contend that the dimensions through which to filter could be **way of working**, **culture** and **infrastructure**. However, although the filtering dimensions could provide an initial direction for prototype formation, knowing only what to filter can neither fully determine how to form a prototype nor provide strategies for devising it. Therefore, once the purpose of the prototype is filtered, the proper manifestation should be selected. To do so, all of its three dimensions must be considered: material, fidelity and scope, as they all inform and impact the way a prototype is being devised. We stayed close to the dimensions provided by Lim et al. (2008) by substituting only resolution with fidelity as the term is more regularly used both in design and software development literature. However, the majority of the example variables we provide stem from our research in Air. The dimensions and their corresponding sub-dimensions can be found in Table 3. These dimensions and their variables are not exhaustive, however. They simply provide a general guideline of factors that might be considered. However, this framework requires further research and elaboration.

Table 3: An overview of the manifestation dimensions

Manifestation	*Description*	*Example variables*
Material	*Different types of physical and digital materials that can be used when prototyping products and services*	*Physical material (e.g. paper, plastic, wood, Lego)* *Methodology* *Data* *Sessions*
Fidelity	*Fidelity refers to how closely the prototypes resemble the final product in terms of visual appearance, interaction style, and level of detail (Petrie & Schneider, 2007).*	*Low* *Medium* *High* *Mixed (Petrie & Schneider, 2007)*
Scope	*The number of aspects of the design solution a prototype covers*	*e.g. Template* *Tool* *Method*

We believe using such framework will assist in creating a common understanding of the nature of prototypes used in similar contexts. Further, it will help to design an organization that can further develop new technologies, explore contextual implications and generate profitable business models. It will also provide a language for articulating the characteristics of a particular prototype that could be used to prototype organizations.

Conclusion

This article started with the contention that in order for an organization to continue being relevant and profitable, it needs to create an organizational structure that will allow it to rapidly and iteratively develop emergent technologies and understand how they impact its context. Then to exemplify how this could be done we reported on our initial efforts of growing a small team into a department, whose purpose is to rapidly develop, test and implement new ideas. The transformation was achieved largely by the extensive use of both generative (boundary objects and conscription devices) and evaluative (MVPs and experience) prototypes. This allowed us to outline a framework that can explicate and systematise the conceptualisation of organizational prototypes in a rational way. As such, this research provides an ample ground for further investigation in two directions – understanding the way both generative and evaluative prototypes can be used to further develop and implement emerging technologies and discerning the role a department that continuously prototype its parts could play within an organization.

Discerning possible ways to further develop emerging technologies

The first direction stems from the fact that we are still in the early stages of development of technologies such as AI (what Vinge (1993) terms narrow AI) and their potential impact and implications are still largely unknown. The discernment of the possible implementation areas and their business value is also in its infancy stages. While the presented here WoW's build-up does not directly specify how to deal with such emergent technologies, it provides a solid foundation for such due to its iterative and adaptive nature. Therefore, more research is needed to determine how to work with a technology that continuously changes the value it delivers as it interacts with data and the users, as AI does. We contend a viable initial direction to be the use of prototypes due to their ability to make the abstract future effects of a solution tangible (Lim et al., 2008).

However, to do so attention has to be paid to both generative and evaluative prototypes. Based on our action and literature research, we argue the former to be suitable for the exploration of the problems connected to emerging technologies and their implications on society. Evaluative prototypes such as MVPs are already largely recognised for their ability to test assumptions and validate business hypotheses (Reis, 2011). Both types are of equal importance and should be continuously employed throughout the development process of a solution to ensure its successful deployment/implementation.

More research is needed in this area, however, to identify the ways such prototypes can be created and built upon. It is our contention that the structure we developed in Air provides a solid foundation for doing so. Moreover, it is conductive and favourable to both generative and evaluative prototypes since the department's organizational structure was largely a result of multiple prototypes. Last but not least, further research is needed to understand the ways such prototypes can be implemented within existing ways of working, cultures and infrastructures and the implications they will have on organizational structures. We are currently carrying an action research to gain initial insights on the topic.

The role of the department-prototype

In the process of this research we continuously prototyped every single element of what later became a newly-formed department. This led to a department built upon an amalgamation of several layers of prototypes serving different purposes. Therefore, we argue that the department itself could be seen as a big prototype geared towards the continuous exploration of its changing context and validation of its ongoing hypotheses. Seeing the Air's department as a prototype is not far removed from the way the most successful startups in the past two decades have made the development of an MVP central to the way they grow and

structure themselves. The definition of a startup is a "temporary organisation whose goal is to search for a sustainable and profitable business model" (Livingston, 2007). The ability to be flexible and continuously pivot in terms of market or product strategy is another marker of what being a successful startup entails (Hoque, 2012). These definitions are well-aligned and complementary to the transformation of the Air's four-person team. However, the development of the department we described needs to be further researched to explore the roles such organizational unit can play within a bigger organizational structure and how it can contribute to the profitability of the firm. Moreover, additional insights are needed to discern how such a department can continuously prototype itself and foster both generative and evaluative prototypes.

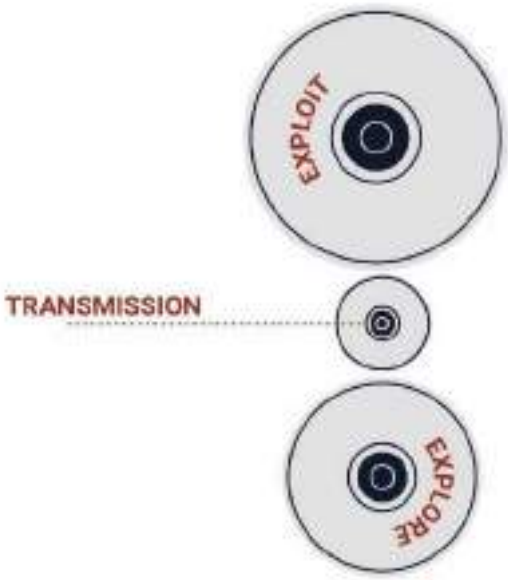

Figure 1: the three wheels of DLA (Stoimenova & De Lille, 2016).

A concept that can point at initial search directions is that of design-led ambidexterity (DLA) introduced by Stoimenova and De Lille (2017; 2018). DLA is based on the notion of ambidexterity defined as "the ability to simultaneously pursue both incremental and discontinuous innovation… hosting multiple contradictory structures, processes, and cultures within the same firm" (Tushman & O'Reilly, 1996). As such, implementing organizational ambidexterity allows companies to simultaneously manage current business demands and adapt to environmental changes (Mom et al., 2015). It constitutes of three elements, employing the metaphor of three constantly rotating wheels. Exploitation allows the firm to improve the efficiency of implementation and production of its already existing capabilities and knowledge. Exploration is characterized by search, experimentation, play, flexibility and investigation, and can result in new knowledge (Tabeau et al., 2016). However, many challenges exist when trying to make the collaboration between exploration and exploitation wheels smooth (i.e. rotate in the same direction) (Oehmichen et al., 2016) due to their distinct nature, roles and influence they have on innovation outcomes (Tabeau et al., 2016).

The Transmission is designated with the task of ensuring the smooth and profitable collaboration between the other two wheels. As its name suggest, it transmits and adapts the signals from Exploration, so the Exploitation can pick them up easily. Moreover, it gives signals back to each wheel to ensure their corresponding structures, processes and cultures could be adjusted accordingly. It is also in its nature to continuously adjust its size and rotation pace to ensure the smooth collaboration of the exploration and exploitation wheels. From the three elements depicted in Figure 1, we argue the structure and role of the transmission can provide a fertile ground for a department that continuously prototype itself. However, further research is needed to understand how to fully build a department that acts like a Transmission and its implications on a firm's structure and profitability. As such we are continuing our investigation of the department through the means of action research.

We are entering a new innovation era of multiple emerging technologies. Organizations are faced with three options: don't adopt new technologies, rely on companies such as Microsoft, Amazon and Google to provide them with the infrastructure that can run (or provide) data, or further develop and understand how the technology can be applied to their specific context. It is the latter two options that offer multiple benefits to firms, if employed well. The impact and potential of such technologies are still largely unknown, so are their business models. Therefore, both cases require companies to create the necessary capabilities to quickly adapt and respond to such changes. We are too early in the technology development cycle to fully understand and predict its implications. However, an organizational structure that can continuously and rapidly adapt to its changing social and technological environment is of paramount importance.

Despite the plethora of innovation frameworks such new developments can instigate, they will always need to be adapted to a context. However, due to the unexplored implications and changes such new era will entail, it

is difficult, if not pointless, to attempt to create such. This, in fact, is the epitome of a wicked problem to which we cannot find the best answer. However, we need an approach to deal with it. Our work with Air leads us to believe that a viable way to tackle such a problem is through continuous prototyping that essentially turns the organization into a prototype. However, we intentionally did not specify how such structure should look like. Instead we introduced the initial stages of a framework that allows organizations to rapidly discern which way of working, culture and infrastructure are most suitable for their context and fit with their ambitions. We believe establishing such capabilities in a firm can prove invaluable for its sustained profitability and relevance.

doi: 10.33114/adim.2019.5g

Introduction

Global changes in the 21st century appear intractable as social, technological and environmental trends force the contemporary organization to address these uncertainties in vision and strategic direction (Vecchiato, 2012). Enterprises across nearly all sectors of the globalized economy must adapt competitive strategies to anticipate specific political, resource, and market uncertainties that could impact expected growth and broader social benefits (Buehring & Liedtka, 2018; Wilkinson, Mayer, & Ringler, 2014). Yet the inclusion of strategic foresight within system, product and service design projects has yet to reach its potential in business enterprises.

Given the uncertainties these often-cited global trends impose, why are decision makers not relying on strategic foresight to inform design decisions and strategic product service development? The most popular business design processes continue to be decidedly short-term reasoning practices: Agile, Lean, and Design Thinking are at least three problematic methodologies that might repel or constrain the uptake of serious futures anticipation. Business foresight practices are commonly relegated to strategy development, thereby informing business models and competitive strategy, but not necessarily the productive design capacity of the enterprise.

While design often addresses complex business problems for today's world and the immediate future, strategic foresight develops alternative scenarios for the futures in which these solutions will exist. Scholars and educators in these core fields are devoting increased attention to the question the most effective organizational process or fit for successful, actionable long-horizon strategies (Bishop, Hines, & Collins, 2007; Heskett, 2009; Rohrbeck, Battistella, & Huizingh, 2015; Slaughter, 2002).

The themed track features 4 submissions from nine authors who share important insights, new knowledge, and research outputs relevant to design and innovation management practice and the integration or effective processes of strategic foresight applied to decision-making.

In the paper titled "The Role of Horizon Scanning in Innovation and Design Practice", Isabel Meythaler and Elies Dekoninck focus their investigation on how horizon scanning (HS) is used by practitioners to create foresight for design and innovation. They address two questions: first, how do innovation practitioners spot and act on changes in the business environment, consumer and technological landscape? Second, what methods, tools, and approaches are used? Key insights from sixteen in-depth expert interviews are reported. The authors make three contributions. First, they discuss the role and importance of horizon scanning for innovation and design. Second, they identify dominant methods and approaches used within horizon scanning. Third, they compare the methods typically used by different types of innovation practitioners. The authors report that HS in conjunction with creative and lateral thinking, technology scouting as well as human-centred

thinking have two outcomes: first, it facilitates the early detection of emerging trends and technologies and (b) it facilitates turning insights into actionable ideas, increasing the likelihood of more successful product development, meaningful innovations, and sustainable competitiveness. These findings are insights and guidance for managing horizon scanning and incorporating it into innovation and technology management strategies.

Challenging predetermined frameworks and biases to planning the future, Timothy Stock and Marie Lena Tupot put forward an argument for designers practicing foresight to overcome their inherent bias toward a world informed by the known and experienced. It is proposed that exploring and planning for the future requires a deeper understanding of a cultural system and language that represents the dynamics between the concrete (known) and abstract worlds, thus needing a mapping system that could help designers to think on multiple abstract levels to anticipate change and make sense of signals, signs, and cultural meaning relevant to their future designs decision-making. This paper is bringing to our attention the need for new design foresight relevant research approaches needed to deal with uncertainty, and the causality of sustainability, and ethical futures considerations. The authors draw on fundamental research design considerations relevant in futures studies, providing relevant examples and case studies in support of the argument that the prevailing design ideology and vocabulary is informed by one of materiality and technology.

In the paper titled “Bringing futures scenarios to life with video animation: A case of disseminating research to non-expert audiences”, Jörn Bühring and Nury Vittachi draw attention to research disseminating practices expanding beyond traditional media of publication. That is, research findings in the social sciences, including scenarios produced in futures research, are typically reported in client reports, monographs, white papers and journal articles. The purpose of this paper is to investigate video animation as a way to communicate futures scenarios to nonexpert audiences, corporate decision-makers, and their staff. The process presented in this paper is based on a case study in which academics and designers at a design school took the findings of a financial services futures study and applied storytelling and visualization techniques to bring futures scenarios to life with video animation. The study outlines the four-step process of developing a video animation – the challenge, the exploration, the interactions, and the delivery. Each stage in this process involved techniques and choices to realize the objective, to bring the future to life and make it real for a general audience. The paper concludes with ten recommendations for producing quality videos based on future scenarios.

Finally, Eliana Ferrulli, Caroline Nohra, and Silvia Barbero’s RETRACE project cites a systemic design study connecting the functions and methods of strategic foresight to regional planning and development strategies. The challenges her team engages involve the creation of a policy and economy learning network across five regional enterprise communities, with eight partners coordinated by a systemic designer team in the EU-based project. Here the formation of a foresight-based strategy is driven by the necessity to conceive coordinated actions for multi-sectoral transitions to circular economy programs. Coordinated regional engagements such as RETRACE are fairly rare in other parts of the world. Their application of advanced systems-oriented design and foresight as cross-cutting (generalized) approaches in regional development policy provides appropriate methodological pluralism for a creative learning strategy. Many aspects of such a high-complexity engagement might be forbidding to other policy making or design thinking approaches –Such bio-socio-economic transition planning is certainly complex enough of a program. With the project engaging over 70 stakeholders from different countries and regions, touching dozens of companies and planning actors, totally different local economies, it is clear to see the requirement for a systemic approach.

With this eclectic mix of ideas and contributions, the Design with Foresight track explored the value of strategic and creative foresight in design and innovation, together improving the designer’s and the organization’s learning to adopt new methods in their innovation practices.

doi: 10.33114/adim.2019.01.344

This paper aims to investigate how horizon scanning (HS) is used by practitioners to create foresight for design and innovation and which methods, tools and approaches innovation practitioners use for spotting and acting upon changes in the business environment as well as in the consumer and technological landscape. Thus, this study contributes to the field of horizon scanning and innovation management by presenting the results from 16 in-depths expert interviews with innovation practitioners. Specifically, the aim of this research was to: discuss the role and importance of horizon scanning for innovation and design; identify dominant methods and approaches used within horizon scanning; and compare the methods typically used by different types of innovation practitioners. This study discovered that HS in conjunction with creative and lateral thinking, technology scouting as well as human-centred thinking not only facilitates the early detection of emerging trends and technologies but also facilitates turning insights into actionable ideas, increasing the likelihood of more successful product development, meaningful innovations and sustainable competitiveness.

Keywords: horizon scanning, practitioners, interviews, dominant methods, comparison

Introduction

Ever-increasing consumer expectations, the subsequent launch of products with new, more convenient and improved features, and the emergence of technological advances create highly-competitive and fast-changing business environments. Therefore, the need for businesses to place innovation at the core of their business operations is intensified, as innovation is widely regarded as being key to success and a vital element for ensuring future growth and survival (Tohidi & Jabbari, 2012).

Companies' inability to foresee and react to new technologies, new customer demands or competitors with new products, services and business models is one of the main reasons why they cease to exist (Watson, 2017; Brown, 2007). It is argued that companies adopt future-oriented approaches to proactively equip themselves with methods and tools that enable them to anticipate and act upon signals of change and emerging trends and technologies in order to operate more sustainably and competitively in today's complex economic and volatile environment. In fact, a survey of 91 executives discovered that 24% classified "lack of coherent vision for the future" as one of the biggest obstacles to transform in response to market change and disruption (Anthony et al. , 2016). Another report confirms the prior findings as 42% of 270 innovation, strategy, and R&D executives regard the "inability to act on signals of change or developments critical to the future of the

business" as a major obstacle to innovation (IL & KPMG, 2018). This paper set out to investigate how Horizon Scanning (HS) tools and methods used in innovation and design practice might help address these challenges.

Horizon scanning: Terminology & Definition

Although the practice of HS has received increasing attention in academia and industry in the past few years, no consensus concerning a universal definition has been reached yet.

One of the most cited and prominent definitions originates from the UK Government's Chief Scientific Advisor's Committee, defining HS as "the systematic examination of potential threats, opportunities and likely future developments including – but not restricted to – those that are at the margins of current thinking and planning. Horizon scanning may explore novel and unexpected issues, as well as persistent problems or trends'' (van Rij, V., 2010a). Other authors have diversely described horizon scanning as an: ability (Williams, 2018), process (Könnölä et al., 2012) or technique (Brown, 2007). Table 1 provides an overview of more specific definitions which also includes some information on practical implementation and benefits proposed by the selected authors.

Table 1: Overview of definitions of horizon scanning

Definitions	*Source*
"Horizon scanning is the practice of **monitoring the business environment** and tracking the **changes** in the environment that could have an impact on individual businesses"	(Brown,2007).
"Horizon Scanning can be completely **explorative and open** or be a **limited search** for information in a **specific field** based on the objectives of the respective projects or tasks. It seeks to determine **what is constant, what may change, and what is constantly changing in the time horizon under analysis**. The time horizon can be short-, medium- or long-term"	(European Commission.,2015).
"Horizon Scanning eschews the attempt to create projections of the future; it instead **aims to continuously and objectively explore, monitor and assess current developments and their potential implications for the future"** "The use of Horizon Scanning is intended to develop an organization's capability for **identifying subtle environmental changes, allowing organizations to cultivate a high awareness and understanding of their environment, leading to a quick and effective response to changes and events"**	(Rowe, Wright and Derbyshire,2017)
"Effective horizon scanning involves **systematically tracking and analysing trends**, alongside anticipating what might 'disrupt' these trends in the future. It is not about 'making predictions' but rather **looking at what might possibly happen, and what will probably happen in the future, based upon available data"**	(Beers,2016)
"Horizon scanning aims to **spot changes** in the world around us before they become 'old news', so that **decision makers can plan on how to exploit or mitigate these changes,** securing the most positive outcome for their organisation. This means **systematically monitoring a wide range of information sources and indicators**, with the intent of identifying patterns and 'weak signals' of coming disruptions that could have a severe or a transforming impact on our world"	(Marteaux, n.d.)

To understand the concept of HS, it is elementary to look at environmental scanning, which entails the examination of the current macro-level environment, consisting of political, economic, social, technological, legal and environmental (PESTLE) factors. Whereas environmental scanning is primarily concerned with present and known trends, HS focuses on monitoring the environment on a longer-term scale to spot, track and assess changes and their potential implications for the future (van Rij, 2010a; Rowe et al. ,2017). Classifying HS as a foresight tool, Van Rij (2010b) acknowledges the uncertainty that any future entails and

states that HS is “neither about forecasting nor fortune telling” but rather the development of actionable insights and solutions, which contribute to informed decision-making by seeing the bigger picture.

The process of Horizon Scanning

HS consists of data collection and data analysis including a mixture of quantitative and qualitative methods. Depending on its objective, HS can be either conducted in a completely open form (exploratory scanning) or a more limited manner focused on a specific area (issue-centred scanning) (Amanatidou et al. ,2012; European Commission, 2015). As there is no standard process for HS and literature concerning its practical application is rather vague, Rowe et al. (2017) developed a framework for guiding the process of HS, illustrated in Figure 1.

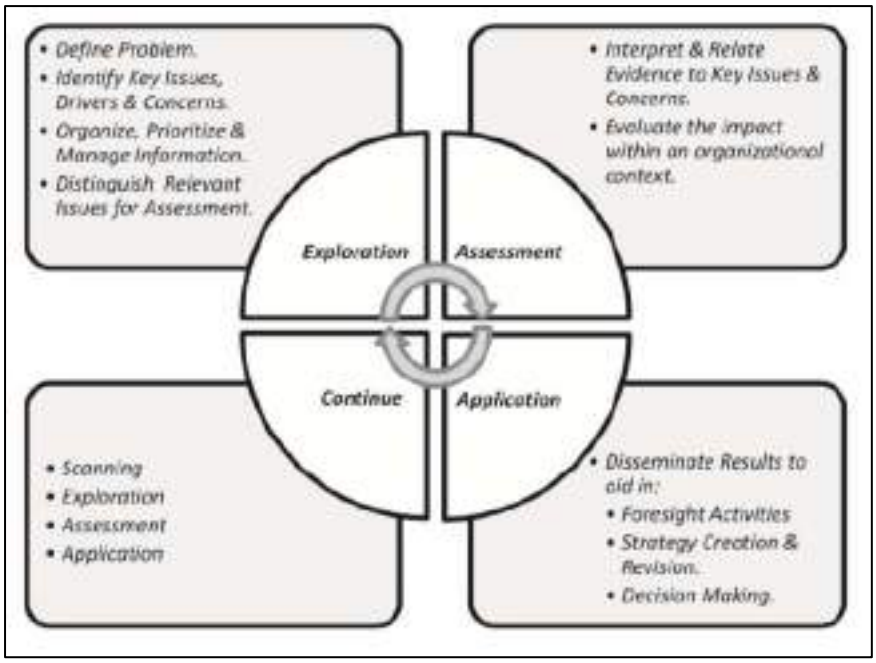

Figure 1: Horizon scanning process (Rowe et al. ,2017)

Exploration represents the starting point and spans throughout the whole process as it incorporates the continuous gathering of information, monitoring and scanning of the external environment which can be undertaken manually, automated or web-based. Furthermore, Palomino, et al. (2012) distinguish between network-based HS and web-based HS, arguing that web-based HS complements rather than substitutes network-based HS. However, Rowe et al. (2017) underline that due to the vast amount of available information, HS may lead to information overload and paralysis. They emphasize the importance of identifying patterns and sifting out valuable signals from meaningless noise which requires a developed set of skills, knowledge and expertise based on intuition and individual judgment.

Regarding HS as a strategic foresight tool, Rohrbeck and Schwarz (2013) link HS to innovation management and argue that it is crucial for new product development as it enhances the exploration and identification of promising new innovations. Having studied 77 companies, they discovered that strategic foresight reduces the level of uncertainty in R&D projects, enhances the understanding of customer needs, enables the identification of potential customers and market understanding as well as aids in the identification of opportunities and threats regarding firm’s product and technology portfolio. Therefore, the aim of this research was to: discuss the role and importance of horizon scanning for innovation and design; identify dominant methods and approaches used within horizon-scanning; and compare the methods typically used by different types of innovation practitioners.

Methodology

Semi-structured interviews were conducted based on a pre-prepared questionnaire, which primarily consisted of open questions and ‘probes’ to obtain in-depth information. Examples of open questions were: ‘What

methods do in-house innovation managers, innovation consultants and entrepreneurs use to horizon scan latest trends (top-level strategic trends)?' and 'How do in-house innovation managers, innovation consultants and entrepreneurs learn about specific technologies?'. Examples of probes were: 'Could you tell me about a project or product you worked on where you have (successfully) applied horizon-scanning?' and 'Do you follow any routines for gaining and internalizing knowledge?'. Additionally, closed questions were posed to receive factual information and summary questions to validate answers. A total of 18 semi-structured interviews were conducted and recorded in the period of June-August 2018 with the sample consisting of intrapreneurs, innovation consultants and entrepreneurs. Each interviewee was provided with an introduction and definitions of HS to ensure clarity and validity.

In the search for potential interviewees, topic-related industry papers, academic journals and LinkedIn were used. The interviewees were evaluated and selected to provide a variety of: positions, type of workplace, industries, and levels of practical experience.

Table 2: Screening process according to job titles

CASE	JOB TITLES
Intrapreneur	Chief Innovation/Technology Officer, New Product Development, Innovation Catalyst/Strategist, Consumer Insights, Research Scientist, Manager R&D
Innovation Consultant	Technology/Innovation Consultant, Strategy Insights & Innovation Lead
Entrepreneur	Founder, Co-Founder, Chief Innovation Officer

Subsequently, 93 potential candidates were contacted of which 18 individuals from 3 countries -namely the UK, Germany and the US -were interviewed. However, 2 of the 18 interviews were excluded from the study as they did not entirely match any of the three participant profile types.

Table 2: Interviewee information

CASE	CLASSIFICATION	INDUSTRY / FOCUS	DURATION (in minutes, seconds)
1	Entrepreneur	Tech/Drones	68:45
2	Entrepreneur	Tech/Logistics	43:44
3	Entrepreneur/Intrapreneur	Tech/Medical & Consumer Goods	78:26
4	Entrepreneur	Tech/Data Science & AI	25:18
5	Intrapreneur	Consumer healthcare	55:19
6	Intrapreneur/ Consultant	Government/Consulting	64:35
7	Intrapreneur	Software	42:45
8	Intrapreneur	Healthcare/Research lab	40:25
9	Intrapreneur	Government Innovation Agency	65:53
10	Innovation Consultant/Intrapreneur	Consulting	64:21
11	Consultant / Intrapreneur	Consulting	65:39
12	Consultant	Consulting	23:57
13	Innovation Consultant/Intrapreneur	Consulting	97:59
14	Innovation Consultant	Consulting/FMCG	70:23
15	Innovation Consultant/Intrapreneur	Consulting/Industrial & Product Design	62:53
16	Innovation Consultant	Consulting	66:05
17	Non-attributable *excluded	------	41:58
18	Non-attributable *excluded	------	35:30
			~ 1002 min.

All interviews were transcribed verbatim to ensure accuracy and detailed completeness. Afterwards, the anonymised transcripts were sent to the respective interviewee for approval, ensuring that the data was correctly captured and that no breach of confidentiality was made. Figure 2 shows that, 4 of the 16 interviewees are categorized as “pure” intrapreneurs, 3 as “pure” entrepreneurs, 3 as “pure” consultants, 5 as intrapreneurs and innovation consultants and 1 as intrapreneur and entrepreneur.

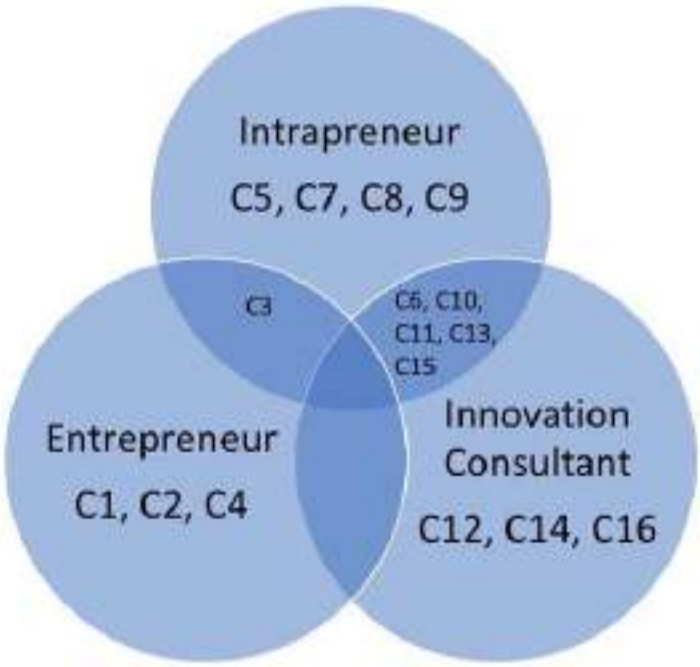

Figure 2: Classification of interviewees

Thematic Analysis

For the data analysis, the transcripts were incorporated into NVivo and coded using thematic analysis which aims to identify and analyse patterns of themes (Mortensen, 2018) as well as minimally organises, reduces and describes a data set in detail (Braun & Clarke,2006). Therefore, whereas codes were generated by identifying recurring topics and relevant information across the data sets, themes were generated through the proactive interpretation of the codes by allocating identified codes into broader themes. Furthermore, thematic analysis can be used for both explorative studies where one does not entirely know what patterns to search for with the themes depending on the data as well as deductive studies where one actively searches for pre-defined themes based on existing knowledge (Mortensen, 2018). In this study, due to the information gathered during the literature review and interview process, codes and themes emerged from both approaches. Table 4 provides an overview of the most relevant and dominant themes and codes.

Table 4: Data Points extracted and generated from NVivo

Theme	Codes (sub-codes)
Importance of HS - Advantages & benefits of HS	- Competitive advantage & resilience - Informed decision-making - Risk minimization & mitigation - Awareness and preparedness – minimizing uncertainty
Disadvantages & Challenges of HS	- Human intuition – bias - Information overload - Lack of time
Methods & approaches	- Web-based (news, academic journals, industry publication, market data reports) - Network-based (expert&personal network, conferences, networking events) - Tech scouting – collaborations & partnerships - Investigation of adjacent industries, sectors and companies - Consumer engagement – brainstorming, co-creation, observation - Exploration & evaluation – questioning, experimentation, pivoting - Pattern recognition – connecting dots
Additional frameworks	- Design thinking - Divergent and convergent thinking
Future implications	- AI

Limitations

Because the interviewees have transitioned within companies and job roles during the course of their careers, some can be attributed to more than one category. Therefore, making the comparison between the methods typically used by different types of innovation practitioners difficult to do comprehensively. As the length of their career paths spans between 6 and 28 years, the insights of the selected interviewees inevitably relate to their overall cumulated experience, indicating best practices based on past experiences and knowledge. However, the findings do not include insights from early-career practitioners as these were missing from the participant set.

Findings

Dominant methods and approaches used within horizon-scanning

Web-based HS

To get a general sense of current trends and technologies, the starting point of HS is gathering information on consumer behaviour and needs, market and technological landscape. The most common tools mentioned are reading and analysing academic journals, news articles, white papers and publications from industry and academia as well as market data reports.

“Typically, it’s keeping the finger on the pulse all the time“(C14)

C12 notes that the credibility of online information must be judged carefully, especially for novel and complex topics and that the capability of sifting out valuable from invaluable information is crucial. C13 further states that one needs a “good filter for distinguishing information and for removing the fake news”. Due to information overload and lack of time, most interviewees have activated newsletter/newsfeed functions to stay up-to-date, allowing them to quickly scan and monitor trending topics on a constant basis. After a topic of interest has been identified, they dive deeper into the subject matter by extracting relevant academic and scientific literature and industry publications, which tend to have a higher credibility and detailed coverage.

“I guess the key problem is time - I think for everyone, especially when you cover a broad area. It just isn’t physically possible to regularly check all these sources and journals yourself, so you are reliant on information feeds”(C9)

Whereas intrapreneurs usually have access to data reports from market insight research companies, entrepreneurs usually do not have the financial capital and need to gather the data themselves. The paradox is that although intrapreneurs are equipped with reports, they are overwhelmed by their complexity and struggle to retrieve actionable insights.

“Because quite often corporations have overlooked something, so you look for interesting and different insights and research data points and then look at what opportunities you can create from this because perhaps they haven’t thought of that”(C10)

Furthermore, intrapreneurs and consultants raised concerns about the value of market data reports as the reports oftentimes are perceived to be rather generic and partially useful.

“Yes, we do look at them but we take them with more than just a grain of salt”(C8)

Network-based HS

Another dominant method is attending conferences. Whereas conferences are regarded as a great platform for meeting people that can help spur innovation opportunities and idea generation, the actual content and topics being covered are often perceived to be out-dated, superficial and focused on recurring known top-level mega-trends. Therefore, the general consensus is that conferences are only of limited use when it comes to accelerating innovation. Innovation efforts, future-oriented visions and strategies are highly bespoke, unique and dependent on the organisation’s aims and objectives. The importance of networking was emphasized as it enables individuals to exchange opinions and viewpoints on emerging trends and technologies and their potential areas of application as “a lot of it involves conversations with companies that then reinforce and inform” (C6). Additionally, connecting with individuals at conferences is useful in that it may spark business investment opportunities, potential partnerships and further areas of investigation.

“Anyone who's in innovation needs to be active in terms of networking and networking in the triple helix model, so universities, industry and government agencies. Having those three in play [and attending] networking events or conferences within a particular topic area is probably the best way to pick up the latest trend and to use as validation”(C11).

Experts

75% of interviewees highlighted the importance of their professional and personal network of experts which they have established throughout the course of their career. More specifically, experts play a vital role not only for sparking and feeding ideas and gaining detailed knowledge about a trend or technology but also for making sense of potential areas of application.

“If I needed to have a technical discussion, I would turn to the most appropriate person to have that discussion rather than me sitting down and trying to become an expert”(C9)

Additionally, contacts are approached to test and validate ideas and information in a timely manner, with C8 noting that “different media [are used] to spot the trends and personal interactions to validate them”.

“Beyond screening academic journals and magazines, to get quick answers and perspectives, your network is really important. Just so it does not remain theoretical and hypothetical, it is important to have discussions with those who are actively working in that field so that [clients] don’t get the feeling that it’s just a lot of research and not tangible enough”(C16)

Moreover, conversations with network connections oftentimes enable innovation practitioners to spot possible overlaps or gaps in the market which could potentially turn out to be fruitful opportunities and enable them to stay informed.

“You ideally have a team of people and a personal network to create your savviness”(C11)

C13 states that “horizon scanning is having the right network, seeing the trends because if you want to do something new or go into a new area, you'll use your trusted network to get second opinions”. However, C14 and C9 stress the importance of drawing upon a diverse set of experts to extend one’s knowledge base and

learning curve and that opening up one's network and identifying knowledgeable experts is equally important for preventing bias and subjectivity.

"I know if I have invited certain people to a panel, we would have gotten a very skewed view of the world from it. So, it is like any system – it is only as good as the people and the information that you are tapping into"(C9)

Investigation of Adjacent Spaces

The importance of calling in subject-matter experts and diverse individuals from adjacent industries is particularly important to gain awareness of trends and technologies from adjacent sectors as they may be transferred to one's own product portfolio and business operation, resulting in the generation of incremental and radical products innovations.

In fact, each of the three types of innovation practitioner indicated that they scan and monitor adjacent industries for:

(1) existing technology which was not considered for own industry before

(2) existing technology which has had an advancing breakthrough

(3) emerging technology which could be applicable to one's product portfolio

(4) identifying gap and moving into adjacent space by adapting one's existing technology

"Taking something from one industry and putting it into another - that's innovative"(C5)

Furthermore, looking at adjacent spaces might trigger surprising and unexpected insights that one may have not been able to generate if HS was narrowly and solely focused on one's product category or industry. Thus, exploring and monitoring adjacent industries, markets and companies oftentimes results in novel opportunities and clarity of thoughts.

"Horizon scanning for me is looking: where have been successes in adjacent market? Has that been done in the market I'm interested in? How can we transfer that success?" (C11)

Additionally, C16 and C5 further mention that in order to position and paint pictures for several possible futures, drawing upon product analogues and adjacent business successes, trends and practices is highly useful to substantiate evidence through past indicators, highlighting that "this is where it is not a science, it really becomes more of an artform where you have got to be creative and show why it makes sense" (C16).

Experimentation

A crucial activity for boosting innovation and product development capabilities is to experiment, constantly ask questions and challenge the status quo, not only to understand the trends' and technologies' implications but also for finding the right problem to solve, executing on it accordingly and ultimately to find the right product-market-fit. Experimentation touches upon three different aspects that include brainstorming and testing, going back to basics and becoming an expert for understanding the technology and matching it with consumer needs.

(1) New or existing technology: brainstorming how to apply it to a product

(2) Existing products: brainstorming what new technology could be integrated and married with it - positioning it differently to fulfil changing consumer need

(3) Existing technology: Adapt for moving into adjacent space

"We slightly adapted it - so that existing technology was used in a different way for a different product. But the new way of applying this existing technology made the product look magical, novel and amazing"(C15)

To truly understand the underlying technology, its implications and applications, the act of asking questions, staying curious, playing around with the technology, testing and conducting experiments is often more fruitful for gaining specific technical knowledge than solely relying on experts whose expertise may be flawed or only partially useful for one's own needs and requirements.

"I always used to go along to someone that was potentially supposed to know more than me on something and I just remember asking in a very child-like way: "but why?" "but why?" "but why?". And they were just like "I don't know" - so it's really good if you can find out for yourself and not rely on experts" (C15)

Technology Scouting

All three different types of innovation practitioners stated they actively engage in tech scouting to uncover trends and technologies by scanning start-ups, academic research institutions, government entities, competitors and corporate research labs that develop or apply emerging technologies which may be applicable for one's own innovation projects. Moreover, exposure to these levers not only aids in the identification of upcoming technologies and trends but also in the collaborative investigation of technologies that are in their infancy which ultimately catapults them at the forefront of the competitive landscape. Additionally, sharing and complementing knowledge enhances the chances of identifying and assessing change and accelerates the development of technologies as every stakeholder can incorporate their unique knowledge, expertise and assets, which maps onto the open innovation approach.

"We come from an applied technology's view, academics come from a research view, the clinicians come more from a need's view. And so, in many cases bringing those views together helps us make sense out of the hypes"(C8)

C3 states that particularly large corporations pursue immersing themselves in a rich and diverse ecosystem "due to strong competition [as they] have realised the need to get involved with technologies at an ever-increasing earlier stage in order to beat their competitors to those technologies", indicating their objective to act ambidextrously.

Moreover, intrapreneur C8 states that hosting and attending hackathons, boot camps, university or business challenges acts as an avenue to spot and evaluate potentially relevant start-ups and researchers "where we try to see what they are developing as a potential view of the future because scientists are horribly bad at predicting the future - that's why they try to shape it instead. So, we need to sometimes look at multiple options that may materialize - bet on one and risk-mitigate on the others" (C8).

Ultimately, depending on the company's area of interest, its innovation strategy and product portfolio alignment, tech scouting may result in:

(1) forming partnerships to jointly co-create and advance technology

(2) identifying companies that own patented technology - try to get exclusive license before competitors

(3) acquisition of technology by merging with or acquiring respective company

(4) decision to bring technology in-house by replicating or reverse-engineering it

Connecting the Dots – Associative Thinking

All participants mentioned the importance of connecting dots as innovation occurs by combining different pieces of information and recognizing patterns as well as understanding the wider implications, conversions, interrelations and articulations of the spotted trends and technologies.

"HS is a practice that requires being educated on it – it's not necessarily a science, there is a lot of art to it because you have to use your creative mind when you converge a political, technological and economic indicator to understand what implication that is not only going to have on your business but also on the market and your consumers"(C16)

Hence, the general consensus among the participants was that connecting the dots is key for making sense out of the noise and develop innovative products accordingly.

"Innovation occurs when people connect dots; when they connect consumer insights and trends and they connect it with technology - they get eureka moments and it sparks ideas and new ways of thinking and new perspectives. So, doing horizon-scanning leads to, and catalyses, innovation and also to respond better to changes faster"(C3)

Human-centred methods & Design Thinking

Having been mentioned 77 times, the consumer plays a vital role across all three different types of innovation practitioners. Because market data concerning consumer trends does not always display accurate information on true consumer needs, habits and behaviour, the interviewees state that truly understanding the consumers' pains and jobs they seek to accomplish is the most vital and crucial aspect for commercial success which can only be achieved by offering unique and convenient products and services.

Furthermore, they indicate that most products fail due to insufficient consumer insight and not because of its technology. C10 further notes that solely relying and launching a product based on its technology will most likely result in a poorly thought out product as the consumers' needs have not been considered and addressed. Therefore, all three different types of innovation practitioners indicate that they deploy iterative human-centred methods, which map onto the design thinking philosophy that "brings together what is desirable from a human point of view with what is technologically feasible and economically viable" (IDEO,n.d.).

Thus, the importance to start with scanning for consumer trends by brainstorming, co-creation workshops and observing consumer behaviours is highlighted because "if you just constantly scan the technical horizon, you could be wasting your time. So, you need to generate insights around your consumer's behaviour and how that is changing and apply your technical know-how to solve those needs" (C10).

"In terms of market research, for me, it is not good relying on another person to be your eyes and ears about why a product would work or not. If you are inventing and developing that product, you need to be the person that speaks to potential users and see all the problems yourself" (C15)

HS can be linked to the method of divergent and convergent thinking which originates from the creative design process. Known as the Double Diamond Model, the four phases of discover, define, develop and deliver indicate the creation of several possible ideas (divergent thinking) before refining and narrowing down to the best idea (convergent thinking). As depicted in Figure 3, the iterative nature of the process is stressed for finding and confirming the problem. In fact, C7 underlines that the purpose of both design thinking and HS is finding the right problem and that "innovation is an equation of problem-finding + problem solving".

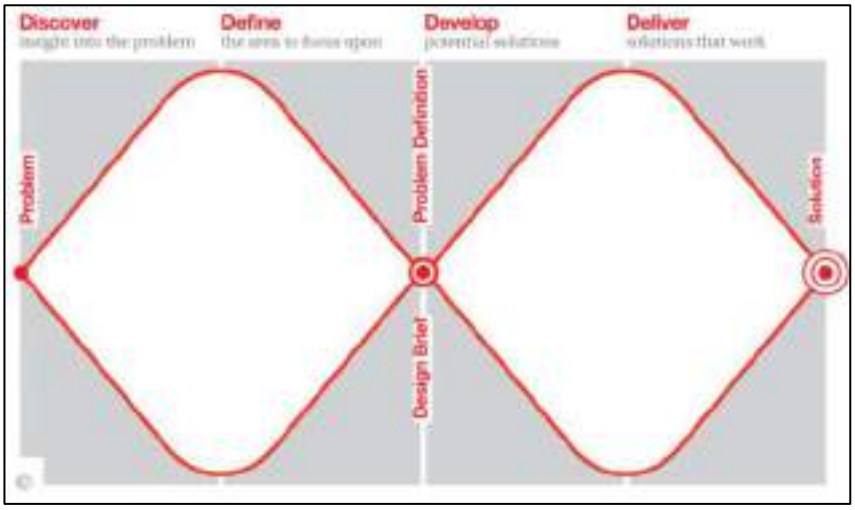

Figure 3: Double Diamond Model (Design Council, n.d.)

Future Implications: Artificial Intelligence

Due to recent advances in AI, 5 out of 16 cases mentioned that the future of HS may potentially entail AI conducting the web-based scanning, screening the internet for relevant trends and insights. In fact, C4 states that by leveraging data science and collecting publicly available data sets online, using predictive algorithms and machine learning, it is possible to discover patterns and capture weak signals before they become apparent and mainstream which humans may not have been able to spot.

As HS and trend-spotting involves scanning, absorbing and assessing signals based on subjective opinion and intuition, C4 argues that data science techniques offer individuals complementary, counter-intuitive, impartial and objective perspectives, ultimately resulting in simplified and better decision-making.

"Highlighting interesting signals in all the noise is the only way we can make things actionable – and when you manage to do this and translate data and insights into something actionable, that is where the real value occurs"(C4)

However, as AI is currently neither able to connect dots, interact with humans to understand their needs, pains and motivations nor to contextualise, transfer and interpret information, it lacks the creative component of HS that is key for sense-making and developing innovative products.

"AI is useful for identifying patterns, but the human is crucial for making sense of those patterns"(C4)

"At the end of the day, human creativity will never be beaten"(C13)

Discussion

Role and Importance of Horizon Scanning

This study provides insights into the practice of HS within innovation and technology management and sheds light on the methods and approaches that innovation practitioners use for conducting HS and ultimately product development.

Whereas Amanatidou et al (2012) distinguish between exploratory scanning or issue-centred scanning, participants underline that depending on the company's stage, maturity and innovation portfolio, the nature of HS changes, indicating that for new product development and early-stage start-ups in the fuzzy-front end of innovation, "*there is no point in horizon scanning everything in terms of technology – it wouldn't necessarily be a good use of time"* (C13) and that scanning existing products, regulatory pathways and IP protection are vital for accelerating the likelihood of success, highlighting HS's overarching nature. On the other hand, for companies that are positioned in the commercialization phase, HS shifts to scanning existing competitors, market opportunities and potentially disruptive start-ups that might be joining the market within a relatively short timeframe (C9).

Hence, whereas one needs to define HS's scope and objectives early on by divergent and convergent thinking, continuously HS the environment to be prepared for arising opportunities, developments and threats is equally important, supporting, further specifying and extending the proposed HS process by Rowe et al. (2017).

"*One of the challenges is having a technology which is ahead of its time and understanding why it's not moving forward but being ready to pick it up again. So, it is serendipity – so it is the prepared mind [and] in the world of the blind, the one-eyed man is king" (*C13*).*

Additionally, HS is crucial for developing innovative products and achieving commercial success as HS spurs awareness which is "*important for de-risking the breakthrough innovations because otherwise you've invested hugely until the last moment and then it falls apart because of something you didn't look into; it accelerates the incremental innovations"* (C8). Hence, HS's widely acknowledged purpose and value of minimizing risk, capturing opportunities and making informed and timely decisions by gathering information and gaining knowledge about the environment, market and consumers is supported by the study as *"ideally, you want to be the most knowledgeable, so you can make an informed decision […] rather than reacting to something that you are not quite sure you fully understand"* (C6).

> *"Horizon scanning is fundamental to creating something that has a good chance of success and is improving your chances of success. If you operate in a cave, you might make something but its chance of success outside of that cave is incredibly slim. I mean the chances are incredibly slim already, so it is next to impossible if you don't look beyond yourself" (C1)*

The final quote included below sums up importance of HS:

> *"I mean the easy way to look at it is "what would happen if you didn't horizon scan? You'd be trundling down the road with no headlights. So, it is absolutely crucial for driving innovation but also for future success of businesses and economies"(C6)*

Dominant Methods and Approaches used within Horizon Scanning

HS is a creative process which entails the acquisition, collection and synthesis of knowledge in order to make sense of the future and derive actionable insights (Könnölä et al.,2012). However, most scholars neglect or underemphasize the creative component. There is neither a magic formula nor straightforward rule for driving innovation and considering that the fuzzy-front end of innovation is highly iterative, non-linear and

unstructured (Rohrbeck, 2013).Therefore HS within innovation management is also a mixture of structured and unstructured processes and thus, requires the expertise, intuition and knowledge of experienced individuals.

Although Palomino et al.'s (2012) differentiation of web-based and network-based HS is validated by the interviewees' practices, it is only partially complete and not exhaustive in terms of practical application as it was discovered that screening adjacent spaces, connecting the dots, experimentation, tech scouting, bringing in experts as well as immersing oneself in a broad and diverse eco-system are important elements of HS. Thus, the true value of HS lies in continuous and collective learning as it enables individuals and companies to gain awareness, spot and act upon changes more rapidly and wisely and operate ambidextrously reducing the likelihood of being disrupted or missing opportunities. Particularly, scanning adjacent spaces allows individuals to spot existing and emerging technologies and companies for potential collaborations, identifying analogues or companies that may cannibalize and replace one's business – hence, companies can detect opportunities and threats prematurely and thus, make informed decisions accordingly.

Comparison of Innovation Practitioners

Table 5 provides an overview of the findings, broken down by innovation practitioner and methods that are primarily and secondarily being used.

Table 5: Summary of findings, broken down by innovation practitioner and use of method

Innovation Practitioner	**USE OF METHOD**	
	Primary	Secondary
Entrepreneur	- Web-based desk research - Networking events - Conferences	- Collaborations & Partnerships - Experts - Experimentation
Intrapreneur	- Tech scouting - Experts - Adjacent spaces - Design thinking	- Conferences - Market data reports - Networking events - Experimentation
Innovation Consultant	- Market data reports - Internal & personal network - Adjacent spaces	- Design thinking - Networking events - Conferences

Due to limited resources, entrepreneurs tend to be more active gathering information via web-based desk research and more engaged in networking events and conferences for pursuing business investment opportunities, whereas intrapreneurs usually have access to data reports and subject-matter experts in-house.

Drawing upon analogies from adjacent spaces enables consultants to substantiate their recommendations to clients, whereas for intrapreneurs it typically fuels inspiration.

Due to rigid hierarchical structures and organisational inertia, intrapreneurs in larger corporations increasingly adopt open innovation and tech scouting initiatives by proactively facilitating events with third-parties for boosting their savviness as well as innovation capabilities. Regarding tech scouting, entrepreneurs and their research partners benefit by receiving funding, mentoring and exposure to an established company, its resources and network, resulting in greater likelihood and higher chances of developing and commercializing a successful product.

Conclusion

As the aim of the study was to investigate the role of HS in innovation practice, it sheds light onto HS' importance, advantages and challenges. Having gained insights from 16 innovation practitioners, dominant methods and best practices were discovered and analysed. The study's main implication highlights that HS is a complex endeavour, that requires time, effort and resources, and exceeds the mere quantitative and

qualitative collection and analysis of data, as believed by many executives and market research companies that provide innovation practitioners with reports believing that insights on PESTLE, market and consumer trends suffice for driving innovation.

However, it is rather a question of sense-making - how to capture, spot and combine trends and how to translate those into meaningful and actionable insights that offer and maximise value, not only for the consumer but also for the stakeholders. Thus, it requires the correct interpretation and combination of spotted trends and technologies and evaluation of potential areas of application which entails creative thinking, exploration and validation through various sources.

Furthermore, this study discovered that HS in conjunction with creative and lateral thinking, technology scouting as well as human-centred thinking not only facilitates the early detection of emerging trends and technologies but also facilitates turning insights into actionable ideas, increasing chances for more successful product development, meaningful innovations and commercial success. By proactively immersing oneself into a broad and diverse eco-system, individuals can collaboratively and collectively shape the future and create value, secure first-mover advantages and mitigate risk of being disrupted. Thus, companies and individuals that incorporate the practice of HS develop a sense of awareness and understanding of the environment which allows them to anticipate and proactively respond to changes as well as make informed decisions concerning their product portfolio and strategic business operations, increasing the likelihood of resilience and sustainable competitiveness.

One challenge and obstacle of HS is its practical implementation as it is not a straightforward, sequential or linear process that follows a strict pattern or a specific set of steps. Hence, this makes it particularly difficult for companies to capitalize on HS and requires the expertise, experience and educated judgment, instinct and intuition of individuals that are capable to spot weak signals and drivers of change which could have positive as well as negative implications. Furthermore, due to the vast amount of available information, the ability to sift out valuable from invaluable information is crucial for organisations to capitalize on the correct trends and technologies; because if poorly executed, HS will lead to information paralysis, product failures and missing out on business and innovation opportunities.

Managerial Implications

The findings of this research may be used as insights and guidance for managing horizon scanning and incorporating it into innovation and technology management strategies. As HS can be regarded as a combination of art and science, companies should foster the creativity of their employees in the innovation process and establish specific roles for trend-spotters and technology scouts as well as allow employees to dedicate time and resources to scanning the horizon.

Suggestions for Future Research

Future research could entail more qualitative research on the methods in order to investigate which tools and approaches are most effective and correlate to companies' innovation performance. More research is needed into the challenges associated with spotting weak signals. Furthermore, although the field of Artificial Intelligence exceeds the scope of this paper, the author suggests for future research to be carried out evaluating how AI might impact horizon-scanning, if AI may potentially replace humans' activities to scan the environment as well as humans' ability to connect the dots, ultimately evaluating if AI might be capable of generating innovation strategies.

Mapping Abstract Futures

STOCK Tim* and TUPOT Marie Lena

doi: 10.33114/adim.2019.02.186

The future we need to explore is more abstract than it is concrete. As designers, we are constantly conjuring ideas based on a concrete world to improve what we have already seen. Within these predetermined frameworks, we unintentionally bring our own biases to planning the future based on what we know and what we consider safe. However, methods of gathering evidence must reveal the essential dynamics and tensions of the individual in the context of society. The cultural system that represents this process of adaptation can be plotted as a system of language that reflects the dynamics between the concrete and abstract worlds. A craving for such emotional intelligence requires that we expand our binary world into an abstract space for which only the human brain has the capacity. We need such a systematic view in order to think intuitively on multiple levels at the same time.

Keywords: applied sociology, epistemology, semiotics, strategic foresight, systems thinking

The Limits of Our Perception

The landscape of future planning is broad. It can be commercial and explore consumer products, or it can be a landscape of peace and democracy. However, in all cases, we establish predetermined limits of what we explore. We need to foresee all intersecting futures related to the work under consideration. Myopic approaches keep true innovation hidden. To predict any ramifications, we need to be unafraid of the inputs. We can always pull back. We tend to look for what we want to see at a particular moment instead of engaging tensions and evoking provocative ideas.

Consider the artist Piet Mondrian. He could paint a house as well as any other early 20th century artist could. However, his curiosity about his fast-changing environment led him to see his perspective in abstraction. A house is not simply a house in its immediate setting. A house lives in the context of the world surrounding it. What we really see in a Mondrian painting, as well as in other abstract works, is the functioning of the mind that produced the work, not the limited constraints of the apparent subject. We should always allow our minds to go beyond boundaries. The process should be constant and iterative.

We are challenged to re-examine the methods we use to frame the future. We live in a world where there are rallying cries for sustainability, global awareness, safety, privacy, and inspiration. These concepts are no longer tangential but can thrive as progressive initiatives that are fundamental and universal. Our perspectives on the future have much to do with the ideological biases in our research methods. We seek shortcuts and quick classifiers. However, quick classifiers no longer exist. The ways in which we classify and organize information need to be protean, working in tandem with our evolving intelligence.

Design has become cemented in the language of the machine age. As it leans toward speeding up the future, it exposes us to unintended future possibilities. Its methods of inquiry and analysis are biased toward what

technology can do much more than we can foresee as real human societal needs. A sustainable and ethical future requires an abstract framework of ideation. Abstraction literacy refocuses our thinking on well-formulated ideas, thus keeping design rooted in its essence.

We spend great amounts of time and money quantifying waning concepts. Quantifying things lends confidence. It gives us a platform to build on—a green light. However, quantifying abstract ideas worries us. If the query is framed correctly, there should be no problem quantifying abstract ideas. Still, we tend to default to educated opinions. A primary problem lies in how quantification is defined.

“More” still equals “better.” That should not be valid. We should be looking at the effects of the numbers on trajectories. If we do not, we open ourselves to the possibilities of the worst that could happen. People thought social media was a brilliant way to network. We did not expect the current negative affect on our health and society.

Because the word trajectory implies movement through space and time, it compounds the complexity that is desperately needed to be explored. Such exploration should empower us to think as we classify, analyze patterns, and evaluate effects.

Jammed in the Machine Age

The ideology of the machine age has left an indelible imprint on both forecasting and the design frameworks it informs. Le Corbusier's idea of "machine for living" best defines the dominant ideological relationship between the designer and the world brought forward into the information age. Le Corbusier noted, “A house is a machine for living in...An armchair is a machine for sitting in and so on” (Corbusier & Etchells, 2014).

Design evolved to become an engineering function, satisfying needs at scale. That language of efficiency and scale can be observed today in everything from suburbia to iPhones. Materiality has become the de facto meaning of design. Consequently, forecasting has become distorted by this process. Legacy design thinking abides by the laws embedded in the materials themselves, not in the world around them. The future we imagine depends on the expanding feasibility of the applications in our existing design vocabulary.

Ironically, the core of Le Corbusier’s philosophy is that the “machine for living” would be positively adapted to the materials and social conditions of the time (Ghyka, 1927). If the machine for living were positively adapted to our social conditions, then this process would be protean. However, in this model of materiality, technological utopias quickly became dystopias. The “appification” of the home is in the interest of what technology can do rather than what we truly need. Do we need constant surveillance to survive? We forget to look at the future in decline. What might go wrong in the context of success? These questions have been largely overlooked.

How could we not see the future decline of suburbia as we planned it? Why stop progress? We do not know whether we should be harnessing progress until it is too late. Robert Moses and Henry Ford had valid sustainable ideas, but we prioritized only industrialization.

In his article “For geoengineers, a scientific existential crisis” (Undark.org), Dave Levitan quotes Joshua Horton, a research director of geoengineering at Harvard University: “The world is full of things we wish didn’t exist but ignore at our peril” (Levitan, 2019). According to Levitan, technofixes for the climate crisis are not anyone’s first choice. These issues hit home hard.

An epidemic of loneliness accompanies our hyperconnected mobile world. Blind spots occur when the future is framed from a dominant position of technology over human response. Unraveling the future forces designers to consider the broad responsibility of purpose and sustainability to adapt to the lives of people rather than conform to the machines. Problems of bias and blind spots are to be solved now before increased technological momentum.

Revealing the “Unknown Unknowns”

Over the last century, advances in trend forecasting emerged from periods of war. An advantage during wars is the ability to assess the influence of weather on actions taken on the battlefield. We measure predictions of the immediate cost. In World War II, the ability to predict the weather delayed D-Day and allowed the window of opportunity by Allied forces on June 6. The assessment of risk and uncertainty informs the framework

developed for a set of tactical actions. We assess the available data and combine this knowledge with the available materials to propose a set of scenarios within that framework.

According to StrategyByDesign.com, “The military historian Liddell Hart says that the purpose of strategy is ‘to diminish the possibility of resistance...under the most advantageous circumstances.’” (Rhodes, 2011). Troops were warned to expect the unexpected within an articulation of a set of operating principles. The forecast model merely directs the path based on a finite set of variables and available materials. It does not consider the long-term aftermath. We feel those effects today.

The military forecast model is a framework of “known unknowns.” Donald Rumsfeld used this phrase at a press conference in 2002 to refer to the lack of evidence linking Iraq to weapons of mass destruction. The structure of knowing includes “known knowns” (things that will happen), “known unknowns” (risks we are aware of) and “unknown unknowns” (risks we are not aware of). “Unknown unknowns” present the most significant challenge. They represent the realm of abstraction, involve human variability, and require a broad scope of consideration.

American psychologists Joseph Luft and Harrington Ingham coined the “known” terms in their analytical technique called the Johari Window. The technique is used to examine what we know about ourselves, what others know about us, and what we do not know about ourselves or about others. Its purpose is to move us beyond a single perspective of the self and improve how we function in the world. The logical exercise determines and classifies the gaps in understanding, forming an algorithm of self-actualization. Identifying the notable voids is critical.

Figure 1: The Johari Window. Source: Luft & Ingham (1955)

At the 2019 Consumer Electronics Show (CES) in Las Vegas, product launches highlighted the struggle between the concrete and abstract domains of design foresight: a television disappears from view and a wearable device tracks how you sleep. These designs convey the existential crisis. Why do we want our electronics to disappear? Why are we not sleeping? Buckminster Fuller referred to this phenomenon as “weaponry over livingry” (Fuller, 1963). Fuller’s concept of “livingry” places design within a broader system of consideration. All the preliminary questions must be thoroughly investigated before we compound the problem.

Developing a Sustainable Model of Design Foresight

A current challenge to design thinking is the sustainability of purpose. Sustainability does not follow a linear path, but designing sustainability has become an excuse to make more consumer products and services. The more we dilute the process of investigation, the more we obfuscate the path to innovation, cluttering the world with designs that further agitate cognitive dissonance. The underlying thinking is that analysis slows the

production process, and complicates the path to completion. Design further complicates by saturating experiences with “tweaks.”

Consider personalized pre-packaged prescriptions. AI and machine learning promote pharmacy automation to increase accuracy and efficiency. This comes at a cost. Eventually, automation will allow human pharmacists to better interact with patients. At present, a senior person might be put off by the early stage processing of pre-packaging and perceive a complete lack of interaction regarding their care. A lack of compliance is sometimes the result.

Foresight always should consider the living abstract layer that designs will enter. The aforementioned disappearing television indicates that we feel crammed to technological capacity. The wearable sleep device processes more data than we can handle. In design, there is both a perfect future and a negative future. The application of design foresight should not lean too heavily on a bias toward material design perfection. We allow products to be visible when ease and elegance are applied to their design. Usability does not affirm that something is needed. The assumption of usability is made in the context of the product that exists in the first place.

The Technological Echo within Design Foresight

The absence of the natural process of evolution creates an echo effect in design. We design tools that design tools that design tools. In art, the term mise en abyme refers to the technique of placing the copy of an image within itself, suggesting an infinitely recurring sequence. The method is known as the Droste effect, named after an early 20th century Dutch brand of cocoa powder that used the technique in its packaging illustration. That algorithmic echo is the essential metaphor of the machine age of forecasting. From the assembly line to the “selfie,” our relationship to technology has reached the point of distortion. We surrender our forecasting to the “known unknowns” of the mechanical process, thus becoming the mechanics of our inventions.

Figure 2: Example of the Droste effect. Source: photograph of Droste’s cacao tin, designed by Jan Misset (1904)

Elizabeth Holmes and her company Theranos provide an example of the Droste effect. Holmes stole admiration by modeling herself after Steve Jobs. Her mission of democratizing healthcare offered a model of aspiration. Investors saw what they wanted to believe, and collectively drove the visibility of Theranos until it fell apart at the policy regulation level. Aspiration cannot be designed toward. The sustainability of health and society requires that design truly looks at the meaning of democratizing healthcare. We are already seeing reactions to Uber and its eclipse of accessible public transportation systems. We need not more apps. We need thinking.

Moore’s Law is the observation that the number of transistors in a densely integrated circuit doubles about every two years. This law became a forecasting model used to predict the growth of technology. The linearity of a forecasting model based on materiality alone leads to exponential distortion. The exponential trajectory

creates behavioral unpredictability. The more significant challenge then becomes how we can develop our designs to anticipate and adapt to this abstract layer of human response.

We assume that the perfectly ergonomic phone will create perfect communication. The opposite is true. How the design is received, contextualized, and eventually rejected must be considered in forecasting the evolution of its use. The utopia of suburbia becomes a dystopia of economic instability. The gap in our forecast lies beyond the explicit nature of design but within its implicit connection to the unpredictability of human expression. These “unknown unknowns” are biological, not mechanical.

Learning from the Process of Evolution

Practitioners of design foresight can learn from the natural world. Evolutionary biology reveals the interconnected ways in which change manifests. An example is the flight of birds. Feathers are interlinked with the meaning of flight. However, science has revealed that flight was not forecast by the presence of feathers. Flight is a secondary adaptation of thermoregulation. Opportunity affected the response of the birds to the environment imposed on them. To understand evolution is to understand the ways in which unexpected traits take shape. The feather becomes the trait of flight only in the context of its environment. This process of exaptation demonstrates that the biology of flight is a far more incremental process than we might think. The feather adapts to the environment and, in turn, the feather shifts from the trait of insulation to the trait of mobility and flight (Parry, 2013).

Our cognitive development follows a similar process of adaptation. The system of meaning creation and adaptation can be modeled using Piaget’s theory of cognitive development. Piaget’s theory describes how humans acquire, construct, and use language in their world. In the processes of assimilation and accommodation, we move from one framework of meaning to another framework of meaning as the context changes (Piaget, 1966). A child learns by interacting with the physical world and develops abstract concepts of the meaning of things. For example, as a child learns the concept of “hot,” other implied language enters into the schema, such as “danger,” thus framing a narrative that the child uses to apply to new phenomena.

This process of accommodation is the psychological framework of abstraction. It is how new lineages in culture emerge. Our language defines the reality in the context in which it is presented. In effect, it is a schema that provides us with a template for processing all that follows it. These schemata are the essential reality of design and foresight. Schemata reveal the ways design will work or not work in the future. They reveal the discrete relationship between the seen and the unseen, that is, the abstract and the concrete.

Social Systems Reveal Cultural Abstraction

A return to the fundamentals of sociology helps us determine what we can consider evidence to measure cultural adaptations. Biological analogies of creative synthesis influenced Emile Durkheim's model of social causation. A system of social facts shapes our world. We are not isolated individuals but interconnected organisms and parts of a whole. The interplay of individual and collective adaptation frames our world. In *The Rules of Sociological Method*, Durkheim outlined the following:

> *Sociology cannot dissociate itself from what concerns the substratum of collective life...If the population clusters together in our cities instead of being scattered over the rural areas, it is because there exists a trend of opinion, a collective drive which imposes this concentration upon individuals. (Durkheim, 1950, p. 58)*

This collective system is the framework that our design must occupy. Our methods of gathering evidence must reveal the essential dynamics and tensions of the individual in the context of society, both explicitly and implicitly. It must reveal the connection between what we perceive as material evidence and what is hidden as implicit responses to our environment. The traits that emerge are cycles of dissent and aspiration that emerge in our social exaptation.

Like feathers adapting to flight, language and behavior are adapted as cultural mythologies. Our design foresight must consider that shift in schemata from the adherence to rules to the starting point of a symbolic design rebellion.

Mapping the Concrete and Abstract Layers

The uncertainty and chaos of forecasting are traits of cultural change that reflect the relationship between the explicit and the implicit. Hidden biological response and human expression attempt to mitigate the chaos. These traits are the abstract ideological underpinnings of “unknown unknowns.” They influence our everyday life and consumption. The symbols and language of culture make apparent the abstract layer, serving as evidence for application in the design process.

The cultural system that represents adaptation can be plotted as a system of language that reflects the dynamics between the concrete and abstract worlds. We can use a model, such as the Johari Window, to examine how culture responds implicitly to reveal traits of future behavior. We can then see the inception points of cognitive dissonance as well as cognitive aspiration. The patterns reflect a holistic view of how design functions in the world. We can then track how culture migrates in a taxonomy of words, images, and gestures.

Language reveals the abstract world of implicit meaning before it takes concrete shape in cultural norms and values. Semiotics, the study of linguistic signs, provides us with the tools to distinguish the abstract and concrete elements of culture. These linguistic signals represent the dynamics of cultural adaptation in direct relationship to the environment within which they emerge. The relationships between residual, dominant, emergent, and disruptive codes of meaning are given a cognitive, social context. The process of signification that shapes these codes consists of a series of social facts that rise and fall. They can be measured and patterned to reveal the abstract spaces that determine the context of uncertainty.

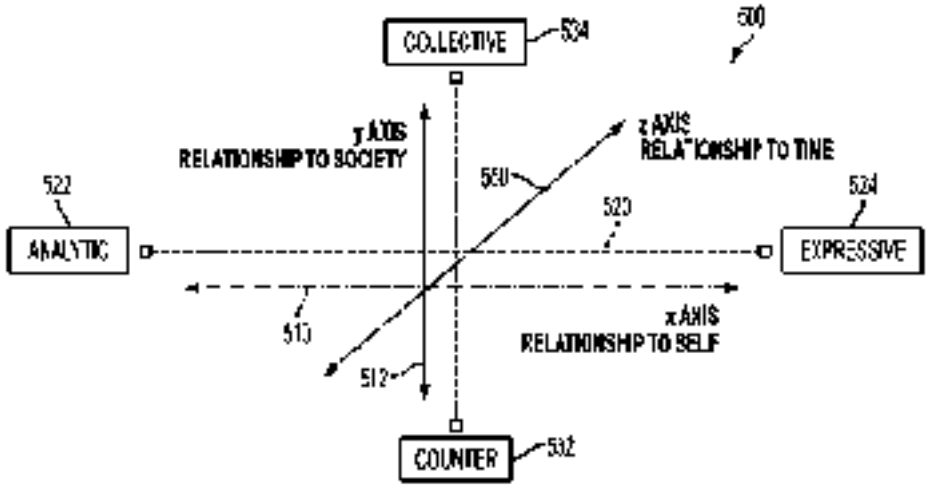

Figure 3: A system and method for culture mapping. Source: U.S. Patent No. US9002755B2.

The matrix diagram (Fig. 4) is based on a patented method of analyzing and classifying open and closed corpora into discrete behavioral archetypes that can be visualized as a system of signifiers within a semiotic square (Fig. 3). It classifies and quantifies linguistic signifiers along three principal axes. The x-axis represents the relationship to self from analytical to expressive. The y-axis represents the relationship to society from affirming societal norms and values to resisting societal norms and values. The z-axis represents time. This framework provides an ideological systematic view of the dynamics and patterns that emerge in expressed language, including words, visual images, and gestures. It contextualizes the relationship between certainty and uncertainty.

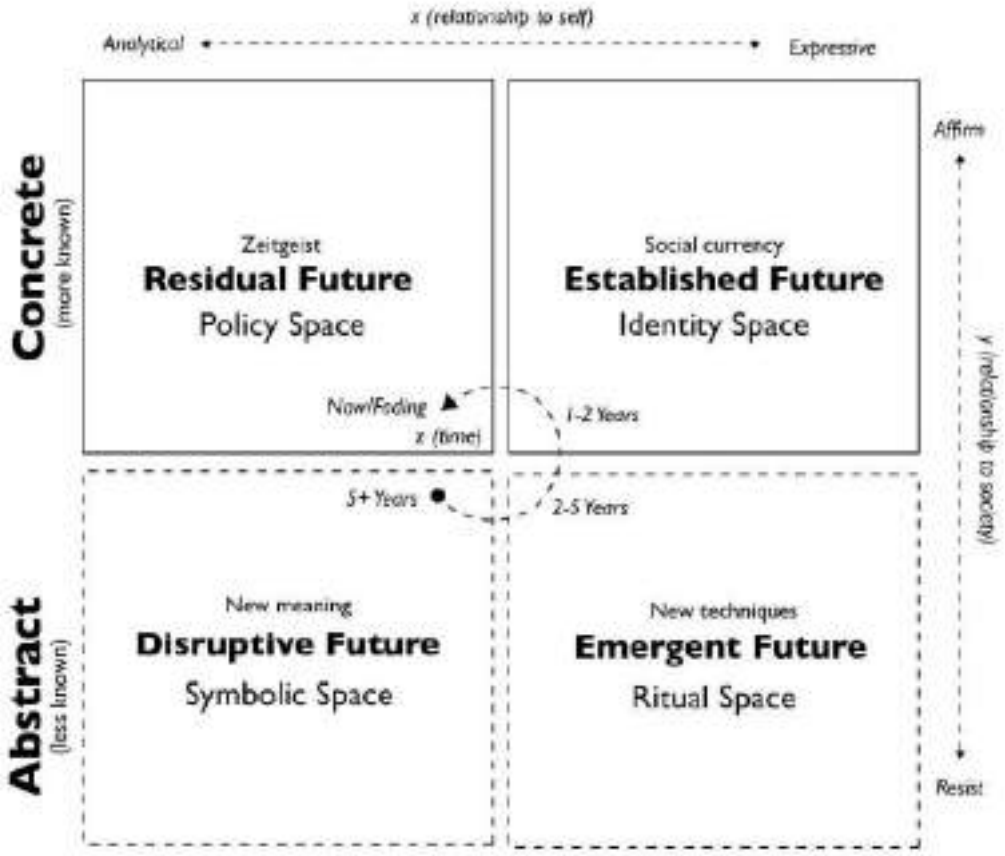

Figure 4: Abstract/concrete foresight matrix, adapted from a system and method for culture mapping. Source: U.S. Patent No. US9002755B2.

The framework maps the relationships between discrete elements of the collective social system to reveal gaps. We can also use this mapping of layers to reveal the migration of meaning. The migration is charted by classifying the coordinates of human expression.

In the matrix model, the two top quadrants represent the concrete layer of cultural meaning creation: identity and social currency migrating within the framework toward social zeitgeist and public policy. This layer affirms societal codes. The two bottom quadrants represent the abstract layer where new meaning creation forms. This layer resists societal codes. New meaning emerges as a pattern of dissent to the social order. It manifests as symbolic and philosophical traits that eventually are made physical through new techniques and rituals. These techniques and rituals become the social currency that informs the concrete layer when the schema is updated.

Ideologies emerge within these domains as taxonomies of expressed language, revealing codes of social cohesion within discrete social groups. The method allows for visualizing the full picture of the variability of how design works as part of a complete living system, including dynamics beyond the control of the imagined isolated user. The reality is that there is no "user." The individual is always connected as part of the larger system.

The described archetypal framework reveals the narrative variability that is promoted by environmental, political, and social forces. It is rooted in Carl Jung's essential cognitive theory of psycho-physical patterns common to all humanity (Robertson, 2009). And, much like Jung's hero's journey, it too is a system of shadow and light, entering into the unknown to restore order. Within the framework, linguistic clusters form making apparent relevant archetypes and their codes. By mapping them as a part of a measurable social system, we

can integrate unconscious elements, thus demonstrating how linguistic evidence emerges in patterns that reveal critical schematic shifts.

The Concrete Layer Must Overcome Mechanical Inertia

Design foresight capitalizes on the inertia of materiality. Parsing through an "Established Future" and a "Residual Future," we look for what is popular and then seek to scale it. The traditional framework for design foresight begins ideation by looking at unmet needs within existing design. The diffusion of innovations affirms this approach by assuming that future behavior can be modeled on a linear path toward critical mass. It relies on the predictability of social dynamics, which is more about materiality of design moving from adoption toward economy of scale. It is an additive process. It applies design to the feasibility of existing materials in relation to the articulated needs of a user rather than their unarticulated needs. As we scale on the surface layer of adoption, we undermine the social order we need to keep a design viable. We assume people want more and improved versions of what they have.

Wearable technology, for example. The appetite for data-driven wearable applications has expanded into every area from health and sleep to monitoring the activities of your adolescent. To meet the needs of the "helicopter parent," the global positioning systems (GPS) company Tampa Bay Monitoring provides its ankle-monitor technology for children. It was intended for people released on bail or parole. This designs the idea of passive restraint into our daily lives. Satisfying need alone keeps the design process in the loop of adding applications to mitigate the unease that the technology causes and perpetuates.

The "privacy paradox" has emerged as a measurable trait of social response to technology use. As technology makes it easier to share data, countermeasures emerge to avoid surveillance. We must consider that as we design, we create an unseen response that immediately affects future relevance and sustainability. In their study, Alyson Young and Anabel Quan-Haase (2013) examined the ways in which "the privacy paradox" operated by examining the Facebook behavior of undergraduate students. Their findings showed a distinction between social privacy and institutional privacy.

> *Social privacy concerns revolve around concrete individuals. Therefore, they are accessible and easy to understand. By contrast, institutional privacy concerns deal with companies or public institutions. Institutional privacy concerns describe people's uneasiness and fear that their data is used for unwanted purposes. (Lutz & Strathoff, 2014, p. 85)*

We market a cycle of near-term dependency. Archetypes of material innocence and inertia emerge to propagate that compliance. At the 2019 CES, Deepak Chopra stated, "I think technology has created a lot of stress for a lot of people, but that's not the fault of technology. It's the fault of the people who use technology" (Fowler, 2019). In Chopra's opinion, our future health lies in more applications, not fewer applications and on more data not less, which betrays the essence of design. We have an ethical responsibility to design for a sustainable universal future.

James Williams, a researcher in design ethics at the Oxford Internet Institute leads the resistance against "Big Tech." In response to the conviction that our minds are being rewired for commercial purposes, he posits that the idea of human rights should be extended to cyberspace. We label design as "smart," but it needs constant feeding and adjustments. The result is a dissociation from design as an augmentation of human life. We do not want health applications. We want to be healthy.

The concrete layer of design should culminate in a framework of collective permanence, mindful of its residual imprint. It should represent the sustainable aspiration of our cultural zeitgeist. To that end, we should seek design law that ensures the cultivation of supportive innovation. In developing good law, we maintain the strength of the entire social system. We are also applying the categorical imperative, which is a supreme principle of morality according to 18th-century German philosopher Immanuel Kant (Paton, 1953, p. 134).

We have the potential to accomplish great achievements by affirming the dynamic traits of the social system. Making technology easy and accessible has the potential to create a transparent and collaborative society.

Cracks in the system emerge as breakdowns in our ability to control the uncertainty of human response. In *The Demon Haunted World*, the American astrobiologist Carl Sagan wrote, "Once you give a charlatan control over you, you almost never get it back" (Sagan, 2013). An example surfaced when Samsung mobile phone owners realized they could not remove Facebook from their phones. It was preloaded and blocked from deletion

(Frier, 2019). The lack of control became increasingly uncomfortable when Facebook was sanctioned for selling users' data.

A proposed change to West Virginia's public worker health plan asked teachers to download a mobile fitness app called Go365 and earn points on it by using a Fitbit or other fitness tracker to monitor their steps. The proposal was not successful, but it demonstrated how lines between personalization and empowerment can quickly become sinister.

Leveraging the Abstract Layer as Uniquely Human

The metrics of sustainable design are livability, participation, and knowledge. The signifiers of disruptive design are found in the categories of "Disruptive Future" and "Emergent Future." The evolution of disruptive and emergent futures is triggered by the failures of design codification in the concrete layer. When we consider the symbolic space (i.e., the space of the "unknown unknowns"), we are considering that purpose is an essential foundation of materiality. Artificial intelligence both defines the materiality of our time and tests how technology becomes intimate and interwoven with human thought and aspiration. The line between the human and the machine has begun to blur.

A pattern of response emerges when the policy space becomes disconnected from the social order. Revolution is one human reaction to the overreaching of control. We are wired to rebel for the survival of the species. The symbolic language of dissent and philosophical repositioning emerge within culture as a disruptive challenge to imposed atrophy.

In 2016, Edward Snowden summarized the archetypal dynamics of technology, stating, "Privacy is the fountainhead of all other rights. Freedom of speech doesn't have a lot of meaning if you can't have a quiet space." (Schrodt, 2016). An immune response is a declaration that the system is broken and the starting point for design language that seeks to resolve that break.

We should be empowered in the process of ideation to return to zero. We need to see the power behind zero, consider the points of obsolescence, and be aware of how this space links to deeper sources of meaning. If we can remain connected to the semiotic "notness" of design, we can save innovation from being reduced to meaningless gimmickry.

There is a point at which the analytical expression of dissent is transformed into physical action. The ingenuity of the "hack," improvised solutions, is formed in the expressive abstract space. The hack represents the essence of the natural human order of physically coding the symbolic with a new schema through creativity. In food, it is the point at which organic food becomes a recipe that I can make and eat. We have a right to foods that comply with the standards of organic farming. However, we do not consider the essentialness of this right until we cannot do something that we believe is essential.

We know how to be creative. We also need to think creatively. Apple introduced its Research Kit software to allow medical scientists to gather insights within their own control, thus reinforcing the physician-patient relationship. It is a natural human desire to want balance, information, and a voice. Such initiatives are beginning to pull back on populating consumer applications.

Informing Speculative Design

Abstraction looks at speculative design in a way that better informs the designer about the public in question. It functions as intervention allowing designers to deduct "knowns" and "unknowns" from critical futures, both positive and negative. Yet-to-be-realized information, disruptive and emerging, exists within the shadow spaces of these critical worlds. By methodically exhausting what one can know helps get ahead of and mitigate any potential black swan events. Also, the more a designer knows, the more ambiguity can be built into prototyping to allow for natural, open-ended design.

Mapping abstract futures for a global sports brand speculated a new vision for sports in Asia based on socio-political tensions. Recession and mistrust of establishment affected how teens and young adults saw their future. This could not be explicitly articulated. Younger people wanted to reclaim their national identity, and find their own individualism in a highly collectivist society. The answers lived implicitly in how they went about playing their sports, the type of sports they chose and the badges they wore. They were rebooting national identity for a new generation.

Visualizing this more abstract space of emerging identity empowered the brand to think beyond what any one sport represented. It allowed designers to build meaning and relevance in terms of how people affirm who they are in relationship to their society. It allowed them to cultivate muses to fuel their inspirations through emerging traits.

In Autumn 2018, MIT's Design Issues published *Provocation, Conflict, and Appropriation: The Role of the Designer in Making Publics*. The article discusses various approaches to speculative design. Each case shares an underlying commitment to viewing design as embedded in the production of publics and to making visible their issues and shared struggles. The struggles exist within one framework, but they have varied time trajectories and "notness" spaces.

The evolving approach to speculative design is to shift the designer's role from singular artist to conspirator, bringing greater participation into the role for diversity. Mapping abstract futures doesn't lessen the role of the designer. It better informs their design.

Longitudinal Reliability and Validity

Mapping abstract futures for American food producer Land O' Lakes meant it first needed to understand the bigger context of the future of food. People want nourishing food, safe food, food security, transparency, and sustainability. Their demands follow the same challenges as their expectations for privacy. Within their smaller circles of friends and family, they understand: "Food is what I expect." "Privacy is what I expect." However, when the public circle widens, human scale is lost.

Land O' Lakes wanted to live up to the relevancy that society forecast for them. As a legacy brand, they sought a renewal of identity. What were the signals in the social discourse that held possibility for them? Big food blind spots are typically in terms of what a corporation cannot do or scale. Instead, they create facades of seeming innovation.

However, Land O' Lakes had been nurturing a collaborative system of co-op farming since 1921. They knew there was power in being a "farmer-owned" cooperative. Being "farmer-owned" distinguished them from publicly owned big food competitors. It was their "known known." It was direct and valid. It became the co-op's mantra. Yet, it unexpectedly rooted Land O' Lakes in the concrete layer, leading to implicit biases of traditional farming and nostalgia.

The "farmer-owned" positioning also was not supporting the breadth of agritech at Land O' Lakes. Initiatives were presented as layered, when they were in fact well-integrated. The disconnect and the desire to understand the disconnect was their "known unknown." "Farmer-owned" needed better interpretation.

Natural language processing uncovered that "farmer-owned" and its future was not about self-pride. Thought-leading farmers were preoccupied with the concept of stewardship. Their concern for stewardship thrived from farmer-to-farmer as they shared notes and sought each other's support. The stewardship conversation was the "unknown known" that the outside world was not hearing.

Mapping abstract futures, the team exposed the "unknown unknowns" behind "stewardship." They learned that within a co-op system of stewardship, big learns from small and small learns from big, feeding smart collective knowledge to a future state of innovation. Land O' Lakes' un-siloed approach in terms of farm size allowed for the forward-thinking synergy.

The team also learned that gender dynamics were playing a critical role behind stewardship. This was not about masculinity or girl power or "leaning in." This was still about sustaining farming for the ages, and doing the work to bring real food to people. Many family farms were already run by women (just not designated on paper). Men and women had been working in farming side-by-side for centuries.

The concepts converged under a relatable conviction of "All Together Better," bringing Land O' Lakes messaging back to the collaborative essence of farming -- with a resounding modern focus for the future.

Ultimately, this was expressed through their SHE-I-O initiative highlighting the female role in farming, as well as putting forth voices of Land O' Lakes farmers talking about how they disagree but come together to solve problems.

Each iteration delves into the meaning of stewardship and the gravitas it reflects within "farmer-owned." Further intriguing "unknown unknowns" are found within empirical evidence across Land O' Lakes -- from

rethinking university food services in the midst of student protests to their SXSW Copernicus Project challenging beliefs about how our food systems should be. The protean approach to innovation unfolds as a system of social facts. In-the-flow testing against ideology spaces keeps the process inductive and flexible.

Abstraction and the Value of Human Critique

Abraham Maslow's law of the instrument states, "if all you have is a hammer, everything looks like a nail" (Maslow, 1966). Hence, the process becomes a means to shape materiality rather than shaping the abstract space of how the material will be received and adapted over time.

Mapping relationships between the abstract and the concrete provides a strong model for inductive decision-making. Design foresight that leverages the abstract layer creates frameworks that connect back to the humans involved. Feedback loops should not disassociate the concrete from the abstract. In a provocative talk at the 99U conference in 2017, Natasha Jen of Pentagram described the lack of critique in the process of design thinking:

> *What is design criticism? For those who have gone to design school, you know how important that is in every step of the design, every discussion. You bring forth an idea. You bring forth evidence and then everybody crit the heck out of it...real designers surround themselves with evidence. You've really got to have the evidence and you've got to have the crit in order to make the world better. (Jen, 2017)*

Critique is fertile domain for design foresight. It demands that our investment in evidence be based on the natural order of "messy" traits that will determine the framework of use, moving away from "short-termism" to "long-termism." As technology moves toward increasing intimacy, this ideological challenge will increase.

Abstraction is the ultimate test to re-include the human in the design process. Consider that artificial intelligence is gaining computational power. In 2017, AlphaZero, a machine-learning algorithm created by Deepmind, a Google initiative, mastered not only chess but shogi (Japanese chess) and Go. In a matter of hours, the algorithm became the best player, human or computer, the world has ever seen. We can reach the ultimate machine, but we do not consider the ultimate human.

Artificial intelligence and machine learning are rudderless without an abstract framework for a truly sustainable future. The issues of bias and blind spots are problems to be solved now before they gain increased technological momentum.

The craving for emotional intelligence requires that we expand our binary world into an abstract space for which only the human brain has the capacity. Music has its own metaphor: "It's not the notes you play, it's the notes you don't play" (Popik, 2012). This absence is the essential space that separates humans and the silence that transforms materiality into meaning.

Bringing futures scenarios to life with video animation: A case of disseminating research to nonexpert audiences

BUEHRING Joern* and VITTACHI Nury

The Hong Kong Polytechnic University, Hong Kong
* corresponding author e-mail: Joern.buehring@polyu.edu.hk
doi: 10.33114/adim.2019.03.213

In social science, researchers are often confronted with large amounts of data generated through qualitative methods such as interviews, interpretive narration, and oral history. While selecting an appropriate form of communicating the findings at the end of a research project is every research's obligation, the dissemination of key insights gained from academic research, and presenting these in other formats that effectively extend the research results and new knowledge gained to nonexpert audiences, is many times forgotten. The purpose of this research is to address this gap in the literature by answering the question of how to communicate futures scenarios to nonexpert audiences, corporate decision-makers, and their staff using video animation as a medium. The process presented in this paper is based on a use case in which academics and designers, at a design school, took the findings of a financial services futures study and applied storytelling and visualization techniques to bring futures scenarios to life with video animation.

Keywords: design foresight, research dissemination, storytelling, visualization, video animation

Introduction

In social science, researchers are often confronted with large amounts of data generated through qualitative methods such as interviews, interpretive narration, and oral history. Selecting an appropriate form of communicating the findings at the end of a research project is every research's obligation (Berg, 2001). In academia, the dissemination of the authors work traditionally serves research communities, who are reached through journal articles and conference paper presentations (Barnes, Clouder, Pritchard, Hughes, & Purkis, 2003). However, dissemination of key insights gained from academic research and presenting these in other formats that effectively extend the research results and new knowledge gained to nonexpert audiences, is many times forgotten (Dahlstrom, 2014; Troman, 2001). Top executives in industry know that they can profit from research findings, sometimes directly. Nonetheless, scholarly literature focused on dissemination strategies able to illustrate academic research findings to business stakeholder communities is still relatively scant (Phillipson, Lowe, Proctor, & Ruto, 2012; Starkey & Madan, 2001).

The purpose of this research is to address this gap in the literature, by answering a core research question: "How to communicate futures scenarios to nonexpert audiences, corporate decision-makers, and their staff using video animation as a medium"? Specifically, the aim is to contribute to improved practice and the impact of foresight by providing an exemplar of a research dissemination process in conceptual and operational context. That is, for design and foresight researchers to diffuse the research finding's most salient features outside of the academic setting, could the presentation of foresight data in an accessible video animation narrative become an effective use of medium?

The paper begins with introducing the background that motived this research, before introducing what can be learned from the design and foresight literature with regard to the core research focus in narrative foresight, storytelling, and visualization context, as the relevant areas of inquiry. The paper then outlines steps in transforming written research into animated futures scenarios using narrative storytelling to deliver ideas (Dahlstrom, 2014; Milojević & Inayatullah, 2015; Price, Matthews, & Wrigley, 2018). The process is based on an applied research use case in which academics and designers, at a design school, took the findings of a financial services futures study and deployed storytelling and visualization techniques to bring futures scenarios to life with video animation. Finally, key observations are presented of the applied process framework that can help improve the researcher's understanding of theoretical and practical considerations of presenting research findings to a boarder audience through video animation.

Background to project

Complexity and hyper-uncertainty in business, increasingly effecting almost any industry, are some of the elements that present the context in which organizations view their current and future state. Managing the allocation of resources and capital funding into projects are becoming increasingly difficult for stakeholders responsible to balance short-term objectives, with the longer-term strategic direction needed to adapt and survive amid accelerating change in the external macro-business environment (Buehring & Liedtka, 2018; Hamel & Valikangas, 2003; Vecchiato, 2015; Wolf & Floyd, 2017). To tackle these challenges, decision-makers are called upon to develop their organizational learning by practicing systematic futures thinking to anticipate scenarios of the future (Adegbile, Sarpong, & Meissner, 2017; Rohrbeck, Battistella, & Huizingh, 2015). Developing systematic futures thinking and forward-looking research capabilities can help organizations to envision how seeds of change from today's fringes might make way into the mainstream and how, conversely, the elements from today's mainstream might fall to obsolescence (Cagnin, 2018; Slaughter, 2002). Areas deeply concerned with changes in the external environment, in both theory and practice, are foresight and design - each focused on thinking about, and gaining a better understanding of the future (Buehring & Liedtka, 2018; Cagnin, 2018; Gabrielli & Zoels, 2003; Heger & Rohrbeck, 2012; Wilkinson, Mayer, & Ringler, 2014).

Integrating Design with Foresight

Just as the foresight discipline comprises of a wide range of approaches and activities, such as trend forecasting and storytelling techniques designed to help business stakeholders envision opportunities in the future (Inayatullah, 2008). The practice of design in business encompasses visual communication tools and processes that engage interdisciplinary stakeholder teams responsible for creating sustainable value propositions that ensure the organization's future (Bohemia, Rieple, Liedtka, & Cooper, 2014; Buhring, 2017; Heskett, 2001; Lojacono & Zaccai, 2004). Traditionally, foresight processes focus on the contingency as its entry point, building future scenarios based on key trends and uncertainties in order to lay out a set of plausible futures. Whereas in design, possibilities are taken as the starting point, laying out a portfolio of concepts based on the question "what if anything were possible?" Where the design thinking realm is likely to generate preferred scenarios (in the eyes of users), foresight generates plausible scenarios (based on trends and uncertainties). Similarly, design has the ability to envision, visualize, and communicate things that do not yet exist (Candy & Dunagan, 2017; Dunne & Raby, 2013; Eggink & de la Bruheze, 2015).

The development of futures scenarios is equally central to both foresight and design practices. While effectively disseminating insights derived from, e.g. trend analysis, expert consensus (cf. Delphi method), simulation, causal modelling or other forecasting techniques, the outputs can vary between written text and/or numerous visualization styles. Data visualization, as a communication medium for storytelling, is considered important when the research team is not the same as the one that will have to act and make decisions based on the reported data findings (Vaughn et al., 2013). Equally, stories have proven as an effective way of conserving and passing on information, and framing data through visualization techniques and images as sequences of events, may provide audiences with stronger memories (Austin, 2010; Dahlstrom, 2014; Dator, 2009; Ma, Liao, Frazier, Hauser, & Kostis, 2012). More recently, some scholars and creative folks within design practice have experimented with experiential and enacted immersive scenarios (Candy, 2010; Candy & Dunagan, 2017; Schleicher, Jones, & Kachur, 2010). To this end, however, precious little guidance exists on how to apply the logic of narrative and visualization as understood by writers, designers, or animators to the creation of outputs that bring futures scenarios to life. (Raven & Elahi, 2015).

Narrative foresight and storytelling

Based on established concepts from design and foresight literature theory, narrative storytelling focuses on the stories individuals, organizations, states and civilizations tell themselves about the future (Milojević & Inayatullah, 2015). In this research, the study is focused at the intersection of three areas of inquiry: design and foresight, and methods such as storytelling and data visualization, where the process of communicating the findings derived from a futures study or project to nonexpert audiences, is based on the logic of storytelling as a prerequisite to provide visual representation of narrative fiction (Cagnin, 2018; Dahlstrom, 2014; Raven & Elahi, 2015).

A narrative fiction model, comprising of idea, character, setting, storyboard, composition, technique and colour (cf. Maass, 2002), is used to present data in a format that is more readily accessible yet aimed to be much richer than typical "infotainment". The motivation for adopting a video animation style as a medium is that people in modern societies have undoubtedly become more used to dealing with content on digital displays and screens (Feather, 2013). A century ago, almost all popular fictional entertainment was consumed in books (Blundell, 1988; Thompson & Bordwell, 2003). Electronic storytelling (in the shape of the radio drama or news reports) was in its infancy. Education, similarly, was delivered almost entirely in the form of a teachers standing over textbooks, and that state of affairs continued throughout the 20th century. But there have been rapid changes in the past few decades. Today, the default medium of sharing content is electronic and visual: people watch stories unfold on television, on their computers, on movie screens and even on their telephones (Dahlstrom, 2014; Introna & Ilharco, 2006; Rosen, 2004). Conversely, conversations are more likely to happen by digital means, through text or social media, than by voices (Dahlstrom, 2014).

In an organizational environment, the context in which this design foresight research took place, the objective of practicing futures thinking and foresight is to decide on what decisions management can make today to create a best possible future for the organization (Horton, 1999; Slaughter, 2002). Equally important in strategic foresight practice, however, is to stimulate not only futures thinking through scenarios and narrative storytelling, but to provoke a call to action from the intended target audience once research is completed, and insights have been disseminated (Slaughter, 2002; Vaughn et al., 2013). As Michel Godet, a pioneer in the field of futures studies pointed out:

> *"Even though I introduced methods into the field of futures studies, I think that scenarios are overdone. Making scenarios is fine, but so what? Once a scenario is drafted, what do we do to take action, to make whatever we want to happen or not to happen? We should really be turning them into a project-based approach (Godet, 2012, p. 47)."*

The purpose of using animated video in this design foresight research was to transform the written report findings into narratives and visuals, while at the same time giving the data a new shape to engage and make it acceptable to a nonexpert audience of corporate decision-makers. Empirical studies support narrative and visual processing as generally more efficient; for example, Glaser et al. (2009) describe four important factors in narratives, namely dramatization, emotionalization, personalization, and fictionalization, which makes it an effective form of knowledge acquisition. Stories can change or enhance the observers' perceptions of futures, seeing themselves in different perspectives, and identifying their "self" by interpreting and completing the story in his or her head (Sametz & Maydoney, 2003). Moreover, as Wyer (2014) highlights, narrative cognition is considered the default mode of human thought, which provides the structure and underlying foundation for memory. Hence, the integrating foresight and design principles in forms of 'narratives and storytelling futures scenarios' manifests a basic hypothesis that providing the user audience (i.e. corporate decision-makers) with a format of comprehension, is to gain a deeper understanding of change, and acting on the implications of possible realities emerging in the macro-business environment.

Applying design to foresight outputs for non-academic audiences

In this paper, a real-life use case featuring a major research project undertaken by a university in partnership with a global leader in wealth management, is presented. Large-scale research produced a significant amount of data over a long period of time, as it was really a series of futures study projects spanning over a three-year timeframe. Traditionally, findings would be shared with senior executives in printed report formats. Prior research were futures studies, producing data resulting from varying forecasting techniques designed to help envision trends in wealth management and private banking over the 2030 time horizon. In the 2018 incarnation of this project, a decision was made to produce a portion of the findings in the form of an

animated video—and thus making the most salient findings "consumable" by a larger and more varied group of staff and internal stakeholders.

During this process, a great many discoveries were made about the necessary steps, which have to be taken to make the most of this modern medium, and to successfully bridge these two worlds—or indeed, two sets of two worlds. That is, the communication-style gap between academia and industry had to be bridged, as did the gap between printed data and dynamic images. Furthermore, steps in this process may be considered to have transferable value for design research, futures scholars, and practitioners involved in strategic design and innovation. The following table (1) describes the four process steps taken in this project:

Table 1: *Four process steps in video animation design*

Process Step	Activities and processes	Key considerations
1) The Challenge:	• Outlining important issues at the beginning. o What is the present form of the report data? o Who are the audience members who will ultimately "consume" the key findings? • Transitioning from producer of a research report, to producer of a short film (e.g. a timeline for preparing a traditional research report is very different from the timeline for creating a movie production.) • Identifying the production stages, and their specific objectives.	• Research Data • Technological advances
2) **The Exploration**:	• Clarifying the aims and objectives. • Identifying key activities relating to the writing, editing and filming process. • Familiarization with the research findings; identifying the most salient features of the research data. • What form should the output take e.g. visual lecture, character-based storytelling, narrative animation? • Creative options available, and best formats (delivery systems) to meet the desired outcome(s). • The length of story / narrative animation, respective of target audiences. • Available resource (e.g. time, talent, materials, financials). • Learning from other disciplines.	• Choosing the genre
3) The Interactions:	• Issuing of key research data sets (most salient features) to project stakeholders, and seeking feedback / identify remaining issues. • Project Management: Allowing for multiple iterations between key project stakeholders incl. secondary parties, such as the writers, the animators, and the actors. • Time management: Allowing ample time for extrapolating the most compelling data features. • Developing the script. • Selecting the animation type format.	• Preparing the script • Selecting the data • Applying narrative techniques • Choosing an animated style format
4) The Delivery:	• Rendering and sequencing the video animation. • Issuing of video to project stakeholders, and seeking feedback / identify any remaining issues. • Fine-tuning video animation, sound track, and any additional opening/closing messages	• Gathering audience feedback

Following, are the detailed explanations of each process step:

Step 1 - The Challenge

Research comes in two main forms: quantitative and qualitative. In simple terms, the first involves the collection of numbers and the comparison of data; the second involves interviews, discussions and theoretical projections. In this particular project, there were both types of data, but the emphasis was on the second. Since the aim was to consider future scenarios, there was no actual numerical data available about financial services in the distant (2030) future. The project depended on taking current data available through secondary research, and exploring alternative futures and directions inspired from prior research, which produced a set of futures scenarios developed through Delphi as a proven foresight technique in futures studies. Hence, the findings were necessarily generalized and non-specific. Notwithstanding the rigorous nature of research, anticipation of possible futures must be rooted in firm ground, hence copious amounts of data were analysed and synthesized. Consequently, a portfolio of materials considered as important for the intended audience must be gathered before any work on the video deliverable can begin. In this particular project exemplar, the relationship between the academics and the industry representatives had already progressed over a 3-year timeframe, hence, substantial amounts of documented data was available.

Research Data

The research data generated in prior research (i.e. project 1, project 2) provided valuable insights and trends, additionally, illuminating the early signs of change that would substantially determine alternative futures as influenced by the numerous projected changes in modern society. For example, business activities in the future would involve human face-to-face interaction for some functions, and automated interactions for others. The general move towards convenience would continue. Individuals would expect to be able to use technology to do business anytime, anywhere, and anyhow. And, as with any commercial activity, there would need to be a focus on recruiting future clients at a young age and being aware of their changing needs. There were worries, too. For instance, if more activity was done through digital screens, the relationship-building process between clients and representatives of the industry might be disrupted or destroyed. The change of demographics was also considered key; especially relevant to the rise of Asia's upper middle class population. Thus, in the geographical context of this study, gaining a deeper sense of the emerging needs and aspirations of Chinese consumers was considered important.

Technological advances

Making sense of uncertainty is particularly relevant when technological advances, such as artificial intelligence, machine learning, big data analytics, and hybrid human-machine systems could play a vital role for mature organizations to sustain the effectiveness of their strategic innovations, and the enterprise itself. Hence, technology roadmaps as potential future enablers of client-centric services and experiences was a critical focus in this futures study project. This raised numerous questions that were not easy to answer. For example, if business core functions were going to be more automated, would there be a need for expensive physical buildings on High Street corners? How much of the physical infrastructure of businesses might disappear entirely? If computers did the back-office work, would there be a need for so many staff performing administration? Moreover, if a foresight study is taking a ten or twenty years outlook into the future, what can be realistically anticipate will happen? Technology is generally designed to make life easier. As the first step in defining the challenges, this futures study project was encouraging as the data derived from previous research provided many thought-provoking data sets that would lend themselves perfectly to visual interpretation.

In the second stage, the objective was to explore the ways to select and deliver the information.

Step 2 - The Exploration

The exploration of formats for this project began with researchers having to accept a few simple facts: books are long, movies are short. A film contains a fraction of the amount of data in a book. For example, a Harry Potter movie may be about two hours long. But a Harry Potter audio book can take more than 20 hours to read out loud. So in that sense, films can never deliver as much data as books. But in another sense, the opposite is true. The adage that a picture speaks a thousand words (Magill, 1989) is valid even in its most literal interpretation. One could easily expend a thousand words describing a painting by Hieronymus Bosch and fail to do it justice. In terms of delivery of information, a filmed image has thousands of pixels of data, and may deliver more information (albeit of a different kind) than a chapter of a book.

Furthermore, there is a difference in audience reach and audience impact. A chapter of a book can deliver a large amount of information to the person who sits down and studies it. That may be a small number of people. Books are not passive entertainment – they have to be actively read by participants who have to be willing to do the work, so readers are self-selected enthusiasts for the material. In contrast, movies are more easily accessible, so can find wider audiences, and if well put together, can have as much impact as books (Ma et al., 2012). A short film can have enormous emotional powers. Still, this is not a clear win for movies. Book readers are a self-selected group of people seeking information (data) and willing to work to obtain it, so books end up doing their job well. Movies, in contrast, reach a wider but less focused, less committed audience. Viewers are not asked to work as hard as readers, and thus may reach a lower level of engagement.

Choosing the Genre

Once it was acknowledged that the film would deliver a relatively small, yet critically important selection of the most salient features derived from previous studies, and newly added findings, the next choice-making process was focused on the genre. A futures project would naturally require images of things that don't yet exist. Working within the parameters and financial constrains typical of any research project, it would clearly be impossible to make a live-action movie in a science-fiction mode. The costs associated with producing a short animation movie can vary greatly, when comparing a professional 3D animation production that produces Pixar-style movies with a much more cost-effective 2D animation. While budget constraints are inevitable, the real emphasis in the choice-making process should be placed on illuminating preferable or desirable futures concepts and emerging ideas, which the project stakeholders have carefully assessed and selected based on the research dissemination aims and objectives. However, it must be emphasized that animation project teams opting for a 2D animation format to present their futures study findings, should allow for stakeholder expectation to be managed, as limitations on the animation quality and the length of video requires a balanced approach (Vaughn et al., 2013). Secondary research into the length of applicable video animations, and informed by well-reviewed short animation films in a similar genre, were typically between two and five minutes in length.

In this use case, a small team of animators was engaged to produce a 5-minute animated video. Step 3 in the process explored the interactions between all parties concerned, i.e. academics and the industry representatives, but also the secondary parties, such as the writers, the animators, and the actors.

Step 3 - The Interactions

Professional moviemakers speak of a system known as “the pipeline”; its purpose is the ordering of the processes into an efficient linear timeline (Mullen & Andaur, 2010). The script is written, reviewed and finalized before any production work starts. The video work is then done, and filmed (animated) segments are edited and reviewed and approved before any final rendering is performed. The aim of the pipeline process is to prevent changes after filming or rendering have begun, and thus avoid creating frustration and wasted work.

Preparing the script

Frequent meetings and exchanges between academics and industry representatives, and between academics and animators, were needed. Script ideas were circulated and presented in reiterative form; the logical idea for the “future narrative” script using prior research as source materials, was to show a day in the life of a person doing his or her wealth management banking in the future (i.e. 2030 time horizon). This format would be a simple translation of the key ideas that have transpired from the academic futures studies reports, and converting these into a visual presentation showing a typical day of an individual in the future. However, experiences in this regard have shown that extreme predictions (i.e. events yet to be experienced) can be open to mockery (Tetlock, 1999). Lest not forget that people have been producing cartoons predicting the future since at least the 1950s—showing citizens going to work in flying cars, and so on. As a possible counter measure, design teams could insert detectable elements of self-awareness in the animation cartoon—if the work included a degree of ironic self-mockery, it was less likely to be attacked. For example, in this case study, the opening scene was designed to a 1950s style “day in the life of a future citizen” element, thus teasing the audience to common folklore of science fiction genre. In a subsequent draft, the cartoon opening scene was replaced with a Star Wars parody – rising yellow text and grandiose epic music. This choice-making process was decided as academic statements have the potential to default to over-wordy jargon in a video context. But placing some useful academic statements into the Star Wars passage enabled the project team to deliver key

introductory context-setting lines using academic language in a way that was most probably acceptable to the viewers.

- *Selecting the data*

What data should actually be include? This question took a long time to deal with. The first draft included quite detailed summaries of the main points in the print findings. Subsequent drafts contained less and less material directly lifted from the print work. In this particular case study, all parties eventually agreed to use relatively few direct transcripts of ideas. It should be noted that this was a single case, and may not be representative of most cases – it was a pleasant surprise to the academics and the creative partners that the industry representatives were so willing to move away from a literal transmission of the print work towards a thematic one (Figure 1).

Figure 1: *Animation video story master board - production design – high-level scene sequencing*

The final draft was much more story based, including only a general and quite impressionistic view of the findings. Once this had been agreed, the process went quite smoothly. All parties agreed that while academic reports have lengthy lists of findings, stories, and especially short cartoon-style animations, almost always have a single powerfully delivered message. Subsequently, instead of using the "day in the life of a future citizen" outline, it was decided to tell the story of a single event in the life of a single individual. In this use case, a young person reaching adulthood and dealing with his wealth creation needs. The core message was simple: "*Everything you think you know about handling future wealth creation activities is going to change".*

- *Narrative techniques*

A member of this project was a fiction writer who introduced techniques from narrative production. For example, what is sometimes known as the Sherlock-Watson technique (Eger & Martens, 2017), is when one character regularly explains things to another character – and in doing so, gives necessary information to the audience without the need for excessive narration or voiceover. Another technique in storytelling is the use of the twist at the end (Ekström, 2000). Relevant to the use case, the story included a teacher who introduces the main character to a digital version of himself. The twist at the end was the revelation that the teacher is not a human teacher at all, but the teacher's own digital alter ego.

- *Choosing an animation style format*

Researchers and designers of video animations can often experience frustrations during the iterations of the visual work. There are numerous different software programs which can be used to produce animated videos.

The most popular software programs include Flash™, Blender™ and Maya™ . All of these produce work in very different styles and qualities. The most cost-effective and fastest is Flash™. However, in this use case the results of the first draft looked clunky and unappealing. It quickly became clear that Flash™, while relatively easy to use, can produce uncomfortably simplistic work. Multiple iterations of the visual material storyboards (Figure 2) eventually led to a compromise where the quality was at its best considering the project-related budget constraints.

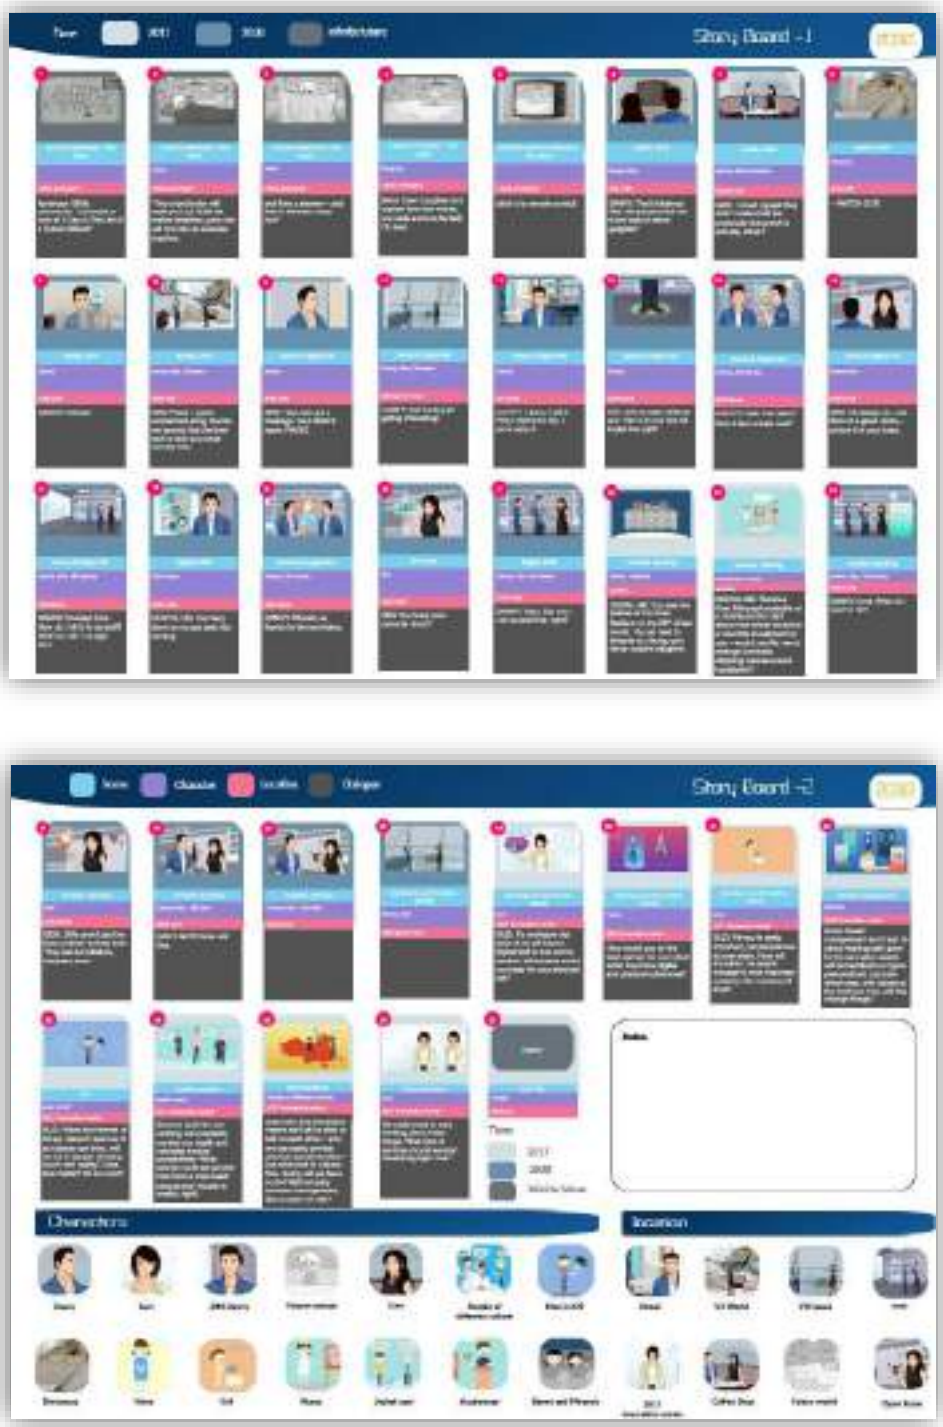

Figure 2: *Animation video storyboards - production design, incl. character development*

Step 4 - The Delivery

One of the main discoveries made in this use case was that what was imagined were the two main considerations – the handling of authentic academic findings and the delivery to a real-world audience – were joined by a third element: artistic validity. The short movie had to work on its own terms, as a short movie. It needed internal logic and had to be artistically satisfying. In the final stages, judicious editing was applied to tighten the scenes and make sure the story elements moved swiftly enough to hold an educated audience's attention. Pacing was vital. Furthermore, a great deal of time was spent reviewing music libraries – using the right soundtrack elements for each scene can make a major difference in touching the audience emotionally (Walker & Boyer, 2018).

The final test of how well the learnings from trials during the production phase were applied in the animation video production, is the first reaction of the stakeholder viewing audience. How they (in this use case they were financial services decision-makers) react is a matter of concern. If busy people are pulled away from their desks to be made to watch a preachy cartoon made by non-bankers about banking, any form of denial or rejection would be an undesired outcome. To disarm accusations that production teams are telling industry players how to do their jobs, the project team decided to end this futures short film with an animated character asking a series of questions – thus presenting the work as a conversation starter, rather than a preaching message. "*Here are possible futures for your industry"*, the movie said. "*But what do YOU think?"*

- *Audience Feedback*

As a final outcome of this use case, the futures scenarios that were transformed into a short (7-min) video animation movie received gratifyingly positive feedback from its intended audience. Futures scenarios and their interpretations were hailed as interesting, thought-provoking and succeeded in sparking rich conversations among wealth management decision-makers and their staff about the different types of business operating model futures [2030]. Unlike with written reports and academic papers, the feedback was instant – as soon as the video animation film was finished, people expressed opinions and shared the ideas that the 'design storytelling with futures scenarios' had triggered.

The following diagram (Figure 3) is a high-level visualization of the actual production design activity flow applied in this video animation project.

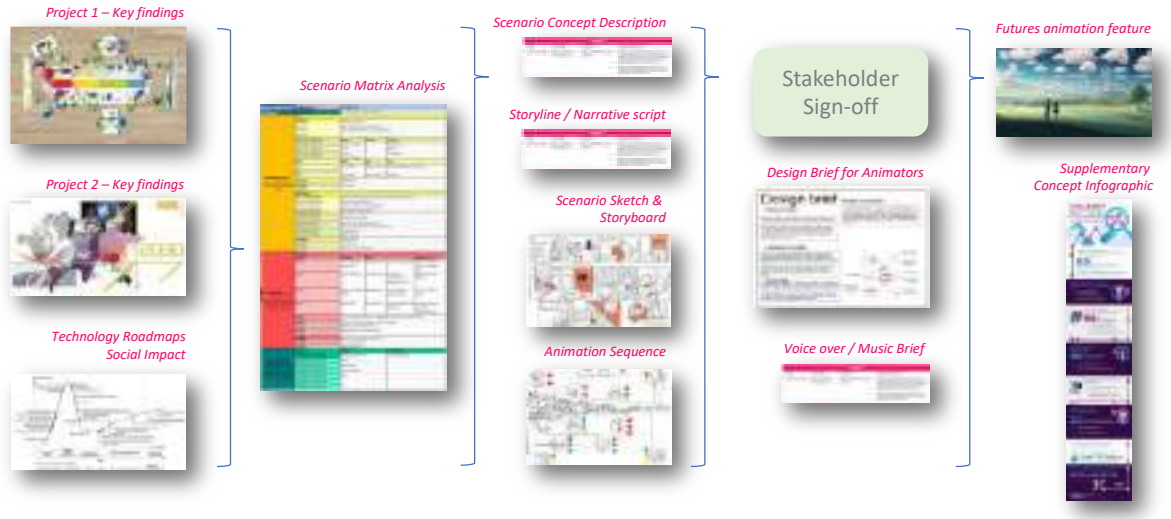

Figure 3: *Animation video production design – high-level activity flow*

Ten key observations

Important observations were made in this use case, which apply strongly to futures narratives animation where artistic interpretation is needed to show things that don't yet exist. It can be argued that futures studies should have an obvious imaginative appeal, hence, the call for adopting visual interpretations. From the learning of this use case, the following table (2) is a summary of key observations made:

Table 2: *Four process steps in video animation design*

Key Observations	Lessons Learned
1) Set Stakeholder expectations	Audiences are used to extremely high production values for screen productions. They regularly see work with quality writing, visuals and acting. Academic researches should not try to compete. Instead, they need to set reasonable expectations for themselves and their viewers, aiming to simply produce watchable, functional videos that provoke interest and can trigger further explorations. As this use case has highlighted, when resource limitations may prevent the production of a hyper-realistic 3D animation, making a simple, likable 2D animation video can be an important medium to deliver a message and provoke questions leading to actions.
2) High selectivity	Successful writers of academic studies pride themselves on the wide comprehensiveness of their work, missing no angles, and covering every possible interpretation of their data. Successful creators of good short films pride themselves on the opposite -- their brutal selectivity and their skill in ignoring all but the key elements. Thus major compromises are necessary. Academic researchers will need to realize that significant elements of their printed report will not be included, and may only be represented in thematic form.
3) Tight scripting	The careful, precise language of academic research findings has the potential to come across as unattractive wordy jargon in TV format, where sentences have to be very short and very punchy. The involvement of experienced screenwriters should be considered as vital.
4) Self-awareness	Academics research delivers serious work. But TV is a medium with a light, entertaining tone, and the presentation of lengthy, hyper-analytical material can come across as too overwhelming for nonexpert audiences. Thus video representation of academic work benefits from a light touch, or even the inclusion of elements of irony, wit or self-deprecation.
5) Deadlines	Academic researchers value precision of language, and the editing process will continue until the writer is pulled away. In filmmaking, however, the pipeline system means that the script must be completely finalized before the production process begins. Filmmakers are strongly opposed to any re-visitation of the script after this moment.
6) Single message	A report containing academic research findings can make numerous important points. In a short film, however, only a single key message can be delivered. Other findings can be included, but only if they reinforce the main message. In this use case, it was: "*Everything about this industry is going to change."*
7) Climax	The delivery of a lecture or the recitation of a paper at a conference is a linear presentation of data—an evenly paced list of facts in a straight line. Films are very different. Animation storytelling videos need to have more of a "story shape", with an introduction, developments, a climax, and a twist at the end.
8) Team game	An academic report is often the work of a single author. Yet video productions are necessarily team games—there are numerous contributors to the final product, from the director to the camera operator to the sound technician to the editor. A strong sense of collaboration is needed, as all the elements, and all the contributors, are important.
9) Audience awareness	Printed reports are "pull" media. They are only read by the interested reader who chooses to read it. But videos are "push" media, unspooling on any type of screen. Thus material should be prepared for a wider, less informed, less sympathetic audience. This is a positive in some ways – more people will see the report. But it can also be a negative. The material needs to be shortened and simplified, without

Key Observations	Lessons Learned
	being “dumbed down”, which is a challenge any production team needs to anticipate.
10) Right for some	Learnings from this use case suggest that the presentation of research material in video form, especially for a futures narrative storytelling project, can be very satisfying--yet it is challenging, time-consuming and requires many man-hours and an appropriate budget. A film (animation video) reaches a wider audience, but also a less specialist, less engaged one. The material can be more easily accessed, but is necessarily simplified. As a result, it can be argued the majority of research reports, especially very technical ones, should continue to be presented in traditional form, as printed documents. But a minority of research reports – especially in the context of futures studies, and their futures scenarios, can benefit greatly from translation into video format. While challenging at times, a positive learning process will benefit academic researchers exploring this type of medium to successfully deliver the key conclusions of a body of research to a wide nonexpert audience, corporate decision-makers, and their staff.

Conclusion

The dissemination of design foresight research brought to light several important issues. An exemplar of a research dissemination process was presented in conceptual and operational context, were the challenge was to concentrate a relatively large number of research insights into a brief animation video of seven minutes in length. A list of academic findings considered most relevant to a nonexpert audience was turned into a narrative story plot that worked on its own terms. Researchers and designers delivered an important message derived from design foresight research in a dynamic format that was designed to getting non-academic staff thinking and talking about alternative futures relevant to their industry. A meaningful experiment was conducted in presenting academic research findings in a different format using narrative storytelling and dynamic visualization techniques. However, this process also illuminated the challenges in bringing futures scenarios to life with video animation. While it was highly engaging, it is important to stress that this type of dissemination activity takes time. Moreover, many of the research findings were identified as being too challenging to interpret in narrative storytelling form; hence, disseminating design foresight research in short video format runs the risk of only conveying a smaller view into a larger research project. At worst, it might be little more than an expanded visual abstract, thus, project stakeholders have to be very selective, and remain mindful of the principle that simplification is necessarily misleading (Punch, 2013).

What was learned from this use case is that researchers and designers have to work hard to concentrate the material, ensuring that a wide range of ideas is delivered quickly and efficiently, but without overloading the story frame. Equally relevant was the realization that what is lost in the amount of detail may be more than compensated for in terms of reach, accessibility and impact (Macoubrie & Harrison, 2013). That is, in a world in which high quality and exciting visuals are the norm for entertainment and education purposes, it is inevitable that academic researchers responsible for effectively extending the research results and new knowledge gained to nonexpert audiences, will have to become innovative in keeping audiences engaged. Furthermore, artistic considerations have to be reasoned in addition to academic ones, as these can subtly change the ultimate message of the work: academic research address the head, while narrative storytelling and dynamic visualization techniques have the ability to also touch the heart. To this end, the objectives for engaging the audience have to be clear upfront to ensure that the approach most favoured by the research stakeholder team, is also the most effective form of research dissemination (Punch, 2013). In this use case, the objective was to experiment with video animation in order to disseminate research results and new knowledge gained to a larger group of nonexpert audiences. In future studies, however, this approach will benefit from adding additional outputs, thus balancing the key findings gained from design foresight research across complimentary median, for example, combining video animation with infographics.

Acknowledgement

The name of the financial institution supporting this project was withheld for reasons of business confidentially. Similarly, details about the bulk of the data generated, or the reporting on the actual key findings, was not intended to be the focus of this paper.

doi: 10.33114/adim.2019.04.366

In the last 15 years, tackling wicked problems have evolved into a process that requires multiple change-makers able to face with complexity. At the same time, it has generated an increasing interest and proficient relation among foresight and design, due to their shared interest in anticipation and future orientation. Such relationships are visible on similarities they both have on the mindset and methodology used when approaching future scenarios. This paper aims to delve into a better comprehension on how the combination of Systemic Design and foresight can think both creatively and systematically about the future and have a strategic role in a policy-making process. This example of collaborative foresight is illustrated by RETRACE Interreg Europe project (A Systemic Approach for Transition towards a Circular Economy funded by the Interreg Europe), demonstrating how Systemic Design with a foresight vision can play a leverage effect in the transition of the European regions towards Circular Economy in a long-term horizon.

Keywords: Systemic Design, Policy-making, Foresight, Decision Making, Circular Economy

Introduction

Today's complex global and erratic changes are rooted in multiple causes which have become interconnected over time. On a worldwide scale, climate change, high rates of poverty and market instability are just some of the critical drivers that have a great impact on how governments of today operate. The interconnected nature of such global trends, reveals uncertainty as a key issue in our society. This demands us to redesign our public policy conditions in order to be more future-oriented towards sustainable development.

Currently, it is impossible to conceive that wicked problems can be solved individually, in fact, an interconnected world requires a structure of interconnected solutions and change-makers able to understand and visualize complexity. For that reason, it is necessary to adopt anticipatory approaches that enable the combination of technology, design, business and social organization such as strategic foresight, systemic perspectives and participatory methodologies which can activate innovative mechanisms of sharing knowledge and experiences. In particular, the Systemic Design (SD) method tackles the complex phenomena through specific design tools which highlight the hidden potentialities of a scenario, delivering new relations among the local actors and entities, through promoting active collaboration among them (Bistagnino, 2011).

In the last fifteen years, there has been a growing relation among foresight and design, due to their shared interest in anticipation and future orientation. This relation is visible on similarities they both have on the mindset and the methodology used when approaching future scenarios. The practice of looking forward into the future should be at the base of our current policies, as the urgency to shift from unsustainable growth to sustainable development, primarily push the governments to face with complexity. Therefore it is needed

nowadays an innovative approach that fosters society to “think outside the box” (Considine, 2012). Precisely, it is exactly in these scenarios where the role of design, as discipline, becomes vital to approach complex environments, meet unexpected solutions and oversees innovative futures contexts.

It is true that policymaking is today more cross-sectoral rather than the past. In fact, we see examples of a bottom-up and top-down approach, groups with multi-stakeholders belonging from different sectors, a growing interest in a more collaborative approach to cope with global challenges (Krauz, 2016).

According to the above, this paper aims to delve into a better comprehension on how the combination of SD and foresight can think both creatively and systematically about the future and have a strategic role in a policy-making process. Moreover, it explores how systemic designer’s mindset and methodology can support foresight practices and strategic decision-making, developed in a collaborative and multi-stakeholders process. We illustrate this process of collaborative foresight through a specific case study, RETRACE Interreg Europe project, aiming at fostering SD as a policy-design method for regions to move towards a Circular Economy (CE) (Barbero, 2017). In fact, this case study shows how SD, with a foresight vision, can play a leverage effect in this transition, in a long-term horizon of 15 years.

The paper is structured as follows. In the first section, the research is framed inside a complex and interconnected context which requires multiple actors and strategies to cope with the major everydays challenges. Here, the three main areas of investigation are introduced - strategic foresight, policy making and design - whose cooperation reveals to be strategic towards a sustainable development. It follows the analysis provided in the section 2, aiming to deepen into the role of design, which evolved over time, shifting its focus on larger systems. The sections 3 and 4 respectively examine in depth the relation between design with foresight and policy-making. Lastly, through the case study reported, this paper features evidence of the fruitful relation among SD and foresight, by deepening the project’s phases, results and future developments.

Future orientation and strategic decision making

In our current era of unpredictable societal and environmental transformations, governments need to be more future-oriented than ever before. While on the one side, society seeks to be affected by quick changes to tackle everyday issues, on the other side a long-term vision is necessary to anticipate unexpected and disruptive events that often occur, as natural disasters or economic crisis, generated by critical drivers such as climate change, poverty and market instability. These events are just the visual expression of the complex phenomena that characterize today’s world, which leads to an inevitable uncertainty.

These complex and persistent situations are commonly called “wicked problems”. The concept of "wicked problem” can be described as a trivial and enduring situation that cannot be solved immediately due to its inner complexity and its exogenous/endogenous relations. As highlighted by Rittel and Webber (1973), a wicked problem cannot be analyzed and solved with the traditional linear and analytical method of problem-solving, since it has multiple causes and interconnections that make it hard to clearly define it (Briggs , 2007). Thus, the description given by Jones (2014) summarizes all the concepts above mentioned defining a wicked problem as:

> *a persistent, interconnected and generally worsening challenge (...) that cannot be “solved” (...) rather understood in their ecology of relationships. (Jones, 2014)*

The concept of wicked problem is widely known among the community of system thinkers, futurists and, more generally, among all those people who face with complexity. In fact the themes of complexity, uncertainty and wicked problems are both at the center of systemic designers’ investigations, as they aim to tackle global challenges, and are also taken into account by policy-makers who are increasingly using anticipatory strategies and tools to tackle social, economic and environmental issues. Among these, strategic foresight has been used since the 1970s, through the evolving conception of future thinking:

> *from a predictable world of controlled solutions to an unpredictable world of continuous learning and rapid adaptation through redesign and innovation. (Wilkinson et al, 2014)*

On that view, strategic foresight has been initially used by the industry as “corporate foresight”. This method is applied to better address decision-making by looking forward into the future. Since 1990 it has broadened its domains to public policies given the higher complexity of today’s globalized world. In fact, it has evolved from being a linear forecasting approach to be conceived as an on-going series of efforts that illustrates what could be the possible futures and what is necessary to realize these (Rohrbeck et al., 2015).

A generic foresight methodology can be summed up in the six steps outline in the table below:

Table I A generic approach to a comprehensive foresight project

Step	Description	Product
Framing	Scoping the project: attitude, audience, work environment, rationale, purpose, objectives, and teams	Project plan
Scanning	Collecting information: the system, history and context of the issue and how to scan for information regarding the future of the issue	Information
Forecasting	Describing baseline and alternative futures: drivers and uncertainties, implications, and outcomes	Baseline and alternative futures (scenarios)
Visioning	Choosing a preferred future: envisioning the best outcomes, goal-setting, performance measures	Preferred future (goals)
Planning	Organizing the resources: strategy, options, and plans	Strategic plan (strategies)
Acting	Implementing the plan: communicating the results, developing action agendas, and institutionalizing strategic thinking and intelligence systems	Action plan (initiatives)

Figure 1: A generic foresight methodology. Source: Bishop et al, 2007

It is important to stress the fact that foresight is not used to predict the future, rather to understand what could be the multiple futures that may occur and the value of learning from these. Through identifying and studying the change drivers it is possible to be prepared for the opportunities and threats of tomorrow, in order to develop in advance the best strategy to adopt.

As Vecchiatto (2012) said:

> *it is a planned learning process that requires strategic agility and adaptive capability about the future in order to react more quickly and more effectively to external opportunities and threats as they arise.*

This means to continue re-assess and re-align the project (or the system) boundaries. For this reason, strategic foresight requires a broader, flexible and open mind people able to navigate through the multiple scenarios that emerge from the changing of variables. As remarked by Wilkinson et al. (2014):

> *In times characterized by low predictability and inevitable surprise, the capacity for anticipatory adaptation, resilience and self-transformation is now seen as the key to long term success.*

An adaptive mindset and the ability to navigate through multiple scenarios, is something proper of systemic designers, as mentioned above. But, before going deeper in outlining the systemic designer's shape, it is worth to track designer's evolution over time.

The changing in the role of designer: from product to system

Nowadays, the design has trespassed its own frontiers making its domain broader and less tangible than ever. While traditionally, this discipline has been linked to the creation of objects, starting from the mid-late of the 20th century design has enlarged its application to services and systems (Ceschin & Gaziulusoy, 2016).

Recently, a consistent stream of designers are applying their skills and methods to go beyond a tangible outcome, towards intangible goals like sustainable behaviors and development. One of the reasons for this change is the increasing recognition of designers' impact. In fact, in the last fifty years, designers have been accused of the globalisation effects on mass production and uncontrollable consumption. In reaction to these phenomena the design community acknowledges to be a "dangerous breed", as described by Victor Papanek (1971) in his book "Design for the real world". Movements around design for sustainability have gained momentum providing a different vision on the role of the design. Therefore, the shift towards the dematerialization is considered the tipping point for design as the beginning of an evolving process towards services and systems. At the same time, it shifted the designers' attention from the single user to the communities as users, becoming a more participatory discipline while expressing its social and democratic nature (Buchannan, 1992).

This demonstrates the different shapes that design has, but it is clear its approach to deal with problems. Designers are able to focus on different scales as they can visualise problems, think about new strategies and

eventually “materialize” their ideas. According to Bicocca and Barbero (2017) it must be acknowledged to designers the ability to:

- **make information simple and accessible,** by managing big quantity of data and making them accessible to an end-user through easy-reading maps, schemas and scenarios (i.e. IDEO cards, gigamaps …);
- **think creatively**, and if applied to policy making, it can bring innovative solutions;
- **create connections in complex systems**, to offer a wider look on the problems and to boost transdisciplinarity. Systemic Designer are able to interconnect the elements of a system, in order to generate new business activities, products and relations.

More recently, due to the higher complexity of social, economical and environmental issues that become interconnected overtime, a new approach is needed in order to deliver systemic an interconnected solutions (Brown and Wyatt, 2015). From that panorama emerges the SD, which means understands and tackle problems on a systemic and complex level. SD merges human-centered design inside complex, multi-stakeholder systems. As explained by Jones (2014), this expertise combines designer skills such as research, reasoning methods and visualization practices, generating new reconfigurations for complex services and systems.

Furtherly, Jones (2014) outlined this evolution process in four contemporary domains of design, which have increasing complexity:

- **Artifacts and communications**: that is the traditional way of conceiving the design practice, as a way of producing artifacts
- **Products and services**: this stage includes the services for value creation (i.e. service design, product innovation and user experience)
- **Organizational transformation**: design as a change-oriented practice, using complex and bounded strategies for business transformation
- **Social transformation**: design as a change-oriented practice, for complex social systems, policy-making and community design

From that perspective, the Department of Architecture and Design of Politecnico di Torino developed the SD approach that reconfigures the flows of material and energy from one component of the system to another, modifying outputs of one process into input for another one, in order to obtain zero emissions (Bistagnino, 2011). This approach favors the visualization of hidden potentialities and supports the active collaboration among local actors, enhancing locally-based value chains (Barbero, 2012). The SD methodological approach has been described by Battistoni (2017) and it can be divided in 6 main steps:

- **Holistic Diagnosis (HD)**: it consists on a desk and field research, combined together to investigate the current scenario on the economic, social and environmental aspect, also considering the flow of energy and matter.
- **Definition of problems and leverages for change**: Starting from the framework outlined in the HD, connections and influences are analysed in order to outline possibilities and threats of future scenarios. Problems are regarded as leverages for change from which the project can be defined and initiated.
- **Design the system**: A new production model is designed whose aim is to tend to zero emissions by optimizing energy and material flows and by valorizing the waste as resources.
- **Outcomes Evaluation:** evaluation of the environmental, economic and social benefits belonging from the new production model.
- **Implementation**: implementation of the previously designed system in the specific context and consequent estimation of the new business plan feasibility.
- **Results analysis and feedback**: evaluation of the implemented system and discovering of new opportunities, making it autopoietic.

Through this methodology it is possible to create synergic linkages among the productive and natural realm of the surrounding territory (Barbero & Fassio, 2011), while reinforcing the socio-economic systems connected to that territory, in a long-time perspective.

Design for foresight and policy making

From the designers' features outlined above, it is important to highlight their future-oriented vision, social vein and capacity to deal with wicked problems. That is why is no surprise the increasing collaboration between designers and governments (Bason, 2014) in the activity of policymaking.

> *Policymaking is the process by which governments translate their political vision into programs and actions to deliver 'outcomes' - desired changes in the real world (Blair, Cunningham, 1999).*

So policymaking has to deal with long-term vision and strategy. This cooperation has often taken shape inside the so-called "Policy Labs" (i.e. Public Policy Lab in New York, EU Policy Lab in Bruxelles) usually set in government administrations (Bailey, 2017), or it is facilitated through the use of collaboration toolkits (i.e. IDEO cards). These ones support participatory processes, communication and exchange of information among different disciplines and sectors in order to combine bottom-up and top-down approaches in governance. Also, a large number of programmes and initiatives promoted by the European Commission witness how design expertise is increasingly involved in the definition of new and innovative strategies. Among these, it is worth to mention the "European Design Innovation Initiative ", the "European House of Design Management", "Design for Europe (2014)".

As pointed out by Bailey (2017) the involvement of design in the process of policy making, enables "organizational flexibility, provisionality, and anticipation". So, the key feature that connects designers to policymaking is the human-centeredness, as both are on the quest towards a better future for society. Furthermore, designers can support the process of policymaking by stressing not only on numeric trends but also on qualitative aspects such as culture, uses or local resources.

Chen et al. (2016) argued on the inadequacy of designers to operate on such a large scale, as in the public policies domain (always detected by the social science), since they are historically focused on the small scale of a product or service. As previously explained, the designer's role has evolved towards the awareness of sustainable development, leading to a more conscious design born in cooperation with other disciplines. According to Bason (2014) design is a "hybrid blend" of anthropology, systems thinking and data science, so problems are depicted differently under his lens; furthermore it enables creative collaboration and communication among different disciplines as it makes policies visible and tangible.

From the point of view SD, it overcomes the problem of the small scale through an holistic approach. Thanks to this, it is possible to constantly shift from the small to the large scale and to focus on a particular policy or intervention, while taking into consideration the bigger picture. Additionally, the SD goes beyond the simple and more common "problem solving" typical of Design Thinking, by questioning on new problems that emerge - or could emerge - from a deeper understanding of the context. Starting from the system mapping and highlighting problems and opportunities for intervention, the SD provides a different perspective of a specific context. As a result, it proves to be an effective method to deal with complexity and problems interconnections.

What strategic foresight and SD have in common, is the capacity to constantly question about past, present and future conditions by continuously re-discussing our assumptions. Nevertheless, the involvement of designers in policymaking is still an emerging trend that faces different challenges. First of all, the resistance from some policy professionals and institutions used to work in a more bounded ground that could not leave space to the openness, non-linear and cooperative methods of designers. Secondly, the rejection of external perspectives, usually uncomfortable, given onto topics and policies that always are developed "behind closed doors". Third, the request of quick response that contrasts with the long-term perspective that an innovative action requires (Bailey, 2017).

Cross-cutting approaches: Foresight and Systemic Design

> Foresight projects tend to account for systemic changes in the search for a future ideal state (Jones, 2014)

As discussed above, the practice of looking forward into the future is something shared from futurists, designers, and policy-makers. This section presents similarities, differences and possible future developments among the three different domains.

Starting from a generic foresight approach (Figure 1), it is interesting to see how similar is the methodology adopted by designers when approaching a new project. Both futurists and designers start with scoping the context: the identified problems and the collected information are delivered under the shape of a scenario, which describes the most plausible futures. After choosing the preferred future onto define the new project, a strategic plan is developed in order to be translated into new solutions that should be later implemented through an action plan.

If, on the one hand, sometimes it has been criticized to futurists the lack of action after pointing out new possibilities, on the other hand, designers, are accused to perform a short-term vision that doesn't favor sustainable development. Surely, it is important to acknowledge how the similar methodological approach shared by futurists and designers can be considered an important common ground of cooperation, on the lead of a multi-stakeholder group of policy-making. On that view, it can be considered that the systemic designers could be the right expert to involve in order to overcome the challenge of performing only a short term view.

From the previous, it can be understood the ongoing synergies between SD process and the Foresight framework (Figure 1). Most certainly, both processes share common points that are those which this paper is outlining, such as:

- **Intrinsic future orientation**: as suggested by the etymology of both names: "fore-sight", which means "seeing ahead, knowing in advance" and "pro-ject", which means "to set forward" (Hines and Zindato 2016).
- **To conceive multiple futures / solutions**, because everything changes so it's not about solving a finite problem, rather tackle the multiple problems that emerge from the changing of variables. Complex systems define a class of problems that are often described as non-linear, adaptive, self-organizing and emergent (Hadzikadic, 2015).
- **To deal with complexity,** and with wicked problems that characterise today's global challenges (Rittel and Webber, 1973).
- **Continue re-assessment and re-alignment of the project (or of the system) boundaries**, always questioning about present assumptions (Weigand et. al, 2014).
- **Micro / macro scale**, SD is able to shift from the specific intervention to the wider context on which this intervention is set. (Bistagnino, 2016)
- **Short / long term**, SD is able to deliver solutions on the short, medium and long term by developing a strategy on multiple scales. (Bistagnino, 2016)
- **Open to a collaborative process of multi-stakeholders** since complex problems cannot be solved in isolation but require the cooperation among science, humanities and technology. (Bason, 2014)

Among the tangible deliverables shared by the two disciplines, other connections are seen through the use of:

- **Scenario**: a powerful visualisation of possible or desirable futures with a strong system thinking basis (Ringland, 2010; Godet, 2010)
- **Action plan**: which materialize the strategy previously developed into a series of actions necessary to achieve specific objectives. This document should also specify the timeline, the actors involved and the expenses (costs or funding) (Barbero, 2017).
- **Roadmap**: especially used in polymaking since it specifies the concrete actions and programmes to address a full-scale implementation, shared by policymakers and stakeholders (Bailey,2017).

Since tackling wicked problems is an evolving process that requires multiple change-makers able to face with complexity, this paper explores how the systemic designer mindset and methodology can be supportive in foresight practices and strategic decision making, developed in a multi-stakeholder group. To enable this analysis it was relevant to summarize and point out the connection points among the two disciplines, as stated before. In order to deliver a wider examination on SD and foresight approaches to the discussion, it will be further narrowed the specific case study of RETRACE Interreg Europe project.

Research Exploration: RETRACE Interreg Europe Project

To illustrate how SD methodology, as proven an effective example of foresight in policy making, it will exemplify through the specific case study of RETRACE.

RETRACE is an European project financed by the Interreg Europe ETC Programme, under the 4.2 Specific Objective – Improving Resource Efficient Economy Policies. Through this kind of projects Interreg Europe aims

at improving the implementation of regional development programmes and policies by promoting experience exchange and policy learning among different regional actors (Barbero, 2017).

In this open-ended learning process, the SD approach has been used as a central methodology, shared among the partners, allowing strategic foresight and policy-making in their transition towards a CE. The goal of RETRACE is to develop sustainable Regional Action Plans (RAP) for each of the regions involved, standing the research on contextual data and matching them with the Good Practices (GP) experimented in the other countries.

The project is headed by the Department of Architecture and Design (DAD) at the Politecnico di Torino, involves 8 private and public partners and more than 70 stakeholders from five regions of EU countries: Piedmont Region (IT), Bizkaia (ES), Nouvelle-Aquitaine (FR), Slovenia (SL) and North-East Region (RO). The coordination of the 8 partners comes from the synchronized work between universities, local authorities, government offices, associations and public administration including:

University	*Managing Authorities*	*Public Company*	*Technological Centre*	*Foundation for the local economic development*
Politecnico di Torino (Lead Partner) (IT)	Piedmont Region / Directorate for regional system competitiveness (IT)	Provincial Council of Bizkaia - BEAZ S.A.U. (ES)	APESA - Association for Environment and Safety in Aquitaine (FR)	Azaro Foundation (ES)
Higher School of Advanced Industrial Technology – ESTIA (FR)	Government Office for Development and European Cohesion Policy (SL)			
	North-East Regional Development Agency (RO)			

Table 1: RETRACE Interreg Europe project partners. Source: (Authors)

Each region gathers a Stakeholder Group which includes a wide spectrum of organizations from development agencies, non profit organizations, social enterprises, research centers and innovation clusters, for a total of 70 actors involved. These stakeholders across the RETRACE regions have been key figures for the development of several proposals grounded in the local context, by supporting the transition to a CE or by creating effective tools for this change.

Figure 2: Project development _ RETRACE Interreg Europe project timeline and phases. Source: (Authors)

The timeframe of RETRACE goes from April 2016 and it will end on March 2020. Two macrophases characterize the project: first the research and then the implementation phase. The phase 1 took place from 2016 until 2018 with a series of intense research activities. Among these, the HD was at the foreground of SD methodology which enabled the collection of qualitative and quantitative data, followed by the analysis of

interactions between them (Battistoni and Giraldo Nohra, 2017). As a result, the data collected were presented through infographics, which enabled an easier fruition among a multidisciplinary team. The scope of the HD was to highlight critical factors, as well as hidden possibilities, through a three steps process:

- **Analysis of the regional framework:** concerning the territory and the industrial sectors, collecting quantitative data from official national databases (e.g. Eurostat), as well as qualitative data based on reports and on-site interviews with local stakeholders.
- **Analysis of current policies:** that addressed traditional sectors on environmental sustainability in the domains of water management, urban waste, energy and environment. The aim was to highlight the potential policy gaps that could obstacle the transition towards CE.
- **Analysis of the principal economic and industrial sectors:** Combining the previous steps through the overlapping of the policy instruments and the context information. This assessed potential synergies at systemic level among other sectors or processes at a regional and interregional scale.

While conducting the HD, the first half of the project was dedicated also to the organization of the Field Visits (FV) which lead to the identification of more than 40 GP (Pereno and Pallaro, 2018). During the field visits, the stakeholders discussed strengths and weaknesses of each good practice, in order to transfer this knowledge to the other partner countries.

After matching the results of the HD and the experiences brought from the GP, specifical RAP were developed. The RAP specified the nature of the actions that need to be implemented, their timeframe, the players involved, the costs and funding sources (Barbero & Giraldo Nohra , 2018). To achieve the RAPs each Region contemplated their current Smart Specialisation Strategies (RIS3) and development targets, which included a low-carbon CE, setting a framework for the future sustainable development of Europe.

In April 2018 the second phase of RETRACE begun, which is consisting in the implementation of the RAPs emerged in the first phase.

In the following section we are going to illustrate the preliminary results already obtained, together with those expected in the future, better explaining how RETRACE is relevant for the scope of this paper.

Retrace's results through Foresight lens

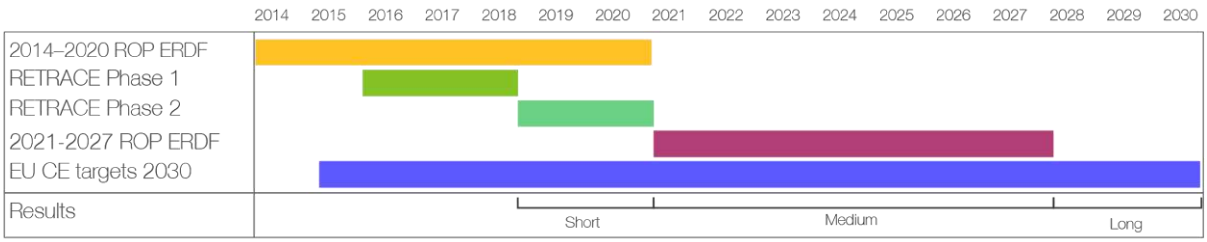

*Figure 3: Project Results development _ RETRACE Interreg Europe project *Regional Operational Programme (ROP) European Regional Development Fund (ERDF) *Sustainable Development Goals (SDG) Source: (Authors)*

In order to understand how RETRACE is framed in the context of "design with foresight for policy-making towards CE" it's worth to do an overall resume, taking the case of the Piedmont region as example.

The HD performed a central role as it scoped the context in a very deep way: in fact, through desk researches and FV, the SD obtained a first scenario related to the current context of the Piedmont Region. Matching these results with policy gaps and taking into consideration the already existing RIS3 of Piedmont region, a RAP has been developed. The RAP can be seen as a strategic action plan in which the policy gaps have been addressed - through the Regional Operation Program (ROP) - with the implementation of 3 to 6 concrete actions (roadmap).

Even if the duration of RETRACE is 2016 / 2020 it should be considered that it operates in the realm of interregional policy making though, it is admissible that the impacts will resonate after the end of the project. Starting from this assumption, RETRACE forward-looking actions have been developed on a short, medium and long term, where the short and medium ones are strategically designed in order to trigger future

implementations and address the change. This practically demonstrates the “actionable and proactive“ mindset of designers that, enriched with a foresight vision, are providing tangible deliverables in the short term, while aiming to activate broader actions in the long term. Though, for each action, a specific indicator to measure its effectiveness has been identified.

The identified actions aim to affect the policies at different levels (Barbero & Giraldo Nohra, 2018):

- **A level that implies a direct activation** of new measures or eventually implies an impact on existing measures, within the defined framework of the 2014–2020 ROP ERDF;
- **A level concerning governance and policies**, in a medium-term perspective;
- **A level concerning culture**, in collaboration with the Politecnico di Torino, to train a future class of professionals who will be able to promote a circular approach to the economy.

From above, we have selected the specific action called “Bioeconomy Platform” belonging from the first level, in order to give to the lectures an insight of a short-term action which have impact on the medium and long term horizon.

Bioeconomy platform

The Bioeconomy platform is framed within the Green Chemistry and Agro-food sectors which, as emerged from the RIS3, are priority areas in which the Piedmont Region is particularly specialised (Barbero & Giraldo Nohra , 2018). This given to the enterprises involved, the technological know-how and a strong concentration of innovation activities and research centers.

The platform has been initiated by a regional call for R&D projects aiming to create “circular connections” between different companies and research organisations, in the field of “Bioeconomy”. On that purpose, the Region intended to finance the development of innovative solutions and collaborative aggregations, facilitating the exchange of knowledge and skills between companies and research centers.

Short Term Results

The first results of this call delivered a total of 11 projects submitted. Furthermore 8 out of 11 projects are connected to CE. Below we report some statistics:

Total 138 partners: 38 Research Organizations, 100 companies

Topics covered by submitted projects and outcomes:

- Biofuels (1 project, 9 companies and 3 RTOs involved)
- Fertilizers (2 projects, 22 companies and 7 RTOs involved)
- Biomaterials/bioplastics (2 projects, 29 companies and 12 RTOs involved)
- Nutraceutics (1 project, 14 companies and 3 RTOs involved)
- New value chains to reuse agricultural and agro-industrial wastes and byproducts (2 projects, 31 companies and 8 RTOs involved).

These results are classified as “short term results” because they are given within the duration of the project. As previously explained, policy actions don’t change in a range of a 4 year project, but they take a more medium and long term adaptation. That said, this first short term results aim to initiate managing authorities in to bigger actions with wider impacts on a medium and long term perspective. Moreover, due to the high interest and participation of companies and research centers on this platform, the following paragraphs make a prevision on what will be the most plausible futures on the mid - long term horizon, based on the current changing drivers. Among these, the overall regional situation is characterised by good resources to transition towards a CE (e.g., research and innovation initiatives, technological development, strong economic sectors with leading industries, key change-makers, networks). On the other hand, it must be underlined that the regional panorama still lacks of a critical mass of industrial and research investments on CE, which calls for further actions (Barbero & Giraldo Nohra, 2018)

Medium-term Results

The mid-term results of the project will be reflected after the completion of RETRACE on the next programing period 2021–2027 ROP ERDF. As explained above, the actions proposed on RAP could only propose tangible-short actions as they were unable to modify the current 2014–2020 ROP ERDF. Furthermore, the CE paradigm on this current programming period is not explicitly addressed as a policy goal. In this context, the RETRACE

actions and strategies will provide an essential input in defining an effective approach to address the CE policy goals on the future programming period for EU funds, in a more systemic and territorial way. On the local point of view, actions like the Bioeconomy platform, will increase awareness and cooperation among industrial, research and innovation players, stimulating other similar initiative that will become real on a mid-term horizon. The eco belonging to this successful action, can resonate also on the national level, creating a wider spectrum of calls which encourage the allocation of more fundings on projects related to CE. On that regard RETRACE supports the improvement of the ROPs especially under the governance point of view, encouraging the focus for new calls to be launched, in order to boost research and investment measures on CE. More generally, the RETRACE outcomes will influence how regions will oversee the development of CE on the next 6 years.

Long Term Results (EU CE TARGETS 2030)

On a long term perspective, the RETRACE results must be framed on the targets that EU has set for a sustainable development by 2030. For that purpose it must be acknowledged the considerable EU policies towards a CE as - the already ongoing - *Circular Economy Package, EU Bioeconomy Strategy and the EU Plastics Strategy* (EC, 2019). Considering the ambitious CE targets of the EU by 2030, the RETRACE inputs are a relevant milestone as they are addressing regions to achieves major environmental-economical-social advantages through the intervention of regional funds. Based on the elements mentioned above, it is possible to oversee the evolution of RAP actions towards EU 2030 CE targets. In the specific case of the Bioeconomy Platform, one of the possible results will be the increasing use of second-hand materials and enhancement of the by-product value chain among the network of connected enterprises.

Overall results

Thanks to the contribution of RETRACE the actions intended in a short term view will influence the call for proposals throughout all 2018. At the same time, with a long term vision, it will allow to orientate and bring out more clearly the planning concerning the processes of resource efficiency and CE.

Designers, in this project, have a central role since they are the experts who are providing the SD methodology. It is important to stress that the methodology is shared and put in practice by all the partners and stakeholders of RETRACE, creating new mechanisms of sharing knowledge and experiences, on the local and inter-regional scale. On that sense, designers are both at the head and in the middle of design-led innovation. As providers and mediators, their versatile role allow a Quadruple Helix approach where university, industry, government and civil society cooperate in order to co-develop strategic decision-making. This reflect a concept of innovation intended as a contamination of different disciplines and sectors. In order to allow this type of innovation, visualization through infographics, schemas, and gigamaps (Sevaldson, 2011) delivered by systemic designers, perform a key role in the process since complex concepts are made accessible and usable through a simple and common language. This action facilitated the peer reviews meetings, generating deep discussions around the regional data presented and enabling a knowledge transfer to the other partner countries.

Cross-cutting projects like RETRACE offer an inspiring example of forward-looking decision-making. Thanks to RETRACE new policy opportunities have been co-developed in Europe, standing on real data and providing real solutions in handling environmental uncertainty.

Conclusions

This paper contributed to address strategic anticipation in design research, by proposing a collaborative approach shared among SD, strategic foresight and policy-making in order to move towards CE in a long-term horizon.

As extensively discussed, complex and wicked problems are key issues in our society that demands us to redesign our public-policy framework conditions. During the research, it emerged that “strategic agility and adaptive capability” are key elements to react more quickly and effectively to the multiple futures that could arise. Moreover, the interconnections of today’s global challenges demand collaboration among different disciplines in order to tackle the emerging challenges and to deliver systemic and interconnected solutions.

Through this paper, it is highlighted how systemic designer’s mindset and methodology can be supportive in foresight practices and strategic decision making, developed in a collaborative and multi-stakeholders process.

On that view, it has been examined how the role of design is changed over time, broadening its lens and shifting its focus on larger systems. Consequently, designers has turned into key players on delivering innovative strategies on the micro/macro scale and on the short/long term. Specifically, Systemic Designers are able to navigate through the multiple scenarios that emerge from this complexity. Literature and the field of practice have shown the intersection points between foresight and systemic design practices. In fact, both design and foresight envision plausible futures and try to strategically design multiple solutions aiming to reach an ideal future outcome.

The RETRACE case study, which supported this research, features evidence of this fruitful relation, proving to be effective in the development of strategic decision making towards a sustainable future.

This paper took the case of the Piedmont Region as an example in order to understand how RETRACE is framed in the context of design with foresight for policy-making, towards CE. The SD methodology adopted in the case study highlights the connections between SD and Foresight. In fact, the holistic diagnosis performed a central role in scoping the context, collecting qualitative and quantitative data and delivering a first scenario. Matching these results with policy gaps and taking into consideration the already existing policy-strategy of Piedmont Region, a strategic action plan has been developed. Finally, the implementation phase of the project, has defined a roadmap of 3 to 6 concrete actions that are going to be developed on the short-medium-long term and aim to affect the policies at different levels: direct activation and implementation (Short), governance and policies (Medium), culture and education (Long). On that view, the RETRACE actions perform an essential input for stimulating the allocation of more EU funds on the next programming period and also fit with the targets that EU has set for sustainable development by 2030.

Inside the RETRACE project, systemic designers performed a double key role as providers and mediators: they share their proper methodology among the partners and make complex concepts and interconnected data accessible and usable to all, through visual maps. This practically demonstrates that systemic designers, enriched with a foresight vision, can play a leverage effect in the transition of the EU regions towards CE, by strategically designing concrete actions which address a long term change.

Track 5.j Introduction: Innovation Through Design for Meaning

AJOVALASIT Marco[a]; GIACOMIN Joseph[b] ; GKATZIDOU Voula[b] and JENSON BENNETT Julie[c] and PETTERSSON Ingrid[d]

[a] Politecnico di Milano, Italy
[b] Brunel University London, United Kingdom
[c] Volvo Cars, Sweden
[d] Precipice Design, United Kingdom
doi: 10.33114/adim.2019.5j

This track brings together researchers and practitioners to share and discuss the approach, subsequent outcomes, contributions and possible futures of the design for meaning landscape.

For many fast moving consumer goods, home goods, office goods, vehicles, transport systems and elements of the built environment there are a growing number of instances in which a business opportunity can only be achieved by exploiting a new technology or a new cultural code (Holt and Cameron, 2010). Such cases of disruptive innovation or radical innovation are premised on the possibility of defining a new meaning for the potential consumers (Giacomin, 2017). The idea that design is a manner for making sense of things (Krippendorff,1989) is frequently discussed in professional circles, as is the idea that design involves doing philosophy with the hands (Wendt 2015). For many practicing designers the activity of design cannot be separated from the intended meanings of the artefact which is being designed.

Within market-driven economic systems the commercially active designers must consider the forms of value and meaning which a product, system or service may hold for its customers (McCracken, 1990). It is in fact frequently claimed that the meaning of a commercial offering is the actual basis of the business (Verganti, 2009). Experts from the branding sector usually concur, an often repeated statement being Aaker's (2002) proposition that "if a brand is "packaged meaning", a slogan can be the ribbon that ties the package together and provides an extra touch". The increased material wealth of industrialised societies has in recent years lead to debate about the meaning of designed artefacts, and about the role of meaning in the innovation processes of commercial enterprises. Numerous indicators point to a certain current glut of products, systems and services in people's lives, and to a trend of increased sophistication of selection on the part of the consumer (Wallman 2015).

Beyond the commercial considerations, it can also be suggested that consideration of target meanings is important towards defining the long term role which an artefact will play in the lives of its owners (Giacomin, 2017). The relational role of artefacts has been neatly expressed by Csikszentmihalyi and Rochberg-Halton (1981) as "the objects which people use, despite their incredible diversity and sometimes contradictory usage, appear to be signs on a blueprint that represent the relation of man to himself, to his fellows, and to the universe". In this view (see figure 3) artefacts are not simply functional tools, but are also relational mediators which shape the long term aims, objectives and behaviours of an individual or of a group.

Considering the importance of meaning in design it is perhaps surprising to note the frequent lack of clarity about these matters in design discussions and in design practice. In many websites, documents and publications of a commercial nature the word "meaning" is deployed without reference to the anticipated nature of the meaning and without reference to the individual involved. Further, semantics such as value, ideology, meaning, function, ritual, myth and metaphor are often used interchangeably, with important

practical consequences in terms of possible misunderstanding. In the words of Sudjic (2008) “design is the language that a society uses to create objects that reflect its purposes and its values. It can be used in ways that are manipulative and cynical, or creative and purposeful. Design is the language that helps to define, or perhaps to signal, value”. It would thus appear reasonable to ask that designers speak their language clearly.

The aim of this track is to encourage the discussion of design for meaning frameworks within businesses, including topics such as:

- developing and managing brands through meaning (paper 1);
- use of data, design ethnography, real fictions and co-creation to support innovation within design innovation teams (paper 2);
- the role of analogies, metaphors and meanings within business design innovation (paper 3);
- organisations and processes for achieving targeted design meanings (paper 4);

In the first paper, *“Making Markets: The Role of Design in the Process of Legitimation”,* the authors examine the impact of design on the evolution of a product market from illicit to mainstream. The authors argue the importance of congruence with normative and cultural-cognitive structures in fostering legitimacy. By means of an ethnographic study of the newly-legal recreational cannabis market in the US, the authors analyse a market that has attained regulatory acceptance in some states but lacks normative and cultural-cognitive legitimacy. The authors offer a framework for managing products in new markets, arguing that design can enable legitimacy by drawing on symbolic relationships to other products, considering affordances, and enhancing strategic socio-cultural innovation.

In the second paper, *“Meaning of artefacts: interpretations can differ between designers and consumers”,* the authors explore an important point in relation to the concept of “meaning” by which the meanings that become connected with products don’t always have to be the meanings intended by the designers. Substantial divergences in meaning might be expected to lead to some degree of commercial difficulty at some point in an artefact’s life cycle. Their research suggested that three primary categories of meaning which designers should consider during their design processes, i.e. function, ritual and myth, covering a spectrum from the purely instrumental to the purely symbolic, could be commonly encountered in practice, either individually or could be co-present to some degree. Their findings also suggest that some meaning divergences occur between designers and consumers, and would appear to highlight the need for carefully executed ethnographic and user testing activities.

In the third paper, “*Design for Meaning of Smart Connected Products”,* the authors explore the topic of meaning-driven innovation from a Product Design perspective. It focuses on the design of Smart Connected Products: internet-enabled phygital products that blend hardware and software. Their work highlights three kinds of meaning that are relevant for Smart Connected Products: the meaningful identity of the object as product category, the meaning of the product in relation to its shape and functionality, and in relation to a phygital ecosystem. The paper reflects on the methods that can support designers in the development of meaningful smart products and presents the “Mapping the IoT” Toolkit, a downloadable tool that guides in specific activities aimed at framing the product’s meaning.

In the fourth and last paper, *“From Hype to Practice: Revealing the Effects of AI in Service Design”,* the authors discuss the current and even hyped topic of artificial intelligence (AI) in the context of service design. It takes in consideration the design principles for the context of artificial artefacts that are produced and consumed in a multi-user context supported by virtual environments and focus on the fact that design is ‘language-like’. It also considers that with the shift towards the application of natural language processing (NLP) tools, services and products go beyond the conceptual and semiotic language. Their paper discusses not only what AI enables for the front and back ends of service delivery but also the practical role of the service designer and service design process in the context of AI-enabled services. The authors evaluate the datasets through coding cycles aiming at identifying the shifts AI brings to service design.

Making Markets: The Role of Design in the Process of Legitimation

HUFF Aimee[a]; HUMPHREYS Ashlee[b] and WILNER Sarah JS[c]*

[a] Oregon State University, USA
[b] Northwestern University, USA
[c] Wilfrid Laurier University, Canada

doi: 10.33114/adim.2019.01.282

We examine the impact of design on the evolution of a product market from illicit to mainstream. We argue the importance of congruence with normative and cultural-cognitive structures in fostering legitimacy. To understand the role of product design in this process, we conducted an ethnographic study of the newly-legal recreational cannabis market in the US, a market that has attained regulatory acceptance in some states but lacks normative and cultural-cognitive legitimacy. By analysing product design and interviewing managers, we find that design plays a pivotal role in legitimation. Producers transform a market by manipulating two distinct aspects of materiality: *material in relation* – how products relate to accepted products, and *material in use* – how design guides and enables consumption. We offer a framework for managing products in new markets, arguing that design can enable legitimacy by drawing on symbolic relationships to other products, considering affordances, and enhancing strategic socio-cultural innovation.

Keywords: market emergence, legitimacy, product design, material culture

Introduction

Markets are complex and evolving social systems. At any given time, the mutual understandings among producers, consumers, and other stakeholders such as regulators and the general public (Weber, Heinze, & DeSoucey, 2008) may make markets appear stable. However, because they are dynamic, they are also susceptible to transition or disruption given new technology, an infusion of new or more powerful stakeholders, or shifting regulation. However, there has been limited examination of an essential part at the heart of the market—the product—in market change. This raises two important research questions. First, what role does product design play in legitimation? And second, how can managers leverage design to foster legitimacy in new or transitional product markets? Our inquiry draws from a material culture perspective, emphasizing the role of objects in regulating social relations, carrying out social functions and providing symbolic meaning (Woodward, 2007) to investigate how products' material elements and associations shape meaning in ways that enable a mainstream market to emerge.

Recent studies of market emergence have emphasised meaning being shaped by marketing communications, consumer practices, and discourse in popular media. While marketing researchers have noted that product design can impact market growth (Giesler, 2012; Martin & Schouten 2014), scholars and managers still lack nuanced understanding of how and why a product's material design promotes legitimacy. Gaining insight into the legitimation of previously stigmatised products or categories is important, whether to help managers

encourage adoption of beneficial products or social advocates weaken the appeal of products that have potentially harmful implications.

The links among materiality, systems of cultural meaning, and mainstream markets are evident in the automotive sector. For example, minivans emerged as a category when marketers identified new potential in a "family vehicle" market positioning and car designers leveraged existing automotive classifications and attributes (e.g. cars, trucks, vans) in ways that facilitated market change (Rosa et al. 1999). Both physical cues—such as built-in children's car seats—and marketing messages referencing space and convenience communicated the desired positioning to consumers, who interpreted and acted upon the information. In this dynamic system, consumers' behaviours in turn generate new signals in the marketplace, which are (or may not be) incorporated into the socially-constructed pattern of consumption and production practices. In this way, attributes signifying "minivan" stabilized as producers and consumers developed shared knowledge structures about the product category (Rosa et al. 1999). However, product meanings continue to shift with evolving social values and product iterations. For example, the sport utility vehicle (SUV) later emerged from the minivan category. The design of SUVs employed visual references to military vehicles such as large grills and boxy, tank-like shapes, which conveyed a sense of control and safety for owners that particularly resonated with American attitudes toward personal safety in the 1980s and 1990s (Lauer, 2005). However, SUVs' popularity waned once environmental movements made fuel economy salient and gas prices increased in the late 2000s (Holt 2012; Luedicke, Thompson, & Giesler 2010). As this example illustrates, markets evolve as meanings change, becoming more congruent with cultural norms and values that shift over time.

The study presented here is the first phase of a larger project examining the role of materiality in the shift of a product category from illicit to legal and increasingly mainstream. Whereas new legislation may pave the way for market transactions to occur legally, regulatory legitimacy alone does not ensure a product's acceptance and eventual diffusion among mainstream consumers, particularly if previous prohibitions prevented learning about the market or if consumption remains counter-normative. Given significant evidence that consumers make product judgements based on visual form (Hoegg & Alba, 2007; Rindova & Petkova 2007) and material properties (Peck & Childers, 2003) among other sensory cues, we posit that product design is an important mechanism for facilitating consumer acceptance and investigate how it can contribute to legitimacy. By underscoring the links between materiality and cultural values, we illuminate the role of material culture in the legitimation process. Specifically, we identify two aspects of materiality, which we term *material in relation* and *material in use* that are critical in shaping product meaning and thereby increasing acceptance.

Objects' material factors are a key element of product adoption and use (Jordan 2000). Design research has articulated the ways that product designers convey meaning and appeal to consumers' aesthetic preferences (Krippendorf, 2006), while marketing research has examined how existing stigma can influence producers' decisions (Giesler, 2012). Yet to our knowledge, no research has examined the role of design in fostering acceptance in new (or newly lawful) markets. While extant work has articulated the importance of product symbolism in marketing and adoption of new products (Homburg, Schwemmle, & Kuehnl 2015), it has primarily focused on symbolism relative to the user (i.e. an object's expressive value) rather than the system of socio-cultural interpretations that give a product this meaning. We build on prior consumer-focused studies to illuminate the role of design as a tool that producers employ to facilitate product comprehension, desire and adoption. Additionally, most research on product design in marketing management has theorized the introduction of new products into mature, stable markets rather than new or shifting markets (Hung and Chen 2012; Luchs, Swan, & Creusen, 2015). In mature markets, consumers have well-established ideas about product function and meaning within the category (i.e. cultural-cognitive legitimacy) and there is generalized social approval for use (i.e. normative legitimacy). For this reason, previous studies have emphasised the role of design in differentiation and competition (Homburg et al. 2015). In new or transitioning markets, however, knowledge and meaning of product attributes are much less defined (Carpenter & Nakamoto, 1989). We extend this work to present cases in which similarity—rather than differentiation—can provide a strategic advantage as companies work together in the early stages of a newly regulated market to teach consumers about the category as a whole.

To understand the role of material form in the legitimation process, we examine a previously illicit product in the process of acquiring legitimacy: the market for recreational cannabis (marijuana) in the United States. In particular, we study the recreational cannabis market in the state of Colorado, where individuals over the age of 21 have been able to legally purchase marijuana from licensed retailers without a prescription or license since 2014. This regulatory shift, and the commercial transitions that have followed, represents a significant market transformation and an ideal context for study. Because recreational consumption occurred in an illegal

(and thus unregulated) market prior to 2014, many mainstream consumers lack an understanding of the product category or associated consumption practices. The result is that few consumers have developed preferences related to specific brands, retailers, product forms (such as edibles, beverages, topicals, tinctures) or delivery mechanisms (including vaporizers and transdermal patches). The social stigma surrounding marijuana consumption is longstanding, and negative stereotypes are often invoked in the debates taking place among media, activists (both opponents and proponents), producers, and consumers. Thus, current producers must be particularly mindful of breaking away from pervasive and embedded stereotypes (Dunne 2014) if they are to engage consumers' attention and shift attitudes from aversion to acceptance.

Finally, this context is fitting for examining the evolution of mainstream markets because while cannabis (the botanical genus name for marijuana) is not yet legal throughout all of the United States, producers have already undertaken considerable efforts to make it appealing to the mainstream market in anticipation of federal statutory acceptance. These include developing products, brands, and retailscapes that are purposively distinctive from the prevailing, negative imagery surrounding the category (Birkner, 2015; Halperin, 2015; Klara, 2014). Whereas the materials and modes of consumption previously associated with marijuana include bongs, pipes, rolling papers, and "magic" brownies, the new products populating the shelves of contemporary cannabis retailers include carbonated beverages, lip balms, skin lotion, premium confectionary, and slim vaporizing pens.

Literature Review

Market Systems and Legitimation

Markets undergoing transition face a unique set of challenges; product markets that appear without any precedent to aid categorization—or depend upon the construction of a new or modified categorization—have difficulty attaining legitimacy. For example, consumers confronted the first "horseless carriages" with trepidation, fearing motorcars to be both deviant and dangerous (Chiu, 2008). New industries become accepted not purely though regulation, but through the more complex, social process of attaining legitimacy (Scott, 1995; Suchman, 1995). Legitimacy is the quality or property of an institution being regarded as "appropriate, proper, and just" by social actors (Tyler, 2006, 376). Legitimation can be understood along three axes: normative, cultural-cognitive, and regulatory (Scott, 1995). Regulatory legitimacy entails legalization, oversight, and enforcement by the state. Normative legitimacy is achieved when a market or company aligns with social morals and values (Scott, 1995; Suchman, 1995), and cultural-cognitive legitimacy is achieved when the market is not only understood by individual consumers but incorporated into existing cognitive structures, tacit knowledge, and assumptions (Humphreys 2010a).

Objects exist somewhere in between the legal, normative, and cultural matrix, and can affect these elements in important ways.

Product Design

Design is an important domain for marketers, as it determines the properties of an artefact that help express its function (Bloch, 1995) as well as its emotional and symbolic value (Verganti, 2008). Design research in marketing has examined consumer response and preference (e.g., Bloch 1995; Moreau, Bonney, & Herd 2011; Mugge & Dahl, 2013; Orth and Malkewitz, 2008; Veryzer & Hutchinson 1998); product innovation (e.g., Gemser & Leenders, 2001; Schreier, Fuchs, & Dahl 2012; Verganti & Öberg, 2013), and branding (e.g., Beverland, Wilner, & Micheli, 2015; Beverland 2005; Kreuzbauer & Malter, 2005). Yet these domains of research tend to focus on individuals rather than examining how marketplace meanings are shaped at a collective, symbolic level.

In a recent review of the marketing literature on design, Homburg and colleagues (2015) identify three dimensions of design: functional, aesthetic, and symbolic. Consumers' operative and stylistic preferences are addressed through products' functional and aesthetic aspects, but design also appeals to consumers' emotional and sociocultural needs (Dell'Era & Verganti 2011). Designers draw from and encode cultural meanings in products with the expectation that consumers interpret meaning from the product's symbolism (Bloch, 1995). However, this symbolic dimension refers not to individual preference, but to categories of social meaning.

Although the development and interpretation of product meaning plays a vital role in legitimation, we know little about how producers—whose primary domain of control is the physical product and related marketing communications—may strategically leverage product form to turn a previously illegitimate consumption practice acceptable and appealing to a broader consumer base. Product design and development teams make decisions about product materials, form, and appearance with the intention of making artefacts appealing to the consumer (Hsiao & Chen 2006; Redstrôm 2008; Sudjic, 2009) but also to meet the expectations of other stakeholders including regulators, shareholders and critics. The attempt to conform to convention inevitably communicates the product's symbolic qualities (Redstrôm, 2008; You & Chen 2007). Thus, we must understand how design—whether of products, packaging or merchandising and distribution—imbues meaning and influences adoption.

Material Culture

Material culture can be summed up as the "social implications of things" (Miller, 1987: 85), a frame that highlights the capacity of objects to shape individual behaviour (Sunstein & Thaler 2012); subconsciously establish consumer expectations that shape social norms and guide cultural associations. Material culture foregrounds the cultural values manifest in material objects. We argue that materiality primarily shapes product meanings in two ways: through its symbolic relationships with other objects, which we call *material in relation*, and by influencing consumer interaction, which we call *material in use*. *Material in relation* describes the relationship of a material object to other objects: contemporaneous, past or future. These associations can affect perceptions of legitimacy in that they can be either consistent or inconsistent with valorised cultural meanings. For example, e-cigarettes were designed to retain some material elements congruent with cigarettes, such as their shape, but to avoid problematic associations like tobacco. E-cigarette designs thus tend to emphasise the "clean" coolness of technology (inclusion of LED light and battery operation) over the "dirt" associated with the smoke and ash of traditional cigarettes by vaporising a liquid rather than burning plant material). Thus, material elements of the design rework symbolic associations between the new, hopefully "desirable" product and older, stigmatized products. Forty (1986) describes how the new electrical appliances of the 1930s were designed to mimic previous category types—electric cookers looked like their gas predecessors, which had in turn imitated coal—but also to convey a series of new, desirable associations: electricity was clean, silent, instant, modern, and revolutionary (pp, 197-8).

Importantly, designers employ materials and forms to create and communicate both meaningful similarities (Srinivasan, Lilien, & Rangaswamy 2006) and differences from competitive products. We posit that by signalling comparative similarity and difference to existing products, product design plays a pivotal role in the legitimation process.

Materiality also potentially affects legitimation through *material in use*. Here the material elements of design play a role not through their symbolic relations with other objects, but through their affordances possible (Gibson, 1977; Norman, 1988): by directing action, becoming congruent with some user goals and incongruent with others. Material comes to have meaning by virtue of being used in a particular way for a particular task (Heidegger 1927/1996). Evaluating affordances may tell us what types of objects are likely to become legitimate and which are not.

Despite the many ways that the design of objects shapes consumer acceptance, both at an individual and collective level, marketing researchers have given little attention to the properties of material objects as they relate to market transition and legitimation. This is surprising, because both the design and consumer psychology literatures have demonstrated that the appearance of objects influences consumer perception and valuation of those objects (Argo, Dahl, & Morales 2006; Hekkert, Snelders & Van Wieringen 2003).

Method

Data collection

Our study of the recreational cannabis market began in 2014, when Colorado legalised recreational cannabis. We began with ethnographic immersion in the state's capitol and most populous city, Denver. One of the authors contacted individuals featured on a prominent national news programs and newspapers requesting interviews. Once these were arranged, she employed a snowball sampling process, asking interviewees to suggest others in the industry that should be contacted and, if contact was successful, asking those individuals

in turn to suggest further resources. The result was a series of semi-structured interviews with nine prominent industry producers and marketers in their offices or manufacturing facilities. Interviews lasted an average of 1.5 hours; each was audiotaped and transcribed verbatim. The author asked interview subjects for recommendations of retailers (dispensaries) to view and events. She then visited these venues (as well as others) and conducted nonparticipant-observation of dispensaries in Denver to examine retail design, product mix and merchandising as well as engage in *in situ* conversations with retail store staff about consumers' responses to specific products. She also attended the 2014 annual Cannabis Business Awards ceremony to access producers' discourse regarding market strategies, trends and consumer insights.

A summary of the data is provided in Table 1.

Table 1: Interview and Observational Data

Name (pseudonym)	*Organization*	*Title or Role*
Alan	Brand A: cannabis consumer packaged goods	Chief Marketing Officer
Anne	Brand A: cannabis consumer packaged goods	Director of Marketing
Barbara	Brand B: cannabis branding consultancy	Co-founder and Strategic Director
Beth	Brand B: cannabis branding consultancy	Co-Founder and Creative Director
Carol	Brand C: cannabis-related special events organizer	Founder
Donna	Brand D: cannabis business developer	Co-Founder
Janice	Brand E: cannabis retailer/dispensary	Owner
Frances	Brand F: recreational cannabis testing lab	Operations Director
Gillian	Brand G: cannabis-related public relations consultancy	Founder
Company	*Description*	*Engagement*
Brand B	Cannabis-related branding consultancy (branding, store design, public relations)	interviewed firm's founders in their offices
Brand A	One of the largest and most established consumer packaged goods companies	met president and interviewed CMO at headquarters (spoke by phone with Director of Marketing)
Brand C	Cannabis-related special events organizer; planning and catering	interviewed president/founder at office
Brand H	Retail store billed as "The Apple Store of Cannabis"; first recreational cannabis-only retail store	emailed with owner, observed merchandising; service interactions; spoke with manager
Brand I	Retail store with snowboarding theme	observed merchandising; spoke with two bud tenders (employees); took photographs
Brand J	Retail store recommended by informants for its accessible, upscale design.	spoke with manager and two bud tenders (employees); took photographs
Cannabis Business Awards 2014	Annual award ceremony for Denver-based businesses; primarily entrepreneurs	observed awards ceremony; spoke with other attendees; spoke with salespeople at trade booths; some photographs

Ethnographic and Visual Analysis

All three authors read and independently conducted open coding of each transcript and set of field notes. We shared, analyzed, and discussed the textual data in multiple meetings, allowing for patterns in the data to emerge and then engaging in discussion. Semiotic analysis was conducted on product imagery and designs. We catalogued the data and adopted several analytic categories of critical visual analysis: form, medium, genre and comparison. Form is the way a subject is presented; medium refers to the material form of object; genre refers to a type or category; and comparison foregrounds the features of something by juxtaposing it with something similar but significantly different (Rose, 2005; Schroeder, 2006). We considered these categories in our analysis, comparing products in this newly legal market with existing products.

Findings

We find that materiality plays an important role in the legitimation of the recreational marijuana market in Colorado. The primary challenge for firms in this new market is to employ material elements in ways that shift product connotations away from existing, stigmatized meanings and toward interpretations congruent with accepted products and social practices.

In terms of the mechanisms facilitating the market's legitimation, our interview and visual analyses reveal that designers and marketers attempt to establish recreational cannabis as a legitimate market for mainstream consumers by pursuing congruence between new recreational cannabis products and established, legitimate cultural meanings. Producers' work comprises two distinct types of framing: *material in relation* and *material in use.*

Material in Relation

The first way that designers and marketers shape product meaning is by manipulating material in relation. That is, producers introduce products that are related to existing, legitimate product forms and thus congruent with normative cultural meanings. Producers make strategic decisions about goods (e.g. product form, packaging, advertising) in order help consumers categorize and reframe the product towards desirable associations and away from possibly objectionable associations. Prior research has established that designers do so when introducing innovative products for which there may be category ambiguity (Goode, Dahl, & Moreau 2013). By emphasizing similarity to legitimate products and difference from previously stigmatized products, designers influence the creation or modification of meanings that consumers ascribe to the product. The relationship of an object to other objects affects how consumers ascribe cultural-cognitive legitimacy to it.

We find that the ways that physical products resemble one another plays a key role in legitimation as a framing process. For example, marijuana is linked to intoxication as well as smoking, which traditionally has been one of the dominant modes of cannabis consumption. These associations are problematic in part because cigarette smoking recently has lost legitimacy in the United States as health officials and regulators have attempted to abate tobacco consumption. Designers of cannabis products, then, must not only introduce product forms that will attract prospective consumers, they must also avoid materially signalling association with an undesirable class of adjacent goods. Circumvention of negative associations also has implications for sensory faculties beyond the visual; in the case of cannabis, this includes smell and taste. Accordingly, producers seeking normative legitimacy design goods in forms that avoid undesired connotations, and the result has been a proliferation of edibles and topical applications (foods and lotions infused with THC, the active ingredient in cannabis). Thus, designing objects that contrast with forms and meanings of illegitimate, existing material objects enables producers to encode products with new, legitimate meanings.

An excellent example of designing material in relation is the recipient of the 2014 Cannabis Business Award for Best New Product: a transdermal patch like those used to promote smoking cessation by a company called Mary's Medicinals (Figure 1). Visual analysis of the transdermal patch foregrounds its form as innocuous; packaged in a slim, discreet foil packet, the company's brand identity connotes an old-fashioned apothecary. The opaque, colourless package appears without marketing artifice or hyperbole (the company's tagline is "For us, it's simply black and white"); its typography evokes a time when pharmacists were professional chemists who produced their own compounds. This impression is underscored by the stamp of a product number, reminiscent of the numbering on other handmade or limited-edition goods. The only image is a tiny cannabis leaf set in a plain square. The product *medium*—a small (2 inch x 2 inch), white, adhesive square—is similarly banal, as it is worn on the skin, under clothing. The patch's *genre* is that of bandage, connoting care and

comfort rather than self-indulgence or amusement. Retail staff asked to describe the product emphasized its discretion (as does the company website). Scent-free, it was described by more than one budtender as "cannabis you could consume at work," evoking the internet slang "(not) safe for work," a phrase used to advise users of things that are considered (in)appropriate for public consumption and underscoring how innocuous the product is interpreted to be.

Figure 1: Mary's Medicinals transdermal patch. Image source: cannabis.net

The producers in our study worked on two relational aspects of cannabis products: their difference from stigmatized products (e.g. cigarettes) and their similarities to acceptable products (e.g. bandages). Evoking specific and culturally determined material codes, designers can thus suggest meanings for new offerings by defining the product through a network of semantic relationships (Krippendorf & Butter 1984). These, in turn, provide category cues (Goode et al. 2013), signalling both what the product is (or is like), and what the product is not.

"Donna," co-founder of a cannabis business development organization, is keenly aware of the need for new product forms to avoid associations with smoking. Contrasting the emerging smokeless product forms such as topical lotions and vaporizers against existing delivery forms that require a flame source for consumption such as bongs, pipes, or dabbing rigs (a device that vaporizes concentrated cannabis when heat is applied with a butane torch), she wryly commented, "I do not believe the majority of Americans want a blow torch involved with their evening relaxation activity."

Because new products stand in relation to those already in the market, producers make a concerted effort to foster associations with conventional goods with which their product may share properties or attributes. In the case of cannabis, related categories include alcohol, medication and confectionary, because: each is expected to be consumed at adults' discretion, in moderation, and is motivated by a desire for pleasure or relief. Just as private label packaging is often intentionally designed to resemble the leading brand (Kapferer, 1995), so too is comparison encouraged between cannabis products and common goods through design elements such as brand identity (logos, colours), packaging, and marketing communications imagery. For example, House of Jane® produces single-serve coffee pods infused with THC. Combining coffee with cannabis and packaging it in ubiquitous single-serve pods can be seen as a deliberate attempt to transfer the legitimacy of coffee, a commonplace beverage which is "used" to alter mood or alertness, to recreational marijuana. By drawing directly on the visual cues and meanings of an accepted and mundane product like coffee, designers employ the practice of reframing (Dorst, 2011), creating an analogy between consumption of THC with conventional products that may be used similarly.

The use of analogy and metaphor—creating an association between a source and a target through comparison—is a central design practice (Blackwell, 2006; Cila, 2013; Moreno et al. 2014) which also has been explored in the marketing literature as an important means of communicating product semantics. Importantly, although producers in our study signal similarity to legitimate products, the process does not produce homogeneous branding and product design. Just as in mainstream product categories, brand positioning varies, and design plays an important role in expressing brand personality. Further encouraging normative

legitimacy, these representations appeal to social values such as innovation and technology. We observe that discourses associated with new technologies can also provide a legitimizing function; cannabis for this "new" market is framed as innovative, rather than old. "Anne," the marketing director at Brand A, explains:

> *We are an innovative company. Innovation on delivery-assisted products [new ways to consume] is led by our science team. It could be something that is a format that we are going to be the first to bring market…[like] a dissolvable strip, an ultra-thin film [like Listerine breath strips. We also look at fast moving consumer goods.] It's winter, so we have the opportunity to capture a huge amount of consumer traffic that's coming to the mountains in Colorado. We want to see a seasonal product out there, and we know that a small chocolate bar is something you can innovate quickly and roll out efficiently. We ask ourselves, what are the top sellers? What do you see in Starbucks? You see a lot of hot chocolate, and a white chocolate peppermint bar coming out of every good chocolatier…so we said, 'Let's go for it.'*

By actively studying other industries, producers in our sample—fully aware of their category's extant associations as well as desired replacements—intentionally forge parallels with specific products, places and meanings intended to overwrite existing cultural symbols. Most of the producers we interviewed were equally conscious of the risks of weak or undesirable category comparisons.

Previous research has shown the importance of media framing, network creation, and consumer collaboration to legitimacy, but these are elements external to the product. An object's materiality, and its capacity to encode and convey cultural meanings, is an important mechanism that can enable legitimacy. Positioning products to invite and facilitate comparison with other goods is the hallmark of *material in relation*.

Material in Use

The second way that producers shape meaning is by designing products that promote legitimacy through *material in use*. As revealed above, the physical resemblance of one product to another has implications for legitimation. However, product design imbues not only relational capacities, but functional ones as well. Producers also strategically employ material design to influence consumers' uses of products at two critical points—acquisition and consumption.

One purpose of design is to "provide [users] with information to express the usage, the function, and the other symbolic qualities of the product" (You & Chen 2007). This is a special challenge in the cannabis context, because it is an experience good and even where recreational use is legal, there are restrictions on how it can be displayed for sale. In categories where product quality is difficult to assess prior to use, designers must communicate necessary information and meanings prior to use through careful attention to shapes, materials, colours, and forms (Crilly et al. 2004; Orth & Malkewitz 2008). Marketing director Anne joined Brand A with experience in consumer packaged goods and luxury brand development, and is well aware of her industry's constraints:

> *Consumers don't have the opportunity to engage with our product. They can't walk over and pick it up, which makes it a very different challenge to connect with consumers in a meaningful way. Consumers are very, very tactile, they like to turn something over, pick it up, see the weight of it. If you can't touch a package, it's hard to connect […if I'm a consumer, I want to] walk into a dispensary and engage with a brand that feels good to me, and feels that it's approachable and safe, and innovative, and trustworthy. That's really where we can start to move the needle with design, [so] that once they get to the store we can communicate 'Honestly, this is the brand for you. We're trusted, we're safe, we're tested.' You relate to our packaging—really, to our brand—on a tangible level.*

Similarly, acquisition is unlikely if the consumer is uneducated or intimidated by a product's use, and consumers may need to be "taught" how to use the product to achieve satisfying results (Becker, 1953). Here, materiality in the design of educational materials is used to facilitate information transfer. This is particularly evident in the context of recreational marijuana, where many new or lapsed consumers may fear overconsumption of THC.

In an effort to establish legitimacy of recreational cannabis, retail service personnel in dispensaries serve a function similar to sommeliers, making personalized recommendations for a strain, dose and product delivery system based on consumers' prior experience and goals. Educational materials build cognitive legitimacy by helping consumers interpret product attributes such as the level of THC. For example, consumer packaged

good company Dixie Elixirs produces a card that is distributed at point of purchase with recommendations for product selection based on the consumer's experience with cannabis, body weight and personality type. The card's accessible design and tone not only teaches consumers how to select products to maximize satisfaction, but its presence reassures neophytes that they are not alone in needing guidance. In this way, material elements of the products and accompanying marketing materials guide use in socially desirable ways.

An important function of brands is to instil trust (Aaker 2009), and this is no less true for products in new markets. Consumers use brands as a signal for reliability and assurance, particularly under conditions of high risk or uncertainty (Erdem & Swait 2004). Indeed, branding may be particularly important in markets seeking legitimacy, because consumers have concerns about risk (Humphreys and Latour 2013). A second means that producers employ to foster trust is through packaging and product forms that protect consumers from known risks as well as facilitate successful product use. Alan, CMO of Brand A, describes the company's new chocolate bar, designed to facilitate moderate consumption:

> *It's almost the size of a Ghirardelli [mass market chocolate brand] square, and the good news is that it's a 10 mg piece of chocolate. We've actually demarked it into quarters, and it says on each quarter '2.5 THC.' So, you can break it off if you want, have 2 ½ milligrams, or have the whole thing in 10 mg [one adult dose]. We began the line because we quickly realized that not everyone not understands necessarily that 75mg or 100mg [of THC] is a lot and you shouldn't have all that…we want people to be able to have the whole thing, to not be scared, not have a bad experience.*

These products have been strategically designed to meet regulators' standards without frightening or otherwise deterring consumers. Compliance with regulations, safety labels and re-sealable packages also ensure that prohibited consumers, such as children, do not accidentally access the product. Thus, the object's form helps guide consumers toward desired uses and away from potentially problematic ones. As such, design integrates aesthetic components – such as form, color, texture – with invitations for action (Djajadiningrat et al. 2004).

Discussion

Regulatory change is not enough to allow a mainstream market to emerge if an overwhelming majority of eligible consumers remain too apprehensive to participate. Producers of recreational cannabis goods face significant challenges in achieving normative and cultural-cognitive legitimacy. They must overcome deeply entrenched negative stereotypes about marijuana consumers, educate a marketplace of non- or lapsed-consumers with limited understanding of the modern industry, and design products that can be interpreted as normative, safe, and desirable. These challenges are deepened by the need for companies within the industry to innovate and establish competitive value in the newly created market. Each of these issues can be impacted by design. *Material in relation* focuses attention on how an object relates to other, existing, objects. Designers build congruence between (currently) stigmatized goods and accepted products in adjacent or analogous categories while also distancing the new products from other stigmatized objects. *Material in use* points to ways that material elements can facilitate successful, normative consumer acquisition and use. Producers strive to both educate and indicate relevant product information so that expectations for a product are aligned with experience and to deter normatively problematic uses.

Managing Product Design for New Markets

Our findings suggest several implications for managing products in emerging market categories. Although marijuana in the United States may be a unique context, our findings are broadly relevant to product development in any new or transitioning market.

Our findings suggest that companies should design products that activate shared knowledge structures related to legitimate market categories but be equally sensitive to undesirable associations that may be hidden by existing, taken-for-granted understanding of established markets. While recreational cannabis producers longed for the acceptance enjoyed by other goods considered legitimate for adult consumption such as alcohol, they also underscored how their products offered relative advantages, such as a propensity for calm, rather than aggressive, behaviour and the low likelihood of hangover.

In addition, we suggest that in the initial stages of legitimation, consumer acceptance will be greater if product forms (as opposed to brands) are visually like competitors', because this promotes the development of new,

shared knowledge structures of the category among consumers in ways that facilitate purchase behaviour and engagement. Our findings suggest that at least initially, producers employing a strategy featuring *material in use* do so similarly to others in the industry. This mutually-reinforcing mimicry can aid the category, particularly until a dominant design emerges (Srinivasan et al. 2006).

Prior research has demonstrated that a consumer's level of product expertise influences product adoption. Our research demonstrates that *material in relation* is a key component of producer strategy to make a previously stigmatized product acceptable and appealing to mainstream (i.e., generally novice) consumers. As managers strive to align their products' material elements away from undesirable socio-cultural meanings related to illegitimacy and toward new social meanings related to other, legitimate consumption domains, they invariably produce new, discontinuous innovations. Relating designs to existing products allows new consumers to consider otherwise intimidating products.

Our findings also suggest that designers should attend to details that facilitate consumers' cognitive associations with established, legitimate markets. Evidence in the data suggests that this can be accomplished, for example, by borrowing product form, materials, packaging, sensory elements, and branding. In our data, many producers emulated designs from legitimate product categories by using principles of similarity, difference, analogy, media, and genre.

Our recommendation to attend to design at the outset of market development diverges somewhat from results in other industries, where product design becomes more important over time (Bruce and Daly 2007). Our findings also suggest that aesthetically pleasing designs are essential to providing sensory comfort and pleasure (Bloch, 1995) and ensuring normative congruence, thereby lessening defensive tendencies and facilitating the establishment of new social norms.

Ultimately, the materiality of both products and retail spaces are critical elements of the marketing mix. Yet new products and products in previously stigmatized markets have a legitimacy problem: whether unrecognized or considered unacceptable by consumers, managers must grapple with a series of strategic decisions when (re)introducing new products. Our work underscores the importance of careful product design in concert with deep consideration of the socio-cultural environment in which products are acquired and consumed.

Meaning of artefacts: interpretations can differ between designers and consumers

AJOVALASIT Marco[a]* and GIACOMIN Joseph[b]

[a] Politecnico di Milano, Italy
[b] Brunel University London; United Kingdom

doi: 10.33114/adim.2019.02.266

Previous research has suggested three primary categories of meaning which designers should consider during their design processes, i.e. function, ritual and myth, which cover a spectrum from the purely instrumental to the purely symbolic. The research hypothesis of the current study was that the previously identified three primary categories of meaning would be commonly encountered in practice, and that statistically significant differences would occur between designers and consumers. A semi-structured questionnaire was deployed with ten designers and with ten consumers using a set of twenty photographs of designed artefacts. The results suggested that all three categories of meaning could occur individually or could be co-present to some degree. The results further suggested that statistically significant differences occurred between the group of designers and the group of consumers in the indicated category of meaning and in the adjectives used to describe the artefacts. The findings suggest that some meaning divergences may be occurring between designers and consumers, and would appear to highlight the need for carefully executed ethnographic and user testing activities.

Keywords: Function, ritual, myth, meaning, human-centred design

Introduction

There has in recent year been much debate in professional circles regarding the meaning of designed artefacts. Numerous indicators point to an excess of products and to a trend of increased sophistication of selection on the part of the consumer (Wallman, 2015). Consumers are claimed to increasingly favour purchases which are rich in emotions (Chapman, 2005 ; Oatley, Keltner & Jenkins, 2006), experiences (Schifferstein & Hekkert 2007 ; Shaw, Dibeehi, & Walden, 2010) and meanings (Dunne, 2008 ; Wendt, 2015).

Regarding meaning, standard dictionaries of the English language suggest that the word “meaning” can express at least three possible concepts: the sense or signification of a word or sentence; the significance, purpose or underlying truth of something; the motive or intention of something. The meanings which consumers associate with commercial products were considered by Friedman and Lessig (1986) who noted that “one can regard consumer behaviour as a continuum ranging from information processing to aesthetics consumption. On the one extreme we can see a logical, methodical information-processor using choice heuristics. At the other extreme we see the consumer aesthetically consuming based upon such feelings as fun, elation, and hedonic pleasure”. Fournier (1991) extended the logic by suggesting that consumer objects can be grouped according to the nature of the consumption experience so as to place them along a continuum from the utilitarian to the hedonic. Eight categories of consumer meaning were defined. They were objects of

utility, action, appreciation, transition, childhood, ritual enhancement, personal identity and position or role. Adopting a similar point of view to categorise a large number of commercial projects, Diller, Shedroff and Rhea (2008) suggested fifteen categories of meaning: accomplishment, beauty, creation, community, duty, enlightenment, freedom, harmony, justice, oneness, redemption, security, truth, validation and wonder.

Krippendorff and Butter (2007) suggested four theories of meaning in relation to the artefacts of design: a theory of meaning for artefacts in use, a theory of meaning for artefacts in language, a theory of meaning for artefacts in their life cycle and a theory of meaning for ecologies of artefacts.

The claims of sociologists regarding the constructed nature of meaning and its relativity to a given culture at a given point in time are supported by several studies of the meaning of artefacts. For example, research by Csikszentmihalyi and Rochberg-Halton (1981) has shown that meaning can change as a function of age, gender and other demographic descriptors. Further, studies such as those of Watson (2002) or Wallendorf and Arnould (1988) have shown that the meaning associated with an artefact can change substantially as a function of the cultural context in which the artefact is emerged.

Through examples such as that of the motor vehicle, Pantzar (1997) has suggested a natural cycle for some artefacts of design which begin their existence as luxuries and toys, becoming more central to society as time passes, eventually becoming necessities or commodities. Through examples such as eyewear, Pullin (2009) has instead suggested a natural cycle in the opposite direction for some artefacts of design, which enter society as functional tools and as time passes become objects of identity and personal expression.

An important point in relation to the concept of "meaning" is that studies on semiotics and sign process (Fisch, 1986) have suggested that the 'intended sign content' chosen by a creator may turn out to be different from the 'received sign content' of an end user. Siefkes (2012) specifically suggested that "the meanings that become connected with products don't always have to be the meanings intended by the designers" (p. 9). Whether designer notions of meaning are being received by consumers to a high degree, or, instead divergent from that of consumers to some degree, is a question which can be suggested to merit investigation. Substantial divergences in meaning might be expected to lead to some degree of commercial difficulty at some point in an artefact's life cycle. Further, knowledge of possible divergences might prove useful towards the prioritising of the design processes involved, for example by prioritising ethnographic and validation activities.

Three Categories of Pre-existing Meaning of Designed Artefacts

Giacomin (2017) has suggested that any commercially active designer would be expected to clarify, decide upon and communicate the following at some point in the design process if meaning is being considered an important characteristic of the artefact:

- the relevant corporate or brand ideology;
- the form of value which the consumer is anticipated to derive from the artefact;
- the meaning which the artefact is anticipated to provide or facilitate for the consumer;
- the adherence between the artefact and some existing function, ritual or myth;
- the opportunity or need to define a new function, ritual or myth due to technological or societal change;
- the focal metaphor of the artefact;
- the physical, informatic and manufacturing specifications of the artefact.

The visual representation which was proposed as a means of capturing the concerns and questions is shown in the framework of 'design for meaning' in Figure 1. For simplicity of use, the diagram was organised with the starting point being the corporate or brand ideology (Hatch & Schultz 2008) and the terminating point being the final product, system or service specifications. The diagram is subdivided into two sections in relation to the fundamental consideration of whether the artefact should adhere to an existing technological or societal stereotype or, instead, whether there is the opportunity or the need to define a new meaning due to technological or societal change.

Giacomin (2017) suggested that for many fast moving consumer goods, home goods, office goods, vehicles, transport systems and elements of the built environment a deviation from an existing function, ritual or myth can be problematic, but that there are a growing number of instances in which a business opportunity can only be achieved by exploiting a new technology or a new cultural code (Holt & Cameron, 2010). Such cases of disruptive innovation (Bower & Christensen, 1995 ; Clayton, 1997) or radical innovation (Dahlin & Behrens 2005 ; Norman & Verganti 2014) are premised on the possibility of defining a new meaning for the potential

consumers. The establishing of such new meanings was expressed by Giacomin (2017) using the term "meaningfication", which was defined as:

> *The use of data, design ethnography, real fictions and co-creation for the purpose of designing artefacts based on new meanings which emerge from the interconnection of evolving patterns of technology, experience, personal identity, societal identity, value assignation and consumption. (Giacomin, 2017, p. 22)*

When a designer identifies an opportunity which interconnects several previously unrelated technological and cultural codes, and articulates one or more product, system or service concepts which address the opportunity, the process can be described as one of "meaningfication".

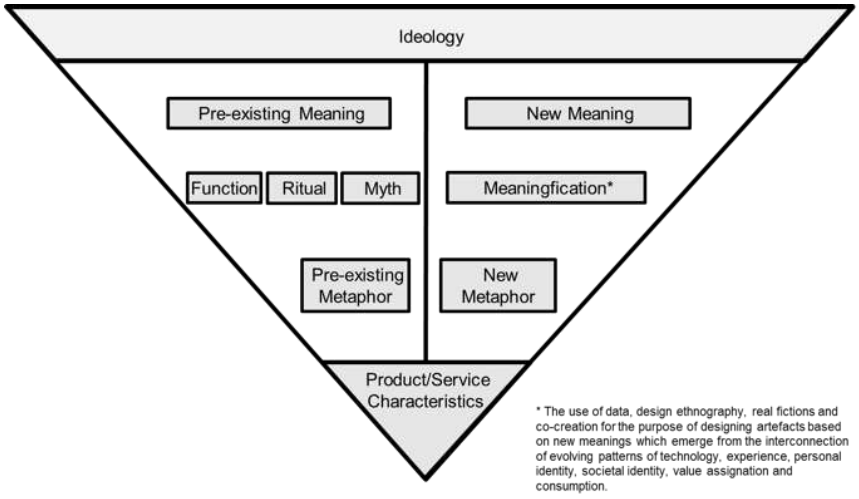

Figure 1: Framework of design for meaning. source: Giacomin, 2017

Three primary categories of pre-existing meaning are proposed in the framework of Figure 1 covering a spectrum from the purely instrumental to the purely symbolic. These categories of meaning can occur individually, or in the case of some products, systems or services might be co-present to some degree. Each category of meaning involves dialogue which focuses mainly, but not exclusively, on one specific consideration to optimise. The concept of "design for meaning" suggests that the three categories of pre-existing meaning of function, ritual and myth can provide a bridge between the global meaning of an artefact and the specific metaphor which is deployed by the designer.

The category of "function" is meant to reflect all those situations in which a physical or informatic use is acting as the focus of attention, with less attention being paid to the psychological or sociological considerations. The category of "ritual" is meant to reflect all those situations in which the meaning of the artefact is closely related to action of a symbolic nature. The category of "myth" is meant to reflect all those situations in which the meaning of the artefact is mainly symbolic, thus not necessarily requiring dedicated externally visible activity on the part of the consumer.

The aim of the study presented in this paper was to investigate the potential usefulness of the "design for meaning" framework for distinguishing between meanings when organising the design of artefacts. The objective of the current investigation was to establish if the three previously identified primary categories of meaning are commonly encountered in practice, and to note any statistically significant differences in meaning between a group of designers and a group of consumers. For this purpose, a set of twenty well known commercial artefacts was chosen as the basis for the exploration of associated meanings.

Methods

Participants Selection

Review of the ergonomic, psychological and sociological literature suggests that the use of ten participants can often be considered sufficient for purposes of qualitative analysis (VanVoorhis & Morgan, 2007). Given the

exploratory and qualitative nature of the current investigation it was decided to assemble a group of ten designers and a group of ten consumers for a total of twenty individuals.

To be selected each designer had to have more than three years of design experience, preferably in commercial practice. To be selected each consumer had to have no experience in a design related discipline. In order to reduce one well known source of bias, the sampling was performed in such a manner as to ensure equal numbers of male and female participants in each group. Efforts were made to also achieve a relatively similar distribution of the demographic descriptor of age. Across the complete group of twenty individuals the participant age ranged from 22 to 48 years with a mean value of 28.2.

To simplify recruitment and procedures all individuals were staff or students of the university. All were unpaid volunteers. All phases of the recruitment process and of the study itself were performed in compliance with the university's ethics policy and with the terms of the specific ethics approval granted by the university.

Artefacts selection

Given the exploratory and qualitative nature of the current investigation it was decided to use representative designed artefacts which provided a wide spectrum of characteristics along a continuum from the utilitarian to the hedonic. The selection criteria adopted with respect to the design for meaning framework were the following:

- the artefact is a commercial product;
- the artefact's brand association is expected to be evident;
- the artefact's design metaphor is expected to be simple enough to be understood;
- the artefact does not exhibit significant hidden product characteristics.

Additional selection criteria adopted for the study were the following:

- the artefact is commonly encountered in everyday life;
- the artefact is expected to be familiar in terms of affordances and stereotypes;
- the artefact is not contentious in terms of meaning or association with world affairs.

After shortlisting it was decided to choose the final artefacts from the commercial sectors of durable consumer goods and of fashion, because analysis of the shortlist highlighted that these two commercial sectors offered a wide variety of artefacts which people encounter in everyday life. The twenty final artefacts are shown in Figures 2 and 3.

Figure 2: Seven fashion goods used in the study

Figure 3: Thirteen durable consumer goods used in the study

Working Definitions of Function, Ritual and Myth

Working definitions of the semantics "function", "ritual" and "myth" were required for use in the study so as to minimise variations in response due solely to different, potentially incorrect, interpretations of the semantics on the part of the participants. In order to keep the guidance as simple and intuitive as possible the dictionary definitions referenced by Giacomin (2017) were adopted:

Function:

- the way something works or operates;
- the natural purpose of something or the duty of a person.

Ritual:

- a series of actions or a type of behaviour which is regularly and invariably followed by someone;
- a set of fixed actions and sometimes words performed consistently and regularly, especially as part of a ceremony or collectively.

Myth:

- a traditional story, especially one concerning the early history of a people or explaining a natural or social phenomenon;
- an idealised, exaggerated or fictitious conception of a thing or person;
- a widely held but false belief or idea.

These definitions were provided to the participants in the form of written text which was presented for a fixed period of time during the induction and familiarisation stage of the study. In this manner, it was presumed that each participant was provided equal access to the core definitions of the study and similar time for reflection and understanding.

Procedure

Each participant (n=20) was received separately in a closed room in the Human Centred Design Laboratory of Brunel University. Upon arrival the participant was provided the background information to the study, including the relevant health&safety and ethics considerations. The participant was next asked to read the written working definitions of "function", "ritual" and "myth" which had been adopted for the study.

The lead researcher next presented each of the twenty artefacts, one-by-one, by means of a large photograph and asked the participant to respond to the following questions:

- *"Is function an obvious meaning which can be associated with this artefact ? Yes? No? Unsure?*
- *If "Yes", can you suggest at least three adjectives which describe the artefact in terms of function?*

- *Is ritual an obvious meaning which can be associated with this artefact ? Yes? No? Unsure?*
- *If "Yes", can you suggest at least three adjectives which describe the artefact in terms of ritual?*
- *Is myth an obvious meaning which can be associated with this artefact ? Yes? No? Unsure?*
- *If "Yes", can you suggest at least three adjectives which describe the artefact in terms of myth?*

For each artefact the question set attempts to first identify the presence or absence of each of the three a-priori defined categories of meaning, then moves on to request adjectives which describe the way the artefact manifests that meaning.

The forced choice format was used for the meaning attribution in order to elicit deeper processing, to minimise satisficing behaviours (Smyth, Dillman, Melani, & Stern, 2006) and to reduce acquiescence (Schuman & Presser 1981). The option of selecting "unsure" was provided in order to avoid the potential bias which can occur when people are forced to choose an answer that may not be completely true for them (Smyth et al., 2006). The collection via an open ended format of three adjectives to describe the artefact was instead inspired by the ethnographic criteria of Hanington and Martin (2012) which aim to extract balanced and unbiased views from people.

To minimise learning and fatigue effects the order of presentation of the working definitions of the categories of meaning on the instruction sheet were randomised for each participant, as was the order of presentation of the twenty artefacts. To further reduce the bias which is caused by artefact order of presentation (Gescheider, 1997) the participants were asked to respond to each artefact based on its own merits, independent of the preceding artefacts. Across the complete group of twenty participants the time required to complete a study session was never greater than 16 minutes for any given individual.

Data analysis

All written responses were initially recorded on sheets of paper and then later transcribed by the lead researcher into the NVivo software (Bazeley & Jackson, 2013). NVivo supports qualitative, quantitative and mixed methods research by means of a variety of statistical algorithms and logical tools. Using NVivo, counts were performed across the complete data set consisting of all the responses from all participants. The number of times a category of meaning (function, ritual or myth) was cited was totalled for each individual artefact and across the complete dataset of twenty artefacts. The number of times a category of meaning was cited was also totalled for each individual participant and across the complete dataset of twenty participants. Statistical analysis of means and ANOVA were then performed across the subgroups which were being compared.

Results

Table 1 presents the total number of times a category of meaning occurred across the complete database of twenty artefacts and twenty participants. The numbers provided in Table 1 are the sums obtained by counting how many times the category of meaning was found in the database. Table 1 does not contain an "unsure" column because none of the participants chose that option for any of the artefacts used in the current study.

Table 1: Number of times a category of meaning was selected across the complete set of twenty artefacts

	Category of meaning		
	Function	*Ritual*	*Myth*
Consumers (n=10)	128	112	101
Designers (n=10)	117	76	81
All Participants (n=20)	245	188	182
All Participants Percentage	**39.8%**	**30.6%**	**29.6%**

Table 1 suggests that the category of "function" produced 245 responses which accounted for 39.8% of the total tallied across the complete set of twenty artefacts and twenty participants. Table 1 also suggests that the category of "ritual" produced 188 responses which accounted for 30.6% of the total, while the category

"myth" produced 182 responses for 29.6% of the total. A two-tailed normally distributed ANOVA performed across the dataset (n=20 people) at a 95% confidence level suggested that there were no statistically significant differences between ritual and myth responses, while instead the differences were statistically significant between function and ritual, and between function and myth.

The sum of the responses for the three categories of meaning is 615, which exceeds the value of 400 which is obtained by multiplying the number of artefacts by the number of participants. This confirms that in the current study the participants frequently indicated more than a single category of meaning for a given artefact. In fact, several examples can be identified in the database where a given artefact was considered to possess some amount of each of the three categories of meaning.

Table 1 also suggests that the group of consumers, who were anticipated to have no background in design theory or practice, attributed more meanings than the group of designers. Differences between the two groups were particularly evident in relation to the categories of "ritual" and "myth", suggesting that typical consumers may be considering semiotic and symbolic content which is not immediately apparent or relevant to designers. A two-tailed normally distributed ANOVA performed across the dataset (n=20 people) at a 95% confidence level suggested that statistically significant differences existed between the responses from the consumers and those from the designers for the categories of ritual and myth, but not for the category of function.

Table 2 presents the total number of recorded adjectives for each category of meaning across the complete database of twenty artefacts and twenty participants. Table 2 suggests that the category of "function" produced 1050 adjectives which accounted for 42.5% of the total. Table 2 also suggests that the category of "ritual" produced 688 adjectives which accounted for 27.8% of the total, while the category "myth" produced 732 adjectives for 29.6% of the total. A two-tailed normally distributed ANOVA performed across the dataset (n=20 people) at a 95% confidence level suggested that the differences in the number of adjectives between each of the three categories were statistically significant.

Table 2: Number of adjectives used for each category of meaning across the complete set of twenty artefacts

	Category of meaning		
	Function	*Ritual*	*Myth*
Consumers (n=10)	542	406	402
Designers (n=10)	508	282	330
All Participants (n=20)	1050	688	732
All Participants Percentage	**42.5%**	**27.8%**	**29.6%**

The sum of the adjectives for the three categories of meaning was 2470, which is more than the value of 1845 which is obtained by multiplying the 615 indicated meanings by the 3 adjectives which were requested for each meaning. This suggests that many participants provided more than three adjectives with respect to each of the categories of meaning which they had indicated.

Figure 4 presents an example which illustrates the frequency and nature of the adjectives which were provided by the participants. Figure 4 contains three representative artefacts which might be expected to span part of the spectrum from the purely instrumental to the purely symbolic, chosen from among the twenty which were used in the study. For each of the three artefacts the adjectives are shown under the artefact image, subdivided by the participant group (designer or consumer) and by the category of meaning (function, ritual or myth).

From the examples of Figure 4 it can be noted that the three primary categories of meaning can occur individually or can be co-present to some degree. Further, it can be noted that there was a propensity for a greater number of meanings and a greater number of adjectives among the group of consumers with respect to the group of designers. Among the examples shown in Figure 4 it can be noted that the picture frame, in particular, appeared to be viewed in mostly instrumental terms by the group of designers while the same artefact was assigned a wide range of instrumental and symbolic meanings by the group of consumers.

Discussion

The research hypothesis of the current study was that the previously identified three primary categories of meaning would be commonly encountered in practice, and that statistically significant differences would occur between designers and consumers. The results suggest that all three categories of meaning, i.e. function, ritual and myth, do occur in practice, individually or in co-presence. The results further suggest that statistically significant differences occur between groups of designers and groups of consumers in both the indicated categories of meaning and in the adjectives used to describe artefacts. The results would thus appear to support the research hypothesis.

A point of note in relation to the results is the prevalence of functional attributions. For both the group of designers and the group of consumers, functional meanings were the most frequently attributed and functional adjectives were the most statistically prevalent. The results suggest a greater facility, or at least a greater propensity, for instrumental judgements.

Nevertheless, as Krippendorff (2007) and Siefkes (2012) have advocated, the functional meanings are not the only ones which people associate with artefacts. The meaning attributions and the adjectives collected in the current study suggest that the group of consumers, in particular, viewed many of the artefacts in a hedonic manner. Adjectives which were frequently encountered included such examples as “attractive”, “desirable”, “fun” and “exciting”. The current results provide empirical evidence in support of those who advocate “The Semantic Turn”, i.e. the paradigm shift from an emphasis on how artefacts should function to what they should mean (Krippendorff, 2007). The current results also provide empirical evidence in support of those who advocate “Human Centred Design”, i.e. the design process involving of a series of questions and answers which span the spectrum from the physical nature of people’s interaction with the product, system or service to the metaphysical (Giacomin, 2014).

A finding of the current small exploratory study was that some divergences in meaning may be occurring between designers and consumers. For most of the artefacts used in the study there were a greater number of ritual and myth meanings indicated by the group of consumers than by the group of designers. The situation is understandable given the difficulties in imagining all the possible semiotic and hedonic meanings which an artefact might take on for an ethnographically diverse public. Nevertheless, the current results seem to highlight the need for carefully executed ethnographic and user testing activities.

The large number of meaning attributions and the large number of meaning adjectives found in the current study would seem to suggest the potential usefulness of the framework suggested by Giacomin (2017) for distinguishing between meanings when organising the design of artefacts. Further research is therefore underway to extend the existing study to larger random samples of artefacts from selected commercial sectors.

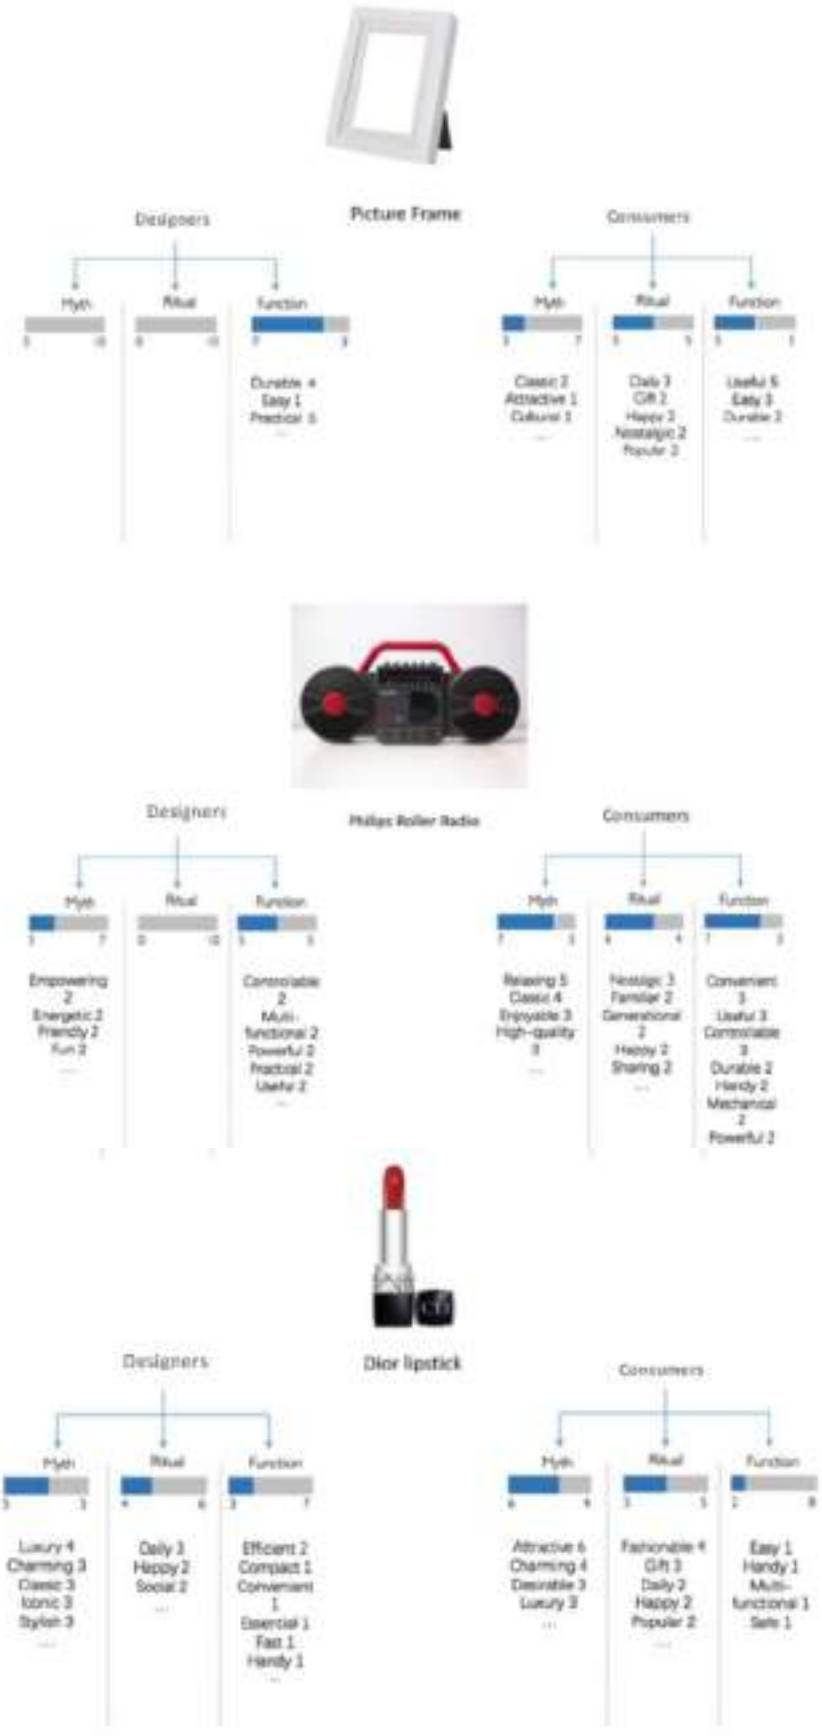

Figure 4: Adjectives provided by the designers and the consumers for three representative artefacts

Conclusions

Previous research has suggested three primary categories of meaning which designers should consider during their design processes, i.e. function, ritual and myth, which cover a spectrum from the purely instrumental to the purely symbolic. The research hypothesis of the current study was that the previously identified three primary categories of meaning would be commonly encountered in practice, and that statistically significant differences would occur between designers and consumers.

A semi-structured questionnaire was deployed with ten designers and with ten consumers using a set of twenty photographs of designed artefacts. The results suggested that all three categories of meaning, i.e. function, ritual and myth, could occur individually or could be co-present to some degree. The results further suggested that statistically significant differences occurred between the group of designers and the group of consumers in the indicated category of meaning and in the adjectives used to describe the artefacts. The results would thus appear to support the research hypothesis.

A point of note in relation to the results of the current study is the prevalence of functional attributions. For both the group of designers and the group of consumers, functional meanings were the most frequently attributed and functional adjectives were the most statistically prevalent. The results suggest a greater facility, or at least a greater propensity, for instrumental judgements.

A finding of the current small exploratory study is that some divergences in meaning may be occurring between designers and consumers. For most of the artefacts there were a greater number of ritual and myth meanings indicated by the group of consumers than by the group of designers. The current results thus seem to highlight the need for carefully executed ethnographic and user testing activities.

This paper tackles the topic of meaning-driven innovation from a Product Design perspective. It focuses on the design of Smart Connected Products: internet-enabled phygital products that blend hardware and software. This category of products represents a positive field of exploration for meaning-driven innovation. The paper highlights three kinds of meaning that are relevant for Smart Connected Products: the meaningful identity of the object as product category, the meaning of the product in relation to its shape and functionality, and in relation to a phygital ecosystem. The paper reflects on the methods that can support designers in the development of meaningful smart products and presents the "Mapping the IoT" Toolkit, a downloadable tool that guides in specific activities aimed at framing the product's meaning. Tests with the Toolkit proved the effectiveness of using cards with critical questions as a way to deepen design concepts and reach a common, meaningful vision.

Keywords: Meaning-driven innovation, Product Design, Smart Connected Products, IoT, Design Tool

Types of innovation and meaning driven innovation

There are two main kinds of innovation that concerns products: incremental and radical.

Run-of-the-mill, incremental innovations represent a progressive improvement of certain parameters of the product. Norman and Verganti (2014) compare it to a "hill climbing" activity, since it tries to modify iteratively few product's characteristics to achieve newer, better versions, and gain more quality over time. It is not known in advance where is the peak of this hill to be climbed. The techniques of Human Centered Design, with fast iterative cycles of research, prototyping, and user testing, are proved to facilitate in the path towards incremental innovation.

Radical innovation instead, aims not to climb the same hill, but to find a new one with a higher potential. This kind of innovation has been labeled in different ways such as radical, discontinuous, generational or breakthrough innovation. Interest in radical innovation originated with Schumpeter (1934) and was seen as a way to challenge the power of monopolists.

Dahlin and Behrens (2005) defined three conditions to allow ex-ante identification of potential radical innovation and ex post evaluation of its impact. To be defined as radical, an invention must be novel and unique, hence dissimilar from prior inventions, and finally, it must be adopted and influence the content of future inventions: this transforms it in a successful change agent for the industry.

Radical innovation can be driven by technological epiphanies, that open up to new possibilities and promote different visions, and by deliberate changes in the meaning of product (Verganti, 2017; Norman & Verganti, 2014).

For example, when unspoken dynamics in sociocultural models arise, new meanings can re-align the industry to people's aspirations. This may be achieved by addressing new performance needs with attributes that are currently not valued by existing customers (Bowler & Christensen 1995): a cited example is the Nintendo Wii, that radically innovated the market of gaming consoles because it focused on immersivity instead of on realistic graphic quality, the performance that was more valued by previous consoles.

For Norman & Verganti (2014), radical innovation is seen as comparable to technology-push innovation: to reach it, it is crucial to develop a strong internal vision, rather than applying the iterative HCI methods.

In the next section the concepts of meaning and meaning driven innovation are deepened.

Meaning and Meaning-driven Innovation

In a simple way, it can be said that the "meaning" of a product is the "reason why" behind it, "the profound psychological and cultural reasons people use a product" (Verganti, 2011, p.384).

Going deeper into the nature of meaning, it has been widely accepted that is composed by a "bundle of components" that include both objective and subjective elements, such as experiences, feelings and images.

Meanings can be categorized in three types: lexical meaning, philosophical and psychological (Friedman and Lessig, 1986). Psycological meanings in particular are those focusing on a person's subjective perception and affective reactions (Szalay and Deese, 1978).

The meanings of a given object can be characterized by three dimensions: tangibility, emotionality and commonality. These dimensions have been discussed for example by Friedman (1986) and Hirschman (1980).

Tangibility concerns whether the attribute at the basis of meaning is tangible, in the sense that is objective and verifiable through the senses, instead of being subjective. It reflects if the meaning is located in the object itself or in the mind of the user.

The emotional side of product meaning is an important component of the meaning of an object, that cannot be detached from the objective side. Emotional responses to products can range from low to high intensity, going from simple affective reactions to true emotional experiences such as enjoyment and excitement.

The third dimension of meaning is that of commonality, that identifies the degree to which meaning is shared by members of the culture, or if it has a more individualized and personal character. It is linked to the source that is more responsible of the assignment of meaning to the object. For example, it is a cultural source if the meaning is assigned by advertising and shared media opinion. It is a personal source if meaning is created by the user through time, experience and interaction, such as an object received as a gift from a dear friend, your most comfortable pair of shoes, or your favourite toy when you were a child.

Different researchers focused on framing and categorizing diverse kind of meanings in order to deliver meaningful customer experiences. For example, Fournier (1991) defines eight categories of customer meanings: objects of utility, action, appreciation, transition, childhood, ritual enhancement, personaly identity, and position and role. While Diller et al. (2005) suggest fifteen categories of meaning: accomplishment, beauty, creation, community, duty, enlightenment, freedom, harmony, justice, oneness, redemption, security, truth, validation and wonder.

Product meanings have many connotations, depending on which theoretical perspective is hold, for example Affordance Theory, Product Semantics, Product Emotions. Thanks to the highly sociological nature of meanings, they can be shaped and in a sort of way controlled by designers (Giacomin, 2017).

This is a topic of study in the field of product semantics: while semiotics is the study of signs, semantics is the study of their meaning, and applied to design, it concerns how designers encode meaning into their products to communicate with the user.

Design is seen as a form of communication (Krippendorff & Butter, 1984) in which the symbolic qualities of products are the messages to the user. The meaning of a product must be imagined connected from its contexts of use and in relation to the user's cognitive models (Krippendorff, 1989).

Meanings can be attributed to artefacts through a process of semantization. Siefkes (2012) proposes seven principles of semantization: function, style, iconic associations, individual experiences, cultural allusions, connection to social groups, and connection to specific contexts.

Giacomin instead proposes a framework diagram of design for meaning that identifies if an artefact should adhere to an existing societial stereotype of if there is the possibility to define a new function, ritual or myth. He calls this "meaningfication" and defines it as

> *the use of data, ethnography, real fictions and co-creation for the purpose of designing artefacts based on new meanings that emerge from the interconnection of evolving patterns of technology, experience, personal identity, societal identity, value assignation and consumption.*

The next section applies the topic of meaning to the design of smart products.

Design for Meaning of Smart Connected Products

In this paper the term "design" is used referring to the industrial design practice:

> *Design is a strategic-problem solving process able to drive innovation through innnovative products, systems, services, and experiences (World Design Organization, 2015)*

Design is an activity of meaning creation. As said by Krippendorff, "Design is making sense of things".

The term "Smart Connected Products" identifies tangible products with computational capabilities, conneced to the Internet and - possibly - to other objects. Their characteristic feature is being cyber-physical (or "phygital"): it means having both a tangible/physical form and a digital/intangible part. This digital counterpart is what Greenfield (2006) calls "Informational shadow" and what Semmelhack (2013) defines as "Digital Avatar", and is one of the two states in wich the product exists.

Smart connected products are *IoT products* because they are part of the Internet of Things, "a world-wide network of interconnected objects uniquely addressable, based on standard communication protocols" (INFSO D4 & RFID INFSO G.2, 2008), a network "Available anywhere, anytime, by anything and anyone (ITU, 2005).

This paper discusses why smart connected products are an eccellent field of application and exploration for meaning-driven innovation. The insights presented derive from the authors' academic and professional experience. In particular, the analysis of case studies of smart connected products (Vitali, 2015; Arquilla & Vitali, 2016) led to the definition of a Toolkit to support designers and their teams in the development of IoT products (Vitali, Rognoli & Arquilla, 2016; Vitali & Arquilla, 2018). The Toolkit is later described as a case study in this paper.

There are three kinds of meanings that are specifically relevant in the design of smart connected products.

- The meaningful identity of the object as product category
- The meaning of the product in relation to its shape and functionality
- The meaning of the product in relation to a phygital ecosystem

1. The meaningful identity of the object as product category

The suffix "Smart" is often abused to call attention to those products with relevant technological features, or that try to solve a specific problem in an intelligent way.

There is no univocal definition of what a "smart product" is (Gutierrez, et al, 2013), but the term is used to identify objects able to gather and process data (Kiritsis, 2011), with an autonomous and adaptive behavior (Maass and S. Janzen, 2007) providing a natural product-to-human interaction (Sabou et al, 2009) and active communication with users, environments or other products and systems (Venta, 2007).

Smart products suffer from identity crisis. They are not strongly culturally semantized. Their smartness is often translated in the ability of being controlled by a smartphone. This label of being "products with an app" links to meanings that don't communicate efficiently their worth and innovative elements: they are oftenseen as tech gadgets. What smart connected products need, is a well-designed identity and specific value proposition. "Focused, divergent and with a compelling tagline", like an effective blue ocean strategy (Kim and Mauborgne, 2005).

Analyzing the consumer electronics market, three macro-categories of smart products emerge:

1. In the first case, the object is the technological, connected version of an analog product. For example, a smart water bottle that tracks how much water is drunk during the day, and that sets reminders for the user. Adding connectivity and technological features for this category of products can be seen as a radical innovation.
2. In the second case, the object is smart because it is the "smarter" version of an electronic/digital product. For example, an internet-connected weight scale that lets users record their weight in time. Adding connectivity for this category of products can be seen as an incremental innovation of its technological features.
3. In the third case, the object is smart because it combines new and existing functions, resulting in a new product category in the market. This kind of intervention tries to satisfy user needs in a radical new way. An example is the Roomba vacuum cleaner, that offers a new vision for home cleaning, combining initially unrelated topics of "home robots" and "vacuum cleaners".

The semantic dimension is a powerful source of competitive advantage (Battistella, Biotto, De Toni, 2012).

For all three categories, there is a need of semantization, or what Giacomin interprets as meaningfication: *"customers are implicitly invited o think differently about the opportunities and value propositions which are on offer".* (Giacomin, 2017). Innovative aspects of the products must be framed with new meanings.

In the first and second categories of smart products, there is also the need to clarify if the meanings of these smart products still align with the pre-existing meanings linked to their unconnected counterparts.

A successful example of this is represented by Nest, a connected thermostat, that through technology was able to shift the identity/meaning of the thermostat from a static, passive, and hard to personalize element of the house, towards an active and reactive element, that automatically answers to user's presence and habits. This shift from the pre-existing values led to a new vision for the market of thermostats.

Another example concerns the creation of new visions in the market of Smart TVs. Samsung reflects on the role in the room of large, wall-mounted TVs, trying to suggest new meanings. Samsung proposes "The Frame" a TV that when switched off becomes a personal piece of art displaying selected high-resolution images from a curated art gallery. In this way the TV acquires a meaning in the room, even when is not switched on. Another innovation is the "Samsung Ambient Mode", that lets the TV screen disappear, simulating the texture of the wall on which it is mounted. Complementarily, LG presented at CES 2019 "Signature R" a rollable OLED TV, that lets the screen physically appear only when needed.

In these examples the new meanings and visions redefine the architectural role of the TV, trying to anticipate future user whishes.

Figure 1: From left to right: Samsung "The Frame", Samsung "Ambient Mode", LG "Signature R"

The communication of the new values is crucial to redefines the smart product's identity and its position in the marketplace.

An exemplar case study of meaningful communication is the Apple Watch video series "Real Stories" (Apple, 2018, link in bibliography) that documents stories in which the functions of the smartwatch were able to deeply impact its users, for example by saving their life thanks to the heartbeat alarm notification, by calling an

ambulance after a car accident, by calling for help for being rescued when lost at sea. With the interviews in the video, the smartwatch shows that it can be a meaningful device for health and safety, and not only a product aimed at sport athletes.

2. The meaning of the product in relation to its shape and functionality

The second level of meaning concerns the meaning in relation to the product's shape and functionality. This kind of meaning is traditionally addressed by the field of Product Semantics.

A short digression about analogic artifacts highlights what electronic products lack.

The shape of analogic artifacts is expressive. Through its affordance, the object "offers what it does because of what it is" (Gibson, 1977) and communicates how it could be used (Maier, & Fadel, 2009), and the action through which interaction takes place (You & Chen, 2007). Through shape and materials, the artifact communicates signs and messages that will be interpreted by the user in a subjective way. A successful design manages to communicate effectively and consistently to the receivers what the designer wanted to express. Therefore, the ability of the designer is to make the design comprehensible to the receiver/user by presenting qualities that will cause and fulfill certain expectations (Kazmierczak, 2003).

In electronic products, the link between shape and function is often lost. Electronic products are able to perform multiple functions which, however, are not evident, traceable or geometrically comprehensible in the shape of the artifact. Often this leads to anonymous shapes that do not communicate or invite interaction. Additionally, many smart products can't even be manipulated, since interaction takes place through external interfaces and via smartphone.

These aspects are the first three of what Krippendorff and Butter (1984) define as the four semantic infelicities in design: the product is undistinguishable or unidentifiable by the user, the product does not promote the correct way to manipulate it, it lacks transparency and it is not clear how to use it.

Therefore, a designer dealing with smart connected products should try to reduce these infelicities. One possible strategy is to design a shape that highlights and expresses the way of interaction with the product. Another strategy is to use metaphors to bring the meaning of the product closer to its primary function, and make it more comprehensible by aligning with the mental models of the user.

For example: what shape should a wireless router have? What is its archetype? Technically, a router is an antenna that transmits a signal, that is why many routers have visible antennas, for a better perceived performance. Instead, the wi-fi router "Asus Blue Cave" has a characteristic shape with a circular hole, marked by a blue finishing (Fig 2). This product doesn't show any antenna, and its shape is more similar to an air purifier. The shape uses the metaphor of "airflow" to relate to the flowing of data. In this way the shape is more meaningful, according to the product's function.

Figure 2: From left to right: Asus "Blue cave" wi-fi router and three smart speakers/home assistants. Amazon Echo 2nd gen. with Alexa, Apple HomePod with Siri, Google Home with Google Assistant.

Following the same perspective, there is also the stimulating challenge to reflect on new metaphors and formal archetypes for emerging product categories such as the home assistants (Amazon Echo, Apple HomePod, Google home…), that currently materialize as cilindrical smart speakers.

3. The meaning of the product in relation to a phygital ecosystem

Connected objects can be categorized according to their ability to process information, functionalities, and degree of interactivitiy. Rowland et al (2015) for example distinguish between multipurpose computer devices with powerful processing capabilities and rich interaction (e.g. smartphones, smart TV, game consoles ...), embedded devices specialized to answer to specific needs with less processing power (e.g. smart thermostat, smart weight scale, smart bottle …), and connected sensors in which the gathered data is more important than the physical interaction with the product (e.g. flood sensor, air quality sensor …).

Due to their phygital nature, connected products can be interacted with in a tangible and digital way. This blurs the line between product and service (Breschi et al, 2018). Analog products are “finished” once manufactured and sold, but connectivity allows the physical connected products to become avatars, physical stand-ins, for services.

Due to their dual nature, connected products follow more the dynamic logic of apps and software, rather than the static life of physical matter and hardware. “Design is never done” quotes Google, and so are IoT products.

The connected product and its functions need to be framed in an ecosystem. The object is not isolated but social, and in relationship with physical and virtual things, data, and processes. The ability to position a smart product in a compatible ecosystem is crucial: ecosystems are “the competitive unit in the battle to establish leadership in IoT” (Agrò, 2018). Objects can be augmented by services, or be included in the customer experience offered by a service provider. The more connections it has, the more the product could be considered as valueable and meaningful.

From the point of view of product design and UX design, this implies the need to design and manage a multiplicity of touchpoints, both physical and digital (Rowland et al, 2015). Therefore, when designing the product is important to define a balance between the tangible and digital aspects, in relation with its functions, and with the user’s expectations. This will deeply impact the meaning of the artifact. For example, the choice of making a key feature of the product only accessible through an app rather than with physical interaction will create a different user experience. In many cases, such as for connected sensors, the object can’t be interacted with directly and its meaning depends on its ability to provide a meaningful interaction with data.

At a more technical level and linked to the intangible, digital part of the product, few considerations need to be made regarding its ability to "work" even in the absence of an internet connection. The object may be internet-dependant to perform its primary function (e.g if it requires cloud connection to operate), or may perform part of its functions even in the absence of connection. This kind of technical choices can also have a great impact on the user experience.

> *The user experience of all these connected objects is simultaneously the Achilles’ heel and the possible golden key for what makes IoT devices like wearables meaningful to people (Adobe, 2017)*

Practical case study: designing meaningful connected products with the “Mapping the IoT Toolkit”

Reflecting on the meaning of Smart connected products with the “Mapping the IoT” Toolkit

Designing smart connected product is a complex task that requires effort from multidisciplinary teams. There are multiple aspects that designers need to be accounted for; in particular the design of the service offered by the product, the physical and digital interaction touchpoints, and the architecture of the product with its components.

The initial phase of the design process is crucial to frame the problem that the product is addressing, identifying possible user needs/desires, and envisioning new meanings, trying to go beyond superficial solutions, and to outline a coherent vision. This phase can also be called metadesign (Giaccardi & Fischer, 2006). The aim of a metadesign process is to define the reason why of the project from the point of views of the user, of the market, and of the company itself. It is a phase of meaning creation.

The “Mapping the IoT” Toolkit (shortened as “MTIoT” Toolkit) aims at giving support during the design and metadesign process of smart connected products, helping multidisciplinary teams to discuss and work

together, framing the problem, and creating a common vision. It is mainly intended for designers, but it can be used by whoever wants to approach the design of IoT products. The Toolkit is distributed with a Creative Commons license and is free to download. The Toolkit helps designers and teams during 4 main phases of the design process, described by 4 activity guides. The activities supported by the guides are:

- "I want to start a new project" helps setting the research phase at the beginning of a new design project, identifying sources and selecting case studies
- "I want to analyze smart products" introduces a guided research exercise, exploring and comparing case studies
- "I want to brainstorm ideas" describes brainstorming exercises with the MTIoT Deck
- "I want to make my concept better" offers an exercise to focus on the concept and its meaning

All activities exploit a set of cards - the "Mapping the IoT" Deck - and may be used in conjunction with fillable canvases.

The cards of the deck and are divided in 7 different topics: user & context, design, technology, interaction, experience, strategy, meaning. Cards are two sided and provide questions: the horizontal side of the card introduces a topic with one main question, while the vertical side deepens it with specific "what if" questions. Each topic is identified by a colour and a letter on the bottom of the card (Figure.3).

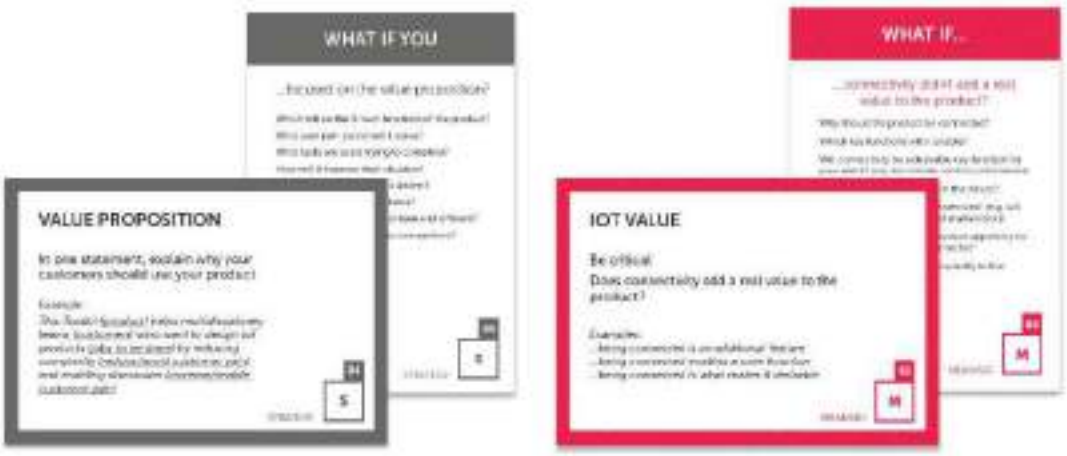

Figure 3: Example of a strategy card and of a meaning card of the "Mapping the IoT" Deck

The cards are a knowledge repository to remember many of the features that need to be designed in complex smart products. They can be used as an input for reflection, and as diverging inspiration. The questions are an input to discuss the idea and the meaning of the product, therefore the cards have more impact at the beginning of the design process, between problem framing and concept definition. (Define, Develop, Deliver in Figure 4) (Vitali & Arquilla, 2018).

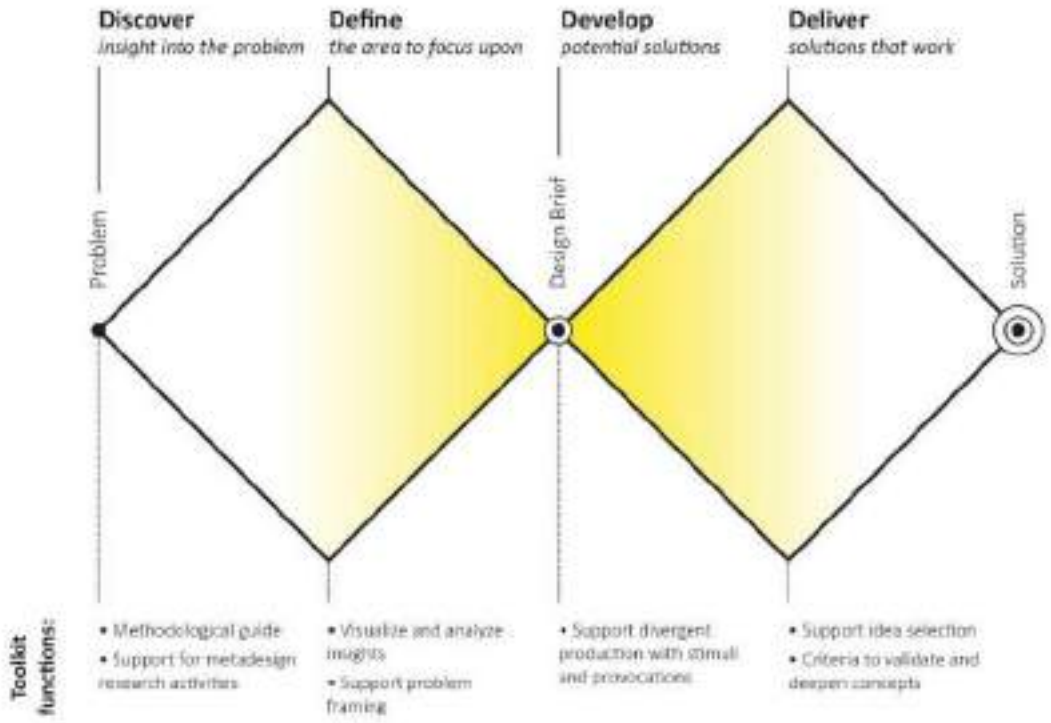

Figure 4: The "Mapping the IoT" Toolkit functions positioned in relation to the double diamond representation of the design process.

The subdivision of the deck in topics pushes the team to concentrate on specific aspects of the product.

Group activities, facilitated by the Toolkit, are aimed at defining a clear vision for the smart product definition.

The elements of the MTIoT Toolkit that mostly focus on framing the meaning of the project are three: Meaning cards, Strategy cards, and the Activity guide "I want to make my concept better".

1. "Meaning" cards (the cards with fuchsia edges in Fig.3) propose critical questions that want to challenge the designer in observing the concept in an objective way, evaluating strengths and weaknesses.
2. "Strategy" cards (with grey edges in Fig.3) reflect on the uniqueness and market positioning of the concept, with a focus on its business model and competitor analysis. They want to support the development of the product's value proposition. These help to frame the meaning of the product for the market.
3. The Activity guide "I want to make my concept better" introduces an activity to be done in conjunction with the deck cards and the "sum up your smart-product idea" canvas (Fig.5). The canvas is split in 7 areas, that follow the cards'subdivision. It is printed and used to summarize the initial design concept of a smart product. Then the cards of the deck are used to discuss and deepen the initial idea with the team, by asking and answering questions. The exercises "forces" the designer to frame the idea and its meaning for the user/context, and for the market.

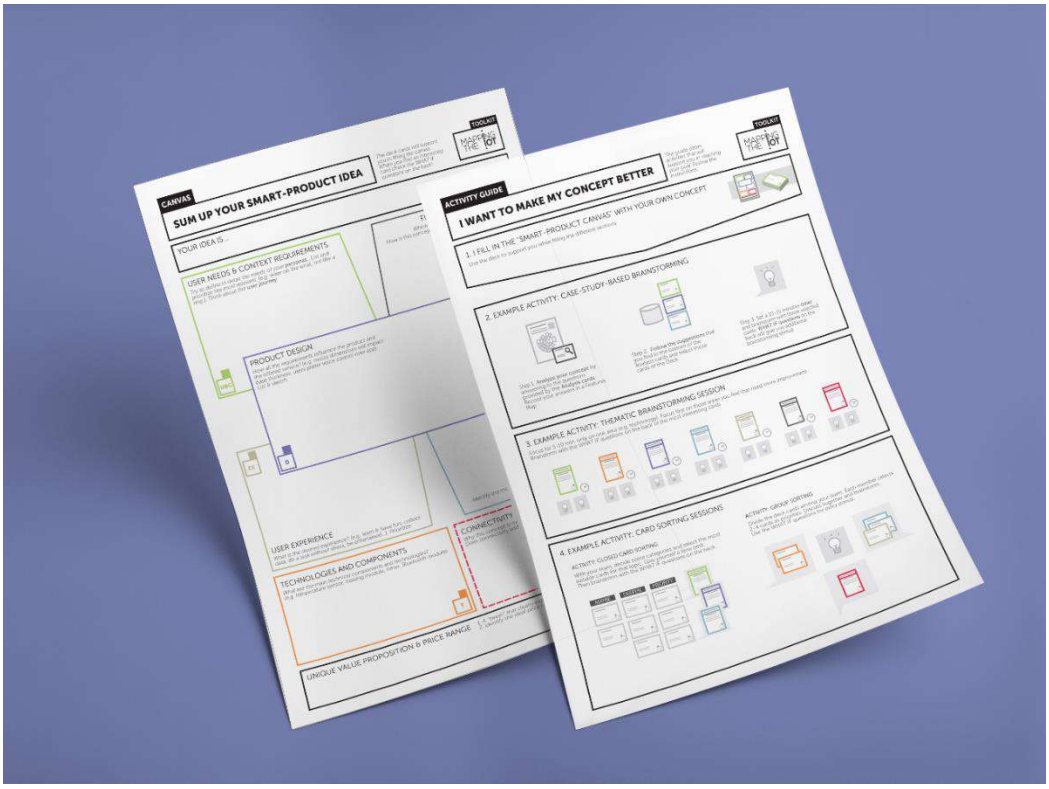

Figure 5: The Activity guide "I want to make my concept better" (on the right) describes an activity that uses the MTIoT deck cards and the "Sum up your smart-product idea" canvas (on the left)

The Toolkit has been tested and presented in different occasions, with academic peers, professionals and design students and is being formalized as a teaching support at Politecnico di Milano.

Among the recent tests and presentations:

- Academically: test at Miteinander at Chemnitz University of Technology 2018, DRS conference 2018, NordiCHI conference 2017
- Professionally: "Product of Things 2018" in Tel Aviv, "IoT Connected design event 2018" by IoT Italy in Treviso, "Workshop Explore Innovation and design trends 2017" in Milan.

Test A and Test B following the "I want to make my concept better" Activity guide

The MTIoT Toolkit is a kit that evolves constantly, following user insights: like smart connected products, it is upgradeable and is currently at its 4th version. Recent structured tests focused specifically on the dimension of meaning generation.

This paper describes two Toolkit tests that involved students at their second year of Master's Degree in "Integrated Product Design" and in "Design and Engineering" at Politecnico di Milano Design School. In both cases students were designing smart products for their final course (Final Synthesis Studio) in collaboration with different companies (Braun, Midea, Enovia-Yape).

Test A involved students of the Master's course in Integrated Product Design. The aim of the course, called "Smart/Design Lab." was to develop innovative appliances that reflected on the topics of food, drinks, clothes care, and beyond-the-screen interaction.

27 groups of students tested their own initial idea by following the Toolkit activity "I want to make my concept better". They summarized their starting concept on the "sum-up your smart product idea" canvas, then used the cards to analyze and deepen their idea according to the areas proposed by the cards (user & context, design, technology, interaction, experience, strategy, meaning).

Cards were used as a discussion tool inside the team, to identify the weaknesses and opportunities of their concept, to make choices and give it a stronger identity. The activity with the Toolkit was done without a

facilitator, but the course staff was available for clarifications. The MTIoT Toolkit was used like a cultural probe: groups could discuss freely, and they were asked to self-document their process. The day after the activity each group received a survey aimed to evaluate in a qualitative way what was the impact of the Toolkit on the project.

The limits of this test were:

- All groups were working on different projects, so the starting point for the use of the Toolkit wasn't exactly equal: some groups started with a more advanced concept than others.
- The activity in class lasted an afternoon, but the Toolkit was also used independently by some groups.
- The survey data were collected anonymously, unrelated to the individual group projects. Data are qualitative and represent the subjective point of view of the participants of the test.

Test B involved 32 students of the Master's course in "Design and Engineering". In this case all 9 groups of students started from the same brief: redesign an existing self-driving robot drone, by finding new use cases, meanings, identities.

The 9 groups of test B performed the same activity proposed to test A group: work with the team and summarize the starting idea in the "sum-up your smart product idea" canvas, then use the card to discuss together. In this case the activity lasted an afternoon, and at the end of the day the students received the survey.

The limits of this test concern the fact that the Toolkit was used in a more advanced moment of the design process. Few groups already decided some formal/functional elements of the product and were beginning the engineering process. In this test, the survey was administered individually and not filled as a group.

Test results

As mentioned before, the survey was anonymous and was aimed at probing the perceived impact of the Toolkit during the design of smart products. The survey employed closed and open questions. Closed statements were rated through a linkert scale ranging from 1 (strong disagree) to 5 (strong agree). In total, 60 surveys were collected.

The Mapping the IoT Toolkit received a positive response. In particular, the cards were appreciated, and many participants stated that they would use them again for their project. "Did you like the Toolkit approach" received an average response of 4.1 and "Would you use the cards again" an average of 4.0.

> *"The cards are a great medium; the questions are really well thought of and very helpful"*

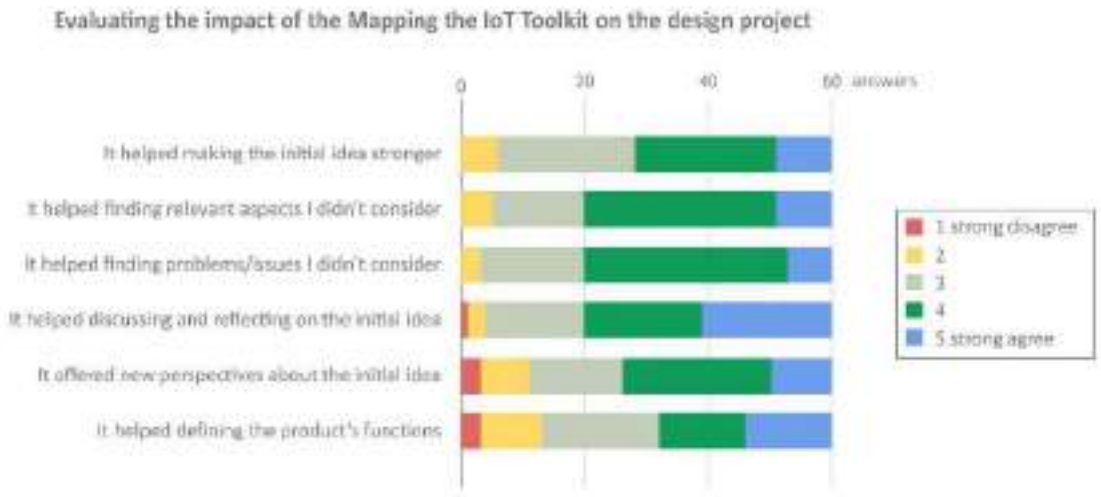

Figure 6: Summary of survey responses, evaluating the impact of the Mapping the IoT Toolkit on the design project

The MTIoT Toolkit was mostly appreciated as a support for discussing and reflecting on the concept with the design team (avg. rate 3.9). The tangible cards facilitated the development of personal visions that through discussion merged in a single common vision. They assisted in clarifying the purpose and direction of the product, while maintaining a ludic approach: for some participants, the whole exercise was seen as a game.

The critical perspective offered by the cards was aknowledged. The questions were a continuous push to deepen and inquire the concept. They were recognized as useful to identify new elements of the project, and to spot possible issues. "It helped finding relevant aspects I didn't consider" and "It helped finding problems and issues I didn't consider" were both rated 3.7 in average. "*It is like a continuous review of the project*", said one participant.

> *"Useful for group discussion. It let space for everyone to express their thoughts and allowed to think about aspects that we hadn't deepened - such as problems concerning technical-technological components and feasibility"*

The MTIoT Toolkit helped also students that weren't designing a technological product.

> *"We used it to improve our project, that wasn't a smart product, but still some cards were very useful for the discussion"*

Questions were also appreciated as source of inspiration (avg. rate 3.6) during the brainstorming phase. *"Questions can stimulate and enrich, steering the brainstorming"* commented a partecipant.

The tangible aspect of the Toolkit was seen as a positive feature, liked by 30 participants out of 60 (50%): 10 participants said that they would prefer a digital version, while 19 said that they would use both versions.

> *"The physical aspect is very important. Touching the cards and exchanging them through the group is very useful"*

In some cases, the Toolkit was able to make the initial idea better/stronger (average rate 3.5 out of 5) and helped to define the product's functions (avg. 3,4). Overall the cards were considered useful (avg. 3.8), and the canvas too (avg. 3.7). Participants considered positive the methological aspect of the Toolkit and the exercises guiding the design process of smart products.

> *"I would use it again. I think it is a tool for students, professionals and for whoever wants to design following a guide during the different phases"*

Although it was decided to test the toolkit with groups that already had a concept, the tool was considered relevant to be used during the initial phases of the design process, when there is more freedom of action on the project.

> *"It was very useful, I wish we had it presented before in the concept ideation phase" said a participant in test A. "We used it in an advanced stage of the project, we should have used it also before" said a participant of test B*

Some negative aspects of the exercise with the Toolkit were:

- The lenght of the exercise: it can get quite long when a group deepens too many cards
- Some questions in the cards were perceived as repetitive
- The tool didn't help in defining the product's shape (average rate 2.3 out of 5), but it was useful to design the interaction.

Conclusions

To summarize: the change in user's lifestyles, new sociocultural models and technologies are drivers of meaning-driven innovation. They lead to the demand of different meanings, a divergent "why" for products to exist. This is particularly true for smart connected products, that are technological objects with a physical and digital component (hardware and software).

This paper outlines three different kind of meanings that are relevant in the design of smart connected products:

1. The meaningful identity of the object as product category: smart products are not strongly culturally semantized. Designing a smart version of an existing product (analogic, or already electronic), or designing a new artifact that results in a new product on the market (e.g. the Roomba vacuum cleaner) requires an alignment with user's lifestyles. Connected products should have a strong identity that differentiates them from -or relates them to- the pre-existing meanings of their unconnected, "less smart" counterparts. Their role in the market needs to be clear, otherwise they will be labeled as smartphone accessories, "products with apps".
2. The meaning of the product in relation to its shape and functionality. For electronic products the link between shape and function is often lost: the functions can't be perceived, nor are geometrically comprehensible. Designers have the opportunity to reduce semantic infelicities by producing shapes that express the way of interaction, and that use metaphors to bring the meaning of the product closer to its primary function.
3. The meaning of the product in relation to a phygital ecosystem. The phygital nature of IoT products blurs the boundaries between products and services, and leads to the need to design multiple touchpoints, both tangible and digital. IoT products should be social, in relationship with a compatible ecosystem of physical and virtual things, data, and processes. It is important to frame the role and meaning of the different phygital touchpoints and features, in relation to the user's expectations, while being aware of technical limitations.

The paper explored the notion that to achieve meaning-driven innovation is important to start from a strong vision coming from the inside-out of the company, rather than relying on HCD methods (Norman & Verganti, 2014). A meaningful personal vision can be reached through critical thinking, discussion, and with a drive to deepen and challenge the design aspects of the product.

The tests with the "Mapping the IoT" Toolkit saw that in action. Two classes of Master's degree students at the Design School of Politecnico di Milano were challenged in the design/redesign of smart products. They used the "sum up your smart-product idea" canvas and the "Mapping the IoT card deck" in a group activity with their teams, to summarize and deepen their initial concepts.

The results emerging from the two described tests are:

1. It was appreciated to have a support for critical discussion with the team, as it helped to develop personal visions and to achieve a common one together.
2. The questions on the cards were a constant challenge for the initial idea. By answering and discussing, the concept was deepended, especially in terms of technical/technological aspects, and interaction.
3. Tangible cards were acknowledged as a good tool for teamwork, with a ludic approach.
4. Participants considered positive the methological aspect of the Toolkit and the exercises guiding the design process of smart products.

Therefore, the tests positively evaluated the use of question-cards to challenge the vision of the product and create a shared, more meaningful one.

> *The point is not that they miss ideas. they are overwhelmed by ideas. But they keep going in the same direction" (Verganti, 2007)*

The Toolkit is published with a Commons License, and freely downloadable on its website (mappingtheiot.polimi.it). It wants to facilitate the design process of smart connected products, helping to design a meaningful product/service offer. It has been tested and presented in many occasions, both academically, and with companies and professionals.

Now, the aim is to make the "Mapping the IoT" Toolkit grow: the team is open to collaboration to make it evolve. The discipline of product design can positively contribute to the area of smart products. Complex connected products require a renewed culture that takes elements from different design fields, such as product design, interaction design and service design, to generate new and coherent meaning ecosystems for positive and evolved user experiences.

With the rise of artificial intelligence (AI) in the past decade, AI has become known in everyday products and services. One of its application forms is that of AI assistants, such as voice assistants and chatbots. While new types of customer service channels have been introduced through these assistants, until now, the intelligence of AI has mostly resided in the backend systems of services. Studying a service design process and practices focussing on AI-enabled services, the present research draws on a multi-method approach involving seven expert interviews and five use cases on AI assistant projects in industry. The authors evaluate the datasets through coding cycles aiming at identifying the shifts AI brings to service design. The results present and discuss the emerging fields of change in service design, namely, the application of AI, service design process with AI and role of the service designer in the creation of AI-enabled services.

Keywords: Service design, artificial intelligence, design process, role of a designer

Introduction

This article discusses the current and even hyped topic of artificial intelligence (AI) in the context of service design. It introduces the emerging fields of change in service design, namely, the application of AI, service design process with AI and role of the service designer in the creation of AI-enabled services. The paper discusses not only what AI enables for the front and back ends of service delivery but also the practical role of the service designer and service design process in the context of AI-enabled services.

Regardless of the rather long history of AI (Steels, 2007), its application in the fields of service design, design management and design research is still in the early stages. The full potential and implications of AI in service content and delivery may not yet have been fully discovered. The development indicates that AI is taking a role as an orchestrator for personalised service content (Reavie, 2018), and it is becoming an enabler for value creation in digital service channels (Vargo & Akaka, 2012). While user interactions are shifting away from single interfaces towards the widening range of possible user touchpoints, the variety of provided service functions is increasing the complexity of service systems. Services are increasingly built through networks and various channels. Thus, the interactions between humans and large-scale systems are increasing and need to be inquired further (Kile, 2013).

In the 1990s, Krippendorff (1997) already introduced design principles for the context of artificial artefacts that are produced and consumed in a multi-user context supported by virtual environments. In this work, he

emphasises the interactivity of artefacts and suggests design becoming 'language-like'. With the shift towards the application of natural language processing (NLP) tools, services and products go beyond the conceptual and semiotic language that Krippendorf (1997) refers to. Here, machine-generated spoken and written language becomes the means of providing content and creating service value for users. The *Design in Tech Report 2018* (Maeda, 2018) also suggests that conversational design is becoming one of the key areas in computational design. The Institute of Electrical and Electronics Engineers (IEEE, Global Initiative on Ethics of Autonomous and Intelligent Systems, 2017) also points out the relevance of the design, distribution and usage of AI-enabled systems in their standard for 'ethically aligned design' for autonomous and intelligent systems.

Through its application in everyday products and services, the visibility and awareness of AI have grown in society in recent years (Kile, 2013). Although AI often resides in the invisible backend systems, as one category of AI-enabled services, AI assistants are visible for users as a service channel. Divided into the two modalities of text-based interaction and voice interaction, AI assistants can take the forms, for example, of chatbots and voice assistants like Apple's Siri, Microsoft's Cortana, Amazon's Alexa or Google Assistant. In addition to the rise of AI-enabled interfaces in the consumer market, the topic of AI assistants has been increasingly addressed in academic research in different fields.

Recently, the research discourse focussed on AI assistants has shifted from the technical feasibility (Chen, Yu, & Fong, 2018; Yan & Zhao, 2018) and architecture (Hauswald et al., 2016) towards more value-oriented topics. While AI assistants introduce a shift of service interactions from graphical user interfaces (UIs) towards conversational interactions (Allen et al., 2001) and natural language, the research investigates the realm of assistant performance as it is connected to the real customer needs (Brandtzaeg & Følstad, 2018). To learn more about the acceptance of the new interaction form, research has been conducted to elucidate how AI assistants are perceived by human beings (Harris, 2004; Loi, 2018; Zamora, 2017).

Studies on the individual elements of AI assistants, such as character design (Arafa & Mamdani, 2000) and the representation of emotions, empathy (Shi, Yan, Ma, Lou, & Cao, 2018; Vögel et al., 2018; Yang, Ma, & Fung, 2017) and social awareness (Zhao, Sinha, Black, & Cassell, 2016), support the formation of a comprehensive understanding on the user experience with AI assistants (Moussawi, 2018). As AI assistants function through digital channels, it is easy to involve the user in early testing and feedback loops. The technical setup and widely available tools for creating AI assistants encourage the co-creation of solutions with users (Lee, Lee, & Lee, 2017). Beyond the design of functionality, content and representation, the creation of AI assistants also requires ethical considerations (Schlesinger, O'Hara, & Taylor, 2018) and reflection on their social impact (Følstad et al., 2018).

Explorations on design approaches for AI assistants have been presented in previous research and guidelines from various perspectives have been created, from the design (Shevat, 2017) and practical implementation of chatbots (Janarthanam, 2017) to the design of voice user interfaces (VUIs; Cohen, Giangola, & Balogh, 2004; Pearl, 2016). Previous research has also suggested solutions for specific design phases, such as ideation and prototyping (Moussawi, 2018) and introduced overall design principles (Chefitz, Austin-Breneman, & Melville, 2018) and strategies for examining the effects of the design solutions in AI assistants (Jain, Kumar, Kota, & Patel, 2018).

Based on systematic literature research, this paper discusses AI assistants as a form of AI application. The authors consider the implications that the use of AI brings to service design practice. We draw special attention to the current application of AI in services, phases of the service design process with AI-enabled services and work of a service designer. This research responds to the research gap and need to produce new knowledge about the changes AI brings for the practise of service design. It asks the following research question: What are the implications of the change AI brings to the practice of service design?

Theoretical Background

Service Design: History, Process and Activities

Service design is an interdisciplinary field with the goal of providing a comprehensive understanding of the challenges it focusses on, whether they are systems, products, processes or services (Stickdorn, Hormess, Lawrence, & Schneider, 2017). Starting with a human-centric view, service designers aim to build understanding and engagement with all the actors connected to a service system to find the real needs and expectations that should be addressed in the design process and solution (Buchanan, 2001; Miettinen &

Koivisto, 2009). As service systems are varied, with multiple layers of complexity depending on the context, service designers aim to make the overall system visible and perceivable so that it can be addressed and taken up in the development of new solutions (Patrício, Fisk, Falcão e Cunha, & Constantine, 2011). Through co-creation and the engagement of key stakeholders and users, service design facilitates collaboration and innovation (Steen, Manschot, & De Koning, 2011).

Although service design is still a young academic discipline and just recently evolving in industry, the changing interdependency between the role of a service designer and the application of service design practices is affecting its disciplinary understanding. Until now, service design practices have mainly been applied by professional service designers. After the rise of service design in industry and beyond, which has resulted in the growth of agencies in the intersection of service design and business (Maeda, 2018), designing services no longer solely belongs to service designers (Sangiorgi & Prendeville, 2017). With similar tendencies in design research, the concept of silent design, stated by Gorb and Dumas (1987) in the 1980s, needs to be considered for today's and tomorrow's understandings of service design. Gorb and Dumas (2011, p. 56) point out that products, services and systems are designed by so-called silent designers, meaning 'by individuals who are not called designers and would not consider themselves to be designers'. Especially in the adoption of service design in industry, where our case studies have been conducted, the role and practices of service design are still fragmented and blurred. This suggests the need for research at the intersection of service design and industry.

Some researchers already claim that the role of designers is becoming more diverse (Polaine, Løvlie, & Reason, 2013; Stickdorn, Hormess, Lawrence, & Schneider, 2018; Tan, 2012; Yee, 2013). Next to becoming a specialist in service design methods, tools and practices, the role of a service designer in industry is often associated with both the management and facilitation of projects (Miettinen, 2016; Minder, 2019) and the collaborative orchestration of different human perspectives in the design process of services.

Although embedding technologies and digital channels in service solutions is not new to service design (Rytilahti, Rontti, & Miettinen, 2015), AI-enabled services are bringing a new element to the design process via new forms of communication between humans and machines. However, with the new type of service channels that AI-enabled services bring to the market, the delivery of services needs to be rethought. On the one hand, the service systems are becoming broader, with additional data sources and connections to service networks. On the other, the provided service content and interaction through the voice or chat interface should remain intuitive and approachable. When content delivery no longer depends on one type of interface, a broader understanding of service systems is needed to successfully place interfaces to meet users' expectations and needs. This is where service design can bring knowledge and inform the ways of working (Følstad & Brandtzæg, 2017) for creating AI-enabled services, such as AI assistants.

AI: History, Forms and Application

Although AI has only become more known among consumers in the past decade, the development of AI technology had already begun in the 1950s in the field of computer science (Lungarella, Iida, Bongard, & Pfeifer, 2007). The aim of AI is developing technology and machines that can perform intelligent tasks that otherwise only humans would be able to do, such as making predictions, recognising patterns in data and behaviour, processing and producing natural language and carrying out optimisation and automation (Smith & Neupane, 2018). The advancement of technology, access to increased computer power and large amount of available data have made it possible to use AI in more meaningful ways in consumer products and services (McCarthy, 2017).

AI is a large field that can be divided into two main sub-areas, which are as follows: machine learning (ML) and deep learning (DL). ML employs algorithms that learn from data to carry out actions, such as predictions or decisions, and its performance improves over time as it accesses more data. DL has higher complexity in its systems; for instance, it can include neural networks that are employed for building algorithms that can perform tasks independently. Instead of writing code, data are fed to the generic algorithm, which then builds a logic based on the data (Russell & Norvig, 2016).

In the context of services, the application of AI can be divided between the front and back ends of a service. In the case of the back end, the actions occur behind the scenes, when, for example, ML and DL provide tools for analysis, prediction and optimisation, automation of mundane tasks and processes, personalising content and forming a loop of continuous learning and improvement. In the service front end, AI is commonly applied through NLP, which enables human–machine interaction, for example, as an intelligent assistant. In previous

literature, intelligent assistants that utilise AI skills to provide service content and functions are mainly described according to their interaction forms. Assistants using text-based interfaces are defined as chatbots (Paikari & van der Hoek, 2018), while assistants using voice can be characterised as VUIs (Cohen et al., 2004). In this article, the term 'AI assistants' is used for both chatbots and VUIs.

Broadly defined, AI assistants are computational systems that utilise natural language (Shawar & Atwell, 2007) to understand the input from users, either as written text or voice, and perform tasks based on the recognised intents of the user. The front end of an AI assistant, beyond the text or voice interface proper, is built through a character with the definition of personality, tone of voice and background story. In the context of digital customer services, an AI assistant can be considered a new form of customer interaction channel. Due to their rather wide appearance in current services, this paper considers AI assistants as an example for applying AI in services.

Research Approach

The presented inquiry was conducted as a practice-based study in industry between 2017 and 2018. The dataset consists of five use cases accompanied by seven expert interviews. As the use cases represent the application of AI in the form of AI assistants, the expert interviews contribute individual perspectives and future tendencies of AI in service design, as well as the status quo of AI application in design agencies. The cases and interviews complement each other to elucidate the connection between service design and the use of AI in the design and development of AI-enabled services. The research analysis has been done using a qualitative mapping methodology in three coding cycles.

Research Data

The five case studies result from one corporation under different functions and brands in Germany. They have been documented through project deliverables, reports, design outcomes and participant observations from one author acting as a design researcher in the firm. The length and scope of the projects vary, as does the composition of the project teams. The projects have been chosen to complement each other with different priority themes, project lengths and provided insights into the service design process.

Table 1: Description of Case Studies

Case Study	*Topic*	*Pursued Customer Value*	*Design Phases*	*Service Interface*	*Deliverable*
1	Service sales	Access to information, connection to retailer	Content definition, character design, conversation flows, UI design, prototyping, testing and implementation	Chatbot on website	Customer-facing pilot
2	Customer support	Find information quickly and easily	Content definition, conversation flows	Chatbot on website	Customer-facing pilot
3	Mobility services	Find the right service solution for current need and situation	Content definition, UI design, prototyping	Smartphone application	Prototype
4	Product support	Find information quickly and easily	Content definition, conversation flows, UI design	Chatbot on smartphone	Proof of concept
5	Service orchestration	Proactive personalised services	Content definition, conversation flows, UI design, prototyping	Smartphone application	Prototype

The case study approach was identified to be the most adequate research strategy, as it allows for investigating 'a contemporary phenomenon within its real-life context, when the boundaries between the phenomenon and the context are not evident' (Yin, 2011, p. 23). A purposeful sample of cases was selected to provide material rich in information and diversity, focussing on the role of AI in (service) design processes of innovation projects. The selection criteria were as follows:

- Specific application forms of AI (e.g. AI assistants, chatbots, VUIs);
- The inclusion of designers, AI experts and data scientists in the process;
- The flexible role of the designer in the project; and
- The project representing different group sizes and applications of design methods.

The semi-structured expert interviews aimed to gather opinions, experiences and reflections on service design and AI through predefined themes (Flick, 2009). All seven experts were selected due to their knowledge level at the intersection of design and AI and their work experience of more than 10 years at a design agency. The interviewees act as designers, data scientists and directors in Germany, Finland or the United States (Table 2). The interviews were conducted face to face except for one, which was conducted via Skype; each interview lasted 60 minutes, and it was recorded and later transcribed word by word.

Table 2: List of Interviewees

Interviewee	*Role*	*Country*
1	Chief digital officer	Finland
2	Data science lead	Finland
3	Creative director	Finland
4	Service architect	Finland
5	Senior consultant	Germany
6	Service designer	Germany
7	Senior service designer	United States

Analysis Methodology

The research analysis consisted of a three-stage (visual) mapping process inspired by different coding stages (Saldaña & Omasta, 2017) and pattern-matching approach introduced by Yin (2011). The authors collaboratively applied open coding for the first cycle, followed by versus coding in the second coding cycle to define the occurring fields of tension. This was done using the Atlas.ti program. The last cycle defined thematic clustering of the main themes and formed implications around the research questions; this was done non-digitally. Both datasets were approached using the following questions for the first and second cycles:

First cycle:

- How is the role of a service designer described and perceived by the interviewees and in the projects?
- How do the interviewees perceive AI? How is it connected to their daily work?
- What are the future opportunities and challenges when involving AI in service design?

Second cycle:

- Where is AI changing the existing practices in the design process?
- Where is AI adding something new?
- How is the add-on affecting its direct context in projects and beyond?

From the third coding cycle, three main topic areas emerged, which were as follows:

- The application of AI in service design;
- The effect of AI in the service design process; and
- The role of a service designer within an AI-inclusive service design process.

Empirical Findings for Revealing the Role of AI in Service Design

The analysis of research data revealed three main topic areas of insight, which are as follows: the application of AI in service design, effect of AI in the service design process and role of the service designer in the AI-inclusive service design process. The empirical findings are discussed under these three topics in the following sections, combining the results from expert interviews and use cases. The interviewees are referenced in the text by their identifying numbers (see Table 2).

The Application of AI in Service Design

The analysis demonstrated that the application of AI in service design is still in its early stages. In 2018, many application forms of AI, including AI assistants, were still at the peak of inflated expectations in terms of Gartner's hype cycle (Panetta, 2018). This also affects consumers' expectations of the applications of AI in everyday products and services. Behind all the hype, often, the real results are not yet appropriately addressing the user's expectations and real needs (2). Design agencies investing in AI first explore where AI adds value to the service design process. While doing so, they are also aware of the challenges and gaps between the status quo and the effective use of AI (3). Aspects like access to good quality data and useful technological tools are some of the challenges faced when considering AI in designing services. So far, the application of AI has mainly been decided case by case according to the goals of the service, user needs, available resources, knowledge, tools and data. None of the interviewees mention an already established process that they can conduct, iterate and adjust when designing AI-enabled services.

Concerning the potential value AI could add to service design, the dataset shows consistent results. The interviewees claim that using AI in service design should start from the purpose and user needs instead of a technology-first attitude: *'Not every possibility is a good possibility, and it needs to be evaluated before it is established in a service. We shouldn't implement AI in a service simply because we can'* (5). When AI is taken as a part of a service design solution, it is important to manage the user expectations and remain realistic about what can be done with good quality (4). As interviewee 6 noted, *'An AI-enabled service has to be based on a business model. It has to have an economic purpose. Then there has to be user need, and of course, it has to be technically feasible'.*

According to interviewee 4, currently, AI is mostly used in the back end of services. For example, AI is doing analytics and providing quantitative information about the use of a service. This type of information can be used, for example, in the personalisation of service content by proactively recognising the needs and behavioural tendencies of users. Such self-learning systems are becoming more common and increase the accuracy and usefulness of the content to users without engaging AI in the service interaction (5). By collecting and analysing quantitative data, AI can fill the knowledge gap on user behaviour that otherwise would only be learned about through qualitative data, such as interviews and user studies (1,4).

In the front end of services, the current application of NLP has shown most potential in the form of AI assistants by providing new forms of service channels through voice and text. Herein, AI technology is already advanced enough to prove its benefit in language-based interfaces. However, according to the interviewees, the crucial aspect of the frontend application is still its situational adaptation. The fit of technology to the changing human behaviour depends on the time and context of usage. Through proactive data analysis, detection of user behaviour and profiles and prediction of user actions, AI can reveal the user behaviour patterns and adjust the service output accordingly (4).

The interviewees expect that, in the future, AI will take a bigger role as support for the service design process proper through data analysis, as well as in the form of new tools for automating some of the tasks using generative models. In service interactions, AI already offers possibilities for improving human–machine interaction, but the interviewees still draw on the importance of real human-to-human interaction in the services. They point out that, in cases that are either urgent or complex, users still often prefer interacting directly with a human service agent. According to the interviewees, it is not really a question of either human or machine, but instead, providing multichannel services where both possibilities are available.

The Effect of AI in the Service Design Process

The service design process model introduced in this research draws on the analysis from the use cases and is reflected through the interview results (Figure 1). The use cases showed regular patterns in two areas, namely, in terms of the activities performed in creating AI assistants and regarding the definition of the service scope.

The double diamond model was used as a reference for pattern matching. It was observed that the four common phases of 'discover', 'define', 'design' and 'develop' are insufficient for communicating the main activities in designing AI assistants. Jylkäs and Borek (in press) propose a seven-phase model for the design of AI assistants. In this paper, the authors extend the process to 10 phases identified through the present analysis.

The 10 process phases—'discover', 'define', 'ideate', 'design', 'prototype', test', 'develop', 'implement', 'operate' and 'scale'—form five diamonds representing the diverging and converging thinking inspired by the original double diamond model (Figure 1). Between each pair of diamonds, a deliverable is produced as a base for the next phase. Although the service design process is rather iterative and can be made to go back to a previous phase at any time, a general structure for the process phases can be identified through the analysis of use cases. In addition to looking at the usual targets of service design in the service content and service front end, the model includes the perspectives of business and technology as essential parts of the process.

Using AI in a service design process also requires knowledge and expertise about AI in the team (4). The involvement of data engineers (DE), data scientists (DS) and information technology experts (IT), such as developers, is also shown in the model in each of the process phases. Since many DS, DE and IT teams are working on an agile workflow (Abrahamsson, Salo, Ronkainen, & Warsta, 2017) that supports short cycles and iteration, having shorter cycles in the service design process also makes the connection to other organisational processes easier.

Figure 1: Service design process for AI-enabled services. Created by T. Jylkäs.

Discover and Define

The phase of discovery consists of understanding the customer needs and expectations, exploring the technical possibilities for realising the service, discovering the available data sources for training the service and understanding the business requirements and context. Here, AI provides a way of collecting large amounts of quantitative data and analysing them rapidly (1). Analysis of the quantitative data through algorithms gives a new channel to the service design process to obtain user information without human bias. Through consistent analysis, AI can reveal the needs and expectations of users and find patterns and connections that are otherwise difficult to identify from a large amount of data (2). Data mining and data analytics can also be used for scouting high-level trends in the beginning of the process to give an overall direction and validation for the design challenge.

In the definition phase, the scope of the service is defined in terms of functionality, service content and interface requirements. It also includes the selection of technological tools and the set of data used for designing and developing the service. In the use of AI, it is important that a human understanding is combined with the technological approach to ensure that the results will fit the user expectations, fulfil the purpose of

the service and create concrete value (2,4,5). According to the interviewees, in the beginning of the process, the produced ideas may often become too broad, fuzzy and unfocused to be realised due to still existing technical or data-related limitations. On such an occasion, dividing the ideas into a long-term plan and smaller short-term solutions is helpful. Focussing on solutions with a narrow scope and lower complexity first will lay the foundation for the future solution by building on knowledge, collecting data and improving the solution over time.

Ideate and Design

In the ideation phase, the functionality's scope is converted to a list of concrete actions and tasks that the service carries out. The separation of 'ideation' from 'design' in this model lies in the recognition that ideation is still open for exploration and generation of a large number of ideas, while the design phase focusses the work into creating design elements that fit into the defined design brief. In the design phase, AI may have a greater role in automating mundane tasks, such as translating hand-drawn sketches into interface designs or analysing existing services and data to give suggestions on design decisions (2,3) in the future. A common trait for the design of AI-enabled services is the inclusion of technology in the process in an early phase. During the ideation and design phases, first versions of algorithms are already generated to give an idea of the possibilities and boundaries of the solution. The concept description resulting after the design phase includes a technical description and requirements that can be used as a guide in the prototyping phase.

Prototype and Test

Prototypes have an essential role in creating AI-enabled services. They not only help in determining the technical possibilities, but they also display the functionality and value of the service (5,6) in a concrete form. Although the tasks and actions where AI is involved may be intangible and complex, concrete prototypes make it possible to present and test the service features with users and stakeholders. The test phase also reveals the gaps that may have been overlooked during earlier phases in terms of the identified user intentions. Using real technology already in the prototyping phase differentiates the approach from today's service design processes, where prototypes represent the look and feel of an interface without the real functionality behind it. The use of real technology provides an emotional experience about how AI is involved in the final service interaction.

Develop and Implement

The development phase focusses on the realisation of the final version of the service at a level of quality acceptable for go-live and usable for users. In this phase, the service content and interface are finalised, and the final algorithms are developed. The development phase continues as implementation. Although these two phases often occur in parallel, they have been separated in the process model to illustrate the importance of the role of implementation in the process. As an AI-enabled service like an AI assistant often combines several service functions and orchestrates a large range of content for the user, it may be connected to many existing services and platforms in the backend system. Therefore, the implementation and integration effort may be extensive and may include the official approvals for quality and legal matters set by the business context.

Operate and Scale

When the implementation is completed, the service can go live, and the phase of operation starts. AI assistant projects typically start with a small scope of functions and content. They collect feedback using qualitative and quantitative data to improve the service over time. Establishing a continuous learning and improvement loop is part of the operational effort. The data collected from user interactions serve as a valuable source of information for the service design process. For instance, they can be used to identify possible areas for scaling the service functions, which becomes relevant after the first version is functioning steadily. The team can consider adding further functionality to the service, or alternatively, adding further languages and market areas to increase the service coverage.

The Role of a Service Designer in an AI-inclusive Service Design Process

AI evolves the changing role of a service designer in two respects. It nudges the application of technology in the service interface and to the service design process; in addition, the roles and tasks related to the process face some changes when AI-enabled services are co-designed. Experts like DS, DE and IT provide technical knowledge to the process. A substance expert from a business unit contributes knowledge about business requirements. A service designer remains the voice of the user and translates those requirements into the

design solutions (4). In an AI-inclusive service design process, the tasks of a service designer may include user research, ideation, creating design concepts, UI and user experience (UX) design, prototyping, and testing the solutions with users. In the case of designing AI assistants, language plays a relevant role in the communication between the user and service. Thus, the tasks of screenwriting and copywriting may also partially be taken by a service designer.

In the researched use cases, the team constructs vary, but all the cases are united through the role of a service designer as an interdisciplinary facilitator. Interviewee 6 states, '[B]eing a service designer means that you always have to understand the requirements and the possibilities that are there, and then you have to include them in designing a solution'. Interviewee 5 would 'see the role of a service designer to consider the perspective of [the] customer and business, and to translate them into something tangible'. Collecting the requirements, needs and possibilities of users, business and technology positions the service designer as the connection point among team members and stakeholders. This may also be one reason why, in several use cases, the service designer also had a role as an overall project manager.

The role of technology is significant in designing AI-enabled services. This leads to an earlier inclusion of technology in the process, taking different roles throughout; further, it requires a certain level of understanding about the technology among all the team members, including the service designer. A facilitating service designer should also have basic knowledge about the AI technology used in the service to succeed in meeting all the requirements and needs through a solution that is realistic to develop and implement. This allows a service designer to interpret the technical possibilities and boundaries in the design solution, as well as to communicate user requirements to the technical team members appropriately.

According to the interviewees, one of the most prominent and challenging aspects of embedding AI in the work of service designers is the possibility of including quantitative data and numeric tools in a meaningful way in the design toolbox. Through AI, service designers access larger amounts of data in an efficient way when parts of the analysis are done by a machine. The automation of data collection and analysis is an asset that can support the design decisions by adding a second opinion next to the qualitatively gathered insights. The combination of qualitative and quantitative data may also affect how the process of designing services is structured in the future, especially in terms of forming the understanding around the design challenge, user needs and affecting circumstances around the service.

Although AI can provide information and suggestions for the direction of the design work, it lacks the ability to interpret the information. Therefore, the service designer retains the role of a sensemaker (Weick, 1995; 2). Herein, the numeric methods from AI are combined with the creative reasoning of the designer (3). With access to information from various sources, in a sense, service designers become curators that utilise the results of computational models to form design outcomes that fulfil the user needs, fit into technical boundaries and create business value.

In addition to the previous aspect of information, automation through AI may also take over some of the tasks that otherwise would be done by a (service) designer. This may concern, for example, the tasks in UI and UX design when ideas are translated into prototypes and final designs. The reduced amount of tasks for designers enables them to focus on the more complex questions around the service, such as its purpose, value creation or ethical implications (3). While everything becomes measurable through AI, it makes standardisation, optimisation and automation of services easier, leaving out the frictions that make the products and services unique. The differences that define the identity of the service are those where the service designers' informed intuition is needed, both today and in the future.

Discussion

This paper discussed several aspects of service design for AI-enabled services. It introduced both the role of service designer and the service design process proper. It is already clear that the context of AI changes the paradigm in service design; however, this needs further research. The introduction of AI changes the role of the service designer, facilitating more diverse skills and capacities throughout the design process. AI-enabled services demand a service designer's broader technological orientation and ability to adapt.

AI-enabled services add a concrete technological design perspective to the service design process, differentiating it from the typical frontend-oriented processes (Miettinen & Koivisto, 2009; Sanders & Stappers, 2008). Further, the question of service scalability needs to be addressed in a systematic way. The research indicates that there is a need for more study on how service design can contribute to the scalability

of not only manufacturing and product service systems (Koren, Wang, & Gu, 2017) but also AI-enabled service delivery systems.

Since the research is drawn from one type of application of AI, namely AI assistants, further research needs to validate the findings in various application forms and design processes of AI-enabled services. As the number of real-life use cases and expertise for the use of service design expand, the knowledge base for the use of service design in the AI context increases. The limitation of this study is constructed through the selection of use cases and number of interviews. As the body of data increases, the role of the service designer and the service design process model will become more precise. Yet, the research already shows the first implications of possible changes AI may bring to the practice of service designers and the discipline of service design through new ways of working. In this way, this paper already responds to the need to know more about AI in service design.

Conclusions

The research introduced three main areas in service design that are affected by the involvement of AI—the application of AI in service design, effect of AI in the service design process and role of the designer in an AI-inclusive service design process. Although the application of AI technology is in the early stages in practice, the research shows the two following main areas of current application: in the back end of service as a new channel for quantitative data supporting the analysis and in the front end of services as a language-based interface for users in the form of AI assistants. In the future, the automation of tasks, standardisation, personalisation and support for decision making may bring further value out of AI to the service design field.

The change AI brings to the service design process comes through the use of technology early in the design phases, starting from data collection and analysis, exploration of algorithms in the ideation and design phases and prototyping and testing the solution with real technology. The inclusion of AI in the service design process implies several short iterations that can easily be connected to the agile workflow of DS, DE and IT.

The changing role of a service designer comes through the access to larger amounts of information combining qualitative and quantitative data. This allows the designer to act as a curator of content, making sense of the information and translating it into a design solution that simultaneously meets the user needs, business requirements and technical possibilities. The research analysis has shown that the service designer remains a facilitator in the design and development of AI-enabled services, requiring a holistic understanding of all fields connected to the service design process.

[b] Tongji University, China
[c] Estonian Academy of Arts, Estonia
[d] Parsons School of Design, US
doi: 10.33114/adim.2019.6a

The initiative to this track was taken by the Norwegian research group Materiality, Technology, Sustainability (MaTecSus), and professor Ingvild Digranes at the Western Norway University of Applied Sciences.

In art, design and craft education at different levels, the digital and the material meet, either as integrated wholes, as collaborations or as violent collisions. In such collaborations or collisions, the existence of materiality can be understood differently depending on the viewpoints of art, design and craft educators. Some educators move seemingly effortlessly across digital and physical materiality in their practice (Nimkulrat, Kane, & Walton, 2016). For other educators the concept of materiality exists as something separate from the digital, while others speak of digital materiality as a space where the digital becomes "something" and gains materiality (Bratteteig, 2010).

Dunin-Woyseth and Nilsson (2013) deems the linkages between 'design research connoisseurs/critics' and 'design practice connoisseurs/critics' vital for understanding practice-related disciplines. In this new orientation towards research, practitioners are also researchers, including educators in theory-led studio practice in universities and colleges. The practitioners not only own the studio but also the research on professional practice and education. Consequently, a new stage in what can be coined the 'professionalization project' has been reached, where designers and design educators have come quite far in establishing their jurisdictional boundaries (Nolin, 2008). The next natural step is to start discussions on a common value base and establish a stronger professional identity.

This track extends its discussion to how the coexistence and collision of the digital and materiality transforms societies and impact people's ways of experiencing things. The educational field is bound to be dealing with value laden questions from several ideological positions (Dewey, 1997). However, avoiding turbulence of questioning different positionings is unhealthy, and bold thinking often emerges from turbulence. We see a need to open the discussion into the topic of materiality in the digital age. It is a start in a discussion regarding how educators from kindergarten and onwards work with, through or even against the digital in relation to materiality, i.e. how digital practices transform the research and education dealing with the topic of materiality.

The aim of this track was to raise questions such as;

- How will we in a world that is so rapidly changing educate for all the ethical and aesthetical aspects, and how do we address the topic of materiality in the digital age?
- How will educators from kindergarten and onwards work with, through or even against the digital in relation to materiality?
- How will digital practices transform the research and education dealing with the topic of materiality and sustainability?
- How can education address the balance or imbalance of the intangible, of culture, atmosphere, pedagogy and ethics, in the meeting between the digital and materiality?

- How can we challenge the dichotomy of digital/material, that can exist symbiotically and in endless ways, and
- How can we address ensuing tensions between social innovation and education?

The ensuing discussions might transform how art, design and craft educators prepare for the meeting between the digital and materiality.

Six papers were accepted to the track, and they show a broad approach to this track, with rich discussions in regards to topics.

Peter Haakonsen and **Laila Belinda Fauske** (Oslo Metropolitan University, Norway) authored the first paper *Learning to create images with computer code.* They address the fact that programming is becoming a part of the school curricula in Norway both in lower and upper secondary education in subjects such as art, design and craft. The as questions regarding what programming can to the learning processes of these subjects. The concept of 'Tinkering' is introduced, to describe a creative phase in a learning/working process, emphasising both creation and learning. In the project that they present, visual images are created via computer programming to enhance the main author's learning. The paper discusses tinkering as a learning process that is relevant and motivating in relation to programming within art, design and craft education.

Ingvild Digranes, Jon Øivind Hoem and **Arnhild Liene Stenersen (**Western Norway University of Applied Sciences, Norway) has co-authored the paper *Learning about materiality through tinkering with Micro:bits.* This paper discusses two pilot projects in Art and design education at the teacher training at Western Norway University of Applied Sciences. As a point of departure, the pilots try to address the new curriculum of Art and design, where digital knowledge is described as stretching from using simple digital resources to master and shape your own digital products. In general design education the digital is no longer limited to two dimensional visual modelling as previously practiced. This new approach in a subject where making and materiality is central, tinkering and designing allows for explorations in both 2D and 3D. The pilot case studies demonstrate the importance of bringing coding and the material aspects of tinkering, making, and creating into play in combination.

Francisco Zamorano, Catalina Cortés, Mauricio Herrera, and **María Elena Errázuriz** (Universidad del Desarrollo, Chile) authored the paper *Designing an intuitive interface to enhance trigonometry learning.* They show how in the last three decades, the application of TUIs (tangible user interfaces) in education has demonstrated its positive influence on performance and learning of students. At Universidad del Desarrollo in Chile, the monitoring of diagnostic tests over time has pinpointed difficulties and challenges in the teaching-learning of trigonometry in first-year Engineering education. This study consists of several steps, designing and validating a tangible interface to learn trigonometry in the classroom setting. Principles of the theory of Embodied Cognition and Blended Interaction is applied to model an intuitive, collaborative and meaningful learning experience. During the design process, three Intermediate Models were tested with several types of users, and two Prototypes were tested with an experimental group. User-testing highly contributed to the design of the interaction experience and the interface, progressively defining the functional and pedagogical aspects.

Delane Ingalls Vanada (University of Florida, United States) authored the paper *Engaging in Materiality: Issues in Art and Design Education.* The paper shows how in the training of art and design educators, modes of engagement that can build capacities for connecting theory to practice through creative research and connections to the physical materiality of art, must not be overlooked. Whether online or on-the-ground learning, artist-teachers must not disconnect from the power of engagement with and the materiality of art. This paper places a focus on ways that teacher training programs can anticipate and activate attitudes of new materialism and design thinking, providing a much-needed anchor in the digital age. With a contemplative view of art practice as research, projects in an art and design education program elevate opportunities for exchanging understanding, promoting dialogue, and approaching learning and research as relationship. Intentionality in the ways that the practice of teaching itself is also materiality, as a living practice, along with the training teachers as designers and facilitators of cultures of making, thinking, and learning are discussed.

Ingvard Bråten (Western Norway University of Applied Sciences, Norway) authored the paper *Experiencing (from) the inside – Mediated perspectives in kindergartens.* His paper presents a case study of preservice kindergarten teachers' use of new form of digital imagery. The paper introduces spherical cameras and digital microscopes and discusses their affordances when introduced in practical use in teacher education and in kindergartens. The use in kindergartens was introduced through a class of 34 teacher students in kindergarten

education. The students were specializing in Arts and design at Western Norway University of Applied Sciences. The use of images from spherical cameras and digital microscopes were analysed based on data from student responses through two questionnaires, group presentations and discussions in class, and an analysis of various media material produced by students.

Liv Mildrid Gjernes (Western Norway University of Applied Sciences, Norway) authored the final paper of the track, *Aarup 1960 and the poetics of materials.* It has as its premise that all design has its own conditional modes of expression; however, these are realised through the maker's sense of the possibilities of materiality. The essay takes inspiration from a reclaimed piece of 1960s furniture designed in the modernist idiom, and is based upon autobiographical experiences, original works from own and contemporary aesthetic practices, and associated thoughts in the present. A completely new artistic expression is developed, questioning the strict, use-defined style ideals and letting shape reveal other values and statements than function. The essay succeeds in putting into words how some of the cognitive processes in which creativity, critical reflection and the senses' experience-based insights may bring up something new. It highlights that in creative work, the goal is not to reach a single result; every little discovery made by examining something specific could open up new worlds.

Learning to create images with computer code

HAAKONSEN Peter* and FAUSKE Laila Belinda

Oslo Metropolitan University, Norway
* corresponding author e-mail: peterh@oslomet.no
doi: 10.33114/adim.2019.01.292

Programming is becoming a part of the school curricula in Norway both in lower and upper secondary education – this includes subjects such as art, design and craft. What can programming contribute to the learning processes of these subjects? 'Tinkering' is a creative phase in a learning/working process, emphasising both creation and learning. In this project, visual images are created via computer programming to enhance the main author's learning. The process is structured into stages. The important phases of the learning process are realised as a result of tinkering with existing codes. An important discovery for the learner, and one key aspect of programming images is that, as a mode, it opens up ways to create repetitions effectively, resulting in various patterns. This turned out to be motivating for the learner. This paper discusses tinkering as a learning process that is relevant to programming within art, design and craft education.

Keywords: Processing, programming, tinkering, learning, digital images

Introduction

Programming is a skill that is connected to the term 'computational literacy': It is often defined as a 21st-century skill which is increasingly relevant for children to learn in the schools of today (Bocconi, Chioccariello, & Earb, 2018). In Norway, programming has been an elective subject in lower secondary schools since 2016 (Regjeringen, 2017) but it is eventually going to become a compulsory part of the new curricula in both primary, lower secondary and upper secondary schools (Bocconi et al., 2018; European Schoolnet, 2017). This new curricula for primary and lower secondary schools will be implemented in 2020. In Sweden and Finland, programming is already integrated into the creative subjects (Bocconi et al., 2018). In Norway, programming will become a part of the school subject of art and crafts in lower secondary schools (Regjeringen, 2018). A new vocational program that will become available within upper secondary education – called ICT and media productions (IKT og medieproduksjon) – is also due in 2020 (Utdanningsdirektoratet, 2018). These changes in curricula indicate an educational shift in Norwegian schools.

This paper reflects on how programming can be a relevant part of creative school subjects such as art, design and craft. We maintain a special focus on motivation and the learning process when learning to create images with a computer code. The examples in this paper use a programming language with a difficulty level that will possibly be applicable to lower and upper secondary schools, but one that also aims to be transferable to easier block-based languages such as *Scratch* (Scratch, n.d.) – this learning process is also relevant to children in primary schools. Using the creative process as a point of departure, this paper specifically aims to examine tinkering (Berland, 2016) as a learning process that is relevant to programming within art, design and craft education.

Programming as an emerging part of art, design and craft education

In the report, *The Nordic Approach to Introducing Computational Thinking and Programming in Compulsory Education* (Bocconi et al., 2018), the authors investigate how programming and other new subjects are implemented – or about to be implemented – into Nordic schools. When commenting on the British situation, the report shows that programming emerged in the British curricula during 2014. This initiative is a part of the process of implementing 21st-century skills into the curricula, a set of skills to prepare today's children with the ability to adapt to their future occupations and social life. This involves 'promoting foundation skills, digital literacies, higher order thinking competencies as well as social and emotional skills' (Bocconi et al., 2018).

One key term in the report is 'computational thinking' (CT), which can be seen as an umbrella term that includes programming. In Norway, the term 'algorithmic thinking' is used instead of CT – it is not a direct translation. There is no need to compare these two terms with each other here. We will say, however, that they are similar in the sense that they are both connected to the modern problem-solving skill set; programming, along with digital competence, are both included in this skill set (Bocconi et al., 2018). The new curricula that are to be implemented into Norwegian schools in 2020 are the result of a comprehensive process that was carried out over several years. *Ludvigsen-utvalget* (English: The Ludvigsen Selection) made two public NOU (English: Norwegian public statement) reports, the first in 2014 and the second in 2015. In these reports, 21st-century skills and in-depth learning are both emphasised (Ludvigsen, 2014, 2015). These two reports were the starting point from which the ongoing process aiming towards the new Norwegian curricula originated. The Norwegian process illustrates a common trend in Nordic countries:

> *A common trend emerging from analysis of policy documents and interviews with experts is that Nordic countries have included CT and Programming as part of a broad and evolving definition of digital competence, one that embraces key 21st century skills like problem solving, logical thinking and creativity.* (Bocconi et al., 2018, p. 9)

This paper argues that programming as a subject in compulsory education may prepare children not just to be digital consumers but also to be digital creators. This argument is formulated in the light of Richard Sennet's statement warning about the dangers when people let the machines do the learning and the people become passive consumers of an expanding competence (Sennett, 2008). With this in mind, this paper aims to contribute to the knowledge-building discourse (Scardamalia & Bereiter, 2010) on programming and 21st-century skills in art, design and craft education at different levels.

Tinker

There are many different programming languages. Some are text-based while others are block-based. What they have in common is that the programmers get instant feedback from the material when creating codes: Either the code works, or it doesn't. Making things with a programming language presupposes computational literacy. Berland (2016), following diSessa (2001), describes material literacy as one of three component aspects of computational literacy:

> *This kind of material literacy can come in many forms: through facility in making a complex spreadsheet in Excel; from the ability to pack your luggage using the most efficient procedure; or through evaluating various data structures in program code. Most of what is considered to be material computational literacy is simply the ability to write and craft program code to express oneself and build usable artifacts.* (Berland, 2016, p. 197)

Berland's description can be interpreted in relation to the 21st-century skills and upcoming curricula that are soon to be included within Norwegian schools. Digital competence has a place in art, design and craft subjects at all levels; for example, children in primary schools making stop-motion animation with an iPad app and plasticine and those in upper secondary schools manipulating photographs in *Adobe Photoshop* or 3D-models in *SketchUp* or *Tinkercad* – these examples combine the material with the digital. Tinkering, according to Berland, Martin, Benton, Smith and Davis (2013) and Berland (2016), is a way of playing with a material without necessarily knowing the outcome, thus enacting itself as distinct from experimenting. Tinkering can be defined in various ways. However, Berland and colleagues claim that there are certain common benefits to be drawn out of the various definitions:

> *Tinkering describes both (a) an orientation and (b) a set of activities. […] The set of activities described as tinkering include trial and error, messing around or fussing, finding and using feedback mechanisms (such as testing), or combinations of those activities*. (Berland et al., 2013, p. 568)

This paper illuminates the process of producing digital images created by computer codes through tinkering. A basic assumption is that tinkering can enact itself as a good learning process when introducing programming into creative subjects within school. In this paper, programming language becomes the only tool in a creative process, excluding all elements of physical materiality: It becomes digital imaging within its own premises, with tinkering embodying the mode through which the learner engage with programming.

Approach

This paper illuminates a case where the main author (who has taught digital design software at university level for several years) explores the learning process that stems from creating images through computer programming. His prior knowledge includes a deep understanding of how digital colours behave on a screen with red, green and blue (RGB) as values between 0 and 255. Together with other basic understandings of what a digital image is and how it contains a given number of pixels, this knowledge works as a foundation when starting to program images. Within *Processing*, dealing with these numbers is common and they make sense to a learner of programming in an environment where everything else is new and unknown.

The main author's practical experiences and reflection on actions (Schön, 1991) are articulated through a dialogue between a colleague and the co-writer of this paper. The case is retrospectively divided into stages, where the main author's 'basic textbook learning' started in stage one. In stage two, playing and tinkering with advanced codes led to new learning outcomes for the author. In the third and current stage, he goes deeper into a function that the programming language accrued.

Processing

Processing is a text-based programming language developed for artists and designers. As its founders, Casey Reas and Ben Fry (2009), describe, it is easy to start with – anyone can create an image – and it has been developed with artists and designers in mind. It could have been interesting to write about block-based coding (e.g. *Scratch*), which is suitable for younger children, but the inherent possibilities of *Processing* make it more applicable to this case.

Roger Antonsen (2018) uses *Processing* to visualise complex mathematical phenomena. A recent example of how one might use *Processing* is his creation of eight images which visualise different card shuffles. Antonsen's example shows that *Processing* holds many possibilities in terms of creating images that act in ways that are different to what you may achieve in other image-editing programs such as *Adobe Photoshop* or *Illustrator,* as these programs have a visual approach to image editing. Processing is designed to create and modify images, and it has the potential to create complex and generative art through coding.

Stage one: Basic textbook learning

Driven by his ambitions to create complex interactive images, the main authors' learning of *Processing* started by reading the different handbooks as well as examining *Processing'*s own online resources (Reas & Fry, n.d.). It began as a hobby or leisure activity for the first few years of usage but later he began to implement *Processing* into his professional work. From creating simple rectangles and ellipses on backgrounds, a basic and well-known illustration (of how three circles of RGB colours mix into cyan, magenta, yellow (CMY) and white as they overlap) was drawn. This was a simple illustration based on the foundations that were established through the textbooks – for example, how to place the circles on the background with given *x* and *y* coordinates related to the canvas's size in pixels. These foundations also included how to write the three RGB colours. To make the colours mix and achieve the CMY palette, a function telling the colours to blend according to additive colour mixing was included. The blend mode (ADD) was also similar to software such as *Photoshop*. As in *Photoshop*, it is important to use a black background colour when mixing colours additively: Avoiding white is a key part of this process.

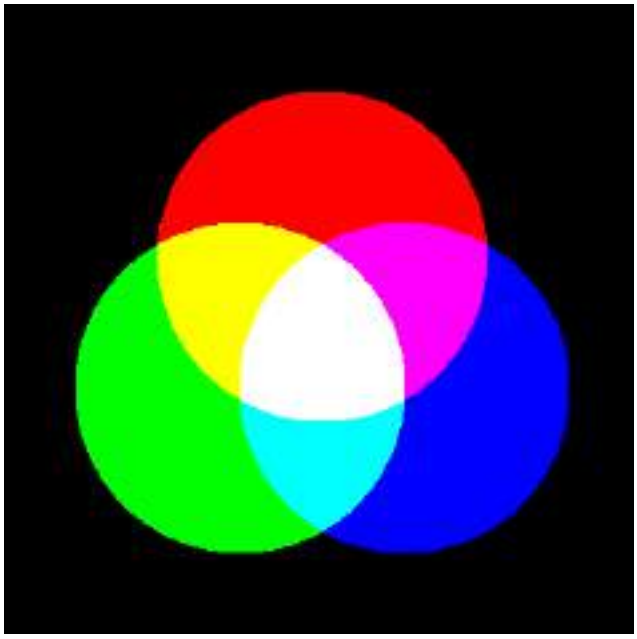

Figure 1: RGB circles with a blend mode set to additive colour mixing creates CMY and white.

This is an example of the practice and testing stage. The goal was to write codes such as this without looking at recipes or textbooks. This kind of visualisation is based on additive colour systems (Kuehni, 2004). As a teacher of digital media at university level, the main author had made such visualisations using *Photoshop* in the past. At this stage, there is very little creativity involved. The focus is on learning how to use *Processing* and to gain a fundamental understanding of what it takes to write simple programs. The target was to let using the blend modes act as a method through which one could experiment with colours. In addition, different ways to create moving images were tested. An easy way to do this was to replace the *x* and *y* coordinates (in numbers) with *mouse x* and *mouse y*, making a shape's coordinates change simultaneously with the mouse cursor. The drawn shapes could then move around on the screen.

Stage two: Playing and tinkering

After a period of learning the basics, it was time to create something more advanced: What if these circles could move and bounce across the screen in different ways? And could these movements be influenced and modified when exposed to stimuli such as sound? Could they first orbit or jump across the screen and then change directions if someone were to shout into a microphone? After searching online, different interactive examples were found that were suitable for modification. Three main products came out of this process, the first of which was a depiction of three RGB circles bouncing across a black canvas, mixing colours additively as they overlapped (similar to Figure 1 but with moving parts).

Advancing from the code for bouncing circles, this project moved into a new stage. At this point, three circles were coloured with RGB contours but without a fill colour. They were bouncing across the screen in the same way as in the previous figure. This time the image became successively lighter as the circles overlapped because the background colour was not in the looping part of the code – which means it is only 'played' once in the loop. The circles were also allowed to change size and proportions when moving the mouse: Both *mouse x* and *y* had an impact on both size and shape. Finally, a reset function for when the mouse button was clicked was created, making the screen darker when it started to become white (Figures 2 and 3). The mouse actions were quite basic and easy to replace with fixed *x* and *y* numbers.

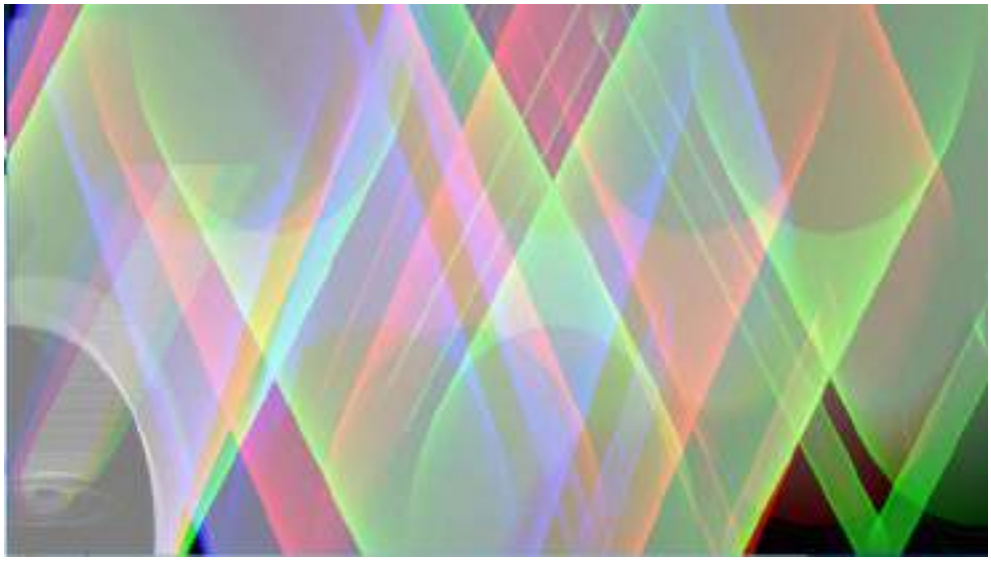

Figure 2: RGB-contoured circles on a black canvas, creating secondary colours (CMY). The canvas gets successively lighter as the circles move across the screen. The different RGB shapes move diagonally and you can alter the pattern by moving the mouse.

Figure 3: Screenshot from Processing showing parts of the code for Figure 2.

At this part of the second stage, a search was conducted online for 'fancy' code scripts with the goal in mind being to combine the RGB colour mixing with complex movements and interactivity – this resulted in the described examples. Here, tinkering with the codes and not always knowing what would happen was an important part of the approach. Testing (instead of reading) the theory was a crucial working process, advancing the work's progress several steps further.

Soon, however, the process stagnated. The code making the circles bounce automatically was too advanced to understand. It was easy to modify the circles to bounce slower or faster, but it was not easy to write new lines of code that would make the circles move automatically and exactly as was wanted. This experiment was put on hold so as to try out a new approach. Figure 4 is based on the available codes that were found online while looking for a way to create transitions between two colours. The code was tinkered with to change the colours

and the principles behind this function – called *lerp* (Reas & Fry, 2006) – which was also learned by the main author through this process.

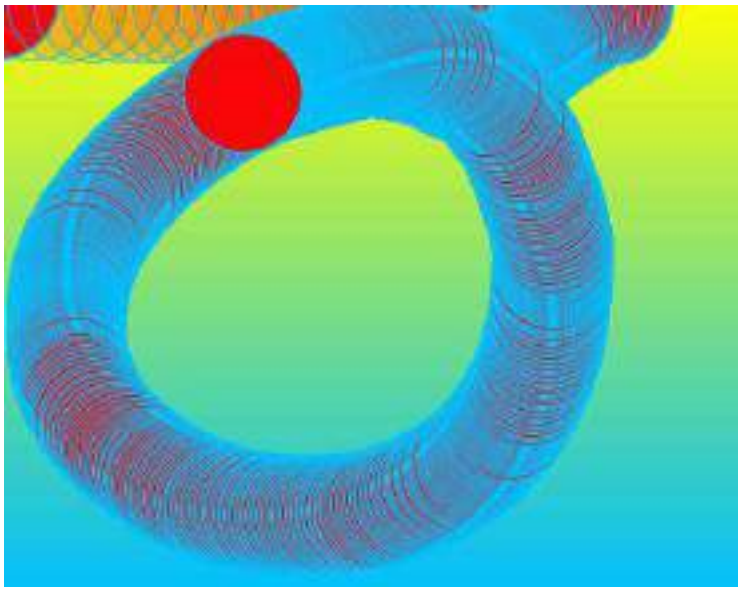

Figure 4: Colour transitions in the background and a circle controlled by the mouse (the background is not in the loop, so the circle leaves a track).

A milestone in the learning process was thus achieved. Other parts of the code started to become interesting. Another function in this code was *easing*, which could make the red circle move more elegantly across the screen as one moved the mouse along the *x* and *y* axis. Without understanding this function well enough, a closer look at a part of the code revealed the *for* structure. This structure seemed essential within different settings but had not been explored by this point. By the end of this stage it seemed possible to start to learn how to use it. Now it was time to go back to the books and the online resources (the reference guide at processing.org), reading and trying to understand the logic behind it.

Stage 3: Back to basics: Going deeper into a function in the programming language

The last experiments may look 'fancy', but they were mainly products that stemmed from modifying and playing with existing codes to mix colours in different ways to try different colour transitions and to play with movement and interactivity. Here, tinkering (Berland, 2016) was the main approach. A motivating element during this stage was to play with something advanced. The main author employed this approach instead of continuing to learn programming systematically (as in the approach in stage one).

The original web resources and the textbook (Reas & Fry, 2006) began with exercises where one drew lines in order to understand the fundamental basics. This was achieved early on in stage one but, as the aim was to learn fast, this approach was abandoned in stage two. By stage three, going back to the basics was essential for further development. It was crucial to look closer at the *for* structure. The logic behind *for* is explained like this: *For* (*i* = init, test, update) (Reas & Fry, 2006). This means that the variable *i* is initiated (e.g. set to a specific value), then tested (stop if this value is higher or lower than a certain number) and then updated (if the test was positive, update with a specified addition). With this structure, it is possible to let a shape copy itself in a specific rhythm, thus making it possible to create patterns. Apparently complex images can be made with just a few lines of code. By this point we were getting closer to formulating the essence of how programming can be an incredibly useful tool in certain situations; its effectiveness. The next example is the first independent exploration of this function, written from scratch and without looking to references. It shows a small ellipse, copied and enlarged in a specific rhythm.

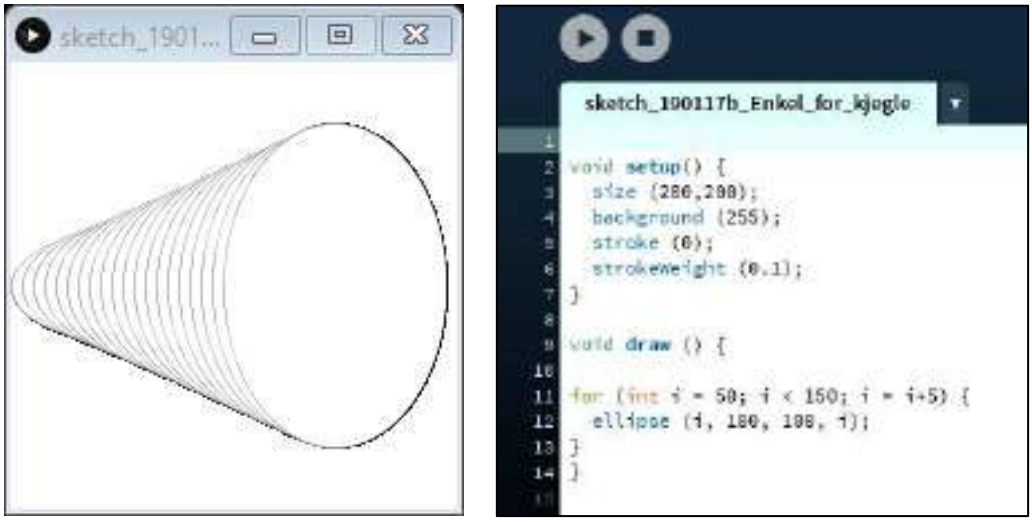

Figure 13: Duplicating an ellipse with a few lines of code.

Figure 5 is an example of an effective way to create different patterns with a few lines of code. This was a milestone in terms of the learning process. It was interesting to write such codes and to experiment and tinker with them, creating new patterns – as opposed to tinkering with advanced code scripts that were found online. After some testing in regard to how to repeat lines according to the *for* structure, the ability to create a grid with a little twist was discovered (Figure 6).

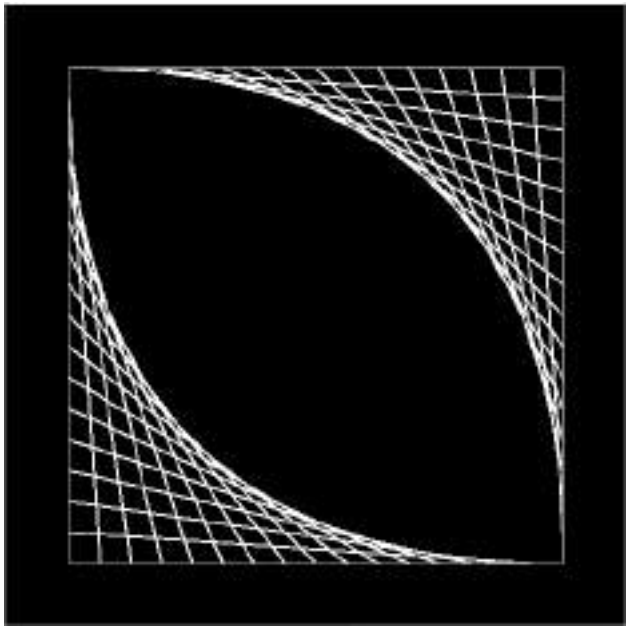

Figure 6: A grid with a twist, achieved after experimenting with the for structure.

At this point, the motivation that stemmed from gaining new knowledge and examining the possibilities became important. This entailed not being so concerned with ambitiously creating fancy interactive images (they could wait). This new mode of learning was fun. It was a decisive moment in the learning process. This resulted in several patterns, exploring different possibilities with one or two variables in the *Processing* code.

After making patterns with one variable, the main author began testing out two variables. The next pattern (Figure 7) is made with two variables: It is a circle placed in a fixed position on the *x* axis. The first variable makes the circle copy itself along the *y* axis at a given rhythm. The other variable makes the circle occur in different sizes, starting at a given number and increasing until it reaches its size limitation (which is defined in the code).

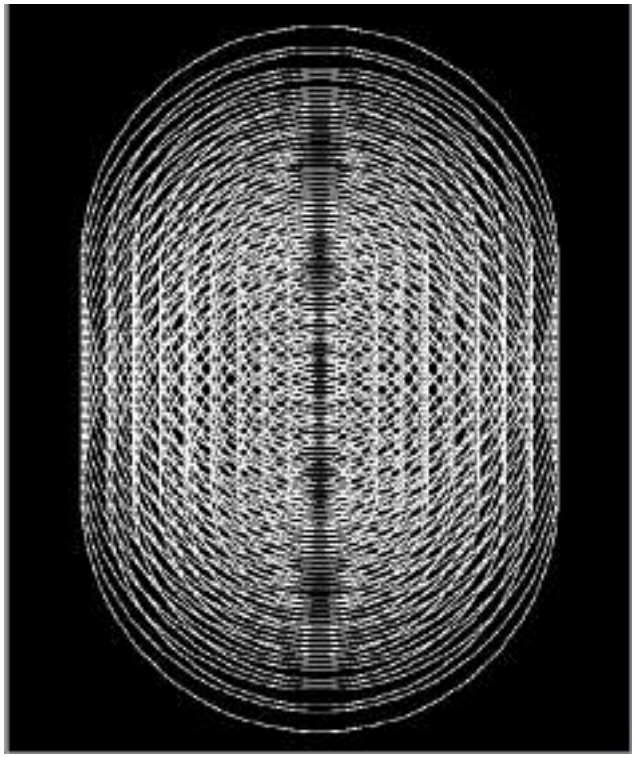

Figure 7: Testing two variables in the for structure: An ellipse duplicating its position and size.

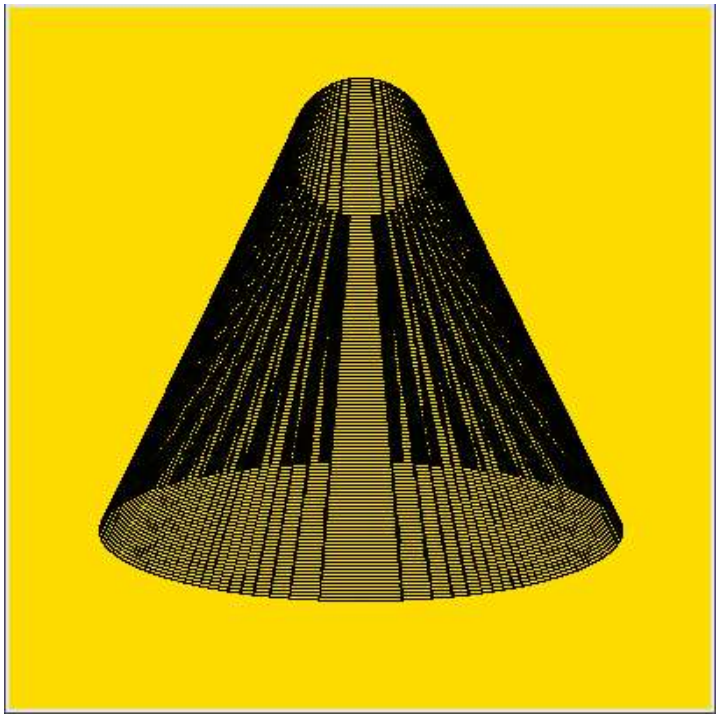

Figure 8: Based on the first cone created with the for command, this is another way to make the ellipses multiply both the x position and the y part of the shape. The yellowish background is there for the variation (the exact colour is RGB 255,220,0).

Figure 8 has two variables (*i* and *j*), both of them increasing at a specified rhythm. The cone is a result of a variable *y* position, increasing with a specified value until it stops at another specified value. The shape has a fixed *x* radial but the *y* radial increases gradually until it stops at a specified point.

Figure 9 resulted from going back and tinkering with the code from Figure 7, without necessarily predicting the exact outcome. The goal was to play with one's own code which was written from scratch, taking it further, working intuitively and seeing the visual results right away rather than trying to understand everything in advance. This was combined with the additive RGB colour mixing from stages one and two. Some of the meeting lines create new colours as a result of additive colour mixing (CMY and white).

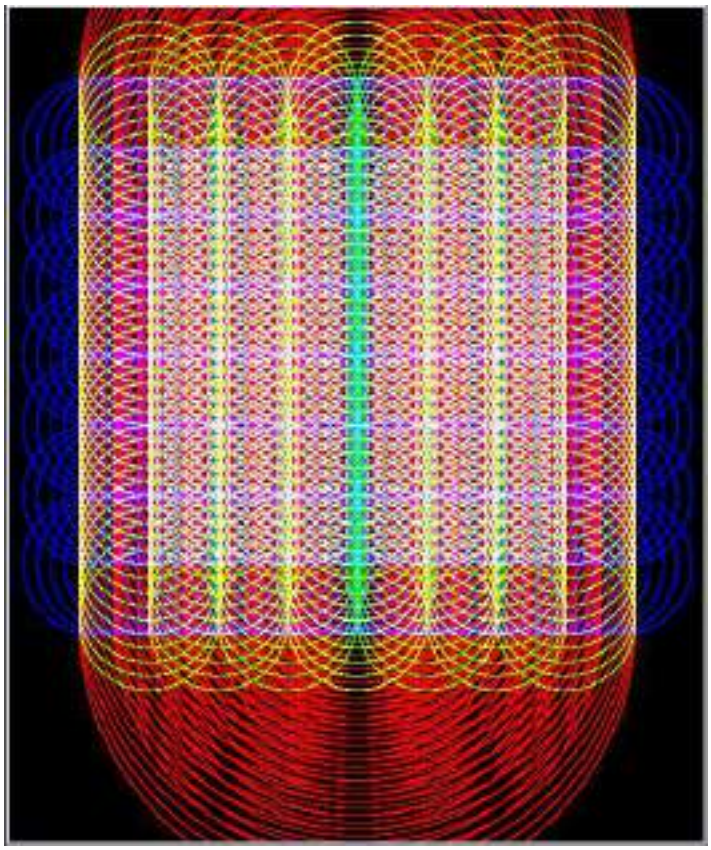

Figure 9: Result of playing with the codes in Figure 7, combining it with the colour-mixings from stages one and two.

By this part of stage three the dialogue between the creative tinkering and the learning process became interwoven with new ideas that arose from the new findings. Practical exercises and reflections on actions (Schön, 1991) drove the working process forward. The *for* structure is a complex function to a beginner but it gradually became simple with practice, making it possible to create patterns. Within the third stage the focus had been to explore this one function, examining its possibilities through many different tests. They started out as simple patterns written from scratch, then both playful tinkering and structured analysis became involved in order to modify the patterns. An effective way to make new things happen in the patterns is to tinker with them without predicting the exact results but while still being able to understand the results after the changes occur on screen. In other words, the process contains a series of alterations between writing codes, seeing the results, taking them further with intuitive tinkering and then analysing the results later. Afterwards it is important to transfer the knowledge gained from the outcomes into new versions, creating new codes analytically. The learning process is not over: It would be ideal to deeply explore another function, advancing further by conducting a new stage.

Discussion

This paper offers a perspective on programming within art, design and craft education with a special emphasis on tinkering as a learning process. The case reflected in this paper has shown that tinkering has been a crucial element throughout the learning process in terms of advancing the main author's knowledge of programming. After using textbooks in stage one, tinkering with existing codes in stage two made it possible to freely play, unconcerned with the systematic learning of advanced programming. This boosted the motivation to enter stage three, developing new codes based on newly achieved knowledge. As a part of stage three, the patterns

created were further developed through 'happy accidents' that stemmed from tinkering. These results were then analysed and refined into new patterns.

When first discovering *Processing* and upon hearing of its potential and opportunities, the main author had high ambitions in terms of what he could create with this software. It held a variety of new possibilities (compared to *Photoshop* or *Illustrator*) and it made it possible to combine digital imagery with interactivity: It may even be possible to learn how to combine images on a screen with a microcontroller kit with censors to create images that respond to physical stimuli. This project started with high ambitions and an even higher level of motivation. However, it also started with a lack of skills and knowledge in regard to programming. Despite this, after learning the basics, it became interesting to play and tinker with existing codes to investigate the software's advanced possibilities. After a period of tweaking and tinkering with several code scripts that were found online, new visual effects were made but without necessarily consolidating how to write similar codes from scratch – motivation decreased as the high ambitions began to seem unreachable. Still, it was interesting to play with these codes, modifying them or creating errors that only left a blank screen.

As Berland and colleagues (2013) describes, tinkering is about messing around and meeting the material's feedback mechanisms. *Processing* gives you instant feedback on whether the code works or not. Either you have created something visual or the program tells you what part of the code needs to be fixed. If you cannot fix it, you may delete the code line (or hide it by writing two dashes in front of the lines). After looking for interesting codes that could be modified through small systematic steps, through playing around until new things happened or until they failed, a part of these codes began to seem slightly familiar as it had been present in several of the projects: The *for* structure. After a period of reading about this structure, the learning process reached a new stage. It had made a small and yet important leap. Now it was possible to see more clearly how some of the more advanced code scripts were built and even how they could be written from scratch. The motivations of the main author increased slightly, and the ambitions were adjusted to a more achievable level. This does not mean the learning process is over; many more phases such as this are needed to achieve proficiency at *Processing*. But at this stage, creating images with code is great fun and because the main author is a teacher of digital media at university level, this enthusiasm may reach (and hopefully influence) his university students.

After working on the third stage, after denouncing the main author's original high ambitions (or at least after putting them on hold), the learning process had to return to a phase that was similar to the very first steps of stage one; the online resources and textbooks (Reas & Fry, n.d., 2006). It was a step back to the basics. But stage two was necessary in order to get there; it was necessary to play with codes and to have fun with the higher ambitions before it felt natural to take this step backwards. After stage one, many of the structures and functions (such as the *for* structure) described in the textbooks seemed incomprehensible. Between stages one and two, looking for existing codes seemed more motivating.

This paper does not claim that computer coding should always be present within art, design and craft education, but it is an attempt to look at how and why it might be relevant to use programming to create digital images. There are many more possibilities that arise from using *Processing* and other such programming languages. This paper gives some examples of how programming images can create other kinds of outcomes than what you can achieve in known imaging software such as *Adobe Photoshop* or *Illustrator*. The learning process described in this paper may serve as an example of how to use programming to create images and how to learn computer coding step by step. However, further research on the topic is needed.

When programming becomes a part of the curricula in lower and upper secondary schools in Norway, creating images with computer coding might become increasingly relevant in art, design and craft subjects. Why should we learn this and at what level of difficulty should an art, design and craft teacher be teaching programming? They are not IT teachers and the students are not attending an IT class. Nevertheless, programming can be used for many different things and it opens up new possibilities in terms of creating visual digital images. You can generate patterns, iterate with small changes in code scripts or even make something interactive.

This paper has shed light on the learning process. Tinkering has proven to be a good way to learn because it combines a playful approach with the instant feedback that *Processing* provides from the materials. This may apply to different programming languages suited for different children at different ages. On the website, Lær kidsa koding (English: Teach the Kids How to Code) (Lær kidsa koding, n.d.), there are different online resources for *Scratch*, *Processing* and other such software, with step-by-step recipes spanning across varying difficulty levels, from kindergarten to upper secondary and beyond. Many of the instructions end with tasks where the users are encouraged to find out the next steps on their own and take the codes to new levels. A

good thing about tinkering with codes is that it is not 'dangerous' to fail. Failing is a fruitful and often necessary part of the learning process. After the initial playful steps, one might have learned something new and become ready to write codes from scratch. Based on the experiences drawn from this project, tinkering is regarded as a fruitful way to introduce programming to both teachers and children in art, design and craft subjects. As the new curricula will be implemented in 2020, further research on this topic is crucial. This includes classroom studies at both primary, lower secondary and upper secondary schools, as well as teacher-training programs.

Learning about materiality through tinkering with Micro:bits

DIGRANES Ingvild*; HOEM Jon Øivind and STENERSEN Arnhild Liene

Western Norway University of Applied Sciences, Norway
* indi@hvl.no
doi: 10.33114/adim.2019.03.306

This paper discusses two pilot projects in Art and design education at the teacher training at Western Norway University of Applied Sciences. In the second round of drafts for the new curriculum of Art and design digital knowledge is described as stretching from using simple digital resources to master and shape your own digital products. It is no longer limited to two dimensional visual modelling as previously drafted. This is in our view a new approach in a subject where making, tinkering and designing allows for explorations in both 2D and 3D. Given that we want to encourage the use of the digital together with the use of physical materials, the pilot case studies demonstrate the importance of bringing coding and the material aspects of tinkering, making, and creating into play. The BBC Micro:bit was used to make coding and mechanical control part of projects made with traditional material. Further research and development should be undertaken to bring such practices into classrooms in primary and lower secondary schools.

Keywords: Art and design education, materiality, programming, Micro:bits, citizenship

Introduction

For many years, UNESCO has advocated the idea of citizenship education, which it describes as educating children from an early age to become clear thinking and enlightened citizens who participate in decisions of importance to society (UNESCO, 2010). In Norway Art and design is a compulsory subject throughout the ten years of primary and lower secondary school education. One of the aims explicitly stated for the education is that it should enable the children to take part in society , develop social and professional adaptability, and a democratic understanding.(Kunnskapsdepartementet, 2016). Digranes and Fauske (2010) links the term to Art and design education and describe reflective citizen as a citizen who is capable of promoting a sustainable future through choices and actions. Design is increasingly seen as a one or the avenues or a way of thinking that can contribute to significant changes in the future (European Commission 2012).

The concept 'design literacy' is often used to explore and address the complex matter of objectives and content in design education from primary to university levels (Nielsen and Digranes, 2012). There has been a move in the professional field toward understanding design products and processes as composed of symbiotic hybrids between design products, media types, services, architecture, technology, programming, communicative spaces, networks and modes of creation, production, and exchange (Knutsen & Morrison, 2010). The challenge will be to define the content and secure the implementation in existing and future practice in schools, when these thoughts are brought into the education at lower school levels.

The Curriculum Renewal 2020 - Developing Art and design in Norway

In Norway there is an ongoing process of renewal of the curriculum for primary and secondary schools meant to be finalised in 2020. In the white paper concerning this renewal; *Fag – fordypning – forståelse: En fornyelse av Kunnskapsløftet. Meld. St. 28 (2015-2016)* (Kunnskapsdepartementet, 2016). Several aspects, such as technological development in different professions, enhancing diversity, new forms of communication, the challenge with too many pupils not finishing secondary school, and the general development in the society, forms the basis for change.

In the drafts for the new curriculum of Art and design, the concerns voiced from the education milieus has been addressed. A highlighting of workshops and studio practice, as opposed to a more theoretical orientation, will serve to bring the focus back to *making, designing* and *creating*. Some of this will be anchored in more traditional craft processes and materials, however coding has been included and will be part of the new and wider concept of materiality that Art and design education will have to incorporate into the curriculum. Still without a clear definition coding can be understood as a higher level, more abstract way of working with the same concepts that characterise programming. But where programming tend to activities that produce new functionality, which a computer can use, coding is more about utilising existing functionality. As of now in the first draft, coding in Art and design is limited to two dimensional visual modelling in lower secondary school (Udir 2018-utkast). However, considering The Professional Digital Competence Framework for Teachers in Norway (outlined below) and the understanding of the reflective citizen that is design literate, to confine the digital or coding to the two dimensional picture plane is in our view a too limited approach in a subject where making, tinkering and designing allows for explorations in both 2D and 3D.

Tinkering in Design Education

The more traditional areas of Art and design, i.e. craft in wood and textiles or drawing, are well established in the school practice. Introducing programming and more intangible artifacts or products requires new approaches. In the introduction to his book *Mindstorms* (Papert, 1980) Seymour Papert reflects upon how computers can be a general tool for children to create for themselves. This view of creation is grounded in what Papert calls constructionism. This is an approach to learning where design experiences result in "objects-to-think-with", which are material objects that can also be internalized mental structures (Keune and Peppler, 2018).

In the future tinkering with computers might be an addition to the traditional tools: the "gears" for the new generation. The same is the case for a large variety of products and services – the digital transforms what was once mechanical into hybrid constructions, controlled by computers. The idea of tinkering (Resnick, and Rosenbaum, 2013) has followed humans as long as we have had a relationship to tools. Tinkering, playing with the possibilities given by available tools, has always been a winning strategy for innovation. We may, however, argue that tinkering has become increasingly important, in a world characterized by rapid change.

Education is never static, rather it is fluent, flexible and diverse. A lot depends on the teachers and the day to day practice in both formal and non-formal education, and the policy that binds them. A EU report from 2012 named *Design for Growth & Prosperity. Report and Recommendations of the European Design Leadership Board. European Design Innovation* provides 21 recommendations for the future development of design and design education in Europe (European Design Leadership Board, 2012). Recommendation 20 is to: "Raise the level of Design literacy for all the citizens of Europe by fostering a culture of "design learning for all" at every level of the education system" (European Design Leadership Board, 2012, p. 73). In some newer educational research within Art and design education the focus has been on what makes it meaningful for the pupils, an as such in teacher training. Approaching design in schools, educational theory of the students' design process emphasizes their ability to carry out a whole creation process, from idea to finished product. Randers-Pehrson's research into Norwegian upper secondary school in Art and design education addresses something similar in her concept of"thing-making". She sums it up as: «The Experience and mastering of the material seems to be one of the driving forces for the students' work. /../. As such, the "thing-making" is a meaningful activity, because it is given shape and becomes "something"..." (Randers-Pehrson, 2016:280). The one factor we aimed to hold constant was that the focus would be on problem-solving, designing solutions, and the aesthetics rather than just the coding. Designed artifacts can be seen as a type of communication and storytelling in itself, and youth move seamlessly between the divide that the curriculum coins analogue and digital (Mäkelä, 2011). However, knowing that pupils value the traditional crafts highly we also need to acknowledge that student engagement and motivation are enhanced through integration of new technologies

in education (Smeda et al., 2014). As the pilots unfolded, we saw several areas of discussion in regards to reaching this further ambition, and a plan for improvement emerged.

Strategy and Method

This paper discusses two pilot projects, fall 2018 and spring 2019, in Art and design education 101 at the teacher training at Western Norway University of Applied Sciences. In both pilots we used the BBC Micro:bit to make coding and mechanical control part of projects made with traditional materials. One of the strengths in doing a case study is that it is a strategy more than a set of methods for gathering data. “As a form of research, case study is defined by interest in individual cases, not by the methods of inquiry used” (Stake, 2000 p.86). From what Yin (2003) and Stake argue, if you manage to identify the case, the methodology will follow as a result of your focus and what you would like to study about that specific case and in light of your chosen theory. A case study gives the frame of context, when your question deals with how and why in the present, and allows for a deeper understanding of a specific area, in this case how tinkering with micro:bits can strengthen the digital *and* material knowledge the student teachers and how and why this approach in itself can be useful in meeting challenges in their future classroom practice. One of the dilemmas in this study is that we would be researchers as well as the educator. We were focusing on being aware of our different roles in the project at all times. To not force our expectations on the situation or other stakeholders did not pose to much of a challenge, as we also went into the pilots without really knowing what to expect. Working within the known boundaries of teaching design studio, programming was introduced as a new factor. Not limiting the approach, but keeping it an open case approach let the involved parties to gather several avenues of data, from teacher logs, student logs, observation notes, photos of project drafts and student works, we let the case inform the data collection (Yin, 2003).

Pilot 1a, 1b and Pilot 2

The study consists of two pilots.The pilots were short projects to see how coding through Micro:bits could be part of an aesthetical exploration in art and design rather than just a technical introduction. The purpose of the pilots was to find out appropriate ways for how the future teachers in Art and crafts could get experience with coding and programming in a task that was placed in the context of traditional methods, issues and thinking of the subject Art and design.There were no clear expectations to how the student teachers might perform, or if the framework would work, or the hardware would perform. It was a test of what we would work with in terms of resources on all levels, human, knowledge, hardware, code, etc.

Pilot 1 was completed with students in their third year of teacher education. It was split into two parts. The first phase (1a) was a short introduction where they only used some basic functionality on the Micro:bit working with “artist books”. Abandoned books were transformed by the students, changing their physical attributes and adding visual, tactile and digital components, all part of a story made of fragments from Alice in Wonderland. As part of their books the students were told to use a Micro:bit and a battery pack as an integrated part of the book (Figure 2 & 3). This approach was designed to be relatively simple, only an introduction to the Micro:bit and how it can be coded. Most students chose to display some kind of message, related to the Alice-narrative, using the LED-display that i integrated into the Micro:bit. The time frame given was six days. The assignment did, however, include a number of digital tools. Every student was working with their own book and the physical integration of the Micro:bit, but they could cooperate when it came to the development of the code.

This group of students were given a more complex assignment a few weeks later (Pilot 1b). This time the students were introduced to different ways of approaching meaning in works of art. The students were then divided into groups of three and the assignment was to create a situation / object in a public place where a viewer can be included in interaction with an “artist robot”. The students were given to following assignment: Use one or several Micro:bits to control a “robot” that take part in the creation of an artistic expression. This expression should be produced over time, through an interaction that either facilitate an artistic experience or manipulate an artistic material”. The time frame was six days, but the students did only get guidance from teachers the first two days.

The second pilot, pilot 2, was completed with students in their first semester. They had both the introduction and a more complex assignment in a continuous period. The assignment was to: “... design a kinetic sculpture for a wall. Through problem solving you will construct a wall hanging sculpture that can be activated by a spectator. You will consider these aspects: volume - it is three dimensional, movement - actual or alluded,

programming will be a part of the movement, and you will consider the spectator role in activating the sculpture. Inspiration has to be taken from organic forms or Sami craft". The timeframe was 3-4 days, with teachers involved mainly in day 1 and 3.

The data in the pilots consists of reflection notes from the lecturers, logs written by students, discussions and photos/films of student works. The student teachers become valuable sources of knowledge. Even though the pilots had a limited scope in terms of time, data, and problem framing, they provided valuable insights towards the design of the main projects to come.

Working with the BBC Micro:bit

The BBC Micro:bit is a handheld, programmable micro-computer, introduced in 2015 and given to 7th graders in the UK. The device has a lot of different functions integrated in a small unit (see Figure 2). The device do also have a large number of connectors, which makes it possible to use the Micro:bit in a huge variety of projects.

The Micro:bit is considered useful for several reasons: it is cheap, all coding can be done online, and no installation is required. The projects can be kept simple, or easily be made more complex through more advanced code and by adding perifer units that can send and receive signals through the Micro:bits edge connector-pins.

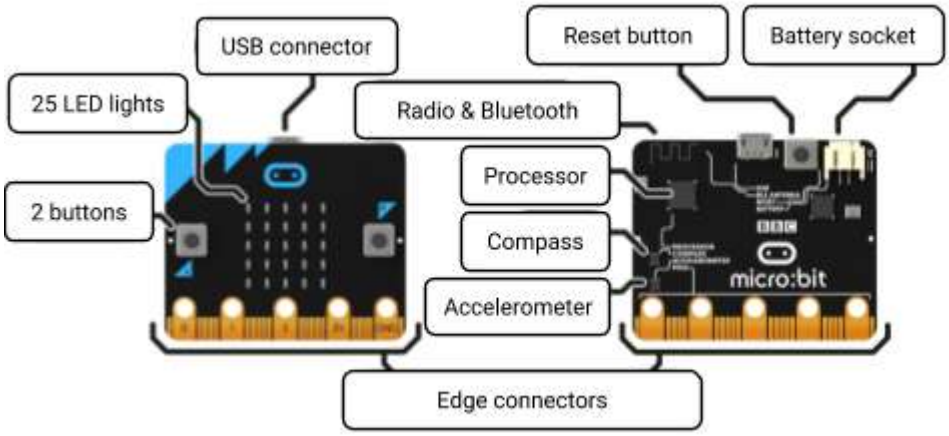

Figure 2: The BBC Micro:bit, a small computer using components developed for mobile devices. The row of edge connectors at the bottom makes it possible to integrate the Micro:bit with a large variety of external devices.

The Micro:bit is programmed through a modified version of Microsoft's TouchDevelop platform, a web-based service hosted at www.makecode.org that allow programming from many devices, including smartphones and tablets. Makecode.org provides an interface that is very similar to and makes skills learned in e.g. Scratch easily transferable, and vice versa.

Figure 3: An example of code developed in project 1a when the students worked with integrating the Micro:bit in books. This script was used to write different messages into the LED-display when the book is turned.

Analysing the pilots

The first introduction to Micro:bits (Pilot 1a) was related to the students working with inspiration from artists books. The coded messages were mostly activated by using the Micro:bit's buttons, but some used the light sensor, the accelerometer or the compass. The scripts were, however, short and straightforward, and most of the students limited their coding to minor modifications of existing code. However, this pilot fulfilled its purpose by introducing the Micro:bit's possibilities, the concept of coding online and transferring the program to the Micro:bit, as well as integrating the device into an existing physical object (Fig 2 and 3).

Figure 4: Several visual elements playing along with the Micro:bit (inside the speech bubble that is going to be all black). The QR-code is used to trigger information presented as Augmented Reality.

Figure 5: A highly decorative element, which in addition to communicate meaning can also serve a practical purpose: in this case a hiding place for the battery pack that power the Micro:bit.

Pilot 1b involved experiments with the possible interaction between the Micro:bit, the code, the material, the site of the performance and the viewer(s). In this project we saw how the Micro:bit, also have material qualities of their own. Working with digital tools can be said to have its own language and materials, including physical interfaces like wires, buttons, connectors, lights, switches, sensors etc. The material that come from the digital domain may contrast the more traditional materials we are accustomed to in Art and design, but the different materials do also blend and sometimes merge into unity. In this project we saw how the new materials meet and contrast the old, familiar materials and some of the groups saw their existing practical knowledge in new light through the encounter with Micro:bits.

At first glance the Micro:bit is a device with some significant limitations. However, the versatility of coding introduces a level of flexibility that made the students able to come up with very different solutions to the assignments. In Project 1b they were to produce a "robot" capable of assisting in the production of artistic

expressions. An example is a group that came up with a solution meant to mechanically transfer paint through soap bubbles, from small cups on to a canvas. The physical setup and coding was relatively straightforward, and the students had a working prototype after a few hours. However, when the digital materials met the traditional, physical materials the students faced several challenges. The group did a long series of experiments with various mixtures of paint and soaps. Because they had to make the interplay between the mechanics and the physical material work, there was no quick fix, and the students explored the materials in a way that is very unlikely to have happened with a more traditional approach to painting.

Figure 6: Several Micro:bits used to control servos that are connected to various physical extensions, each designed to make an instrument play.

Figure 7: Another creation made during project 1b. This group was tinkering with the interplay between gravity and viscosity of paint. They also had to figure out how to construct a lever to make the servo(s) strong enough to control the small paint buckets.

It is worth noting that the code used to control the servos for the music playing project, shown in figure 6, was very similar to the soap bubble machine. Still the final expression is very different. In the music playing project one of the major challenges was to make three different servos move in a way that created a consistent rhythm. This was difficult because the servos did not perform exactly similar, and drifted out of sync. Still, this drifting created new sound patterns that, at least from the teachers' point of view, became more interesting than a monotonous rhythm.

Out of several interesting projects the one shown in Figure 7b may serve as another example to how the material challenges was handled by the students. This group did a good job when it came to the concept and the early prototyping, and they had a clear vision for the final result. Here there is a lot of physics in play. The students had to attaching a small leveler to the shaft to transfer the servo's movement into a rotating motion. In this case the design failed a little, as the prototyping was done without paint in the small cups attached to the shaft. When the cups were filled it became evident that a longer leveler was needed to make it easier to pull by the servo, something that would require a slightly different construction. Again, a lot was learned about the different material qualities during the process.

In Pilot 1, the Micro:bit is interesting out of a number of reasons. First and foremost it promises to bridge a gap between artistic expressions and coding – allowing the computer to take part in artistic expressions. Even though concepts like algorithmic art goes back several decades, arguably as long as we have had digital computers (Verostko, 1994), there is still a weak connection between most art made with digital tools and coding, done by the artist.

Various ways of so called creative production draw heavily on re-use existing material and ideas from already existing works. One can argue that the information society do favor those who are able utilise existing works to develop strategies to collect and process existing information and reformulate it in order to meet personal needs (Hoem & Schwebs, 2005). Re-use is a common practice in all creative work. However, among professionals like "filmmakers, visual artists, photographers, architects and Web designers /../ this is not openly admitted, and no proper terms equivalent to remixing in music exist to describe these practices." (Manovich, 2002).

Almost all authoring and editing software comes with a large number of predefined functions. Therefore, substantial parts of "creative" production become a direct result from selection among predefined functions.

The Micro:bit is different and provides another, yet relatively simple, approach to creative creation. Code can easily be found and copied, and the remixing of code becomes one of the essential parts of the creative process. This was clearly demonstrated when some of the students in this case study brought their newly acquired skills into their internship.

Pilot 2

In Pilot 2 the students had three to four days to work with the tasks at school, where they received guidance from the teachers. This group, students in their first, year had an introduction and worked on their more complex assignment during the one scheduled period.

To focus of the assignment in pilot 2, was to see if the students could produce a design where the Micro:bit and programming could enhance the aesthetic qualities of a kinetic sculpture. The focus on volume, movement and interaction with an audience was the primary focus, and there brief also stated the source of inspiration as organic forms or Sami craft. The motivation for this was to frame the exploration in a way that would challenge through boundaries. This brought some contrasts to view.

The first year students had worked throughout semester with more traditional introduction assignments in different modes of drawing, painting, sculpting and visual narrating. There was a marked resistance to risk taking, and they all had expectations to the assignments in terms of "what I have seen before and would like to be able to do". They kept measuring themselves and their solutions to the known, and getting them to explore materials and play with solutions proved demanding. Even as the brief in Pilot 2 can be seen as "traditional" in Art and design education, i.e. playing with form and composition, volume, materials, inspiration, and addressing a spectator or user etc., the fact that we introduced an unknown material and tool, the Micro:bit with add-ons, it freed the students from desiring a specific outcome. In the idea phase, the groups were willing to explore several different sources of inspiration, different ideas on activation and movement, and kept going back and forth between ideas, sketches, prototyping and adjustments.

Figure 8: One of the groups that played back and forth with form, movement, inspiration, and materials.

Among the more unexpected findings were how the students did explore different physical materials to make this work with the digital material – including the physical Micro:bit, the servos and the code. In his book *The reflective practitioner: How professionals think in action,* design theorist Donald Schön characterise tinkerers as people who have a conversation with the material (Schoen, 1983). We could clearly observe such conversational among the groups of students in our case studies, when students were working back and forth between code, servos and the various building materials.

Even though the individual elements can be considered simple, the students were working with assignments that they developed into solutions that became quite complex. They should learn how to program the Micro:bit, sometimes make several Micro:bits work together, and figure out how to make the elements of the artefact do the movement(s) the way it was intended by the design. The students should also deal with the formal aesthetic means, and in some cases they also integrated a message in their work with creating an artefact. Most of the students also worked with physical materials that they had not, or just to a small extent, previously met.

Figure 9a and 9b: The length of an arm (a) had to be a tradeoff between the distance the plaster face (b) could be pushed and the strength of the servo. The weight of the face and the material the face is pushed into, also have to be considered.

Figure 10: Three related shapes, drawn as vector graphics and cut on a laser cutter at a nearby makerspace. In this case, the students had to adjust their original concept with servos off center and put the shaft as close to the center of gravity as possible.

A limitation that influenced on the students' work were the selection of artistic materials. One of the projects, the branches of a tree were meant to rotate horizontal, but the servos could not manage it because of the total weight of the textile leaves and friction towards the back wall. If these textile materials were changed with lighter materials, the servos could have managed the rotation. There were also other examples that showed the need for a greater selection of materials in the students' process, and more time to get familiar with the limitations or possibilities of the materials. One of the student projects wanted to rotate a spiral to create an illusion of moving colour, but because of the format and the weight of the chosen material the spiral became too heavy to successfully rotate as planned. With another choice of a material the movement in the spiral and the aesthetic form itself, could have been clearer, and also made the rotation easier for the servo.

However, these trial and errors show that the students took the challenge given in the assignments, which was to to learn something new about integrating Micro:bits as a material element. It was also allowed the making of kinetic sculptures that didn't end up working as the students planned in the beginning of the project. The students had been through a problem solving process, a learning process regarding the materials' limitations, and reflections on what would, and would not, work teaching coding in primary and lower secondary schools

Another, unexpected finding was in regard to the finished student work, the students' attachment in light of the work process, and the execution of the finished work and effort to match the brief. One of the challenges in general education is that if the projects become to conceptual, pupils fail to see the value in the finished product. As one of the fundamental challenges facing the subject is sustainability, the idea of creating waste in the classroom is not pleasant. Though learning process, risk-taking, play, experimentation, and knowledge of both materiality and the digital is valuable, when considering what the pupils, and the student teachers' find as meaningful works. Looking at the student work in Fig. 9 and 10, the work in Fig. 9 did not really originate as much from the inspirational sources listed in the brief. The approach was similar to one where the students locked themselves in one idea, and the process of design was connected more to the technical aspect than the aesthetic solution. However, the student work in Fig. 10 was based almost solely on organic form, and every choice, in a very complex back and forth process, was made to enhance this aspect. At the end of the exhibition, the group Fig 9. threw their work out first chance they got, while the other carefully wrapped the pieces and discussed how they could be used as concrete models in later educational practice. This is something to consider in framing the assignments in terms of introducing them into the overarching topics of sustainability in Fagfornyelsen 2020 (Kunnskapsdepartementet).

Given that we want to encourage the use of digital tools across topics and involving the use of physical materials, we do believe the pilot case studies demonstrate how the importance of bringing coding and related activities out of the data lab. When teachers are able to turn their classroom into something that becomes more like a makerspace, where the digital and the material aspects of tinkering, making, and creating with new technologies come into play. The further research, not undertaken as of yet, will be a collaboration

with Bergen municipality, where we bring the project to the practice with classroom teachers, student teachers, and pupils in their internships in primary and lower secondary schools.

Summing up

Future teachers need to be confident in their relationship with and use of technology. As with any material and/or tool this requires training and the individual development of new skills. However, the most important skills are not directly related to individual knowledge and the ability to master technical features. From our point of view, seen from Art and design education, what is most important is to give students an overall confidence towards tinkering – experimenting with technology in ways that do not always need to fulfill a specific goal.

When observing the use of Micro:bits in schools and among our students, most examples are very simple when it comes to the actual code. On the basis of previous observations of practices in schools we initially assumed that students would find existing resources and copy code. This assumption turned out to be the case among all the groups in our case studies. Only those working with very simple code did all the coding by themselves. The vast majority found example code and did modifications – a kind of remixing, as known from computer culture in general. However, this does not mean that the Micro:bit only allow relatively simple coding. We see the students' use more as an expression of the Micro:bit's ability to raise awareness of material qualities in objects that surrounds it. What is really nice is that it provides a point of entry, into coding, even for students that have no previous experience with this way of using computers.

In the process of working with complex problems there is an interplay between a variety of materials. As a result the process will lead to solutions that teachers and students were not at all aware of at the beginning of a project. Thus, the design process becomes most important and the ability to reflect upon how the various materials constantly influence and change each other, as well as the understanding of the initial problem.

The practical educational solutions to secure learning outcomes in interplay with the knowledge aims of *Fagfornyelsen 2020* (udir.no, 2019) lies within the every-day execution of subject content, as implemented by classroom teachers, the next generation student teachers, and the educators in teacher training. In this study we have shown several approaches towards anchoring the new knowledge aim of *coding* in the subject Art and design. When looking ahead, the tinkering with digital technology and physical constructs, to solve design problems, can be seen in a larger context, related to the overarching themes i.e. citizenship and sustainability through design. To manage these tasks teacher education needs to facilitate tinkering and encourage students to experiment. In a sustainable manner, teacher training must let students develop their knowledge to make them more capable of taking part in shaping the use of software and related technologies. The ability to define problems, explore different solutions and come up with a functional design, and finally implement a working prototype becomes a skillset that can prepare students for problem solving in general. The students learn that solutions are not something they can get from specific sources, but something they have to actively engage with through the combination and adaptation of information and knowledge from several sources.

To an increasing degree we develop a more dialogical relationship with digital technology. This has consequences for almost all technical devices, because they are controlled by software. In the future, those who learn to master these dialogues with digital machines will have an advantage. At the same time technology must be managed, mastered and controlled. Increased civic insight and ethical perspectives are seen as important elements in education, and Art and design education is in a position where we need to face the challenges within teacher training (Udir.no 2018). The teachers we educate today will be among those who educate children and young people into this future. We need to equip these students for what is coming, and teacher education must therefore develop a greater practical understanding of how software affects our physical surroundings. The material focus and awareness Art and design can promote in regard to consumption, innovation and entrepreneurship in an ethical setting, becomes one of the arenas that we will have to strengthen. In doing so we have to fully acknowledge the increasing influence and integration of the digital and traditional materials.

Research Perspectives IN THE ERA OF Transformations

Designing an intuitive interface to enhance trigonometry learning

ZAMORANO Francisco; CORTÉS Catalina*; HERRERA Mauricio and ERRÁZURIZ María Elena

Universidad del Desarrollo, Chile
* corresponding author e-mail: catalinacortes@udd.cl
doi: 10.33114/adim.2019.03.216

In the last three decades, the application of TUIs (tangible user interfaces) in education has demonstrated its positive influence on performance and learning of students. At Universidad del Desarrollo in Chile, monitoring of diagnostic tests over time evidences difficulties and challenges in the teaching-learning of trigonometry in first-year Engineering education. This study consisted in designing and validating a tangible interface to learn trigonometry in the classroom setting. The methodology used was a quasi-experiment with first-year students from the Schools of Design and Engineering at Universidad del Desarrollo in Chile. Principles of the theory of Embodied Cognition and Blended Interaction were applied to model an intuitive, collaborative and meaningful learning experience. During the design process, three Intermediate Models were tested with several types of users, and two Prototypes were tested with an experimental group. User-testing highly contributed to the design of the interaction experience and the interface, progressively defining the functional and pedagogical aspects. Comparative analysis of Pre and Post-Test results, demonstrate that students' performance increased by 37.1% after two sessions using the interface.

Keywords: Design, learning, tangible user Interfaces, interaction, trigonometry

Introduction

Traditional education systems have rapidly changed in the last twenty years, incorporating not only more collaborative and inclusive methodologies but also new tools and technologies that encourage participation and interaction. This evolution has gone from the development of software applications, websites, etc. (Camilleri & Camilleri, 2017; Dooley, Ellison, Welch, Allen, & Bauer, 2016; van Loon, Ros, & Martens, 2012), to learning interfaces that provide direct and "tactile" interaction between the user and the interface. Numerous educational initiatives have relied on the benefits of tangible user interfaces (TUIs), especially in primary education, demonstrating the variety of its possible uses. Nevertheless, in mathematics education, and more specifically in the teaching-learning of trigonometry, there is an unexplored potential or gap in the use of tangibility to understand and relate abstract concepts (Marshall, 2007). For example Geogebra, a software to learn mathematics (https://www.geogebra.org) enables simultaneous visual, graphic and numerical representations of mathematical objects that are explored interactively, supporting an intuitive "learning by doing" approach (Kepceoğlu & Yavuz, 2016). However, it is mainly supported only by vision and the corporal interaction is reduced to the individual use of the mouse. The interface designed in this study used the benefits of TUIs in combination with the intuitive and visual learning aspects of tools such as Geogebra. This combination enables to have low entry limits, use multiple senses, approach intuitively, and encourage collaborative learning through social interaction.

Purpose of the research

The main objective of this study was to investigate the formal, perceptual and technological variables to be considered in the design of a tangible educational interface to learn basic concepts of trigonometry.

Four specific objectives were defined:

13. Determine the content and progression of the didactic experience to facilitate learning through an interactive interface.
14. Iteratively design a multisensory interface to facilitate the understanding of concepts of trigonometry in higher education students.
15. Investigate the optimal interactions needed to operate the interface correctly and understand the subject properly.
16. Measure the impact of the experience on student learning.

Theoretical framework

Tangible User Interfaces

Tangible User interfaces (TUIs) are human-computer interfaces that give physical form to digital elements, enabling the user to directly manipulate digital information with their hands (Ishii & Ullmer, 1997). The first approaches to TUIs appeared at the end of the nineties, attributable to the seminal work of Iroshi Ishii in the Tangible Media Group of MIT. Today, TUIs are increasingly accessible (due to the democratization of technologies) and its fields of application have diversified into the public and private sphere: kiosks in science museums, pieces of interactive art, collaborative tables in offices, and more recently in wearable interfaces. In the field of education, several examples can be found in material designed for young children, such as Cubetto (https://www.cubetto.com), assemblable blocks to learn the basics of programming.

The use of TUIs positively influences the cognitive process of the user, enabling agile opportunities of individual and collaborative discovery, supporting the formation of hypotheses, improving understanding through the combination of different senses and supporting the rapid evaluation of diverse alternatives (Jetter, Reiterer & Geyer, 2014). TUIs influence the thought processes supported by experimentation (Resnick et al., 2005) and enable a better use of haptic resources that we develop when manipulating everyday objects that surround us (Ishii, 2007). All of the features described above make TUIs suitable to enable natural and multisensory learning experiences.

This study was centered in the design of a TUI capable of hosting collaboration among multiple participants, who build their interaction experience using and enhancing their pre-existing skills (motor, spatial, social and cognitive). By escaping from the traditional interaction paradigms of the so-called WIMP interfaces -Windows, Icons, Menu, Pointer- (Gentner & Nielson, 1996), the interface fosters embodied, collaborative interactions and activates cognitive processes stimulated and facilitated by design.

Embodied Cognition, Conceptual Metaphors and Blended Interaction

The designed interface focused on concretizing abstract mathematical concepts through the manipulation of tangible components, appealing to the transfer of conceptual metaphors. Mathematical conceptual knowledge is largely metaphorical, making frequent use of conceptual transfer, as when we conceptualize numbers as points in a line. Since many of our concepts are metaphorical, our conceptual understanding is crucially dependent on the nature of our bodies and the physical environment in which they function (Lakoff, 2009).

The Theory of Embodied Cognition states that the way in which we learn new concepts is based on the previous body of knowledge that we store since childhood. Lakoff and Núñez (2000), explain that human beings internalize abstract concepts in concrete terms using ideas and modes of reasoning based on the sensorimotor system. The mechanism by which an abstract concept is understood in concrete terms is called Conceptual Metaphor, which consists of a transfer or "mapping" of a "source concept" to another "object concept" (target). The source concepts are often concrete and have some kind of "body base" (Johnson, 2013; Dodge & Lakoff, 2005; Feldman, 2008; Pecher, Boot, & Van Dantzig, 2011), while the object concepts are often abstract and cannot be directly experienced or perceived. In the pedagogical context of this project, metaphors can serve to convey a basic understanding of abstract notions of mathematics and to encapsulate

them in a vivid and informative "image", thus facilitating the internalization of abstract concepts (Font, Bolite, & Acevedo, 2010).

The present study took the approach proposed by Jetter, Reiterer and Geyer (2014), which links Embodied Cognition with the HCI field, and names it “Blended Interaction”. The cited authors introduce the term Conceptual Blends to explain how users of an interface rely on familiar concepts and the real world when they are exposed to new experiences of digital technology. The mixtures create a new concept from two inputs (cognitive and physical), in this way, the output results in a new concept with a new emerging structure that was previously not available in the inputs. Several authors have postulated that the appropriate combination of previous experiences of the physical and social world, in combination with those already familiar in the digital domain, enable an interface to be understood and operated more naturally (Hutchins, Hollan & Norman, 1985; Jetter et al., 2014). This enables compromising few cognitive resources to connect evaluation and execution when facing a new system. To achieve this objective, four dimensions defined by the authors Jetter et al. (2014) were considered as fundamental variables to design the interface:

- Individual Interaction: focused on individual capabilities supported by multimodal elements.
- Social interaction: group activities subject to pre-established conventions that come from daily life interactions.
- User Journey or Workflow: definition of a journey that is temporarily ordered constituting the experience.
- Physical Space: the form-function of the interface components and the layout of the physical space to define the nature of the experience.

Teaching trigonometry

In traditional teaching, students are subjected to repetitive procedures (Skinner, 1976), and learning is assessed through cyclical evaluations. The research team believes that this type of learning does not usually stimulate creativity or incorporate the premise that human beings add meanings to the thought process (Johnson, 2013). Thus, in this study, the design of the experience is sustained in a constructivist vision: students learn by constructing something with their prior knowledge (Ambrose, Bridges, Dipietro, Lovett, & Norman, 2010) in combination with new input information to produce significant learning (Vygotsky, 1980). In this approach, students are challenged with a problem and encouraged to work on their own to solve it, promoting higher levels of thinking.

Trigonometry is a fundamental requirement for the study of both advanced mathematics and science. In the United States, the National Council of Mathematics Teachers highlights the importance of trigonometry in the study of periodic functions and emphasizes the usefulness of trigonometry in the investigation of real-world phenomena (Curri, 2012). Moreover, trigonometry is fertile in connecting algebraic, geometric and graphic reasoning (Weber, 2005). Nevertheless, despite its importance in both high school and university, research shows that trigonometry remains a difficult subject for both students and teachers (Brown, 2006; Thompson, Carlson & Silverman, 2007; Weber, 2005).

At Universidad del Desarrollo, Santiago, Chile, high-school level difficulties in trigonometry are evidenced by the results of the diagnostic test applied to first-year Engineering students at the beginning of their first semester. Results have shown systematically for several years that trigonometry is a subject that presents comparative deficiencies. As seen on Table 1, in 2017, trigonometry presented the lowest performance (14%) within all the subjects addressed in the diagnostic test.

Table 1 : 2017 Diagnostic evaluation results of the career of Engineering at Universidad del Desarrollo, Santiago, Chile

Thematic Area	*Total number of answers*	*Total correct answers*	*Global performance*
Perimeter areas of simple figures	916	300	33%
Layout and orientation of straight lines in the plane	687	279	41%
Equations and quadratic functions	229	108	47%

Trigonometric problems with text	**1145**	**200**	**17%**
Recurrences and natural numbers	687	160	23%
Solving Equations and Systems of Linear Equations	458	226	49%
Solving Inequations	687	203	30%
Use of trigonometric functions	**1145**	**163**	**14%**
Absolute values	916	254	28%
Total general	6870	1893	28%

Methodology

The methodology of this study is quasi-experimental and mixed, incorporating qualitative and quantitative data collection to inform the development of the design from the perspective of usability and pedagogical effectiveness (Gilbert & Driscoll, 2002; Jetter et al., 2014). The design process was organized using a modified version of the Double Diamond Model created by the Design Council (2014). It considers an iterative process of four convergent and divergent thought cycles (discover, define, develop, deliver). The divergent cycles consisted of literature review, characterization of intermediate models and prototypes, and exploration of design options for the interface. In the convergent phases Intermediate Models and Prototypes were tested balancing user feedback with observation of participatory processes (Resnick et al., 2005), based on two co-dependent factors: the content to be transmitted and the integration of visual, auditory, spatial and interactive components.

The first set of prototypes ("Intermediate Models") consisted in a sequence of three low-fidelity models that were tested to explore particular aspects of interaction. In the following cycles, two higher-fidelity prototypes ("Prototype 1 and 2") were tested to validate the design decisions taken in the preceding cycle. The two user-testing phases with Prototypes 1 and 2 involved thirty minute-long interactions, guided by a Facilitator who used a pre-established script. Each session was documented in video, photography and an observation spreadsheet developed by the researchers. Additionally, in each session a usability and interface validation questionnaire was applied using a Likert scale from 1 to 9 with criteria taken from the VII version of the Questionnaire for User Interaction Satisfaction (Chin, Diehl, & Norman, 1988).

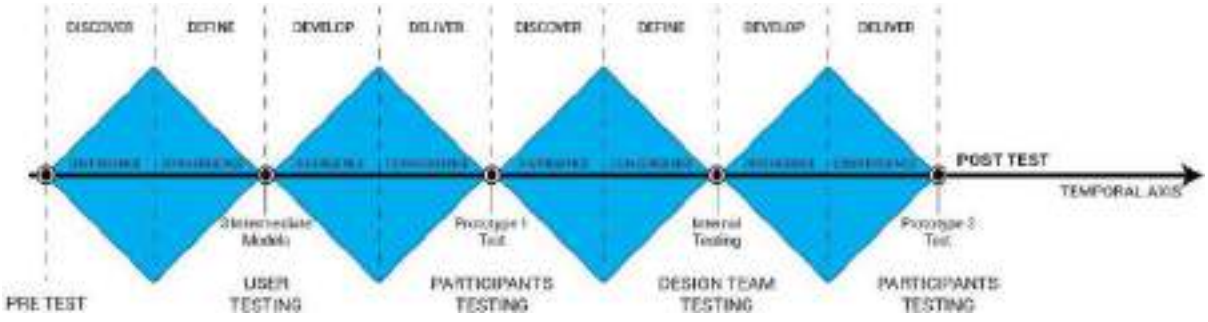

Figure 1 : Adaptation of the Double Diamond model Design Council (2014) that illustrates the interface design process.

Results of a Pre and Post Test were compared to measure the impact of the interface on students' learning. Two groups were established consisting of 119 first-year students from the Design and Engineering careers who carried out the Pre-Test (n=65 in Design and n=54 in Engineering). Within these groups, 31 students (n=13 Design and n=18 Engineering) tested the first prototype, and from that group, 24 subjects tested the second prototype (n=10 Design and n=14 Engineering) and constitute the Experimental Group. The rest of the students constituted the Control Group and carried out the Post-Test without interacting with the interface. The study also considers a third group called "Model testers", students and teachers from both careers who qualitatively tested the Intermediate Models. Figure 2 shows the activities for each group in time.

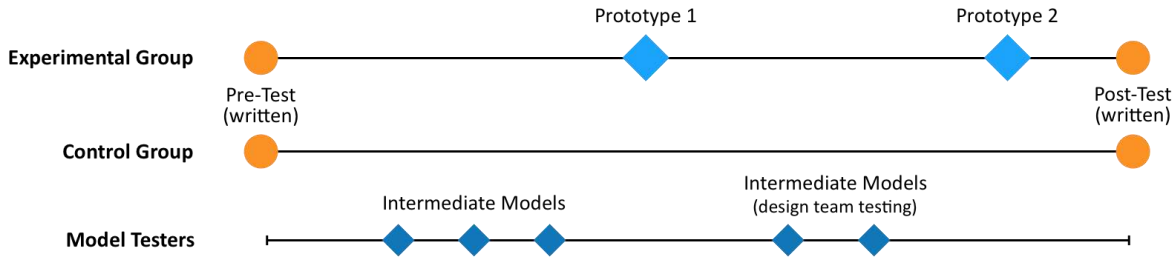

Figure 2 : User-testing, validation and learning assessment activities for each group considered in the study.

Designing the Experience and Interface

To some extent, the flaws in trigonometry learning are due to the fact that students resort to memorization when facing a trigonometric problem (Méndez & Leal, 2018). Studies reveal that learning through the memorization of both concepts and procedures does not lead to a real understanding of the subject and generally only point to the quick solution of a mathematical problem, leaving aside the conceptual understanding and the ability to understand the same concept represented in different ways (Weber, 2005). In contrast, the designed interface considers a multimodal approach (vision, hearing and touch in tandem), thus providing different ways to access the information. The pedagogical experience designed in this study aimed to promote higher levels of thought (Bloom, Engelhart, Furst, Hill, & Krathwohl, 1956; Driscoll, 2000) to activate previous knowledge and/or correct misconceptions and integrate them to the new concepts (Barry, Kanematsu, Kobayashi, & Shimofuruya, 2003).

Pedagogical dimension

At early stages of the design process, five thematic modules were defined to determine the scope of content to be addressed. Having a content framework provided a roadmap for design development and enabled to conceive a coherent pedagogical experience supported by the interface. The contents were defined based on the Pre-Tests, literature review and the previous experience of Engineering professors. The five modules are:

- Module 1 : Cartesian plane and polar coordinates
- Module 2 : Sine values based on an angle
- Module 3 : Cosine values based on an angle
- Module 4 : Periodic functions and sine waves
- Module 5 : Special angles and trigonometric identities

The modules are not necessarily presented in sequence during the experience. To concretize the order of presentation of concepts, a script organized in twelve sequential “scenes” was created to provide a structure for the experience. The script progresses constructively, from the most simple to the most complex. For instance, the first scene is restricted to only understand how the Y axis of the cartesian plane works, and the final scene is about exploring periodic functions and understanding their applications in the physics world. The leading principle that drives the experience is that students are challenged with an open question and encouraged to work collaboratively on their own to find the answer, abilitating students to have clear spaces to err, experiment, explore and discover. It also provides a general guidance for the facilitator that hosts the sessions in respect to the moment in which to ask the participants for specific interactions, what questions to ask, and determining the milestones that require an assessment of the understanding level.

Multisensory dimension

Following one of the principles to create effective interfaces mentioned by Resnick et al. (2005), the interface was designed to provide low limits, high ceilings and wide walls: An effective interface enables novices to participate (low limits), offers experienced higher level activities (high ceiling) and offers a wide range of exploration possibilities (wide walls). In addition, the interface design was built upon the benefits of integrating multiple peripheral senses (vision, sound, and touch) as a teaching-learning strategy (Shams & Seitz, 2008).

The interface provides a graphical and sonic representation of trigonometric concepts, which are explored manipulating physical controllers using different gestures (sliding, pressing, rotating). Some controllers use a

custom design while others are recognizable elements, such as knobs, sliders and buttons. The graphical representation or Graphical User interface (GUI) relies on the Unit Circle model, widely used in trigonometry (Kendal & Stacey, 1996) which is adequate to understand periodic functions and simplifies the calculation of sine and cosine based on an angle (Mesa & Goldstein, 2016). The Unit Circle is drawn on a screen, among other relevant graphical representations: sine and cosine values, the current angle, the cartesian plane, the sine wave and textual and numerical values where needed (Figure 3). Parameters of the Unit Circle are controlled mainly by what we call the "Rotary Wheel", a thirty-two centimeter ring that can be turned in 360 degrees to control the angle that is drawn inside the Unit Circle on screen, consequently modifying trigonometric values (e.g. value of cosine). The rest of the controllers modify additional parameters (e.g. amplitude) and also enable navigating through scenes.

Sound has two roles: First, to highlight relevant information. For instance, when a special angle (0, 30, 45, 60 or 90 degrees, etc) is reached by turning the Rotary Wheel a beep sound is triggered, indicating the user that there's something about that value that is worth exploring and analyzing; The second role is to represent trigonometric concepts as sound (e.g. sine waves represented as a variable tone to understand frequency).

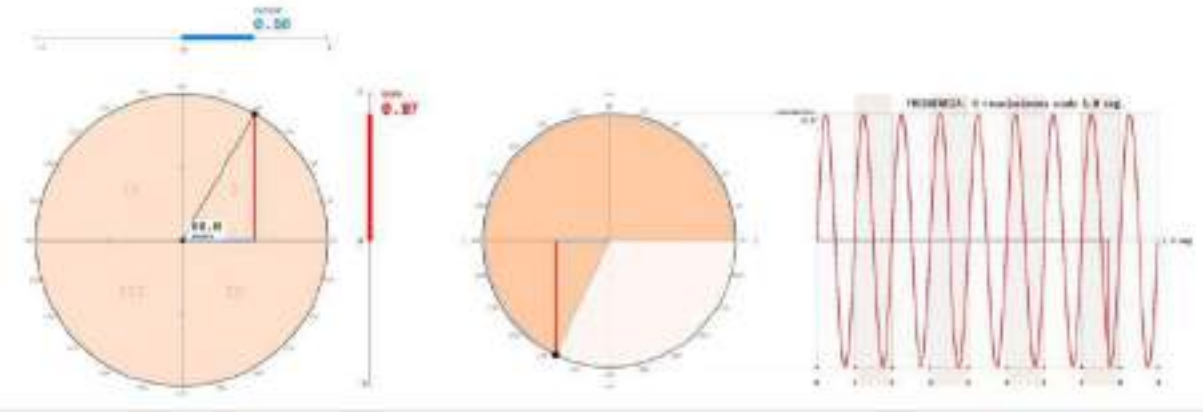

Figure 3 : GUI of the interface (details), where the unit circle, angle, sine and cosine values can be visualized (left). Users can also interact with a visual representation of the sine wave by changing its frequency and amplitude which alters the properties of a tone that is heard through the speakers (right).

Intermediate Models and Prototype development

The design process relied on iterative prototyping and frequent user-testing, a standard method in the field of HCI for interface design that has the following proven benefits: enables to receive feedback from the participants in the early stages of development; guides designers to iterate diverse design options before committing to a particular path; and keeps the design process focused by abstracting the complexities of an integrated design into particular aspects to inform design decisions at each stage of development (Alperowitz, Weintraud, Kofler, & Bruegge, 2017; Dumas & Redish, 1999; Scarlatos, 2002).

The prototypes considered three dimensions based on the model proposed by Houde & Hill (1997): the "role" in respect of its use as a learning mediator; the "implementation" to define the technology and form of the interface; and the "look and feel" to consider the sensory and perceptual aspects.

In all the versions the common technology elements are: a physical device that integrates tangible controllers and sensors, a software that reads and process the data obtained from the sensors, and a 32-inch LCD screen that graphs the GUI and provides visual and sonic feedback based on the data readings (Figure 4).

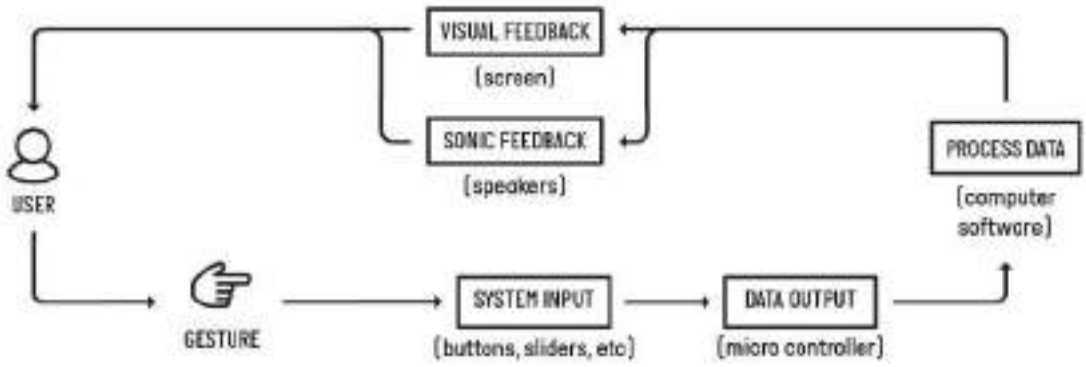

Figure 4 : Information flow diagram of the system.

Intermediate Models

Three intermediate models were designed and tested with 18 subjects, including students and professors from both the Design and Engineering Schools. Each session was twenty to thirty minutes long and included groups of one to four simultaneous participants. The sequence of Intermediate Models enabled to identify unexpected variables and helped resolve aspects such as ease of operation, collaboration dynamics, comprehension level of the content, enhancements of the physical space and progression of the script. For instance, in Model 1 the first iteration of the Rotary Wheel was a control detached from the main screen (Figure 5) and even though it was easily understood and operated, it still remained too close to the "mouse paradigm". It was observed that users had a tendency to touch and indicate with their fingers directly on the screen, performing both deictic and iconic gestures (Rimé & Schiaratura, 1991), which led the team to integrate the Rotary Wheel on the screen for the following model (Figure 6).

Other decisions implemented included: modifying the position and thickness of the Rotary Wheel for better visibility of relevant information on screen, adding additional controls for the users (scene navigation, frequency and amplitude control, visualization of equations), removing/adding scenes and adjusting terminology and style used by the Facilitator.

The analysis of observations and questionnaires responded by users during this phase led the design of Prototype 1 (described in greater detail the following section). A selection of relevant opinions and observations extracted from a general matrix (where all data was transcripted) is presented as a summary in Tables 2 and 3.

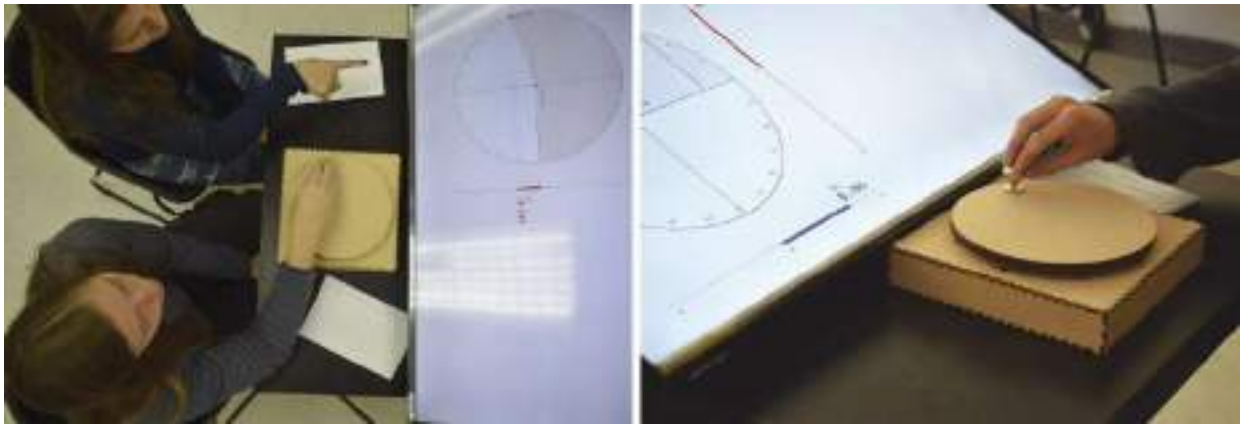

Figure 5 : Intermediate Model 1. Users interacting with the interface during a user-testing session.

Figure 6 : Intermediate Model 2, the Rotary Wheel is now integrated into the screen.

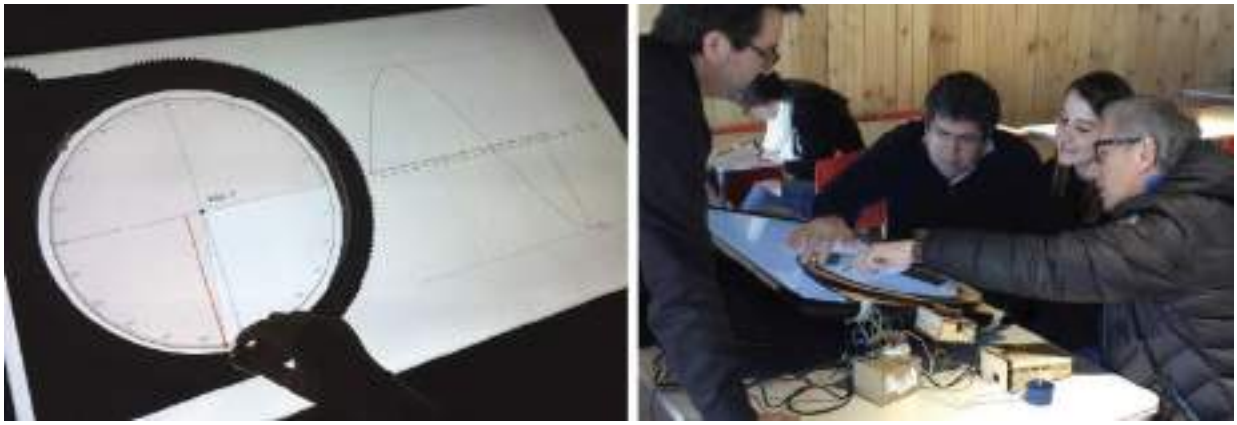

Figure 7 : Intermediate Model 3, user-testing sessions with Engineering professors to collect "expert" feedback.

Table 2 : Summary of relevant observations collected during the sessions with Intermediate Models 1, 2 and 3.

Observation highlights from sessions with intermediate models	
Variable 1 - Interaction	*Variable 2 - Contents*
● Interest in manipulating the interface increases as users understand the operation of the device. ● Users seek for precision in the numerical representation of angles and measurements. ● Users perform unexpected gestures, such as touching the screen to illustrate movement of the elements. ● The experience in standing position leads to a greater use of the body. ● Some students struggle with understanding some concepts when these are influenced by previous misconceptions.	● Users respond automatically to the Facilitator's questions using their prior knowledge and then discard or confirm that response by manipulating the interface: "Oh no! Ah, right!" ● Users tend to verbalize understanding during use: "Now I can only move on the X axis and it goes from 1 to -1". ● As the contents become more complex, the interaction is enhanced using more senses (sight, touch, hearing). ● A productive dialogue is generated with the facilitator and peers. The group combines each member's previous knowledge and new discoveries to articulate a collaborative response. ● The facilitator's script is essential to guide students in the exploration of the interface.

Table 3 : Selected opinions and suggestions from users during the testing sequence of intermediate models.

Users' relevant opinions - intermediate models	
What would you change to make the operation of the interface easier?	• "Add more manipulation controls to handle graphics". • "That the two users could manipulate it [the interface] at the same time". • "Improve accuracy." • "Increase feedback through sounds".
Were you able to understand the contents presented?	• "Yes, it is very well explained and helps to understand the relationships, it creates a mental map." • "If they had explained this to me this way in [high] school, I think I would have understood way better." • "Yes, but I missed an ending as a conclusion."
Was there any aspect that confused you?	• "Trying to explain in simple words the meaning of sine and cosine." • "Determine the radius of the circle." • "None. Perhaps the precision of the values that appear on the screen."
Professors' suggestions - intermediate models	
Regarding the interface	• Incorporate the possibility to visualize equations. • Explicitly display the quadrants in visual form. • Incorporate sound at key moments, for example when curves meet at the same point.
Regarding content	• Deepen the topic of the reflected angles and use the circle to explain Pi and radians. • Incorporate the connection between contents in an associative way.

Prototype 1

Prototype 1 is the culmination of the first process of Intermediate Models and was tested with 31 subjects. The focus of this prototype was to validate the physical configuration, ideal number of participants per group and the progression of the content presented. Prototype 1 differs from the Intermediate Models in the sense that it is an integrated interface and learning experience, whereas the Intermediate Models were more focused on particular aspects and not necessarily on a fully functional device.

The interface consists of an LCD screen (where the trigonometric concepts are plotted) arranged horizontally and slightly angled. Several controls are built into a physical device that wraps the screen, organized by function in two distinct sections, albeit presented as a single integrated device. For this version, laser-cut agglomerated wood was used for its construction.

The main control is the Rotary Wheel (Figure 8), which controls the angle of the Unit Circle represented in the GUI (Figure 3). A series of secondary inputs consisting in buttons and knobs control additional system variables, grouped by function:

- Navigation controls: move forward and/or backward through scenes, change the angle manipulation mode (automatic or manual), activate and deactivate the display of "reflected angles".
- Parameter controls: manipulate frequency and amplitude of the curve that graphs the periodic functions.
- Debug controls (for Facilitator only): calibrate the position of the Rotary Wheel with the digitally drawn angle.

Inside the physical device there are a series of electronic components: two rotation sensors, a microcontroller, pressure sensors (buttons) and a linear potentiometer (slider). The rotation sensors measure angular position: one to measure the angle of the Rotary Wheel and the other to measure the angular position of a knob that controls the frequency. The microcontroller is an Arduino Leonardo that reads the voltage from the different sensors and sends a constant report to the serial port. The Arduino is connected to an external computer (via USB) that receives and interprets the data through a custom software developed in C ++, using the OpenFrameworks library (https://www.openframeworks.cc/). The software is responsible for performing the graphic and auditory output that is displayed through the monitor (Figure 9).

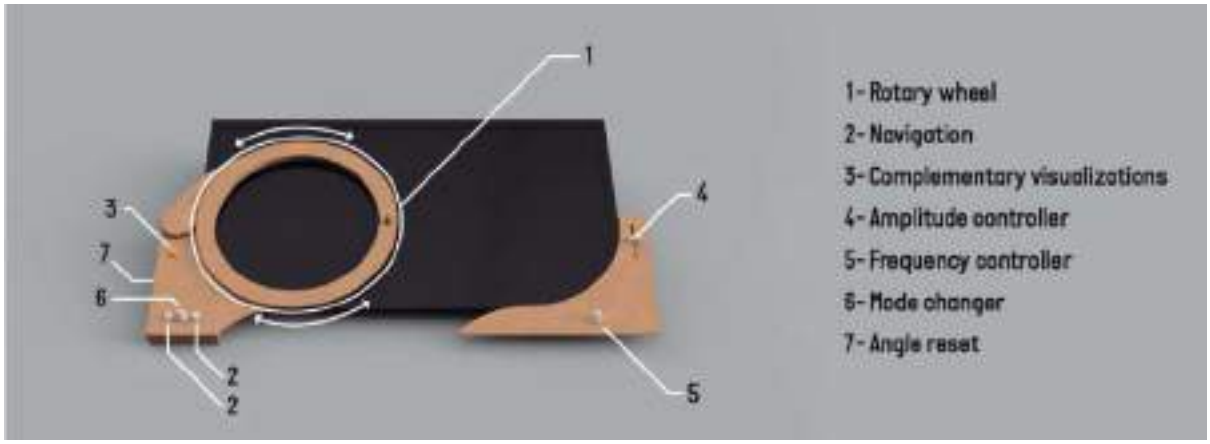

Figure 8 : Schematic render of Prototype 1, showing its configuration and distribution of controls.

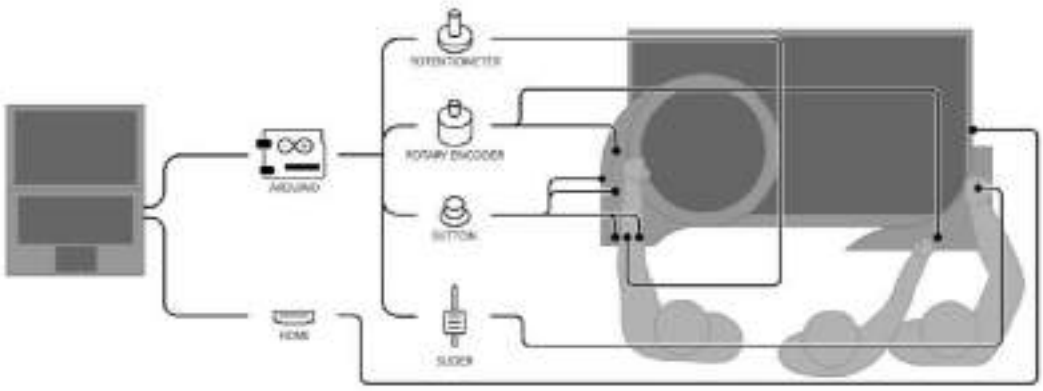

Figure 9 : Diagram of the technology and electronic components of Prototype 1.

Figure 10 : User-testing session with Prototype 1.

Observation helped to conclude that three participants was the ideal number to enable a good field of view of the screen and making decisions based on consensus. An adequate number of users enable a more intimate social interaction (as they are physically close to each other) where nonverbal communication was often observed. It was also observed that on occasions participants had wrong or imprecise preconceptions of trigonometric concepts, which distorted or even prevented the acquisition of new knowledge (Ambrose et al., 2010). To address this issue, it was decided that for Prototype 2 the script would present concepts detached from their technical term at the beginning and introduced progressively throughout the session. For instance, during the first quarter of the experience, the word "sine" or "cosine" are intentionally replaced by "red bar" and " blue bar". This strategy enables participants to understand the meaning of concepts before associating them with their name, facilitating the student to incorporate the new knowledge with less resistance.

Table 4 summarizes the most relevant observations and suggestions collected during the testing sessions with Prototype 1.

<table>
<tr><td colspan="2">Relevant observations of Participants' testing sessions - Prototype 1</td></tr>
<tr><td>Variable 1 - Interaction</td><td>Variable 2 - Content</td></tr>
<tr><td>The use of sound as a pedagogical resource surprises and attracts participants.
The facilitator tends to invade the space of the student when having to operate certain buttons (such as scene navigation).
It is necessary to determine strategies to encourage manipulation of the interface for students who adopt a more passive or observant attitude.</td><td>Participants tend to make predictions of what comes later during the experience.
Participants understand the content progressively and establish relationships between concepts that are intertwined during the sequence of scenes.</td></tr>
<tr><td colspan="2">Suggestions from the users - Prototype 1</td></tr>
<tr><td>What would you change or add to make the operation of the interface easier?</td><td>"An explanation for everyone when finishing each scene."
"Nothing, but it is very necessary that there is someone there to explain."</td></tr>
<tr><td>Were you able to understand the contents presented?</td><td>"I did not understand them well in the beginning but they explained very well in the process."</td></tr>
<tr><td>Was there any aspect that confused you?</td><td>"Some, but seeing the graph again, I would understand."
"No, it was clear how it worked and the fact that sine and cosine had their own respective colors, made it easier for me to distinguish them."</td></tr>
</table>

Prototype 2

Prototype 2 is the culmination of the prototyping process. It was tested with 24 out of the 31 subjects that tested Prototype 1 (seven students could not attend the sessions). Both the content progression and the hardware is similar to Prototype 1, described in the previous section. The goal for this phase was to enhance the interaction experience through a better constructive fidelity and ease of operation. Thus, the main focus was on the redesign of the physical device.

All the electronic components (Arduino, sensors, cables, etc.) were placed hidden inside the structure to facilitate assembly and to achieve a cleaner look and feel of the device. The positions of the controls were reorganized, now providing more control possibilities to the user-end of the interface. A new control zone for

the Facilitator was implemented on the upper side of the interface (where the Facilitator stands) to keep the screen unblocked at all times (Figure 11 and 12). Parts of the Rotary Wheel and the gear connected to the rotation sensor (rotary encoder) were now made out of acrylic (Plexiglas), which performed better under mechanical stress and reduces friction, therefore achieving more precision and smoothness when operated.

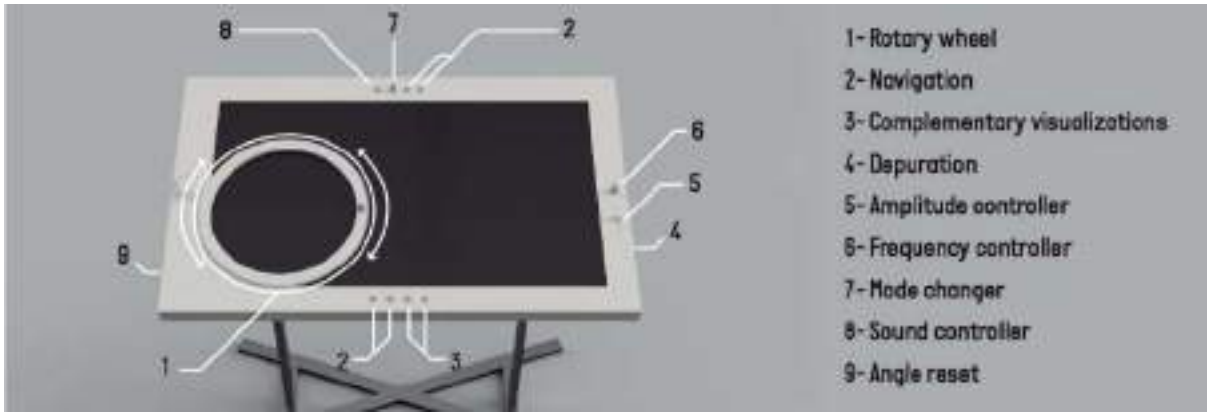

Figure 11 : Schematic render of Prototype 2, showing its configuration and distribution of controls.

The qualitative analysis of data obtained during user testing with the Intermediate Models and Prototype 1 also impacted on decisions regarding the physical space (Jetter et al., 2014). In the previous versions participants were seated in chairs, this limited the users to exchange roles as they had a restricted displacement around the interface. In Prototype 2, a stand for the interface was designed to obtain a suitable height and angle when standing in an upright position, which resulted in a more active, collaborative and fluid interaction, making it easier for participants to take turns when operating certain controls (Figure 12). Overall it was observed that the implemented design changes enhanced the experience as users were more focused on the content and less on the operation of the interface.

Figure 12 : Prototype 2 in use, now in standing position.

Learning assessment results

Pre-Test Results

The Pre-Test was designed and conducted at the beginning of the process of the study, based on the Diagnostic Evaluation of first-year Engineer students (Table 1). It consisted of 12 questions, each one was worth 1 point. It covered the five thematic Modules described previously and included a written introduction at the beginning of the test to even the minimum knowledge level needed to answer the test. It was taken by 119 students: 65 from Design and 54 from Engineering School.

Results of the Pre-Test were low. As seen in Table 5, of a maximum of 12 total points, in Engineering the mean score was 4.35 points (36% yield), and in Design of 2.44 points (20% yield).

Table 5 : Mean scores and performance obtained by Design and Engineering students in the Pre-Test.

Career	*Score (12 max.)*	*Score (12 max.)*
Design (n=65)	2.44	20
Engineering (n=54)	4.35	36

The overall performance in Design was lower than in Engineering (which was expected). However, when analyzing the results by thematic module and by question, the performance curves were very similar in both careers, showing that the difficulties are coincident and that the level of understanding of basic concepts of trigonometry was transversally low (see Figure 13).

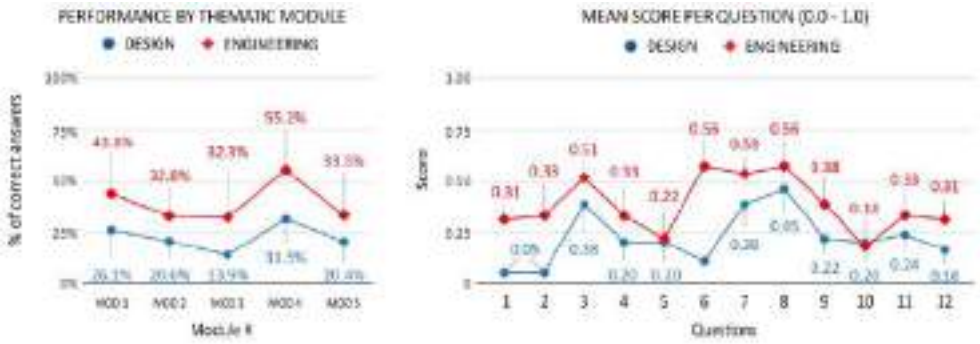

Figure 13 : Pre-Test results by Thematic module (left) and by question (right). As observed, the performance curves are similar in both careers.

Post-Test Results

The Post-Test was identical to the Pre-Test and the same data collection and analysis methods were used. The Post-Test was taken only by the Experimental Group (n = 24, Design and Engineering students) who attended two sessions with the interface (Prototypes 1 and 2). Additionally, a Design Control group (n = 16) took the Post-Test without participating in any session with the interface and without receiving formal instruction.

When comparing the results of the Pre and Post-Test, a significant improvement was observed in the Experimental Group (statistically confirmed by a two sample t-test and a paired sample t-test). In Design, the increase was of 5.0 points, and in Engineering 3.9 (4.46 points when considering both careers). It is noteworthy that even though Engineering students were exposed to additional formal instruction in trigonometry during the lapse of this study (as opposed to Design students) their score improvement was comparatively lower than the score improvement of Design students. Further studies are needed to assess with greater detail the influence of the interface in the case of students receiving additional trigonometry instruction, but the current analysis supports that the interface does have an impact in students' performance overall.

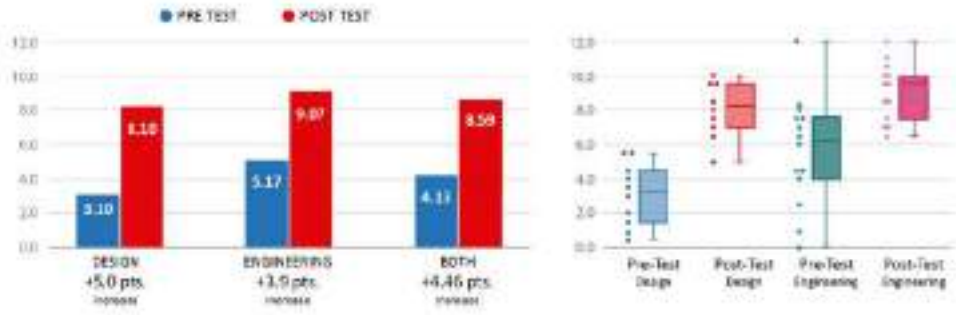

Figure 14 : Comparison of Pre-Test and Post-Test results in the Experimental Group (left). Distribution graph plotting the scores obtained by the Experimental Group on the Pre-Test and Post-Test, disaggregated by discipline (right).

Table 5 shows the comparative performance per question in the Pre-Test and Post-Test for the Experimental Group as a whole. After going through the experience with the interface, performance increased from 34.4% to 71.6%, yielding a differential of +37.1%, which indicates that the experience positively impacted learning.

Table 5 : Performance per question on Pre-Test and Post-Test, both careers.

Question number	*Pre-Test performance (%)*	*Post-Test performance (%)*	*Differential (%)*
1	12.5	91.4	+ 78.9
2	17.5	91.4	+ 73.9
3	39.2	96.4	+ 57.3
4	45.0	92.9	+ 47.9
5	27.5	47.1	+ 19.6
6	35.0	77.9	+ 42.9
7	62.5	77.9	+ 15.4
8	61.7	78.6	+ 16.9
9	40.0	38.6	- 1.4
10	18.3	65.7	+ 47.4
11	30.8	70.7	+ 39.9
12	23.3	30.0	+ 6.7
Average	34.4%	71.6%	+ 37.1%

The performance increase in the Design Experimental Group (n=10) is particularly noteworthy when compared to the Control Group (n=16) of the same discipline. Even though both groups took the Pre-Test and Post-Test, the Experimental Group had an increase of +5.0 points, while the Control Group only increased +0.64 points (Figure 15). This difference strengthens the conclusion that the performance increase is mostly attributable to the interface, and that being exposed to the same test twice did not have a relevant impact on their scores.

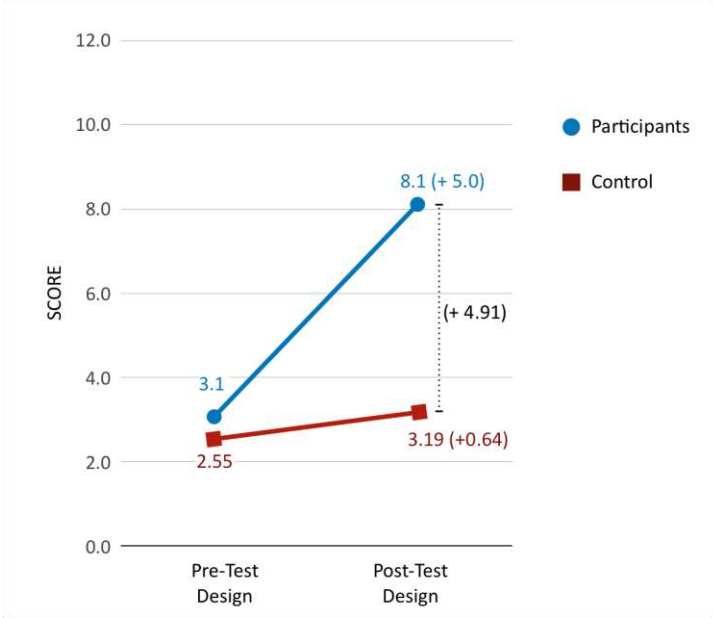

Figure 15 : Score obtained in Pre-Test and Post-Test by the Experimental and Control groups of the Design career. It can be seen that the Control Group does not show a significant improvement, which contrasts with those exposed to the interface that increased their score by +5.0 points.

Discussion and Conclusions

The main goal of this study was to explore the potential of TUIs as a tool to teach and learn basic concepts of trigonometry. Although the fact that trigonometry concepts are hard to teach and learn was justified by the literature, the specific case of students at Universidad del Desarrollo in Chile used as a case study in this research is not generalizable to the Chilean or global context. Nevertheless, results from the study endorse the potential of TUIs as pedagogical tools to enhance learning. Students who participated in the sessions with the interface improved their performance, but most importantly, data analysis showed that their cognitive process was positively influenced individually and collaboratively by experiencing the interface (Jetter et al., 2014). A limitation to these results was not counting with a formal Control Group in Engineering who received formal instruction but was not exposed to the use of the interface. This was due to the loss of Engineering students: some had taken the Pre-Test, but left the career after the first semester, and others failed their first semester and had intensive trigonometry classes during the second semester where they covered advanced trigonometry concepts.

Using multiple senses to transfer the content contributed to diversify the access routes to the information during the learning experience. For example, when participants used the Rotary Wheel, they could see how the angle and values of sine and cosine changed, making the abstract visible in a concrete way. Manipulating a physical representation of digital information proved to be beneficial for students to internalize abstract concepts in concrete terms (Lakoff & Núñez, 2000). Being able to repeat an action as many times as necessary to understand the phenomenon enabled students to reflect and agree on opinions, activating their learning process and making it more participatory. In addition, the use of a simple and non-technical language during the experience, facilitated the construction of metaphors that serve to achieve understanding of abstract notions of mathematics (Font et al., 2010)

It was inspiring to observe the process of co-creation of knowledge among participants from different disciplines when they discussed while using the tangible manipulative attributes of the interface. Students were able to understand concepts that they did not understand before, corroborate or question their previous knowledge, and learn together using the interface.

At the actual point of development, the project could not entirely resolve the design principle proposed by Resnick et al. (2005), to offer low limits, high ceilings and wide walls. Today, the interface offers ideal low limits for novices and partially offers a wide range of exploration possibilities (wide walls) but does not enable more sophisticated interactions (high ceilings). Nevertheless, the research team agrees that the interface in the future could evolve into an educational tool to approach teaching-learning of mathematics for both teachers and students. By appealing more to the understanding of the concepts and less to the direct resolution of mathematical problems, researchers believe that the interface can be a useful ally to facilitate the entry to the abstract approach needed to develop more complex skills in advanced mathematics.

Engaging in Materiality: Issues in Art and Design Education

INGALLS VANADA Delane

University of Florida, United States
delane.vanada@ufl.edu
doi: 10.33114/adim.2019.04.406

In the training of art and design educators, we must not overlook modes of engagement that can build capacities for connecting theory to practice through creative research and connections to the physical materiality of art. Whether online or on-the-ground learning, artist-teachers must not disconnect from the power of engagement with and the materiality of art. This paper places a focus on ways that teacher training programs can anticipate and activate attitudes of new materialism and design thinking, providing a much-needed anchor in the digital age. With a contemplative view of art practice as research, projects in an art and design education program elevate opportunities for exchanging understanding, promoting dialogue, and approaching learning and research as relationship. Intentionality in the ways that the practice of teaching itself is also materiality, as a living practice, along with the training teachers as designers and facilitators of cultures of making, thinking, and learning are discussed.

Keywords: art and design education, new materialism, materiality, teacher training

Introduction

Drawing from the maker movement and literature surrounding digital media learning, Justice (2015) refers to the relational aspects of digital materiality, a paradox that he calls “decentered embodiment” (p. 6). In absence, there can be a greater ability to be ‘present’ or attentive. He believes that in this digital age, agency is not reduced to a person’s will but is rather dispersed among networked systems.

Digital materialism, as Lankshear and Knobel (2011) argue, is second nature to today’s learners. Even those who acknowledge not being artistic in the sense of drawing, painting, or photography or having formal technology training quickly learn to create collages on their smart phones, use editing software to crop or alter images—all within a series of mouse-clicks. At the same time, Lankshear and Noble warn that “without a change in ‘ethos’ within education, the benefits from addressing ‘the new technical stuff’ will remain seriously constrained” (p. 88).

Thus, within this new ethos of materiality and the maker mentality surrounding technology, there is a concern that we not lose the core dimensions that support an aesthetic relationship to creativity such as, “participation, collaboration, distribution and dispersion of expertise, and relatedness” (Lankshear et al., 2011, p. 68). Mills (2009) suggests:

> *While in the past, viewers were assumed to be present in order to experience the mediated form, now viewers themselves mostly mediate through digital technology. Viewers, as well as the many*

> *works of art they can encounter at the click of a computer mouse, exist in a non-physical state, a state of disembodiment in relationship to the work of art. (p. 35)*

While rapid technological changes of this digital age and the tools through which we perceive art and design could distance us from the created object, we must be purposeful about engaging our senses and desconstructing Western notions of hierarchy that exist between human and non-humans (Hood & Kraehe, 2017).

Material Notions in Training Art and Design Teachers

Particularly in the training of art and design educators, we must not overlook modes of engagement that can build their capacities for connecting theory to practice through creative research and connections to the physical materiality of art and design practices. Artmaking engages our senses through materiality, and we mustn't disconnect from the intangible power of the qualities of artworks as things, or what Bennett (2010) refers to as "thing power"—"the curious ability of inanimate things to animate, to act, to produce effects dramatic and subtle" (p. 6). This contemplative view of art practice as research elevates the shared materiality of all things and practices in new materialism (Barrett & Bolt, 2012; Bennett, 2010).

People's capacity to instantly view images online suggests a need for thinking about 'being present' with things (in this case, visual art and artmaking) as more than just objects, and as more of a dialogue. New materialism in art and design education also offers a much-needed perspective on co-creation of knowledge, adopting a stance of 'with-ness,' and adopting artmaking and research as co-creative inquiry—providing a much-needed anchor to managing digital technology (Hood & Kraehe, 2017).

In the training of teachers, we must be intentional about the ways that the practice of teaching itself is also materiality, as its own sort of living practice (Justice, 2015). As described by (Ingalls Vanada, 2013), training teachers as designers and facilitators of cultures of making, thinking, and learning is appropriate for 21st-century education (Ingalls Vanada, 2014, 2016). There is a needed merger between beings and "materiality of 'things,'" as jagodzinski and Walling (2013) argue—toward change and a blurring of the boundaries of arts-based research in the field of art and design education (p. 32).

In what has been called "an age of disembodiment" (Mills, 2009, p. 7), this paper places a focus on ways that teacher training programs can anticipate and activate attitudes of new materialism and the material qualities in art and design practices. Through an action research methodology (Sagor, 1992) that emphasizes opportunities to exchange understanding and approaches research as relationship and knowledge construction, rather than just imparting information, preservice teachers engaged in arts-based inquiry alongside collaborative practices involving design-based problem solving.

Online Learning: Making the Immaterial, Material

Through the lens of a professor of both on-the-ground and online art and design education programs in the U.S., this paper reports on real-world practices that connect theory with practice and allow students to learn more deeply through active engagement with materials and concepts. In developing an online Masters of Art Education course that incorporates design thinking, called "Thinking in Art Education," the researcher also reports on the challenges of creating collaborative, digital learning opportunities for art education candidates that simulate the purposeful encounters or "enacted encounters" of a physical art classroom where making with others supports agency (Justice, 2015, p. 14).

Amidst the challenges of online learning, cohorts of students develop very tight emotional and supportive bonds with peers through the process of their online coursework, discussion board chats, and in live classroom sessions supported by Zoom ©, for instance. In introducing teams of artist-researchers to web-based platforms they could use to create and share 'sticky notes' during a collaborative action research project using design thinking methodologies, they worked together digitally as if they were in a room together. Not surprisingly, these digitally savvy students, comfortable within a new ethos of learning (Lankshear & Knobel, 2011), found many more of their own ways to collaborate online and engage with new digital materials. This is the type of letting go and learner-centered pedagogical practices necessary to teachers of online, art-based classes, as new literacies soon cease to be new. We must empower 21st-century learners to connect digitally, materially and socially. "It's time to shift our thinking from the old model of teaching to a new model of learning," as Thomas and Brown (2011, p. 34) have aptly advised.

Design Thinking and Collaborative Inquiry

With the reality that 21st-century life demands greater interdependence and collaboration, it is important to rethink preparation programs in art and design to better support preservice teachers' hybrid identities and capacities as agents of change, along with developing their abilities as collaborators and facilitators of materiality. In a university course designed by the researcher, undergraduate and graduate preservice teachers (both online and on-the-ground) engaged in collaborative action research assignments as teams through a design thinking model and toolkit called the T-H-I-N-K model © (Ingalls Vanada, 2011). Developed by the researcher, students used the T-H-I-N-K model to investigate real-world educational issues of concern to them in art and design education. The problems they are to solve are not predetermined, as is often the case in project-based or active learning scenarios. Problem finding is in itself one of the most valuable part of the process and provides opportunities for defining educational problems with greater empathy, intention, and depth.

The T-H-I-N-K process (Figure 1) served as a framework and methodological research structure for these new researchers; it guided them to collaboratively identify problems they observe in art and design education, think in more nonlinear ways, and develop empathy. Candidates brainstormed and synthesized ideas, then developed prototypes towards research solutions, all of which encouraged their inductive (thinking wide), deductive (synthesizing), and abductive capacities (using intuition and imagination).

Figure 1: The T-H-I-N-K model ©

As typical of learner-centered processes, there is often push-back as many preservice teachers are somewhat fearful of ambiguous problems to solve, and their skills for ideation are often low (admitting that even in their studio classes very exact parameters determine success). Positive outcomes exist also, as increased motivation and engagement are reported in learner-centered art and design education classrooms that foster personal voice and choice (Ingalls Vanada 2011, 2016). One student commented on their experience with the T-H-I-N-K process:

> *It was energizing and invigorating to know that I can have a hand in change! This process definitely helped me to think outside the box in everyday problems. It also gave me a chance to work with different personalities in a corroborative setting. It was great to hear others' opinions and really listen and discern answers. The skills of thinking, creating, listening and evolving will be used throughout the rest of my career as well as in my personal life (Student participant, personal communication, May 1, 2017).*

In using the T-H-I-N-K model © or any design thinking process (Ingalls Vanada, 2014) art and design candidates may collect both qualitative and quantitative data, based on their research questions. One team in the "Creative and Critical Thinking" class, conducted observations and survey students in art classrooms that led them to realize that "students want to learn about social justice issues in the classroom… sexist dress code[s], offensive words, women's rights, emotions/feelings - developing empathy, LGBTQ, religion, politics,

and gender awareness and equality." They found that a large percentage of the students favored the process of creating over the final product, leading these teacher-researcher to ask:

> *Why? Why do we not engage in more discussion and reflection on social justice issues in our schools today? Why do we take the student voice out of planning and curriculum building? Why do we place such a strong emphasis on the final product and what aesthetic values does that give our students? (Student team 1, personal communication, May 1, 2017)*

Followed by brainstorming and protyping solutions, more questions arose such as, "How can we show teachers ways of using social justice issues in the classroom? How can we develop teachers' skills to discuss social justice issues?" To address these questions—after more mind mapping and ideation—they developed a professional development workshop entitled "*Meaning Matters, An Empathy-Driven Curriculum Symposium,"* creating a website and thinking through the advance planning to allow their ideas to be realized.

Along with the learning to ask better questions, the researcher observed how collaborative action research supports candidates' dispositions, such as: (1) risk taking, "failing forward" and the courage to share one's ideas; (2) self-direction with a make-to-learn approach; (3) managing ambiguity and learning to solve problems along with others and the ideas that differences bring; (4) openness to experience and stronger group trust amidst diversity—race, culture, gender, age, etc. Students self-report these attitudes also (Student team 1, personal communication, May 1, 2017).

Figure 2: Preservice art teachers engaged in design thinking

On-the-Ground Learning: Materiality in Preservice Training

Art and design educators give expression to ideas through art processes and art making. They support their students' abilities to interact with and transform materials in ways that are both bodily and emotional. Contemporary art and its integration into the art and design education classroom is vital (Marshall, 2014), as it provides physical and connected investigations into the nature of things and object's materiality. Teachers sense and experience the material qualities of art, design, and visual culture—interpreting them and inviting young students to be transformed, through imagination and aesthetic inquiry (Mills, 2009).

In on-the-ground programs in art and design education developed by the researcher, students engaged in active learning investigations surrounding critical issues and enduring ideas of humanity, visual art, and

society. In particular, students learned about and created visual responses to works by contemporary artists in the context of deepening dialogue surrounding social justice issues (Ploof & Hochtritt, 2018).

Envisioned was the importance of preservice artist-teachers engaging with, and making art as a way to inquire deeply into topics affecting their future careers as educators and their identities as artist-teachers—an art-as-experience approach (Dewey, 1934). As described in the work by Ingalls Vanada (2017), "interacting with art provides opportunities to disrupt preconceived notions and is a way to challenge students in how they are not just consumers, but also creators—change agents for a better society" (p. 112). The following sections provide examples of student work in a teacher training program that support the intersection of digital and physical materiality.

Art-based Research and Teacher Identity

Arts-based research practices and methods such as action research, visual inquiry and reflection, and a/r/tography are arts-based research movements involving the topic of materiality (Cahnmann-Taylor & Siegsmund, 2007; Irwin & Springgay, 2008; Klein, 2012; Leavy, 2015; McNiff, 2013; Pinnegar & Hamilton, 2009; Rolling, 2013).

A/r/tographic inquiry, as a type of practice-based research, "offers a materiality, a physicality, and embodied approach to learning, that isn't addressed by many teacher education researchers" (Gouzouasis et al., 2013, p. 9). It also offers processes—ways of thinking and knowing—that are grounded in art and design, such as questioning, observation, interpretation, and analysis in what is known to a/r/tographers as "living inquiry" (Springgay, Irwin & Kind, 2008, p. 902).

In this section, strategies for self-study are explored which can support layers of materiality and layers of identity. Preservice teachers followed trails of inquiry that led to becoming more visually reflective practitioners, with a critical approach to dialogue as a culminating part of this work— often related to intersectionalities of their identities such as "race, ethnicity, religion, economic status, social class, gender, nationality, chosen interests, sexual identity, politics, and personal history" (Pfeiler-Wunder, 2017, p. 31).

Anna's Identity Triptych

In a "Contemporary Issues" course, students were challenged to create a triptych—an exercise in materiality and identity—that combined a (1) self-portrait (choosing to focus on relationships with others, their emotional lives, or issues they care about); (2) sense-of-place context; and (3) physical things and material "stuff' that defines them. These three aspects or layers of self worked together to dramatically and visually portray their stories and demonstrated how art-based research adds to the diversity and complexity of a learning community and culturally relevant practice.

Throughout this course we discussed how a/r/tography intertwines the artist, researcher, and teacher as a holistic entity; it embraces an undivided life of artistic expression, reflective and reflexive inquiry, and pedagogy (Gouzouasis, Irwin & Miles, 2013). Students engaged in provocative issues such as depression, suicide, homelessness, gay and gender adversity, pornography, sexual harassment and rape, racial profiling, immigration, and more. Through personal inquiry and artmaking, they investigated their personal identities as also related to teaching, as a way of connecting with their multiple roles.

One student, who we will call Anna, used the assigned triptych project to conceptualize multiple aspects of her identity through performance art from a feminist perspective. From a gender focus on living inquiry, this candidate activated embodied engagement regarding her identity as a woman, through personal performance photography as a form of interpretation and representation. Anna researched the work of Marín and Roldán (2010), who examine the use of photography as a research tool by questioning or problematizing. She used image content relevant to her investigation about personal experiences as a woman and being "body typed," or identified by body parts. Painting her body blue and arranging herself among the plastic limbs and parts of used retail store manikins—also painted blue—she instructed a family member to specifically photograph herself as a series of body parts. In this way, her work was both an engagement with the materiality of her art, as well as a digital provocation of her intended identity statement. The following image is one of three in a series that depict her identity in tryptic form (Figure 3).

Figure 3: Student's Identity Tryptich (1 of 3)

In the case of Anna's artwork as a performance piece, she benefited from the physical embodiment of her inquiry and being photographed as a part of that work. While not physically present to engage with her performance art, her peers engaged with the materiality of her photographed experience, made more engaging because of the large size of the printed artworks and Anna's presence in the room. In a real sense, the materiality of her work was evidenced in both her lived experience and the large printed photographs. As contemporary art, her choice of materials significantly informed and enriched her concept. Her work exemplifies embodiment of the ethos of digital making and learning.

An essential outcome of this assignment happened in the classroom as students shared their work with each other. Preservice art and design teachers become critical makers, but they also serve as critical viewers when they engage with the materiality of what one of their peers has created—not just its physical properties, but their bodily perceptions and senses, understood through their own personal lenses, yet also through the lens of the makers. As future teachers who will soon navigate the questions and ensuing dialogue of their own students, this is essential preservice practice; yet often only happens in the studio classroom and not the art and design education classroom. Artist-teachers gain practice in navigating the various viewpoints of materiality: their own point of view and the view of their peers. In most cases, the content of students' visual reflections were highly personal, adding to the depth of learning and conversations that ensued. They created quality works of art because they cared deeply about what they wanted to communicate through their artwork as attached to identity, which in turn altered the materiality to the viewer.

Self-Study and Visual Reflections with Materials

Self-study is a qualitative research strategy that fosters teacher identity and awareness toward becoming more visually reflective (Klein & Miraglia, 2017; Pinnegar & Hamilton, 2009). Self-study is known as "the study of teaching practice that explores identity, expectations, and the emotional side of teaching through any number of points: critical incidents, practice over time, and/or exploring assumptions, beliefs, and attitudes" (Klein & Miraglia, 2017, p. 25). In engaging in self-studies, preservice artist-teachers blend creativity with critical thinking and practical skill—supporting the reality that the artist-teacher's identity is dependent upon their personal life story as an artist/designer and a teacher—along with many other roles.

Sometimes students' deep inquiries were based on issues or incidents that they observed while in schools for their clinical observations, creating artworks and written reflections that connected their artworks to and sometimes they reflected on artists' works. This issues-based approach to art and design education offered insight into ways they might foster dialogue in their own classrooms and engender the courage to take risks in that regard, rather than skirt around differences of opinion or belief systems (Gaudelius & Speirs, 2002). One student's self-study engaged material processes that led to this response during a practice teaching experience (see Figure 4):

> *I began the day terrified and self-conscious wondering how in the world I was qualified to be in front of a classroom of malleable minds. I wanted to hide my face under a paper bag so to speak, so no one would know just how intimidated I was. I felt like insecurity was stamped across my*

forehead and it kept me from interacting with the students in any meaningful way… Upon realizing that my insecurities did little to gain the ears and respect of my students I tried to muster my confidence. "I AM QUALIFIED TO BE HERE!" I told myself and I tried to carry that attitude into the next class period. This act of "mustering" nearly turned into a mantra of pretending (Student participant, personal communication, May 6, 2015).

Figure 4: Student Self-Study, "I AM HERE"

Visual Inquiries with Contemporary Art

Students in the "Contemporary Issues in Art Education" classes developed by the researcher read chapters in Quinn, Hochtritt and Ploof's *Art and Social Justice Education: Culture as Commons* (2011) and conducted art-based research projects in response to contemporary artists' works. They created artistic or design-based visual reflections that were accompanied by creative writing, poetry, new design media, or narratives about their work. In this process, they connected theory to practice by envisioning practical, postmodern strategies for use in their future classrooms connected to materiality.

An essential outcome of this assignment happened in the classroom as students shared their work with each other after being coached regarding Lerman and Borstel's Critical Response Process (2003). One student reflected upon Blandy's article (2012) that reports on the creation of a commemorative community garden in response to a gang shooting. In response, this candidate created artwork that helped him to process a childhood friend's suicide. He collaged physical memories (pictures, objects of shared hobbies, etc.) to honor his relationship with his friend, becoming its own piece of material culture. In reflecting further, this preservice teacher also imagined using their "method of collecting and sharing stories to help bring healing to students whose lives have been effected by drug use" as a way to bring change in their future classroom (Student participant, personal communication, October 30, 2016). Certainly, professional identities are tied to our inner worlds, as well as outer. (Pfeiler-Wunder, 2017)

Opening up the classroom to dialogue surrounding issues requires reflexivity and vulnerability, but one benefit to preservice teachers was evidenced in a note I received from a former student after she started teaching:

> *Thank you for modeling how to facilitate and engage in critical and difficult conversations. Because of our Contemporary Issues class, I have had the courage to navigate difficult conversations about issues that have arisen in my high school art classes. I was scared, but you showed me how taking this risk as a teacher is worth it (First-year teacher, personal communication, June 3, 2018).*

Provocations and Where to Go from Here

In these critical times, preservice art programs must be concerned with co-constructionist ideals of preparing teacher-leaders who understand the shift needed from disconnected theory toward authentic, real-world practice connected to materiality. In looking at the field of art and design education, there is concern that if we

are to support socially engaged, culturally relevant and informed practices that prepare candidates as needed agents of change, the meeting between the digital and materiality are necessary.

In some cases, art and design education programs may have moved in the opposite direction from punching holes in traditionalism and embracing new materialism. It makes sense that we must find ways to support the identity and effectiveness of artist-teachers by fostering their abilities as researchers, awakened by their connections through direct experiences with materials—whether in online or on-the-ground learning. Using design thinking models to support collaborative action research that fosters a constructivist, maker mentality along with art-based, visually reflective work in preservice teacher training can advance preservice teachers' dispositions as "innovators and future artist-leaders toward success and socially responsible action" (Ingalls Vanada, 2014, p. 4). Their ability to cooperate with material ways of knowing should not be separated from aesthetic experiences with art objects and art making, as ways that humans sense the world and make sense of the world aesthetically. In art and design education, we can shift and change as digital beings, while keeping a vital connection to materiality.

Research Perspectives IN THE ERA OF Transformations

Experiencing (from) the inside – Mediated perspectives in kindergartens

BRÅTEN Ingvard

Western Norway University of Applied Sciences, Norway
inbr@hvl.no
doi: 10.33114/adim.2019.05.254

This paper presents a case study of preservice kindergarten teachers' use of new form of digital imagery. The paper introduces spherical cameras and digital microscopes and discusses their affordances when introduced in practical use in in teacher education and in kindergartens. The use in kindergartens was introduced through a class of 34 teacher students in kindergarten education. The students were specializing in Arts and design at Western Norway University of Applied Sciences. The use of images from spherical cameras and digital microscopes is discussed and analysed, based on data from student responses through two questionnaires, group presentations and discussions in class, and an analysis of various media material produced by students.

Keywords: digital images, spherical media, microscope, 360-images, kindergarten

Introduction

In this project we investigate visual representations made with two digital camera technologies: digital microscopes and digital spheric cameras. The first is used to look closely into visual details – *at* a specific point. The latter represents a complete visual sphere, as seen *from* a specific point. We report from a case study, where students have used these technologies, and discuss how pre-service teacher students are able to utilise these technologies with children in Norwegian kindergartens.

The case study's focus is inspired by Hans-Georg Gadamer's view on aesthetic experiences as processes of meaning making, where meaning making is understood as an integrated part of the interaction with an observable reality (Davey, 2015). Gadamer's notion of aesthetic 'experience' is nuanced through the German language, which distinguishes between *Erlebnis* and *Erfahrung*. Erlebnis is something one experiences, like an event, whereas Erfahrung point towards a result from reflecting upon the initial experience. Erfahrung is when the experiencer becomes aware of the experience – he has "acquired a new horizon" (Gadamer, 1993, p. 354).

When exploring a physical environment our experiences can be said to vary in accordance with perceived affordances (Gibson, 1979). Quite a few sensuous experiences are closely related to size, not only the size of objects and the environment itself, but also the size of the perceiver. When the basis for experiences are mediated – represented in a medium – the medium also come with their own technological affordances (Conole & Dyke, 2004). Experiences will always be influenced by huge number of factors and the interaction between these factors in specific places and situations. Two persons will never have exactly the same experience, even when being in the same place at the same time and/or being subjected to the same mediated representation.

In *Perspective as Symbolic Form* (Panofsky, 1991), the art historian Erwin Panofsky states that perspective literally means "seeing through". Knowledge becomes a matter of perspective, both sensuous and metaphorically. During the Italian Renaissance one defined art as dependent upon the artist's ability to manipulate the spectator's perspective for dramatic purposes (Bolter & Grusin, 2000, p. 26). Following the idea of manipulating and playing with perspective, we like to investigate how the two representative, visual methods can be used by students in their internship in kindergartens, to develop the children's understanding and mediated experience of particular spaces and places.

We investigate this process of experience and meaning making through the following questions. The first question addresses the immediate experience by or through the media:

1. How can images from microscopes and spherical images be used to create individual and/or shared *experiences* (Erlebnis) involving children in kindergartens?

By this initial research question we try to address how the students are able to utilize the different visual representations and whether these affords specific aesthetic qualities.

This leads to the second research question, which addresses more reflected experiences, most often represented by recorded media:

2. How do teacher students develop individual and/or shared *experience* (Erfahrung) through communication with children, mediated with images from microscopes and spherical images?

Both questions are investigated through media products, made by the students together with children, accompanied by a intervention in class and student feedback through pre- and post-questionnaires.

The concept

As individuals, we experience the world differently. As children we saw something else than what we do as adults. Our past experiences and interests affects our perception, but also specific conditions such as size and point of view will vary and affect individual experiences. When coming back to a place last seen as a child, many will express things like "I remember it as much larger". Thus our experiences of the world is connected to our own bodies, and even if a room stays the same the relation between the room and a body will change as an individual grow older (Merleau-Ponty, 1994 [1945]). When the basis for an experience is mediated we also have to consider how various media offer different technological affordances. Media may provide us with perspectives that would often not be available if we were to experience solely with our own body, regardless of the body's age or size. Still, mediated perceptions do not become replacements for bodily experiences, but they can work as extensions (McLuhan, 1964).

Understanding experience though mediation can be seen in light of John Dewey's discussion in *Art as Experience* (1934). Dewey understands aesthetic experiences as something that can be found in every aspect of daily life, as something that should be available to the masses, and thereby contribute to the development of society. Dewey believed that humans are shaped by their environments and the experiences they have, a perspective that can be linked to James Gibson's definition of *affordances*. Gibson understands affordances as what a specific environment "offers the animal, what it provides or furnishes" (Gibson, 1979, p. 127). Affordances can be understood as all the possibilities in an environment, independent of any individual. The environment can, however, be shaped by the actors being present at a given time and by the media and tools introduced in specific situations.

Dewey's understanding of aesthetic experience can be understood as meetings between actors, artefacts, performances, natural objects, etc, and the culture that surrounds them. These meetings will always include material qualities, including technological affordances, which also evolve through feedback from the aesthetic process itself. Thus, what we can characterise as design for experiences has to be understood as integrated with material, culture and previous, personal and collective, experiences.

The virtual gaze

The aesthetic representations given by the digital microscope and the spherical camera have in common what we can call a virtual gaze: we see the world and ourselves through technology (Rettberg, 2014). When spherical images is viewed through "VR glasses" the user look into another world, being visually isolated from from the physical surroundings. A kind of virtual gaze that have many similarities with the field of view

directed by the microscope. One can argue that these media, in different ways, create a feeling of being immersed by the media, even when the perceiver is in another time and place than the perceived object. This idea of visual immersion was proposed back in 1965 (Sutherland, 1965), and first realised with head-mounted displays (HMD) a few years later.

In this project our aim has been to investigate the potential of two mediated forms of gaze, and their corresponding visual perspectives: looking from the outside into small details and, on the other hand looking out from a point, inside a sphere. To achieve the look into details we have introduced digital microscopes. The idea is that the microscope narrows the view down to an extremely individual perspective – a very specific view, focusing on one small detail. The spheric camera does something almost opposite: from a single point the camera captures light from all directions, creating a picture that can be wrapped on the inside of a virtual sphere. The user of a spherical representation can later control the view and see in all directions – the visual representation has a defined visual standpoint, but no pre-selected perspective.

Figure 1 : The four different cameras used by the students. The spherical cameras to the left: Ricoh Theta SC (1a), Samsung Gear 360 (1b) and Nikon Keymission 360 (1c). To the right the digital microscope (1d). All these cameras are off-the-shelf consumer technology.

The two pictures below show two dimensional versions of images meant to be mapped on the inside of digital spheres. The pictures indicates some of the possibilities related to change of perspective when placing the user visually, literally inside an environment.

Figure 2: Two spherical images. The top and the bottom of the image are lines that become represented as points, when viewed with the proper software. The right side of the images also meet the corresponding left side. Thus these images can be seen as analogue to a Mercator-projection, as used to project a globe on to a flat surface. To the left (2a) is an image directly from the 360-camera, where the camera is placed at the bottom of a flower bed. To the right (2b) a manipulated image made from two spheric images: one taken from the inside of a three dimensional, physical map model, and the other showing the terrain at the site that the map i representing. The two images are manipulated into one with the map model in front and the image of the terrain in the background. These images, from a previous project, were among those

presented to the students to give them ideas about changes of visual perspective. These images does of course look very different when viewed on screen with the proper software[1], which maps the flat image on the inside of a virtual sphere.

The digital microscopes we use are specifically intended for children's use (Figure 1d). With a simple tap on the top of the microscope, you take a picture of the object you are examining. However, the microscopes had to be connected by wire to a computer. The pictures below show microscope pictures taken of details from a printed book page and a finger, details we can barely see with the naked eye.

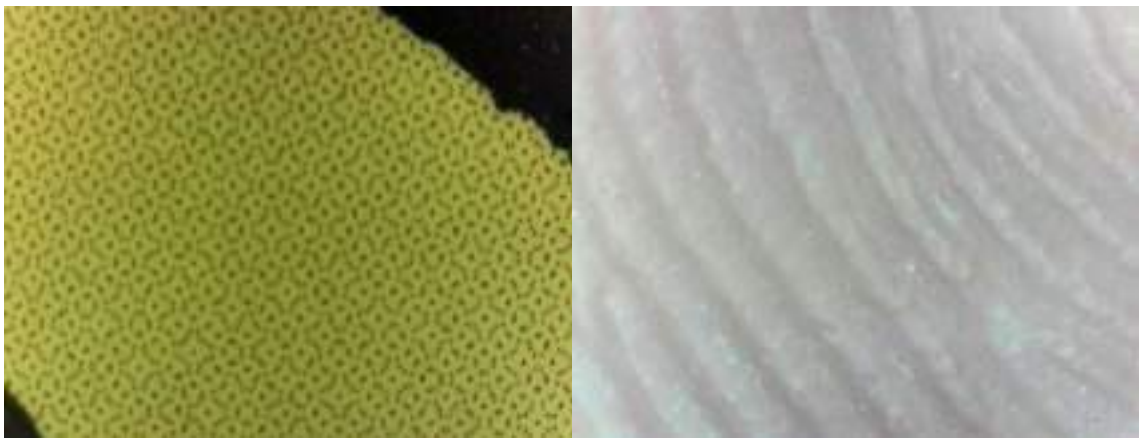

Figure 3: Magnifications taken by a digital microscope, showing a raster image on a book page (3a) and the pattern on the tip of a finger (3b).

The assignment the students were given in their internship was meant to encourage a playful approach to the use of digital media. When introducing digital technology there is always a danger that the digital artefact (physical devices and/or software) will limit the activity, play and imagination if the technology is given too much attention. The Danish drama teacher and researcher Klaus Thestrup has worked with the concept "media play", which he defines as children's play with the media they have access to (Thestrup, 2013, p. 66). Thestrup states that the use of a specific technology should not be given in advance, but be negotiated and changed along the way by the children. The goal, according to Thestrup, must be that children and educators investigate something they are concerned about (2013, p. 307). Researcher on children and media Stine Liv Johansen says that "One of the hallmarks of play is that it focuses on the process rather than the product, which unfortunately is rarely highlighted in play with digital media (our translation)" (Johansen, 2015, p. 86).

Our initial presumption was that students, when working with children in kindergartens, would explore the opportunities given by the different digital cameras. We also tried to encourage the students to offer these mediated experiences as an extension to playful, tactile and bodily experiences, not as an starting point or a final goal.

Findings

As soon as the students were beginning to get familiar with the technological aspects they were challenged to come up with some thoughts and ideas about how they were going to implement this during their internship. During their two-week internship in kindergartens, we asked the students to explore what it means to adopt different perspectives with the children. These perspectives could be created by physical means, and/or by mediated representations. The students visited eight different kindergartens, where the children range from one to six years. In their exploration of perspectives, we emphasized the use of physical materials, bodily

[1] Spherical versions: 2 – https://photos.app.goo.gl/6v6wycXYom3N1MH79 and 2a – https://photos.app.goo.gl/W7Vv2Xb7MR5H7USRA

exploration and the digital tools (spheric camera and microscope). After their internship, the students delivered pictures, "stories of practice"[2] and shared their experiences through group presentations.

Findings from pre-questionnaire and group discussions

The 8 student groups visited 10 different kindergartens. Prior to their internship, we let the students answer a questionnaire to get some insight about their previous experiences, reflections and attitudes regarding digital technology. The students were also able to write longer comments. We received a total of 29 anonymous responses.

10 students stated they had previously used digital technology with children, mostly by taking pictures together with the children. Most of the students were positive (17/29) to the use of digital technology in the kindergarten, some were more neutral (9/29) and only a few were more skeptical (3/29). Quite a few commented that digital technology is a large part of the children's life and therefore the kindergarten must take an active approach. None of the students thought the use of digital technology in kindergarten in general is too extensive. The students either said the use is at an adequate level (16/29), or that digital technology is being used too little (13/29). The students believed many employees in kindergartens have little knowledge about digital technology. Students commented on digital technology being used for the children to sit still (watching movies, playing a game etc.). This corresponds to national surveys conducted in Norwegian kindergartens showing the most widespread activities related to the use of digital media are about taking pictures, retrieving information, listening to music and playing games. It is less about creating something with the children. This is linked to the lack of competence among the employees (Jacobsen, Kofoed & Li, 2015, p. 78).

Only one student had previously used a digital microscope and one had used a spherical camera. We also asked the students if they were using Google Street View, given that this is the most widespread spherical media. We were somewhat surprised that none of the students seemed to use this service often (every week), in fact they either rarely used it (18/29), very rare (5/29) or never (6/29). Those who had used Street View mainly used it to get an impression of a place before they go there.

After answering the pre-questionnaire we lead the students to group discussions. Before their internship, we wanted them to discuss their starting point. The students already knew the children from their last internship. Roughly speaking, we can say the students planned for three different approaches:

1. Collect materials outdoors, and then examine them with the microscopes indoors. (This is much the same as we let the students do when introduced the microscopes. In other words, it is a way of working the students already know.)
2. Introduce the devices for the children, and then plan how to use them based on the children's input.
3. Working with concrete themes or materials related to activities they know the children like. This could be building with Lego or cardboard boxes, examining the body or reading a children's book.

Findings from student presentations and post-questionnaire

The following is based on students visual presentations and the teachers notes from the oral explanations given by the students in class. This part was finalised with a questionnaire where the students gave additional information on an individual basis. Here we received a total of 27 anonymous responses.

The students presentations were dialogic, and not following a specific structure. In the following we have organised some of the reflections and responses focusing on our interest in the affordances of the two media technologies: spherical cameras and digital microscopes. Each paragraph summarises the report form one

[2] «Praksisfortelling» or «Stories of practice» (our translation) is something similar to a personal field note, often used to make students reflect about situations they experience in their training.

student group. Not all groups are represented as there were quite a few examples of almost similar reflections.

Featured student experiences with digital microscopes

Working with the microscope the students asked the children what they expected to see before looking at the image on the screen. This became an engaging activity that kept the children interested for quite some time. Especially two children made many suggestions. The children did, however, experience trouble when trying to keep the digital microscope still and looking at the screen while the software counted down. This worked better when the students showed the children how they could work two and two together. The children especially enjoyed looking at books, and investigate the details that revealed how the printed colors and shapes are composed of raster. These details are hardly visible to the naked eye, and seeing these images was a new experience for the children.

One student group worked three times with the same group of children. The first time they used the microscope to look at food. The second time they chose the theme of body and clothing. The children got to explore this themselves, looking at skin, hair and different fabrics. The last time the children had to choose materials by themselves, and they ended with taking pictures of a book.

The students introduced a group of children to the microscope in a separate room. The children chose to take pictures of toy animals and pearl jewelry. The children were engaged, but a little impatient. Still, they kept on with this activity for an hour without anyone getting bored. Two days later, the same group wanted to try this activity again. This lead to further experimentation, and the children stated that they would like to do these activities on later occasions.

Featured student experiences with spherical cameras

The students made up a story about a fly on the dining table, as a way to introduce the children to a visual perspective seen through the spherical camera. The children found the story engaging, but as soon as the spherical camera was introduced it took away the immediacy from the experience. The children found it much more engaging to hide from the camera. These findings are somewhat consistent with what these students experienced with another group of children. They brought the spherical camera outside, and the children were to place the camera. The kids thought it was interesting to look through the camera, using the viewer built into the mobile application that can control the camera.

The students worked with two four-year-olds, who engaged in building a "fortress" with paper boxes. The students experienced that the children were more into playing, and less interested in taking pictures with the spherical camera. These children also found it more fun when they were allowed to take part in the picture, the idea of hiding from the camera became a showstopper. However, this may be caused by the fact that these students did not manage to control the camera from the app, making live view impossible.

One student group built a cardboard house, big enough to make room for number of other objects. The children enjoyed this activity, but as soon as the spherical camera was introduced some of the engagement decreased. The children did not put much effort in placing objects at specific places inside the house. The children did however show some interest when they were able to recognise the objects they had made, when the picture from the camera was shown live on a big screen. This inspired the children to create multiple installations with Lego figures, which they called exhibitions. The children put the figures into new contexts at several different places: in a box, on a table in a shelf, etc. On their own initiative the children asked that spherical pictures were taken.

One student told about how he was playing hide and seek outside together with three children. The children were sorry because they had to go indoors and the play was is interrupted. The student told the children he knew a way they could continue playing, even when being indoors. The student put up the spherical camera in a room, one of the kids hid and the others saw if they could find him on the screen. One of the children suggested that they could hide a doll instead. They hid the doll in turn repeatedly.

In one of the kindergartens the children had been introduced to tales about anthropomorphic characters where mice had a key role. The students showed videos of real mice, and talked with the children about how the world might look from the mice’s perspective. The students wanted to use the spherical camera to mediated the mouse perspective. They did however spend a lot of time setting it all up, and the camera ran out of power.

A group of boys found it fun to hide from the camera. They also hid the object in the picture and looked it up on the screen, on the mobile, afterwards. This group also found it engaging that they were involved in the location of the spherical camera. This way of working gave the children room for exploration and the students experienced good conversations and reflections with the children about how something looks when the camera was placed in different locations.

At one point one of the students moved the spherical camera out of the window. This way they could look at the same environment from two simultaneous perspectives: one by looking out the window, which became a kind of bird's eye view. The other perspective could be seen on the screen, a kind of frog perspective.

Post-questionnaire

The students were very consistent in their feedback that they would like to use digital microscopes later, when they start their professional career. They found the microscopes easy to use and catching for the children. The students were more skeptical for using spherical cameras. They tell about technical problems and adult-controlled activities. One of the students sums up their use of the spherical camera like this: "We didn't get the hang on it, and we thought it was difficult to catch the children. Probably because we lack knowledge and experience. I think this could be a nice activity with a little more planning and experience."

Figure 4:

"Do you want to use a microscope on a later occasion (when you start in the profession)?"

"Do you want to use a spherical camera on a later occasion (when you start in the profession)?"

Many of the students say they have gained new inspiration after listening to fellow students' presentations and that they now see new opportunities. When we asked the students "Have you changed your view on the use of digital technology in kindergarten?", their responses were reflecting that the students were either neutral or on their way towards more positive:

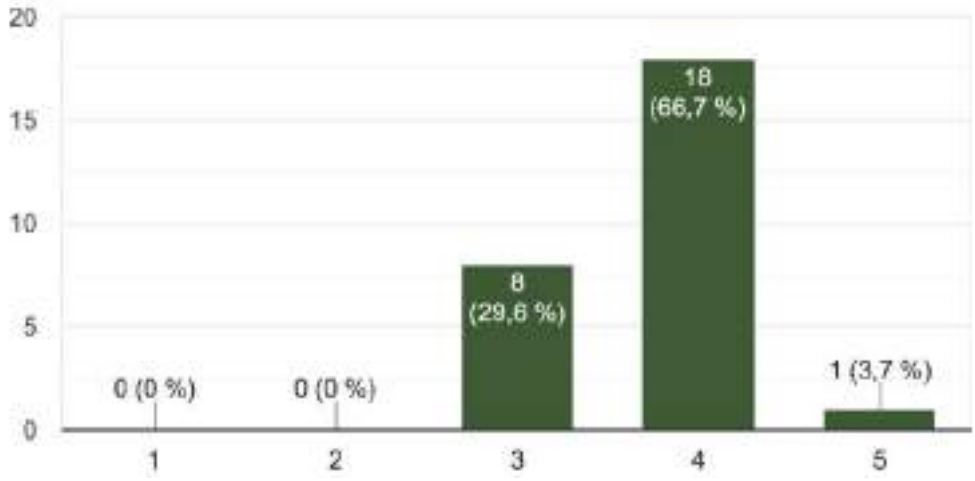

Figure 5: "Have you changed your view on the use of digital technology in kindergarten?"

The answers range from 1 – "More negative" to 5 – "More positive"

Despite technical problems, the students shows a positive view of on using digital technology in the kindergarten. "I am positive about using digital tools because society has changed so much today with regard to the technology and the development that is". The students, however, report that digital technology is not very visible in the kindergartens they visited. This is explained by lack of interest, finances or expertise. A student puts it like this: "The kindergarten had no experience with the use of digital tools, at least not the use of digital microscopes or spherical cameras. An employee had purchased a digital microscope one year ago, but she never used it. "

In the post-questionnaire the students were asked: "Based on your experience, what do you think about the use of digital technology in kindergarten you visited?"

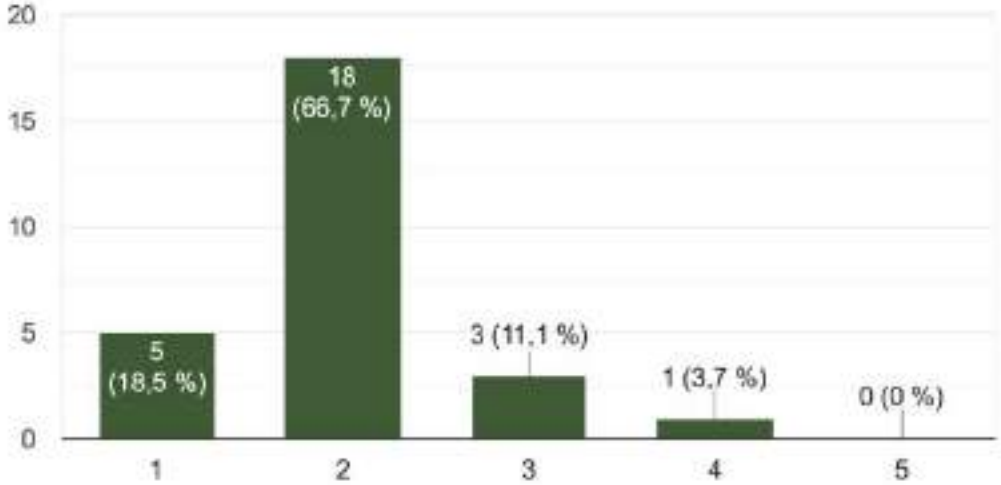

Figure 6: "Based on your experience, what do you think about the use of digital technology in kindergarten you visited?"

The answers range from 1 – "Used way too little" to 5 – "Used way too much"

Discussion

When comparing the students' reflections after the internship with their intended approaches, identified after the group discussions before the internship, we do see clear intentions that were brought into practice. However, not coming as a surprise: few things followed the exact plan, reflecting that learning design always has to give room for flexibility.

The first approach, defined through the first group discussions, focused on collecting materials to examine with the digital microscope: From their reports it seems like the students gave the children relatively large degree of freedom when being outdoors, collecting items to magnify. When bringing this material back to the kindergarten, working indoors, the spatial freedom became more restricted. This is clearly caused by the affordances (Gibson, 1979) introduced by the digital microscope, which has to be physically connected to a computer. The microscope itself can only be operated by one person at a time, but the operation is straight forwards and can be done by small children. The students were able to let one or a few children work together at the computer screen, or they chose to show the images through a digital projector on a big screen. During their test of the microscopes some students discovered that they were able to use the digital microscope as an ordinary webcam. We did not lead the students in this direction, but following the webcam-approach tools like webcamtoy.com can easily be used give the digital image completely new aesthetic properties (Conole & Dyke, 2004). This can open an exciting world of digital play (Johansen, 2015; Thestrup, 2013) where children can interact with the images in a number of new ways.

The second approach, where the students planned to introduce the devices and they play along with the children, came with a clear intention to allow the children to take more control. Especially when using the spherical camera one may assume that the activities could be controlled by the child(ren), given that these cameras can be operated through a smartphone or a tablet computer. The children might be allowed to place the camera, and then take the picture from a remote position, experiencing a specific situation and/or environment for two, simultaneous perspectives (Panofsky, 1991; Bolter & Grusin, 2000).

We did ask the students to try to avoid taking pictures where the children become visible in the picture. This is due to questions about minors, personal information and safety. This became a challenge as long as the spherical camera records information form a complete sphere. Our assumption that this could be developed into a kind of play, where the objective can be to hide from the camera, did only partly turn out successful. Some children found the hiding exciting, but quite a few took the complete opposite approach and found it more interesting to stage themselves in front of the camera. Some of the students characterised this playing with the camera as the children being in a "flow", where the children became immersed in the activity. The students also referred to aesthetic learning processes, reflecting that the introduction of the camera has an influence on processes, and that this brought something back to the learning environment.

The third initial approach was related to working with activities they students knew the children did like. One group in particular followed this approach, a plan that implicated a relatively high level of teacher control. However, even though the theme and the materials might be decided beforehand the following process did open up. One can argue that the key to a successful leaning design is likely to be found in the change between taking control (by the teacher) and opening up for various degrees of participation and control. The students reflected upon whether the smallest children were able to conceptualise the view from the camera and relate his to this perspective. Small children may find it difficult to understand the somewhat technical connection between camera and picture, especially if there is a delay between the action that is photographed by the camera and the time of viewing the final image.

When we introduced the students to the digital microscope and the spherical camera we did this with an assumption that this would introduce new ways of looking at familiar situations and objects. We were also hoping for some sort of division between the immediate experience, the images seen on a screen in real time, and a more reflected experience, when the images were played back after the represented activity was over. As it turned out we can clearly see a number of examples where this duality came into play, but most of the the students were not able to articulate these qualities in their feedback and through group discussion. Only one student did explicitly reflect upon this visual duality. However, he did not see this at the time when using the camera, but was able to see this in retrospect. The situation that triggered this reflection was the incident where a spherical camera was placed outside, below a window, providing an alternative view of the scene that the children were seeing from the window.

When it comes to the digital microscope the students had less to report. This may be because this camera technology did work without any significant problems – there were few pitfalls to talk about. We may also assume that the microscope was not considered a novelty, given that the digital version more or less replicate the functionality from analog microscopes. However, the possibility of bringing a live view of the image, up on a screen, for several children to see, do open for collaborative approaches.

According to the student reports the digital microscope did cause high engagement among almost all the children who were engaged. It is evident that all the children involved had an aesthetic experience, in the sense of Erlebnis. When it comes to the somewhat more distanced experience, Erfahrung, the students came up with few examples. One example did, however, stand out in particular: two student groups did emphasise that the children used the digital microscope to examine rasterized graphics in books. This look into detail reveals some specific features related to print technology, and thereby give the children insight in how images are represented in print, an experience that goes way beyond the immediate experience of what the image actually shows.

According to the Norwegian learning framework plan, the kindergarten is required to introduce technologies, learning materials and methods that can help children to experience in new ways (Norwegian Ministry of Education and Research, 2017). The students did feel that they were able to give the children new technological experiences, following the duality of experience (Gadamer, 1993). Some critics believe that kindergartens should be able to choose to use digital media on their own initiative, not that technology should be imposed through centralised plans. However, we will argue that the most important is what activities one facilitate and whether the children are really becoming active participants and contribute to the use of technology. Even small children have quite substantial knowledge about digital cameras and tablet computers. New camera technology catches another, but the children are often not allowed to use these devices by themselves. Digital competence varies in society and in this context kindergartens may contribute to reducing digital divides.

The students saw the use of digital cameras as an innovative activity for both children and adults in the kindergarten. It is, however, difficult to make a clear distinction between innovation when its comes to use and what can be perceived as innovation, but comes more from the novelty of the media and/or the technical artefacts.

One student group quite explicitly emphasised how the kids see a room, from another perspective than adults. They explained how they had used the spherical camera to represent three different points of view: a toddler, playing at the floor, a small child standing, and the room seen from the height of an adult, standing. The result became quite striking, and an eye opener. The students considered this something one can talk about in the collegium when planning activities and furnish the learning areas.

Several of the students reflected upon the possibility that a somewhat abrupt introduction of the cameras reduced the children's engagement. During their internship they did not have the time to see if the camera could be integrated in a way that the children saw as just another thing to play with, something that they could engage with as an integrated part of an overreaching activity. We saw quite a few examples of how children's creativity does often not lead to products, but tend to have greater focus on the processes. This process oriented approach may be further increased by digital cameras with preview possibilities, which invite to activities that can be conducted away from the camera itself and also favor real-time images without a specific focus on the image as a final result.

The students discussed whether it could have made a difference if they had used a tablet, rather than on a small mobile screen when working with the spherical camera. This seems like a very valid consideration. A larger screen would make it easier to work as a group, and a teacher might supervise the process from a little distance. In addition larger screens will give an interface that can be used by more children with challenges, e.g motorical, sight etc. On the other hand one often tend to look for more technology to compensate for observed deficiencies. From a learning design perspective it can be just as rewarding to work with the perceived limitations. In this case the small mobile screen, providing a limited, but also exclusive view.

Much of the feedback given by the students were concerning the spherical camera. However, this is not because this technology was the most functional. On the contrary, the digital microscope did blend much better into the activities in the kindergartens, and was more appreciated by both the children and the students. The digital microscope was a technology that all mastered, and it offered an immediacy that did not become as clear when it came to the spherical camera. The latter, even though on may argue that it holds a

stronger potential when it comes to change of perspective, did create some distance between the placement of the camera and the viewing of the images afterwards.

Conclusion

Through this project we wanted to find out how digital microscopes and spherical images can be used to create *experiences* (Erlebnis) involving children in kindergartens. We have looked at different visual representations and discussed some of their immediate aesthetic qualities. Further we asked how teacher students develop *experiences* (Erfahrung) through communication with children, mediated with images from microscopes and spherical images. We have looked at the relationship between recorded images, seen in situations that were distant to the events and places that are represented, and how the students were able to reflect upon this.

As expected, it is easier to point out experiences as Erlebnis from the students work in the kindergartens rather than what clearly can be called experiences as Erfahrung. The students found varied ways to use and utilize the digital tools, yet it is limited how many of them who move beyond what we introduced through the training, before their internship. Quite a few students have had children collecting materials, and examined these in the microscope. In their use of the spherical camera, they created various environments before taking pictures. To a large extent the students let their own knowledge and experience with the digital tools decide these activities.

From our findings it seems like the digital cameras could be used to facilitate situation where the Erlebnis-dimension of aesthetic experience became stronger. When it comes to the Erfahrung-dimension there are some indications that the spherical camera brought some other qualities. The more distanced view, in most cases seen in retrospect, do encourage reflection over immediacy. We are, however, not able to be conclusive given that similar qualities were found when looking at stored images from the digital microscope. Further and more thorough studies are needed to clarify the interplay between the media and the situation where the mediated representations are viewed.

The present study has not given exhaustive answers on how to use digital microscopes and spherical cameras in kindergartens. The use and integration of new technologies require both training and expertise. However, we believe that the present study points towards the practical use of digital tools and sharing experiences as ways to explore new learning opportunities, which also may lead to new educational methods.

Research Perspectives IN THE ERA OF Transformations

Aarup 1960 and the poetics of materials

GJERNES Liv Mildrid

Western Norway University of Applied Sciences, Norway
liv.mildrid.gjernes@hvl.no
doi: 10.33114/adim.2019.06.267

All design has its own conditional modes of expression; however, these are realised through the maker's sense of the possibilities of materiality. This essay was inspired by a reclaimed piece of 1960s furniture designed in the modernist idiom, and is based upon autobiographical experiences, original works from own and contemporary aesthetic practices, and associated thoughts in the present. A completely new artistic expression was developed, which questioned the strict, use-defined style ideals and let shape reveal other values and statements than function. The intention of this essay is to put into words some of the cognitive processes in which creativity, critical reflection and the senses' experience-based insights may bring up something new. In creative work, the goal is not to reach a single result; every little discovery made by examining something specific could open up new worlds.

Keywords materials, modernism, post-modernism, meaning, arts based

Underneath the table top of what seems to be a nicely used piece of 1960s furniture that I recently bought is a stamp reading "O.P. Rykken & co, Øystese". The table stands shining in my living room; golden brown and perfected, with a pronounced elegant yet humble visual expression. As in the strophe from the hit song from 1963 written by Vidar Sandbeck and sung by Wenche Myhre says: it´s "a swanky girl on the path of life". There was no room for chit-chat or curlicues in 1960s design. Instead, it's a tight, consistent and unambiguous staging of the table's functional value; the properties of the material have become the fundamental essence.

In the hands of the maker, the material was given the chance to reveal its qualities of both strength and character in its own right. Dimension and proportion were balanced in a *to-the-point* and rational way. "The carrying and the carried" was a regular way of building constructions within functionalistic architecture. In furniture design, the essence was the *materials themselves*. Things were serially produced in a matter-of-fact and industrial way, without adornment or distractions, free from decorations that were found in the popular home-made traditional work. Materials were used with a simple and direct honesty, and even though surfaces could be given a veneer, it was a veneer made from real wood. Wood was wood and plastic was plastic. The praxis of the time can be called a *poetics of materials*, and held an infinite number of trials and solutions. It has accelerated through all epochs with the help of mankind's tireless curiosity and persistent activity, constantly working towards something new. With courage, a new age arose after the Second World War. The use of materials was naturally frugal and scarce, since so much to be rebuilt after the ravages of the war. The population was curious, ready to get rid of the old and invite in a new era, as if they were terrified of being *un-modern*.

The concept of modernity refers to an era that can be said to begin in the Renaissance, writes the philosopher Lars Fr. H. Svendsen in his book *Kunst, en begrepsavvikling* (Svendsen, 2000). He further explains how the style period of modernism began towards the end of the nineteenth century and continued into the twentieth.

Modernism represents the age of reproduction and a continuation of the age of technology. As a style expression, it grew from a reaction to the romantic and quirky forms of expressions that had emerged towards the turn of the previous century. Industrialisation, machine technology and rational form developed as a contrast to the swirly, handcrafted and romantic expressions of pre-modernism, which also accommodated the popular, pre-industrial visual expressions. "Post" means after. According to Svendsen, the age-after-modernism began as the Second World War ended. Even throughout the 1960s, an incipient postmodernism was developing within art, architecture and design simultaneously as honest and factual objects of modernism were finding their way into many homes

During this time, purist and cutting-edge opinions were formed by artists and designers. In this manner, one can detect how the style periods infiltrated each other. In retrospect, looking into the interpretations and retellings the style periods appears purist. Materials, colours, size and structures are used as elements in idioms that reveal *our* time. Postmodernism problematized modernist values and forms of expression by moving from one extreme to another. It recalled memories and allegations of the content of expressions that modernism, in its time, had dismissed as impure, ugly and seedy; ornaments merely regarded as decoration without purpose, or expressions of a criminal mind, which the Swiss architect Adolf Loos (1870-1933) stated in his lecture *Ornament und Verbrechen* in 1910 (https://de.wikisource.org/wiki/Ornament_und_Verbrechen. 20.09.2018).

Svendsen further explains how the distinctive features of modern times developed through "quotations" or imitations. Ornaments and decorations were re-adopted by borrowing from earlier times, manufacturers and artists. "Images that primarily refer to other images," as Svendsen refers to them (2000: 102). He writes about appropriations where the artist makes everything contemporary by adding their own work to part of the expression or by recreating an old motif through photography or paint. Dag T. Andersson justifies imitation or "mimesis" as "the force in all forms of play", and argues that "the mimetic urge" is expressed through our artistic activities (2001: 34). In this manner, the idioms of previous times were brought back, played with and re-examined in postmodernism.

"The basic features of the mimetic relationship to things is perhaps most apparent in craftsmanship," writes Andersson. "The methods of craftsmen are closely related to those of the artists. This clearly shows how a mimetic relationship involves reciprocity between man and things. The craftsman recognises the material's right to find its place through the object's shaping. The material may retain its remoteness even if it is transformed by the way the hand's work brings it closer" (2001: 34).

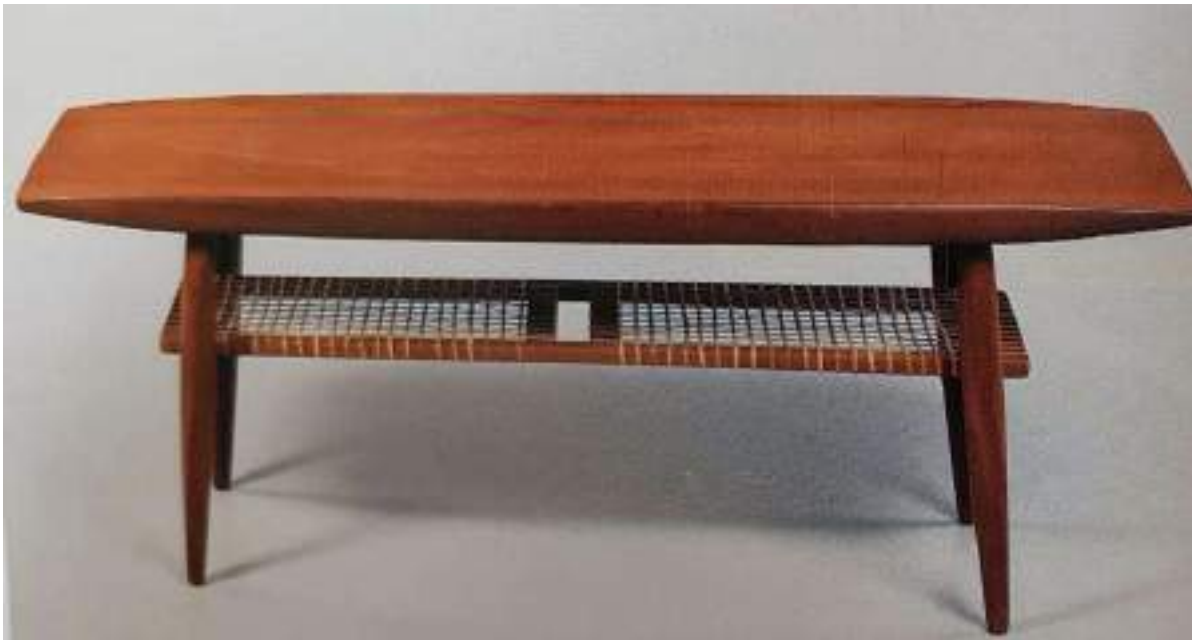

Figure 1. Aarup. Produced for IKEA in 1960. Source: Siesing, A.(2015, p.410)

I remember the 1960s. I experienced how saving materials and anything that could be saved was both normal and necessary. The 1960s still reflected the scarcity of materials after the war, with refashioned clothes and

worn-out rubber boots. We put newspaper in our rubber boots in the winter to try and protect our feet from the cold. But since the boots were full of holes from being used by older siblings, the wet and icy cold seeped into our toes anyway. IKEA was already in business and developing sensible and down-to-earth furniture for the average socially democratic family. The quality of their products must have been something completely different to what it is today, as their range included the Aarup coffee table: a wonderful 1960's idol (Figure 1:)

"Aarup is one of the finest pieces of Danish-made furniture produced in Sweden exclusively for IKEA. It has a quality of the construction, with lavish and rounded mouldings, solid undercarriage, and a newspaper shelf of braided rattan" read its advertisement (Siesing, 2015: 410).

Materials such as rattan and teak were used previously in modernism but in a completely different, simple and poetic manner, with small leaps, elongated arches and softly rounded corners. When combined, these features resulted in something tight and elegant. With this design, the production costs went down, and the object was made available to most socially democratic people. According to Svendsen, modernity is about the abolition of traditions. Wretched old things that the war hadn't finished off were finally thrown away or burned, everything reminiscent of hand-me-downs, worn-out shoes and walking home along long, winding roads. Norway was one of the poorest countries in Europe before the war. There were no busses or cars, only the high heavens and bitter cold. In my childhood home, we took nothing for granted. Internalised traditions of farming culture from the past was combined with pastel colours and modern checker tiles in the kitchen. New elements were added to "lydarmusikken"[1], which flowed from the Hardanger fiddles' mysterious, eternal tones.

Figure 2. Excample:18th century front cabinet. Source: private collection and photo. Source: private collection,photo: Håvard Gjernes

The eighteenth-century front cabinets became the inspiration for newer interpretations of more front cabinets (Figure 2). The last three variations were made by my father for my sisters-in-law and my sister in the 1990s. My aunts painted them in vibrant colours and this furniture lives on between us in a profound and old

[1] In folk traditions, music was communicated without sheet music. Instead, musicians listened to performances and played later.

happiness with its families. I was given a reproduction of one from the 1960s and it stands here, looming in heavy, Norwegian birch. The angular, stout and stabile structure, with its roots in times long past, casts a reserved sidelong glance at the swanky table, which bravely attempts to assert itself with its tropical woods.

This old table was restored before it ended up in the second-hand market. The table top is veneered with the finest teak, but if you take a closer look, you can see that it looks as though the construction is made of pine and stained with a teak-imitating colour. The look-alike-materials are chosen from exquisite subjects and the coniferous, edge-cut winter wood creates a pattern that can be mistaken for teak's sturdy, exotic wood grain designs. Take that, modernism! This piece of furniture pretending to derive from pure, exotic, imported wood is only a home-made interpretation of the real thing. The everyday pine wood board had to do the job once again. Yet, I forgive you little old table, because it's the form and shape that carries an object through time, and whether the materials are authentic is of minor importance. I must admit that I could be willing to drive far for an original 1960s Aarup from IKEA, one made from solid teak and real rattan, weighing 13 kg. Aarup was a rock solid, honest, industrial product, and its massive table top could have been sanded and oiled again and again. Perhaps one of them is waiting in a Swedish basement somewhere, longing to become real again. However, I can appreciate the aesthetics of necessity, and the notion of saving where possible, especially when creating something new. The swanky table is a design that has been imitated. It's a reproduction, a style-copy, whereas a 1960s Aarup was a role model. The only new aspect is the pine masquerading as teak. Skimping is skimping and that is okay. Why use valuable tropical wood when the whole thing can be recreated using home-grown pine from the shops? The understanding of art and the term "aesthetics" has changed since the second world war. Art is no longer unambiguous and true, and Svendsen explains how this has been phased out. He dismisses the notions of "true and divine", which had been understood and decided throughout all of modernism, and instead gives the power of the definition to the interpreter (2000: 25).

In 1936, the German philosopher and art theorist Walter Benjamin (1892-1940) published an essay called, *Art in the age of reproduction* (*Das Kunstwerk im Zeitalter seiner technischen Reproduzierbarkeit*). In this text, he highlights the circumstances of the human experience, when technology sets the premises. Benjamin used the term "aura" in his explanation of the relationship man has to things, which the philosopher Dag T. Andersson writes about in his book, *Tingenes taushet, tingenes tale* (2001). "Aura expresses an aesthetic relationship between man and things, between man and the world, in the way that there are relationships that do not concern the arts alone but any sensory relationship to things," he writes (2001:32).

Since the second half of the last decade, the circumstances for the material-specific, man-made objects have changed completely. However, our sensory relationship to things and their nature still lives in our encounters with them. All knowledge of the practical and living life rests in the human experience. In this manner, our worlds are built from our childhood and manifest themselves in a conglomerate of sensations, memories and experienced knowledge. We try and fail, perhaps by imitating what seems to be there; we copy and imitate, and examine and play with the possibilities in the attempt to get as close as possible to the nature of things, or "aura". Gradually we find the courage and insight to interpret the language of things, as we ourselves understand it. Ideals of different times frame our possibilities. Time opens up or limits our possibilities. It ties itself together with the act of existing, experiencing and conveying the world as we see it.

We express ourselves in everything we make and design, not just in what we articulate verbally or in text. This is why it is so important to design or make things in a close, analogue and one-to-one way. All things, all buildings and surroundings, say something about the spirit of time as it has been experienced, interpreted and told by the individuals that were present. Everything is there, still accessible for new experiences and interpretations. Through our personal and perceptual relationships, we bring everything into our world. "How do we experience what has no name, that is to say, that which is primarily experienced as definite?" Knut Ove Eliassen asks in his essay "Tingenes tale" (2008). He writes about how Foucault thematises "what we can call the meeting of 'things', meaning the experience and naming of them, but also our own experience and naming that through such meetings are made possible" (2008: 174). Bård Breivik (1948-2016) was an inspiring, contemporary artist from Bergen. He referred to his own specific experiences behind his meeting with the work he presented in public space in a lively way. As a sculptor, or maker, he concerned himself with matters of materiality and man-made. "The use of organic materials exposes a human and cultural intelligence," he said in an interview in 2015 (J. H. Landro in Veiteberg & Leppiniemi, 2016: 947). The poetry of materials lives in his understanding of intelligence.

For the designer, the artist or maker, material-based work and the sensory relationship to things drives the process. The senses interpret the materials through the sound of a sharp wood planer, the tactility of

processing a surface, the scent of an oiled shape. You experience a storyline of expression possibilities, which make themselves known and become concrete and understood, supported by the process that shapes them. Conditioned by our sensory relationships to things and the materials they consist of. We search for our things, we thoughtfully draw and sketch, always looking for something precise, for the result of our investigations into what is real and sensory to us; the definite. A careful process revolving around the realisation of inner imagination, made tactile and visible in physical materials.

In the craft of making furniture, the veneer was intended as a way to cut costs. My table is an example of this: the top was intentionally disguised to look as if it was made of teak, while in reality, it is only covered by a thin layer. This layer is glued on a core of some cheap, yet stable material. Veneer is a thin layer of wood, often 'sliced' off the tree-trunk, as one would peel a potato, in long strips down the length of the tree. The strips are then cut into suitable sizes for transport purposes and manageability. Under the finished veneered surfaces is a layer to ensure an even and stable surface. The second outer layer might be plywood, a very sturdy material made from gluing thin wood together, like 'layers' in Photoshop, but in alternating directions. Between these two layers, there might be pieces of wood lamellae lying next to each other, which defines the thickness of the board and is solidly glued to both the top and bottom layer. The reason the wood veneer is glued on is that it must be stable as the wood itself is unstable and hygroscopic. The material lives in the humidity of its surroundings and the cells of the wood absorb or release moisture, resulting in shrinkage or swelling. A newly cut pine board can shrink up to ten per cent. One of the challenges of working with solid wood is that the material continues to live on after it is cut and prepared. Wood craftsmanship has developed all sorts of methods and ways to use and exploit these characteristics. For example, a stile door is built with consideration of this, with tracks in the frames for the panels to sit in, so the wood has space to move according to its nature without bursting the frame apart. It is a respectful way of communicating with the material; no force and nothing falsified. The material is allowed to be what it is.

Insight into the possibilities of a craft and its ways of communication gives us the freedom to move closer towards materials and the aura of things. Treading hard on modernism's clean, purist toes was a strong need for those who came after it. With technical competence, we could make diverse and uncensored re-interpretations. We just *had to* get even after all those strict, cold and normative attitudes we had been exposed to during our art education. Elisabeth Engen, Lillian Dahle and I studied furniture design together in Bergen. For us postmodernists, the assertion that form must absolutely follow function was not just untrue but also wrong. A number of utterances and forms out there in history had been discarded as impure and as decorative crimes, stories that no one had properly listened to. We interpreted colour, ornaments, decorations and qualities of materials as a part of the communications things brought with them from present times. For us, this purity and unambiguousness sounded like a speech from a bygone time. During the 1970s and 80s, the speech represented boring, run-down and unacceptable content. It was like a relationship that you have grown out of or possibly never even felt like you belonged to.

Some things that belong to a particular time and that make up our lives are unchangeable. Other things are volatile, unpredictable and constantly changing, always on the lookout for something else. "Constancy and change means that something remains throughout change," writes Christian Norberg-Schulz in the introduction of his book *Stedskunst* (1996).

In his book, Noberg-Schulz writes about the "everlasting relationship between man and his surroundings", but acknowledges that they are "relations that must be interpreted again and again" (1996: 7). According to him, constancy and change contain all our possible conditions, both the given and the changeable. To be able to add adjustments and investigations as well as bear with the weight of such a re-interpretation, we must "listen" to the time we live in with open and undaunted senses. We must have the will, courage and capacity of implementation to develop our own expressions of our time and improve what we find wrong, humanised and imprecise. The book *Courage to Create* by the American psychologist Rollo May became a cult classic amongst artists and creatives during the 1980s (1975). May managed to put into words the risk of "being totally involved, yet attentive to the possibility that we might be wrong" (1995: 19). The paradox of courage is that it is accompanied with the anxiety of being mistaken; sleepless nights are never far away. May wrote about how this applies to all of mankind, not just artists. He encouraged us to commit to our imagination and

implement what art historian Anniken Thue described in a catalogue from 1986 as “furniture fantasies and fantastic objects.” [2]

My colleagues in the 1980s were Elisabeth Engen (her work: figure 4) and Lillian Dahle (her work: figure 3) They worked with wood in different ways to me, and with a closer connection to traditions of the craft, finding their expressions more closely connected to the actual materials themselves.

Figure 3."Heaven-earth" Small casket 1989© Lillian Dahle / BONO .Source: http://www.lilliandahle.no/ (03.04.2018)

Figure 4."Punk Furniture" PE. © Elisabeth Engen / BONO Source: http://seminarplassen.com/elisabeth-engen.htm (03.04.2018)

In my own work, wood was more of a raw material to be built and joined in rational ways. An infinity of imitations and lush floridities have been made: fluorescent ‘stone walls’, turning spiers, worked surfaces and areas where different qualities were forced into colourful fellowship, built and interpreted by memories and sensations. Thoughts and emotions about colour and form were reborn into new narratives of acrylic, steel-plastic and thick layers of paint. Experiments were ongoing in our working partnership. This was much to the shock and horror of all kinds of purists, and the modernists’ strict and normative view was given its deathblow. Out in the world, many have oriented themselves in the same landscape, such as the well-known Italian designer Ettore Sottsass and his Memphis-group. They designed the patterns of Formica and other design objects that were industrially produced. But we made our things by hand and had full control of our own workshops at our own expense and risk.

In my material-based reflections about the ‘speech of things’ was also a type of ironic humour. What I found especially funny was imitations of imitation. The anchor of authenticity and originality was completely rejected and made fun of. The idea of a pure material that safeguarded the unambiguous and rational function was done with. Imitations and loans were about bringing something back, investigating it once more with a particular view into form, colour and surface. The contemporary judges of taste, who were floating in the wake of modernism, tended to look down on and diagnose our utterances as ‘decorative’; this criminal, ugly and inferior luxuriant that could be traced back throughout my irreverent messing up of all clean and pure. The spectators’ interpretations were often steered by a lack of acceptance of knick-knacks and chit-chat. Any intimation of the function of things was judged in line with Kant’s tastes and overruled as ugly. My works were full of exaggerations and rabid claims. To soak a mahogany surface with thick-flowing, cobalt-pigmented paint was a deliverance dripping of materiality. You use what you have and do as you please, with no ‘master’ looking over your shoulder. Imperfect from a craftsman’s point of view: home-welded iron fittings in a rubbing disharmony with pastel colours for decorative purposes, hazel twigs and cow leather cushions. However, *Seating furniture for the culturally advanced* (1982) was purchased and still lives a quiet life in one of the

[2] The exhibition “Ting” Bergen + Festspillene in Nord Norge, 1986 was supported by Norsk kulturråd and Hordaland Fylke.

country's best-furnished homes. As the 2000s continued, our free-spoken expressions still produced a reaction. Especially from certain art historians, particularly the Swedish and Danish ones, as Jorunn Veiteberg writes in her article *Barbaric tendencies* (2004). Veiteberg refers to French sociologist Pierre Bourdieu's definition of barbaric taste when she writes about the difference between "the two tastes", which she refers to as different cultures. "What is valued in art has value in everyday life. The barbaric taste likes vibrant colours and things with a sensory appeal and is not afraid of sentiment or pathos," she says (2004: 81). She claims that the reason Norwegian artists shook the other Scandinavians lies in our culture. The "barbaric tendency" lives and thrives in the close relationship many of us have to peripheral and scarce folk traditions and wild nature, far away from the avenues of the Swedish and Danish bourgeoisie. Yet, when at public get-togethers, I often meet my works interpreted and exhibited fore mostly as functional objects. My "barbaric" fantasies about things in their own right and speaking subjects are reduced into harmless and almost futile curio cabinets, such as in *Store norske leksikon*: https://snl.no/Liv Mildrid Gjernes (06.11.2019). If *Silver birch for the asphalt jungle* (figure 5) was shown in a similar manner, it must be to reduce the sensory, poetic and sentimental that this thing speaks of.

Figure 5 . "Silver birch for the asphalt jungle" 1986.P.E. Denmark. Source: The artist´s collections
© Liv Mildrid Gjernes / BONO Photo: Rolf M. Aagaard for Aftenposten, 1987.

The birch pictured above is imitated. Its core is wood and its surface is built from steel-plastic and paint. The crown is adorned with aluminium leaves and acrylic paint. It has an inner space that one can carefully open up and close.

In 1985, a selection of my works was displayed at the international exhibition *Homo Decorans- the decorating human* at Louisiana outside Copenhagen, alongside works from the Memphis-group and a number of other contemporary artists, designers and architects from around the world. At this point a comprehensive

movement has developed. Its form reflected many modes of expression and was at least something with a more comprehensive content than modernism's ascetic mirroring of function. It was described as "critical design" or "radical design" in Europe (Hauffe, 1996). My distinctive career as a designer progressed for a number of years with many exhibitions and commissions. Elisabeth Engen and Lillian Dahle are still working on their own. Towards the end of the twentieth century, globalisation and internationalisation eventually led to a launch of competition against poorer countries. This again, led to a wretched situation when it came to working with crafts and material-based things. What Bård Breivik named "a human and cultural intelligence" was on request for tender and pulverized into the currents of globalisation at the same time as, according to Svendsen, the field of art was discontinued. Art became theorised and removed from the concrete by letting the idea or concept carry the meaning. The continuation is difficult to distinguish, as today digitalisation and computer technology challenge our occupation with "materials, time and space", writes Dag T. Andersson (2001).

Technology's pervasive impact on man's relationship with the world progresses unscrupulously. "Not only the arts changed due to technical innovations, but our opinion of matter, time and space became something else," Anderson writes. "New technologies make it possible to exceed the limitations set by the materiality of things. By violating the remoteness of things, technology invades the very nature of them (p.33)(…) things lose their aura when the invasion of technology destroys their remoteness, when the ability to reproduce robs them of their autonomy and their unique character," he continues in his interpretation of Walter Benjamin (2001: 35). Benjamin considers the aura to be a historical phenomenon that must be understood in the context of how humans' relations with the world have historically changed" (or in time, as I understand it). The aura protects the intrinsic value and individuality of things: "It is a question of whether man's individuality is as threatened in a society where things are reduced to goods," says Andersson (p.35).

During the process of restoring my swanky table, the thin teak veneer that covers the table top has been sanded so much that it is now worn down. When the consistently precious tropical wood appears as a shield and stuck on a wood board, the quality of material is dramatically reduced. In these days, table tops given a name such as "Ash", Oak" or "Teak" are made from plastic laminate. They are photo reproductions of the relevant materials, embossed and transferred onto plastic veneers, and bonded to a stable sheet of material in the appropriate thickness. Completely maintenance-free and stable, it is a dead copy of the living. Plastic is plastic, and in laminate it appears to be the king of all imitations. Only those who know the sound, fragrance and taste of wood will in most cases detect the difference. The imitation of material is so well done that even a cabinetmaker might have to whittle or bite it to discern if it's counterfeit.

Veneers can be cut into thin layers from all sorts of wood. "Images" formed by weaving different colours and wood varieties into intricate patterns are called intarsia. Hardening oil salvaged the remaining 1-2 mm of thin, peeled veneer on my battered and sanded table. Originally, the surface was most likely confirmed with a highly polished cellulose lacquer, which in its time created a smooth and shiny layer over the precious wooden surface. Well, until someone who has a strong drink and spills a little of it. The cellulose lacquer was soluble in spirits, and this would soon create rings and blemishes on the shiny surface. Eventually, plastic lacquer was invented. It withstands alcohol and most chemicals as it cures into plastic, just like wood glue does. The plastic coating does not understand that the wood is living matter. A small notch or crack in the varnish is enough for any moisture to reach the wood. Wood will, in keeping with its nature, swell, and the varnish will crackle. This problem particularly arises on soft woods, such as pine. The next solution was therefore to give the entire surface a coating of plastic. Wood was photographed and recreated in thin plastic flakes, ready and self-sufficient in its counterfeit form.

Within the traditions of furniture cutters, horn glue, or hot glue was used. Horn glue is organic and after it has hardened, it can be turned into liquid again, allowing parts to be disassembled with the help of heat. It's the drop in temperature that causes it to harden. The possibility of being able to replace, repair and correct parts allows for a longer lasting object. Today, the plastic product, glue, is also used. It cures as the moisture in it evaporates and becomes an unchangeable plastic. Once this has happened, there's no going back, and the piece of furniture cannot be dismantled without ruining the work. Anything that can be used can be discarded. Wood glue or PVA glue consists of plastic particles and cures as the wood and air in the room draws in the moisture of the glue. This plastic glue is the grief of conservators. Woodwork glued or veneered with old-fashioned glue consisting of horn/hooves/organic material can be salvaged. Since horn glue can be reheated and re-melted, the parts may be carefully taken apart to remove a woodworm-infested part and replace with a fresh piece. Just as gently as removing the old piece, a new piece can be added before glued together.

The slender wood table legs with brass extensions on my little reclaimed table are painted black. The underside of the furniture board that makes up the table top looks to be covered with flame-birch veneer. Tropical woods were readily available in the 1960s. During my crafts education in the mid-1970s, we worked exclusively w Norwegian woods. The warehouse probably had the occasional teak plank, yet the main supply was first-grade carpenter pine of a quality that you have to go to specialist sawmills to get your hands on these days. Formica, the definitive plastic material that was glued to an underlying sheet with a contact adhesive or synthetic resin adhesive, was also invented in the 1950s[3]. The underlying sheet was chipboard and consisted of wood shavings and glue mixed together into a mass that was pressured and hardened into sheets of low-tensile dead material. Formica solved the problem of surface durability, since it consisted of plastic that tolerated both stiff drinks and other strong beverages. During my childhood in the 1960s, the old long tables were eventually replaced with modern Formica-laminated chipboard boards on steel legs, in addition to the living room's coffee table in the wood type teak; shipped in from the tropical latitudes of the Norwegian merchant fleet.

Figure 6. "The Oak Place". Leirdal 2008.Source: http://www.erlendleirdal.com/ (03.10.2018)

The Oak Place is the name Erlend Leirdal has given to the wood trunk he exhibited at the Trøndelagsutstillingen in 2008 (figure 6). An oak tree trunk: big, heavy and resting in its own strength. It just lies there. Throughout the 2000s, the expressions of materiality have moved further away from any interpretation of function and utility, and back to oneself and its possibilities. One needs no other experience than touching it, leaning on it, smelling its scent and perceiving the timeless willpower the wood holds for our senses. I see a strong optimism in this expression.

[3] Respatex (or Formica) is a previously registered Norwegian trademark of a high-pressure laminate of composite produced by Norsk Hydro from 1958. (https://no.wikipedia.org/wiki/Respatex 14.01.2017)

Figures 7 and 8: "Furniture for wonder and conversation", 1997-2007. Liv Mildrid Gjernes. Source: The artist´s collections Photo: Liv Mildrid Gjernes.

For me, it was still about the problematisation of meaning and function towards the turn of the century, as shown in my series *Tuntre* (1997-2002). Tree trunks, equally remaining and surviving parts of something. They still have an "added value", as Austring and Sørensen call it (2006), even though it is simplified. What do visual expressions convey, regardless of time and technology? What meaning and values can we gather from their structures and autonomy? For the speech of things is addressed to us in a direct and completely physical way, in a communicating all their being, completeness and absolute presence. The way things meet our senses, the feeling of space, and the skin's sense for materials is something in itself. In our ears, materials have their own sound, as materials meet our aesthetic experiences with their offers to experience form. They blend in with our experiences and memories, and let their solid materiality frame our lives and tightly contain our history. Expressions in which form manifests meaning has followed mankind throughout time. As a historical phenomenon, and in present and concrete expressions, form and materiality have safeguarded and represented what Andersson describes as a "completely sensory relationship to things" (2001: 32).
All that has given shape to the importance of things in itself is also the medium of our own experience of being in the world. Thus, one can see that the poetry of materiality holds an infinity of trials, possibilities and potential solutions that are driven by emergency, urgency, a need to communicate and restless curiosity. What man-made things can bring to us can be reviewed by new eyes in the future. Such as this little table dressed in the subtle language of the 1960s. It was produced in a series by a small furniture factory established in Øystese in 1913. They were originally called O.P. Rykken & co Furniture Factory and later renamed RYBO (http://www.matslinder.no/2018/09/18/rybo-reklame-for-sybord/ 25.09.2018). As chubby pine furniture of the 1970s filled Norwegian living rooms, this small table was degraded into a room of less importance. However, it was not discarded, and through unknown paths it has retold its stories here in my room, 50-60 years later. Let us look at it once more, with new eyes, as it sits beloved and harmless in the afternoon light, enthroned in its 60's matter-of-fact aura. It rests here now, in our common story about the speech of things.

Norwegian research group Design Literacy at Oslo Metropolitan University (OsloMet) which is led by professor Liv Merete Nielsen has initiative to this paper track. The paper track was accompanied by a workshop.

Design Literacy can be regarded as a catalyst for a move towards a better citizens participation in innovative design processes. By educating the general public to become design literate, there is a chance to support critical innovation and a possible move towards sustainable societies (Stegall, 2006). The challenge is to articulate content, performance and continuity for a critical decision-making process and how this influence critical innovation and design education at large.

The concept 'Design Literacy' addresses the complex matter of objectives, content and practices in design processes and education. Research on multiple literacies has evoked considerable debate and redefinition within several areas of educational research (Coiro et al. 2008); the understanding of literacy is no longer bound to the ability to read and write verbal text or numeracy. Design Literacy (Nielsen and Brænne, 2013) are among newly coined literacies. Design Literacy is connected both to the creation and understanding of design innovation in a broad sense. In today's mostly artificial world, the Design Literacy is regarded as a competence not only for the professional designer, but also for the general public in their position as citizens, consumers, users and decision makers in innovative processes.

Designed artefacts and services influence our lives and values, both from personal and societal perspectives. Designers, decision makers and investors hold different positions in the design process, but they all make choices that will influence new innovations and our future. In order to solve crucial global challenges, designers and investors must cooperate; for this purpose, we argue that design literacy is necessary for all. We argue that the Design Literacies can support practices associated with innovation, democratic participation in design processes, developing and enacting ethical responsibilities, and understanding and supporting sustainable aspects of production and consumption.

The track called for researchers to explore the following points:

- How development of Design Literacy can support critical innovation and sustainable issues
- Progressions in scaffolding Design Literacies from a pre-school to a university level
- The potential of Design Literacy to support collaborative and experimental approaches of projects between: investors/designers, general public/designers, children/designers

- How design education for the general public can represent both a foundation for professional design education and a prequalification for lay persons' competence for decision-making and critical innovation
- How might Design Literacy influence sustainability issues in society?
- What are the challenges of professional design, when everyone wants to design?

Research presented at this track addressing the points above have been useful as a point of departure for the Design Literacy workshop and the creation of the Design Literacy International network. The papers have also been useful for the promotion of critical innovation and to inform policy and for educational implementation. The importance lies in the needs to better inform design education itself, to improve the approach of design educators, and to educate reflective citizens, policy makers, entrepreneurs and consumers in perspective of critical innovation.

Eleven papers were accepted and gathered researchers from US, New Zealand, Australia, Chile, Finland, Portugal, UK and Norway to explore the concept Design Literacy through three sessions.

Eva Lutnæs (OsloMet - Oslo Metropolitan University, Norway) authored the first article *Framing the concept design literacy for a general public*. She explored the concept design literacy from a general public perspective. Asking the question 'What does it mean to be design literate in a context of critical innovation' she reviews three key texts storylines on how to cultivate design literacy and arrives at a definition of the concept design literacy for a general public. Lutnæs was awarded Top III Paper submissions for her contribution to the conference. Her paper was used as a point of departure for discussions in the Design Literacy workshop.

Miika J. Lethonen and Jia Jing Chew (Aalto University School of Arts, Design and Business and Aalto University School of Business, Finland) wrote the paper *Developing design literacy for social agency*. They look into how multidisciplinary teams of students in higher education develop their design literacy in an action-oriented course setting. Based on their initial analysis, blending the boundaries between universities and the surrounding society positively contributes towards developing design literacy. The contribution of design literacy to non-designers in higher education is preparing a workforce that is well-equipped with the skills and knowledge to navigate the complexities of our global human society.

Chris Pacione (LUMA Institute, United States of America) presented *A Framework to Accelerate Universal Design Literacy*. He argues the design is poised to become the next universal literacy. Just as arithmetic was once a peripheral skill until the industrial age brought about the need for math literacy, the socioeconomic conditions of our current age are heralding the need for millions of people to level up in design. The expanding role innovation and collaboration play in our daily work, combined with the ever-increasing complexity and rate of change of today's products, services, and systems are making the case for design literacy. The paper propose a framework with a set of skills to accelerate design literacy.

Úrsula Bravo (Universidad del Desarrollo, Pontificia Universidad Católica de Chile) and **Erik Bohemia** (Oslo Metropolitan University, Norway) wrote the paper *Representations of Design Process* where they argue that visual representations of design processes contribute toward social and material practices of design(ing). Metaphors was used to illustrate that they are active material devices of which circulation, production and consumption are informed and informing perceived complexities, ambiguities and paradoxes associated with design. These models can contribute to the development of Design Literacies. Bravo was awarded Top III Paper submissions for students.

Randi Veiteberg Kvellestad, **Ingeborg Stana** and **Gunhild Vatn** (all from Oslo Metropolitan University, Norway) had written the paper *Working Together - Cooperation or Collaboration?* where they elaborate on the difference between cooperation and collaboration through an action-research project in design education for specialised teacher training in design, arts, and crafts. At the Oslo Metropolitan University including the material areas of drawing, ceramics, and textiles. The project developed the participants' patience, manual skills, creativity, and abilities, which are important personal qualities for design education and innovation and represent cornerstones in almost every design literacy and business environment.

Anita Neuberg (Oslo Metropolitan University, Norway) presented her paper Social innovation for modified consumption by means of the school subject Art and craft. In her paper she asked: How can we, based on the subject of Art and craft in primary schools, facilitate the change in consumption through social innovation? Opportunities for actions were discussed under the subject of Art and craft, in Norwegian general education, ages 6–16.

Fiona Peterson (Auckland University of Technology, New Zealand), **Cathy Lockhart** and Catherine Raffaele (both from University of Technology Sydney, Australia) had written the paper *Adaptive digital capability* development*: Professional learning for educators across disciplines*. In a cross-university project, a mixed methods approach was adopted to design a learning model for digital work practices in line with evolving industry needs. Their responses indicated a predominantly functional digital capability focus in their current learning and teaching practice; rather than integrating functional, perceptual and adaptive digital capabilities, which are in high demand but short supply in industry. They argue it is vital for students and educators to learn and use the vocabulary of technology affordances, to strengthen professional learning for digital work futures.

Rebecca Kelly (Syracuse University: VPA, School of Design, United States of America) presented her paper *Democratizing Design: Can Higher Education Survive?* She claims that the tools and techniques of graphic design have become accessible to the public at large to such a degree that the profession itself may be threatened with extinction. At the same time, design literacy — the knowledge and reasoning beyond the use of those techniques — does not seem to be experiencing the same widespread dissemination. Educators must be innovative in order to prepare a new generation to evolve quickly and continuously. Programs must be fluid and adaptable, which requires educators to treat their curricula as design problems, to be solved with radical thinking and creativity.

Lars Groeger (MGSM, Macquarie University, Australia; 2: RWTH Aachen University, Germany) and **Jochen Schweitzer**, **Leanne Sobel** and **Bridget Malcolm** (all from University of Technology Sydney, Australia) had written the paper *Design Thinking Mindset: Developing Creative Confidence*. Their study examines the effect of an experiential Design Thinking (DT) learning environment on the development of a DT mindset. They analysed the extent to which key attributes of a DT mindset are understood, evaluated and assessed. They provide a framework for learning objectives and exemplary activities to teach and encourage designerly ways of thinking and doing in business education is provided, and argue that a mindset that embodies DT can address deficits in business school education, better preparing students for future work.

John Richard McCardle, **Samuel Dempsey** and **Max Humberstone** (all from Loughborough Design School, United Kingdom) had written the paper *Stressors and creativity in Industrial Design practice*. Current literature suggests that stress influences creativity, and current views are clearly divided on whether any negative effects on creativity are more dictated by environmental stressors or the reactions of individuals whilst under stress. In their study, participants completed a questionnaire comprising of a perceived stress scale and thematic questions. The results suggested that participants who identified as being more affected by their own negative reactions to stress displayed a lower calibre of creativity when time-pressure increased, whereas the participants who were suggested to be more influenced by their environment remained at a relatively constant perceived level of creativity.

Tore Andre Ringvold and **Liv Merete Nielsen** (both Oslo Metropolitan University, Norway) had written the paper *Complexity, interdisciplinarity and design literacy*. For decades, global organisations and researchers have pointed to interdisciplinarity as a way forward for educational systems. Educational research offers great possibilities and gains for students involved in interdisciplinary teaching and learning processes, and the interdisciplinary nature of design thinking and practice can play a vital role in interdisciplinary general education. This paper explores how future scenario-building, as part of general design education, can serve as a framework for inter-disciplinarity in general education and contribute to a better understanding of complex problems, challenges and design literacy.

Irene Brodshaug and **Janne Beate Reitan** (both Oslo Metropolitan University, Norway) had written the paper *Networking for strengthening design literacy*. This paper focuses on design education for the general public and the ways in which students and teachers can become more design literate through the development of networks, such as professional groups for teachers. The emphasis of this study is on how each municipality gives time and space for the development of design competence through professional groups. A well-organized professional group will hopefully contribute to a deeper level of expertise in schools and an increased ability for the general public to recognize design education.

Catarina Lelis (University of West London, UK) and **Oscar Mealha** (University of Aveiro, Portugal) had written the paper *Developing design literacy through brand-based artefacts.* They state that the brand is a powerful representational and identification-led asset that can be used to engage staff in creative, sustainable and developmental activities. Being a brand the result of, foremost, a design exercise, it is fair to suppose that it can be a relevant resource for the advancement of design literacy within organisational contexts. The main

objective of this paper was to test and validate an interaction structure for an informed co-design process on visual brand artefacts.

Framing the concept design literacy for a general public

LUTNÆS Eva

Oslo Metropolitan University, Norway
evalu@oslomet.no
doi: 10.33114/adim.2019.01.224

Educating the general public to be design literate can be a catalyst for both environmental protection and degradation, human aid and human-made disasters depending on how the scope of design is framed – and how 'design literacy' is defined. This paper explores how to cultivate design literacy that supports critical innovation and a transition towards more sustainable societies. The research approach is a literature review of key texts that promote and conceptualize design literacy as part of general education. Four narratives are identified as vital: **a) 'Awareness through making'**, **b) 'Empower for change and citizen participation'**, **c) 'Address complexity of real-world problems'**, and **d) 'Participate in design processes'**. Moving towards more sustainable modes of consumption and production, a design literate general public provides a critical mass of users empowered to question how a new innovation supports the well-being of people and the planet and to voice their own ideas.

Keywords: design literacy, literature review, critical innovation, general education

Innovative design or critical innovation?

Progress depends upon the products of educated minds, stated UNESCO (1997) and launched education as humanity's best hope and most effective means towards sustainable development. Stephen Sterling (2001), however, claimed that: "most education daily reinforces unsustainable values and practices in society. We are educated by large to 'compete and consume' rather than to 'care and conserve'" (p. 21). Educating the general public to be design literate can be a catalyst for both environmental protection and degradation, human aid and human-made disasters depending on how the 'design literacy' is defined and how the scope of design is framed. It makes a vast difference whether students are asked to design beautiful products to increase sales or to design useful and lasting products or services that improve quality of life and mitigate pollution. Vande Zande (2013) defined innovative design as a unique solution that creatively satisfies a problem. A valuable outcome of introducing design techniques of ideation to companies is how unique solutions might advance economic competitiveness and success in a globalized market (Canina, Coccioni, Anselmi, & Palmieri, 2013; Martin, 2009). Judged meaningful in terms of business, innovative design, satisfy just one out of three mutually reinforcing pillars of sustainable development (United Nations, 2002) at the expense of social development and environmental protection.

Citizens of Western societies are facing what Stegall (2006) described as an: "extremely complex sociological dilemma, where the lifestyle that we have adopted is rapidly eroding our ability to survive" (p. 57). At the level of social equity, it would be favourable that all citizens of the world have the same economic vitality, but the capacity of the ecological system is already at its limits. Infinite economic growth, irrespective of its wider consequences, threatens not only social well-being and ecological sustainability, but also economic prosperity (Jackson, 2009; Meadows, Meadows, & Randers, 1991). Mateus-Berr et al. (2013) argued that designers have

played a considerable role in shaping today's consumerist culture by providing their skills and talents to create desire for new products. Design literacy will remain a driver of economic competiveness unless concerns for the environment and human well-being are made an explicit part of judging new ideas as meaningful or valuable. Mainstreamed as three equally important pillars, the global sustainable development agenda has focused too much on economic development, marginalizing both the social and environmental aspects (SANZ, 2009). We have not yet been ready for the task of large-scale changes in our unsustainable ways of living (Giddens, 2011; Intergovernmental panel on climate change, 2018). Critics called for a paradigm shift in which economic development is nested within social sustainability and environmental sustainability (Elmquist et al., 2014). Applying the paradigm shift as a baseline to design literacy requires critical scrutiny of how a newly proposed innovation supports a transition towards a more sustainable future. In the model below, critical innovation satisfies criteria of economic vitality, welfare of current and future generations, and safeguarding of the ecosystem:

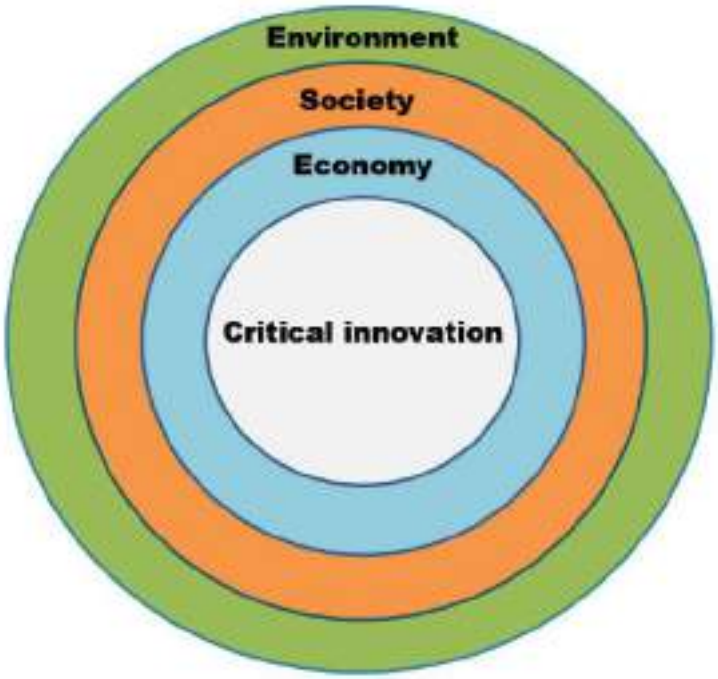

Figure 1: Critical innovation as nested within economic, social, and environmental sustainability

Relating the concept 'critical' to 'innovation' requires the facilitation of critical reflection as a baseline to any design process. Critical reflection addresses the fundamentals of practice, the why of action, and the reasons and consequences of what we do (Mezirow, 1990, p. 13). Critical innovation derives from asking basic ethical questions of how a new idea makes the world better and rejecting practices of overconsumption and destructive results of human creativity. Critical reflection called the foundations and imperatives of the system itself into question, assessed their morality, and considered alternatives (Brookfield, 2010, p. 219). The purpose of critical reflection is profound change in our attitudes and actions. Design and critical reflection share the same transformative agenda. In his seminal book, *The Science of the Artificial*, Herbert Simon (1969) described design as concerned with how things ought to be. The capacity to transcend the known is the expertise of design. According to Simon (1996): "Everyone designs who devises courses of action aimed at changing existing situations to preferred ones" (p, 111). Including design in any curricula fuels change by exploring and questioning existing knowledge and situations. In support of critical innovation, however, further effort is required. Critical innovation calls for everyone first to consider what situations to change, then the socio-ecological consequences of intended change, and who would benefit from a specific situation changing. Critical reflection is a key component to support a transition towards more sustainable modes of production, trade, and consumption. This paper explores how design literacy as a part of general education can support critical innovation and a possible move towards sustainable societies (Stegall, 2006). The research approach is a literature review of key texts that promote and conceptualize design literacy as part of general education. None of the texts synthesized the concept of design literacy into an explicit definition. By reviewing

the key texts' storylines on how to cultivate design literacy, this paper aims to articulate a definition of design literacy for a general public in a context of critical innovation.

Storylines as a method of inquiry

The literature review of key texts on design literacy for a general public is derived from Soini and Birkeland's (2014) approach when investigating the scientific discourse on the concept of 'cultural sustainability'. They used storylines as a semiotic tool to identify generative narratives used to give meaning to specific physical or social phenomena within a discourse (Hajer, 1995). The narratives in this study aim to give meaning to design literacy as a part of general education within the scientific discourse of design education. The discourse refers to ideas, concepts, and categorizations that are produced, reproduced, and transformed in the practice of writing academic papers. As a method of inquiry, storylines encompass complexity and provide a semiotic tool to voice different narratives in a specific discourse.

The first phase of the literature review identified papers that could inform the research question based upon the following criteria for selection: (1) incorporates 'design literacy' into the title, (2) focus on design literacy as part of general education, (3) enacts ethical responsibilities and critical reflection, and (4) written in English. The first criterion delimits the selection to papers in which authors have made design literacy one of the main concept. The second and third criteria ensure papers relevant to explore how to cultivate design literacy in general education and educate a general public empowered to support critical innovation (Figure 1). The fourth criterion enables transparency. As all the selected texts are written in an accessible language, the results of the study are open for inspection to other researchers, and the selected text can be reanalysed in future studies.

The search for relevant papers was completed in December 2018, using Skopus, Eric, Academic Search Premier, and Oria. This search identified eleven papers with 'design literacy' in the title. Three of the papers failed to satisfy criterion 2 as they discuss design literacy in a context of higher education (Formosa & Kroeter, 2002; De Eyto, 2014; Poggenpohl, 2008). Four of the papers did not satisfy criterion 3, enact ethical responsibilities and critical reflection (Pacione, 2010; Jones, 2013; Lerner, 2018; Rahimi & Kim, 2018). As criterion 3 is vital for design literacy to support critical innovation, I will explain how two of the papers failed to meet this criterion. In Lerner's (2018) paper 'Visual-Spatial Art and Design Literacy as a Prelude to Aesthetic Growth', design is framed as the process of giving form or expression to ideas. Lerner focus solely on the positive aspects of visual-spatial learning and involve no critical reflection. Design literacy is limited to the ability to understand and make use of a canon of aesthetic form. Pacione (2010) named "the act of arranging how something looks" (p, 11) as a stereotype of design to stamp out in order to convince a majority of leaders in business and government to support design thinking in companies and as a vital part of general education. Pacione took on a broader understanding of design literacy than Lerner did as he described an iterative process of uncovering and satisfying unmet needs as core design capacities. Still, Pacione's (2010) paper, 'Evolution of the Mind: A Case for Design Literacy', falls short on criterion 3 as no attention was given to the wider social and environmental impacts of design—critical reflection on what unmet needs to satisfy or not by design. Pacione (2010) asked the question, 'What does it mean to be design literate?' (p. 9). In this paper, I ask the question again, but in a context of critical innovation.

Four texts met the criteria, and prior to a description of the second phase of the literature review, their focus and research approach are briefly introduced:

1. Nielsen and Brænne's (2013) 'Design Literacy for Longer Lasting Products' has a conceptual approach as they discussed how design literacy is located amongst other literacies and connected to material knowledge, ecological literacy, and citizenship.
2. Green's (2014) 'Transformational Design Literacies: Children as Active Place-Makers' draws upon an ethnographic study in an Australian primary school in which students aged 8–12 and their teachers designed and made a new garden, 'learning landscape', on the school grounds. The focus is on the potential role of design in a garden-based curriculum and how the children were positioned as participants.
3. Christensen, Hjorth, Iversen, & Smith's (2018) 'Understanding Design Literacy in Middle-School Education: Assessing Students' Stances Towards Inquiry' presents a literature review on design thinking in children's education prior to a comparative study on how 449 students aged 11–15 took a designerly stance towards inquiry in a survey. The authors found no significant difference between how the control group and how the students who had received design education performed. The

focus is on what it takes to educate for complex adaptive capabilities. The study is a follow-up on Christensen, Hjorth, & Iversen (2016). Both papers satisfy all four criteria, and I chose the most recent one.

The second phase of the literature review started by reading the three texts, marking out descriptions on how to cultivate design literacy and for what reasons. Subsequently, a word search was used for a systematic approach by which key concepts in one paper were searched for in the other two.

Table 1, Preliminary analysis, key concepts across the three papers.

Key concept	*Nielsen & Brænne*	*Green*	*Christensen et al.*
Citizenship	x	x	x
Democratic/democracy	x	x	x
Materials/materiality	x	x	x
Transformative/transformational		x	x
Reflective inquiry/critical	x	x	x
Dialogue	x	x	x
Open-ended process		x	x
Agency/agent		x	x
Power/empower	x	x	
Awareness	x	x	x
Complex task/problem/dilemma	x	x	x

The preliminary analysis (Table 1) was a tool to approach the texts from multiple angles and familiarize with shared concepts on design literacy across the papers. The identification of generative narratives, however, relied on the combination of concepts, as meaning is not produced by singular words. Valid narratives had to stand a test of being coherent to the meaning produced in each of the papers as well as descriptors across the three on how to cultivate design literacy in a context of critical innovations. A repetitive process of combining concepts to narratives, revisiting all three texts, moderating narratives and revisiting the texts, identified four shared narratives:

a) Awareness through making
b) Empower for change and citizen participation
c) Address complexity of real-world problems
d) Participate in design processes

Across the shared narratives, the authors voiced different objectives and ways of acquiring design literacy. The third phase of the literature review presents each of the narratives, and discuss nuances and different agendas in the three key texts.

Generative narratives in key texts on design literacy

a) Awareness through making

A shared narrative among all three texts is the significance of placing materials in the hands of pupils. As makers, they transform materials to externalize ideas, and in the making, they connect both to the physical reality and to the conceptual in order to articulate meaning. Nielsen and Brænne (2013) stressed material knowledge as part of design literacy for consumers to opt for longer lasting products and sustainable choices in their everyday lives. Through the mode of making in physical materials, the demand of time and energy in production becomes a first-hand experience to pupils, as well as what it takes a product to become solid, functional, and interesting to use over time. The fusion of craftsmanship and design literacy is not self-

propelled. In their making, the attention of pupils needs to be drawn to the plural context of materiality, a context described by Nielsen and Brænne (2013) as purpose, use, production, transport, ecology, and ethics.

In the narrative of Green (2014), embodied experiences in outdoor sessions teach pupils to work with, not in opposition to, the peculiarities of a garden site. Through months of rigorous mapping of trees, soil, wind, sun, and distance, the pupils accumulated knowledge of the site. Their ideas for the new garden evolved from knowing the material realities and a personal connection to the site. In the first part of the project, the materials were placed in the hands of the pupils for them to examine, and Green (2014) argued that the field trips were critical in empowering pupils to develop, shape, and modify their critical spatial thinking (p. 194). In the second part of the project, materials were placed in the hands of the pupils for them to change the garden site. Green emphasised how making models in clay and three-dimensional maps with a wide range of materials enabled the pupils to advance their ideas and voice their visions.

Christensen et al. (2018) presented design as a basic literacy akin to reading and writing. Skills for materializing ideas as externalizations is among their described learning outcomes for design literacy, alongside abilities of designerly inquiry, ideation, and navigating a design process. In their study, the access to materials and maker settings varied significantly from one school to the other. This was pinpointed as one of the reasons why the FabLab group of students did not perform significantly better than the control group of students in how they took a designerly stance towards inquiry. The authors thus indicated the importance of access to materials and proper studios for design literacy initiatives to succeed. In the article, the authors also entailed an interesting section on the potential pitfalls of the emerging new technologies that make the creation of digital products feasible in schools. As the introductory workshops for teachers usually are constrained to short sessions with predetermined outcomes, the teachers are more likely to opt for activities focused on technological literacy than design literacy. Activities enable pupils to repeat the design of others by the use of technology, but not to take part in the design process. The authors' warning draws attention to the importance of a wider repertoire amongst teachers developed by experiencing a long, complex, and open-ended process themselves prior to the cultivation of design literacy.

The three texts emphasise the importance of first-hand experiences with materials as part of educating a design literate general public. In Green's (2014) narrative, the students examined the physical reality of the garden site to connect to its potential, and in their making of models, they experienced how visualization in materials might voice and advance their ideas. The agenda in the narrative of Nielsen and Brænne (2013) was twofold: designing and making their own products (e.g. garments or spoons) prepared the pupils to judge quality and longevity in products as consumers and provided an arena to enhance pupils' awareness on how conflicts, inequity, and exploitation of nature embed everyday consumption. Christensen et al.'s (2018) narrative on making was to provide students with tools to externalize and share ideas. They emphasised the importance of open-ended briefs, as the making of copies rather would cultivate students' technological literacy than design literacy.

b) Empower for change and citizen participation

The idea of empowerment is a key to design literacy across the three texts, challenging a script of schooling with teachers as experts who hold pre-set answers for pupils to unveil. The educational ideas of Freire (1970) were present in all three texts on design literacy. Freire brought attention to what he framed as the banking concept of education by which students are receiving, filing, and storing narrations from the teachers. The banking concept offers few opportunities for students to analyse how political, cultural, and social contexts shape their lives. Freire's alternative is a practice of problem-posing education. The teachers pose a problem that challenge humans' relations in the world and with the world, and they facilitate a dialogue of co-investigation with students to unveil oppression and situations as historical realities susceptible to transformation (Freire, 1970).

Christensen et al. (2018) promoted design literacy as part of education for citizenship and democracy, followed by an argument on how designerly ways of engaging with complex problems enable individuals to act as agents of change and creators of preferred futures. Seeking a single correct answer and relying on the same tried-and-tested method regardless of situation were described as opposites to the expertise of designers. The authors referred explicitly to Freire's criticism on the banking concept of education along with Biesta's (2008) concept of 'learnification' and Lin, Schwartz, & Bramsford's (2007) difference between routine experts and adaptive experts. The authors did not elaborate further on Freire or propose design literacy explicitly as an alternative to the banking concept; adaptive expertise was their chosen concept to explain a designerly stance

towards inquiry. Drawing upon a wide range of references, the authors framed a designerly stance towards inquiry as being open to new understandings, listening to the complexity by adapting a range of techniques, and gaining a holistic understanding of the existing situation (Christensen et al., 2018, p. 4). The authors found that the FabLab group of students who had received design education through middle-school maker settings failed to improve their designerly stance towards inquiry. Their study pinpointed the difficulties of implementing design literacy to general education and discussed how it challenged the more familiar scenario where the teacher 'has the correct solution to the problem at hand' (Christensen et al., 2018, p. 18).

Green did not quote Freire explicitly, but under the heading 'Agency', she described a shared feature of the countless facilitated discussions during the design of the new garden. They all positioned the pupils as the main stakeholders and required that they work with the emerging tensions and problems that arose during the design process. Green referred to an example of a discussion on how to incorporate a frog pond safely. The teacher's role was not to resolve the issue but to facilitate a space for dialogue among pupils 'that supported their "voice" and empowered them to successfully and safely incorporate a frog pond into the plan'. A key narrative in Green's text on design literacy is the importance of providing pupils with a sense of agency. The principal elaborates on how pupils' agency and decision-making is enhanced by inclusive and unhurried processes. Green connected agency to citizenship by quoting Mannion (2003) on how children are active local citizens of today who are capable of bringing a uniquely valuable perspective to civic discourse. Green positioned the pedagogy of design as a direct contrast to approaches that privilege teacher knowledge and position students as passive recipients, along with Freire's banking concept of education. According to Green, the pedagogy of design permits children to visualize the future and to see themselves as proactive participants with a significant role to play.

Nielsen and Brænne (2013) found the concept of design literacy as one bringing new life to the educational ideas of Freire (1970). The transformative agenda of design shares the ideas of Freire. The core of Freire's (1970) libertarian and humanist pedagogy was for people to discover themselves as permanent re-creators of the world: "To exist, humanly, is to *name* the world, to change it" (p. 88, original emphasis). In the text, knowledge of sustainable ways of producing and using material artefacts are key to design literacy for a general public, empowering them to refuse to buy unethical artefacts along with critical awareness of how groups are socialized as consumers and producers. Making design literacy a part of general educations enhances an alternative counterculture—a critical stance against shallow symbolic design-values and of being seduced through shopping to buy more than we need.

Empowerment of the individual pupil is a shared objective of design literacy, however, at different levels. The pupils in Green's narrative were empowered to voice their ideas and differing perspectives in the design of a garden. The pupils in Christensen et al.'s (2018) narrative were empowered to a designerly stance towards inquiry, to act as agents of change and create preferred futures. The pupils in Nielsen and Brænne's narrative were empowered to criticize and change the system in how they acted as consumers and producers. The last narrative is the one closest to Freire's more radical ideas on education as a means to challenge humans' relations in the world and with the world and to capacitate people to transform the sociocultural realities that shape their lives by their words and actions.

c) Address complexity of real-world problems

Design literacy is promoted as a tool to understand and deal with the complexity of real-world problems across the texts. In the narrative of Christensen et al. (2018), one argument of making design literacy a part of general education is how it facilitates awareness of the complex and wicked nature of problems. All real-world challenges are wicked, they claimed, and the pupils would be better equipped for their future if they developed a capacity to recognize problems as wicked (p. 4). With a reference to Lawson and Dorst (2009), taking on wicked problems is at the very core of design thinking and later elaborated as: "seeing the whole from multiple conflicting dialectical contradictions among stakeholders, including ethical, political, and even spiritual ones" (p. 16). In their study, the authors assessed how Danish middle-school pupils approached a wicked problem of demented elderly disappearing from nursing homes and how to create a secure environment for them without taking away their freedom. Only 5.69% of the FabLab group of students and 2.46% of the control group of students made a designerly stance towards inquiry by explicitly or implicitly recognized wicked aspects of the question posed. The vast majority approached the question with a stance of technical rationality, seeing the wicked problem as tame and focusing on answers that were readily at hand, e.g. implementing a GPS-device under the skin with no consideration of ethical dilemmas (Christensen et al. 2018).

Green's narrative has similarities to Christensen et al. (2018) in describing key features of design literacy as the ability to engage with an unknown outcome and connect to the complexity of the real world. In Green's study, the children were encouraged to undertake detailed mapping of the site for the new garden and 'to work with a degree of uncertainty and chaos alongside adults who support them to visualize the future and make it happen'. Quite contrary to Christensen et al. (2018), Green (2014) concluded with a successful implementation of design literacies in how children are recognized as practitioners who can undertake complex tasks, think critically, solve problems creatively, and apply design knowledge to new situations. Christensen et al.'s (2018) study drew upon a quantitative survey across 17 schools, while Green followed a long-term design project linked to a cornerstone in the school's charter, learning landscapes, and a pedagogical commitment to environmental studies for the past 20 years. Green's (2014) study supports Christensen et al.'s (2018) in their conclusion on how children might develop complex adaptive capabilities given more design education over a longer period.

Nielsen and Brænne's take on complexity was to emancipate the field of design from being associated with only form and colour, not on the complexity of the design task itself. They connected design literacy to Stegall's ecological literacy (2006) and the sociological dilemma of rapidly eroding our ability to survive through the lifestyles we have adopted. Vital to design literacy for a general public, they argued, is awareness of how choices as consumers impact the soundness of the ecological system, knowledge of materials, and the complex process of making and designing sustainable products. Drawing upon Stegall (2006), Nielsen and Brænne made the point that even the most sustainable product would not be sustainable unless every person used and recycled it in a responsible manner. The crucial game changer of overconsumption is the reflective user and responsible consumer who ask for sustainable design and buy only the goods they really need.

The capacity to embrace complexity and navigate solutions that contribute to a better future is a shared goal of the three papers in promoting design literacy for a general public. While Green (2014) and Christensen et al. (2018) focused on the complexity of the task given to the students and their inquiry into open-ended problem-solving, Nielsen and Brænne (2013) described the complexity of the knowledge involved to be a design literate person who opts for sustainable design and responsible consumption.

d) Participate in design processes

Narratives on the importance of personal experiences with design processes is present in all three papers. Green's (2014) object of study was a long-term design process in which students and teachers collaborated in the making of a garden, learning to landscape on the school grounds. She discussed how design literacies expand children's learning and deepen their connection to everyday places. Green's descriptions of the design process were rich and manifold, summed up as two main narratives: the physical and the collaborative. The physical process focuses on how the children connect to the site by rigorous mapping and first-hand observations, visualize their ideas through models and maps, and transfer ideas to a three-dimensional reality by building and gardening. The collaborative process is parallel to the physical, focusing on how the teachers position the students to voice their meaning, debate ideas, and agree on final designs as proactive and empowered learners.

Christensen et al. (2018) developed a design process model for the FabLab group students and their teachers. The researchers made the model sequential to simplify the complexity of the design process, consisting of six phases: design brief, field study, ideation, fabrication, argumentation, and reflection. In a later survey, they asked the FabLab group of students how familiar they were with each of the six phases, and more than half of the students rated themselves as knowledgeable. When the students were challenged to address a wicked problem, however, they were not able to adapt their knowledge derived from working with the design process model and take a designerly stance towards inquiry. The authors concluded that the students gained some routine expertise on the design process during their engagement with the project, but not the adaptive capabilities of designers.

Nielsen and Brænne (2013) had no description of phases in a design process or what procedural skills the students should acquire to be design literate, but they promoted students' understanding of the complex process of making or designing as vital. Core to design literacy, they argued, is awareness of how design processes have an impact on our surroundings and the physical aspects of material quality regarding what is lasting and functional. Their proposed route to these competencies for students included making with physical materials and a 'reflection in action' approach. Although not stated explicitly by the authors, this implies that

students should actively engage in a design process that combines skills of physical visualization with inquiry and critical reflection about the impacts on people and the ecological system.

In Green's (2014) narrative, student participation in the design process offered expanded learning opportunities to the garden-based curriculum and supported them as active place-makers. The design process offered a method to facilitate learning and empower students for ideation. Christensen et al. (2018) made the understanding of designerly inquiry and ability to navigate a design process as the main learning objectives, while Nielsen and Brænne (2013) focused on student awareness of the social and ecological impacts of design processes.

What does it mean to be design literate?

Pacione's (2010) answer to the question of what is meant by being design literate, as opposed to being a design professional, is basic skills in inquiry, evaluation, ideation, sketching, and prototyping. Pacione described phases of a design process, the fourth narrative identified in the three key texts: **d) 'Participate in design processes'**. Repeating Pacione's question in a context of critical innovation adds three additional narratives: **a) 'Awareness through making'**, **b) 'Empower for change and citizen participation',** and **c) 'Address complexity of real-world problems'**.

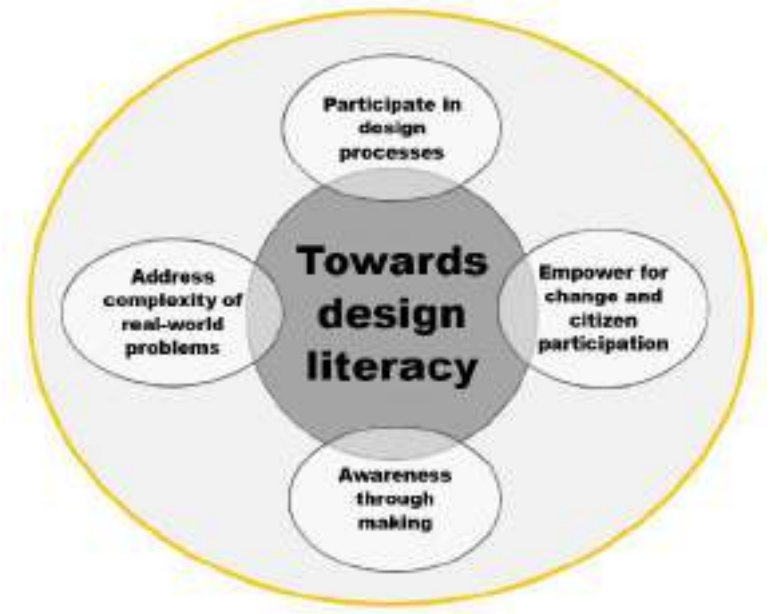

Figure 2: Sketch of a conceptual framework on how to cultivate design literacy in support of critical innovation

Reading and revisiting the three key texts identified four shared narratives on how to cultivate design literacy amongst a general public. **a) 'Awareness through making'** draws upon the significance voiced by the authors of placing materials in the hands of the pupils. As makers, they transform materials to externalize and advance ideas, and in the making, they connect both to the physical reality and to the conceptual in order to articulate meaning. Awareness indicates understanding of the socio-environmental impact of human-made artefacts, and what it takes for products to be solid, functional and interesting to use over time. **b) 'Empower for change and citizen participation'** is a shared narrative on the importance of providing students with a sense of agency and tools to question, rethink, and transform the world around them. Everyone has a significant role to play towards more sustainable ways of living or further destruction, and the authors promoted design literacy as a game changer towards more responsible citizen participation. **c) 'Address complexity of real-world problems'** is framed as a key feature of design literacy, and accordingly, students are challenged to map and navigate conflicting interests and dilemmas embedded in design practices and solutions. **d) 'Participate in design processes'** is the fourth narrative towards design literacy, endorsed by the authors as enabling students to adopt the designer's tools for innovation and understand how designers think. Figure 2 displays a sketch based on generative narratives on how to cultivate design literacy, derived from a literature review of three different texts. So far, the scientific discourse on design literacy in context of critical innovation is in an early stage of

development; the number of articles that could satisfy the four criteria for selection are few. This preliminary sketch would evolve as design literacy is addressed and challenged by further academic writing.

Defining design literacy in a context of critical innovation

The three key texts reviewed to identify generative narratives on design literacy as part of general education were published between 2013–2018. The idea of introducing design thinking to general education, however, is not a recent one, see e.g. Baynes (1974) or Cross (1982). Looking back at the initial arguments on why design awareness represents an important area of educational development, we can see some striking similarities to more recent scientific discourse. Design is a basic way of knowing along with humanities and sciences to serve us in our daily lives and in preparation for social roles (Cross, 1982). Design education was not introduced by Baynes (1974) as a means to shape consumerable items, but to meet "urgent need for the survival as well as the happiness of mankind" (p. 46). The role of design education is empowering the individual for participation in daily life and society. To participate, one needs to know the codes in order to act in line with expected practices. Understanding design as a form of literacy expands the purpose of design education to empower for criticism and transformation. The concept of literacy adds resilience by empowering individuals to challenge established regimes of knowledge and structures of society (Boehnert, 2015; Illeris, 2012). Kolko (2018) combined participation and transformation: "To be literate is to have a voice in society, and to see the things that are happening, build on them, change them, and reject them" (section 11). For a professional designer, transformation as the ability to change an object or service for the better is key, but for the general public, transformation might prove more powerful as rejection of unsustainable design. One aim of identifying generative narratives on how to cultivate design literacy in key texts was to attempt a definition of design literacy in a context of critical innovation. Drawing on the four generative narratives (Figure 2) and ideas of participation and transformation embedded in the concept of literacy, I suggest the following definition:

> *Being design literate in a context of critical innovation means to be aware of both positive and negative impacts of design on people and the planet, approaching real-world problems as complex, voicing change through design processes, and judging the viability of any design ideas in terms of how they support a transition towards more sustainable ways of living.*

Coda

Addressing the complex problem of overcoming a world made unsustainable (Fry, 2009), basic ethical questions of how a new innovation supports the well-being of people and the planet prove just as important to integrate into general education as into the education of professional designers. As Craft (2005) stated: "Promoting children's creativity in the context of wider ethical dimensions of our existence is not an optional extra" (p. 149). In a context of critical innovation, a core part of the teacher's role would be to draw the students' attention to how any design idea would satisfy real-world problems responsibly and towards a better tomorrow. Students need to recognize their capacity to transform unsustainable design practices as informed consumers and to challenge established regimes of policy, fundamentally rethinking definitions of human needs and desires (United Nations Environment Program, 2011). Only a few of a student cohort will become professional designers, but all of them are users of professional designers' innovations in their everyday living and as future employees. In support of critical innovation, the value of cultivating design literacy amongst a general public is empowering a critical mass of users who recognize their capacity to transform unsustainable patterns of living by the products and services they voice and opt for as consumers, democratic participants, and employees.

Preparing a workforce that is well-equipped with the skills and knowledge to navigate the complexities of our global human society is a key responsibility of design and higher education. Extant research has advocated design as one of the essential skills to master in the future, and this design literacy has been claimed to be a critical factor in creating innovations and new solutions towards transforming our societies. To explore how non-designers become more design literate, in this paper we present findings from a study looking at how multidisciplinary student teams develop their design literacy in an action-oriented course setting. Based on our initial analysis, blending the boundaries between universities and the surrounding society positively contributes towards developing design literacy. This, in turn, has pedagogical implications as well as increases our understanding on how design travels to other disciplinary domains.

Keywords: design education, empathy, societal impact, curriculum design, transdisciplinarity

Introduction

The real world is not like the university. In the university, professors make up artificial problems. In the real world, the problems do not come in nice, neat packages. They have to be discovered. It is all too easy to see only the surface problems and never dig deeper to address the real issues. (Norman, 2013, p. 218)

In the quote above, Norman (2013) gently touches upon the concept of wicked problem (Buchanan, 1992; Coyne, 2005; Rittel & Webber, 1973) that has been established as one of the seminal concepts in design practice. Especially now, with discourses around sustainability and intergenerational justice gaining traction, higher education institutions teaching design or its extensions (such as design thinking) ought to broaden their repertoire from teaching design as a craft to design as means of creating agency to solving wicked problems (Burdick & Willis, 2011; Christensen et al., 2016). While we acknowledge that such initiatives have been gaining traction globally in several higher education institutions during the turn of the century, at the same time it is also justified to constructively question what are the underlying political, societal, and economic paradigms that govern and frame how and why we teach design to our students. In a similar vein, extant research has questioned the value and validity of skills students acquire in higher education institutions (Arum & Roksa, 2011; Fink, 2013), and findings from these studies are alarming in the sense that if higher education institutions are not capable of educating their students with transferrable skills, where will they acquire these skills?

The study at hand, however, does not take a cynical stance to higher education nor do we expect to create a causal relationship between transforming higher education and solving wicked problems. In line with extant literature on design and design literacy more specifically (Burdick & Willis, 2011; Christensen et al., 2016;

Nielsen & Braenne, 2007), our aim in this paper is to contribute to research on design literacy by investigating how students in a multidisciplinary graduate program (consisting mostly of design, engineering, and business students) develop and reflect on their design literacy for social agency. More specifically, research question formulated for this study is as follows:

How does multidisciplinary and action-oriented course design contribute to students' design literacy towards social agency?

Instead of seeing design thinking (e.g. Cross, 1980; Dorst, 2011; Kimbell 2011, 2012; Rowe, 1987) as a set of tools and methods but rather as a manifestation of design literacy enables us to reflect on what we could be teaching when we teach design thinking. What is more, we argue that course designs that weave together theoretical reflections and real world challenges have the potential to instil our students with a sense of agency: that is to say, developing design literacy is not only about mastering design tools and practices, but understanding how they can be utilized for creating positive impact in the surrounding world. As Coyne (2005, p. 6) highlights, testing solutions to wicked problems are seldom undone, which is why design education plays a crucial role in helping students negotiate the relationship between the problem and the solution space and their stance towards it. As a concrete output, in this paper we present the SCET (Space - Community - Emotions - Transformation) framework as means to developing design literacy towards social agency.

As mentioned above, course settings with assignments that blend the boundary between the university and the surrounding society are especially fruitful for exposing our students to wicked problems as well as to help them discover them on their own. Moreover, taking design education as the point of departure and bringing students from other fields in touch with design further illustrates how design and design education can serve as catalysts for societal change (Cross 1980, 1984; Glasser, 2018).

In this enquiry, we draw on a multitude of data: students' reflections via their visual learning diaries, interviews with our partners, and finally autoethnographic observations and reflections. While the visual learning diaries enable us to explore how design literacy is manifested and developed amongst the participants and partner interviews provide us with insights on how such course designs are perceived to create value amongst our stakeholders, autoethnography makes our role as instructors and researchers explicit in the data collection period. That is to say, we are not just observing the field but simultaneously shaping and making sense of it (Anderson, 2006).

The rest of the paper is structured as follows: first, we discuss extant literature on design literacy and higher education, then we introduce the proposed framework for curriculum redesign and application to a course context. After, we briefly describe our research methodology and initial findings in this ongoing research before concluding with our next course of action.

Literature review: design literacy and higher education

Design literacy as spatio-temporal transcendence

When talking about design literacy, spatio-temporal transcendence is perhaps one of the most critical conceptual approaches towards understanding design and its value. In essence, design can be understood as conscious acts of improving the status quo (Simon, 1969, p. 55) or similarly as a practice aimed towards the future, and as such it is to a large extent about "acting in and on the world" (Yelavich, 2014, p. 12). As Yelavich (2014, p. 12) continues, "how and where design can contribute to conversations larger than itself" highlights the desire among practitioners and researchers of design to move away from design as a competitive advantage towards design as socio-political mindset towards future and contemporary societies. That is to say, spatiality in design refers to the designer engaging with the problem space here-now by attempting to empathically transcend their own boundaries, whereas temporality refers to crafting the solution space for the future society (Müller, 2018), and here empathy is also one of the key elements. Similarly, movements between the problem space (here-now) and the solution space (future society) can be seen as manifesting validations of design literacy. Thus, for the designer to be able to transcend their spatio-temporal boundaries and in the process develop their design literacy requires empathy.

Given that empathy is such a crucial element in design and various other disciplines, extant research in design (Ho, Ma & Lee, 2011; Hess & Fila, 2016; Smeenk, Sturm & Eggen 2018) and higher education (Ashworth & Lucas, 2000; McAllister & Irvine, 2002; Killick, 2012) has explored empathy from diverse perspectives. Especially in design, considerable amount of scholarly attention has been devoted to understanding our users

and stakeholders to frame the problems we aim to solve (Brown, 2008; Dorst, 2011). It points to leaving pre-assumptions at the door; stepping into someone's shoes and trying to explore how they interact with and experience the world. One of the earliest lessons taught in design education, is the difference between Sympathy and Empathy (Brown, 2013).

However, instead of seeing them as disconnected ideological constructs, we believe that the element of "care" appears to fill the transition void between reactions of "sympathy" and learning the ways of "empathy". Especially because one may feel sympathy towards issues observed in their lives, but taught to employ empathy in assigned situations that lack resonance. Indeed, if higher education institutions teach empathy as a sort of driver for innovation and design-driven outputs, can we speak of empathy as a genuine desire to understand the needs of others?

Customarily, we teach methods and tools to generate user insights that would fuel creative and meaningful solutions. We engage external partners to provide students with first hand experiences, and allow them to work on real issues in the industry and society. Many of these concepts are then evaluated on their novelty, and potential value to generate revenue. The projects are largely driven by commercial value, as is a matter of fact that most project briefs are highly dependent on paying clients and their organisation's demands.

In an ecosystem that relies on these engagements, it would be unrealistic and naive to imagine that the universities would function any differently. Yet, there are numerous social challenges in the world that would benefit from the knowledge and skills we teach, and if we do not nudge our students to start thinking about them, who will?

Higher education institutions as catalysts for social change

Universities were conceived to develop a compliant workforce with skills of print literacy and discipline that would enable them to function in modern corporations and a corporate economy (Dewey, 1938; Kellner, 2003). As a result, higher education institutions are viewed as the most legitimised social agent of creating, discovering, disputing, accepting and disseminating epistemology and its agreement process (Clark, 1998; Marginson & Rhoades, 2002; Hyun, 2011).

In an age of rapid globalisation brought about by exponential development in technology, communication and transportation, it has become increasingly difficult to anticipate the changes impacting society and lifestyles, that much time is spent focusing on utilising technology and creativity for innovations and businesses. Yet, at the same time, as these changes "become concrete only in the consequences which result from their application" (Dewey, 1938, p. 19), we ought to be more mindful of pedagogical decisions. Consequently, neglecting the fundamental social and environmental issues that deserve our attention as well (Stegall, 2006; Thorpe & Gamman, 2011).

Social challenges prevalent before are even harder to ignore now, especially because of digitalisation and our interconnectedness. Viral reports in the mass media make us wish that we could do our part in supporting those who are less privileged or effect change in unfavourable circumstances, yet why are we not doing anything? Do we lack the capacity and/ or orientation?

Spearheading these endeavours, governments around the world have involved academics and private companies in an array of research and consortium projects (e.g. Ambos et al., 2008; Ankrah & AL-Tabbaa, 2015; Bruneel et al., 2010). However, does everything have to be top-down? Is it only possible to tackle these challenges when there is provision from those in power? There seems to be a structure-agency dichotomy that we are not addressing.

An answer to this need and a trailblazer of its time, International Design Business Management, Aalto University's transdisciplinary graduate program, was established in the mid-nineties with the concept to educate future design managers capable of generating revenue and competitive advantages through design predominantly in large corporations. However, with the ever-changing needs of societies, graduates of the program could potentially be in positions where they lead and manage policy change, grow enterprises or champion social movements.

Framework for curriculum (re)design

In recent years, calls for transforming higher education institutions have been raised globally, and as this can be approached as a collaborative effort, most of our teaching methods and contents can be accessed online. In

line with this, here we elaborate on our pedagogical framework that illustrates the main building blocks onto which we base our initiatives. The SCET framework is our first attempt at analytically articulating how to bridge the gap between sympathy and empathy, and as such it is to be taken as framework-in-the-making.

- Learning is not restricted to a physical space we call 'university campus' (Proserpio & Gioia, 2007; Redpath, 2012)
- Learning is about leaving the ego behind: it is not a competition, but a collaborative effort to improve ourselves as well as our society (Bain, 2004)
- Learning is an emotional experience: getting your hands dirty, goosebumps, breaking away from existing patterns (Herrington, Reeves & Oliver, 2010; Meyer & Turner, 2006)
- Learning is transformative, and as such it transforms not only you but also others around you (Mezirow, 1991; Taylor, 1997)

More specifically, the table below fleshes out some of the roles and responsibilities for both teachers and students in the SCET framework introduced above.

Table 1: Roles and responsibilities in the SCET framework

Dimension	*Teacher's roles and responsibilities*	*Student's roles and responsibilities*
Space	Designing and identifying the learning spaces in and outside the campus	Participating in nurturing a good atmosphere in the space, reflecting on the meaning of space when it comes to each individual's learning
Community	Appreciating the knowledge and experiences students have, and attempting to active this in the learning process	Actively communicating about their knowledge and experiences to others, ensuring others are being heard
Emotions	Willingness to revise and develop the course after each iteration, reflecting on their own interests and competencies as a basis for new pedagogical content	Openness towards new ways of learning, respecting their peers, understanding that courses can be open-ended with the teacher merely designing the structure
Transformation	Appreciating change and embracing ambiguity, clearly communicating this in connection with the learning objectives to the students	Exploring their intrinsic and extrinsic motivations for studying and learning, trusting the teacher in that ambiguity and open-endedness in courses is in control

The thoughts above have been formulated based on our teaching experiences in several countries (most notably Finland, Denmark, India, Japan, Singapore and Russia), extant research, and engaging in discussions with our colleagues from different higher educational institutions over the world. Furthermore, we cannot – and perhaps should not – control what the students learn (this would imply control over their previous experiences), but we can draw on various methods and processes to enable the students to take ownership of their learning and thus formulate their own stance to the sympathy - empathy continuum (Dewey, 1930; hooks, 1994).

The SCET framework in practice: Care through iteration

An opportunity surfaced for us to test this framework during the transition of program leadership in 2017. This put us in a favourable position to act as a wind tunnel for this transformation in higher education, and marked the inauguration of our course, IDBM Challenge: A mandatory 3-week introductory course that brings together students from diverse cultural and educational backgrounds, and provides a setting for combining theory with practice. Through practical experience, learning-by-doing, critical and meaningful reflection; students acquire the skills to research, conceptualize, develop and introduce socially sound and commercially successful

solutions. In this context, learning-by-doing does not refer to doing that is complemented by superficial learning afterwards, but instead it echoes with Dewey's (1930, p. 390) knowledge and knowing duality as well as with hooks's (1994) attention to question the mind-body separation in the classroom through the concept of eros. Thus, learning-by-doing is essentially about being present in the world, interacting with it, and creating knowledge through our body and mind.

The first author has taught IDBM Challenge since 2016, and although the first iteration of the course was named differently, the learning outcomes and 3-week structure have remained the same. Being the introductory course, the reasons behind the structure focus on interpersonal relations: namely, by starting the program with an intensive course creates a space where everyone can get acquainted with their peers and thus create a sense of transdisciplinary community already from the get-go.

Moreover, being a challenge-based course where the theme changes every time the course is taught ensures students' focus on the learning experience rather than consulting their peers who already took the course, on how to optimize their participation. Thus, the course should be understood as a living organism that enables its participants to take ownership of their learning experience.

First iteration in 2017: speculative design and outer space

The 2017 iteration was when we first started to consciously pay attention to the pedagogical philosophy and specifically, course design. Challenge for this course focused on combining speculative design (Dunne and Raby, 2013) and outer space by allocating the teams to four decades (2027-2057) with each having its unique brief and setting. For example, in one of the settings the students extrapolated how the current behaviors and challenges could potentially affect how we live, forcing us to eventually move on to live on Mars.

In addition to the team-specific challenge, as a cohort the participants were also expected to organize a multisensory event showcasing their challenges and solutions. This design, then, emphasized learning to take place in three interconnected dimensions: individual, team and cohort to highlight the networked nature of learning (Schenck and Cruickshank 2015). Building on this, while the structure design for the course seemed to create spaces for the students to reflect on and act upon design as a catalyst for social and societal change, the fact that the provided challenges were quite abstract provided us with a sounding board for the 2018 edition that shifted the focus from outer space and future to our immediate surroundings and near future.

Second iteration in 2018: social innovation in first world cities

Using the course as a primer for students to start thinking creatively (and reflectively) about society's "wicked problems" (Rittel & Webber, 1973), we identified a recurring global theme that serves as a point of convergence across the public, private and third sector: the United Nations' Sustainable Development Goals (UNSDGs). However, we noticed that the subject often features developing countries and the predicament of those who may be trapped in unfortunate situations. In contrast, we often refer to countries such as Finland, Singapore, and Denmark as prime examples for other nations (Teo, 2018), and thus in the process forgetting that these developed countries, too, have their flaws that demand attention.

Therefore, we created a twist on the familiar topic for the 2018 iteration of the course by providing the multidisciplinary teams with the following design brief:

Five UNSDGs applied to the context of first world cities that the students currently reside in.

"What does poverty look like in a first world country?"

Two to three teams were assigned to each SDG and tasked to develop concepts that would create positive impact within five years.

In this edition, other than the intentional set-up around the challenge brief, we also structured the course to facilitate the projects that each team was working on. Although we did not explicitly refer to any framework or design process in our teaching content, we enforced key milestones (mandatory sessions) to gently guide the students in adopting the design process by taking them through the various phases of a design project: Research, Insights, Ideation and Validation.

i. **Research (Desk and Field)**
   As these topics were relatively new to the students, we spent a considerable amount of effort in nudging them to think outside of their comfort zones, and to explore the boundaries by physically

going to the field to look for answers. Rather than simply looking at statistics of these pertinent issues, students did field research by conducting interviews with stakeholders. To increase relevance and realism of the challenge, we kick-started the projects with organisation visits in collaboration with partners around the city. This enabled the students to have first-hand experience in witnessing that these challenges are not just conjectures, but discounted (and disregarded) issues. All teams partook in these organised visits, and some even made cold calls to other Non-Governmental Organisations to get a better grasp of the context and challenges around their given briefs. This allowed them to quickly get a good sense of the situation's challenges and user needs.

ii. **Insights Analysis**
Through the intensive field research in the first week, participants then sat down in teams to crystallise and distil their findings into actionable insights. These were done over a series of mentoring sessions. Students did ideation concurrently due to the short time frame given.

iii. **Ideation**
In the ideation phase, students were encouraged to use the Sanpo-Yoshi framework as a guideline for developing the concepts. The framework emphasizes the importance of systemic value: us – client – society. This not only gave the students a sense of agency, but also allowed them to consider factors beyond the monetary or novelty factors of a typical innovation project.

iv. **Validation**
As this was an intensive 3-week course, students did not have the luxury of time to prepare prototypes. Nevertheless, they discussed their ideas with relevant stakeholders throughout the process and finally presented their solutions to a 60-pax audience at a multisensory event they organized at the end of the course. At the event, each team presented their concepts in a PechaKucha format (20 slides x 20 seconds), where teams used a variety of creative storytelling methods to best pitch their concepts. Some presented imagined future scenarios through digitally edited images, while others suggested potential services through a website mock-up or physical artefacts. Each were compelling in their own ways and told of stories that not only demonstrated the students' dedication and interests to the topic or project, but also evoked a sense of agency that shows that they were motivated to effect change in their own ways.

As the historical account of IDBM Challenge above illustrates, the way this course has been designed has evolved throughout the years to further develop the students' design literacy and competences. By adopting a designer's mindset to developing the course, we have explored both the brief and the methods to see what kind of constellations would enable us to create a learning space conducive to nurturing design literacy. By the same token, by blending the boundary between the university and the surrounding society we also enable the course iterations to be influenced by actors outside the university setting. Thus, what we are teaching to our students is also put into practice when designing the course.

Research methodology: Exploring the emergence of design literacy

As the final assessment of the course, students were tasked to submit a Visual Learning Diary in which they were expected to demonstrate what they have learnt by reflecting on the happenings and insights of the course; documenting their thoughts and takeaways from the (lectures and workshops) sessions, taught content (readings, online episodes) as well as team work and community involvement for event planning. Content and stylistic conventions were not evaluated: as long as the participants covered the required topics, they would get maximum points for the assignment. This design decision, then, helped the participants focus on their learning experience instead of hunting for the maximum points.

The visual learning diaries act as basis for analysis on two dimensions: not only do they provide substantial data to assess our pedagogical methods and how the students articulate their design literacy, but they also offer an exceptionally intimate view on how the individuals have experienced the course. Students' course feedback online and during the final reflection session also serve as good measure. During the first session of the course, we sought permission from the students to use their outputs as research data, and since no one declined our data set consists of sixty-seven visual learning diaries. While we will be showcasing excerpts from

the diaries throughout the remainder of this paper, parts of the diaries that might identify the student will be covered or blurred out to respect the students' anonymity.

In addition, interviews with our partner organisations (both public and private) have allowed us to better understand whether there was industry relevance in the solutions developed by our students, and if this format of a course is suitable for continuity. As of writing this paper, the second author has conducted two interviews with our partners: these interviews lasted approximately sixty minutes and they were recorded, and immediately afterwards transcribed also by the second author.

Finally, as being active designers and participants in the process, we used autoethnography to reflect on how our course design decisions have enabled or disabled care and conceptualizations for the emergence of care (Anderson, 2006). Since care as a phenomenon and a way of being in the world is fragile (hooks, 1994), triangulating research data enables us to carefully analyse how course design can support care and how the participants craft their stance to it. The table below summarizes the dataset utilized in this study:

Table 2: Data collected for this study

Type of data	*Key statistics*	*Purpose in this study*
Visual learning diaries in digital format	Sixty-seven learning diaries	Analyzing the learning journey as well as how design literacy emerges and is articulated by the participants
Partner interviews	Two transcribed interviews	Supportive material for understanding how the course enables blending the boundary between academia and the surrounding society
Autoethnographic observations	Notes from debriefings after course contact sessions, internal communication and artefacts focusing on course design and implementation, video recordings of the sessions	Analyze the design decisions and consequences of the facilitators

At this point it should be noted that the visual learning diaries are our main source of data with the interviews and our observations providing additional flesh around the analysis. We analyzed the diaries as multimodal texts (Kress and van Leeuwen, 2006; Rose, 2016) documenting students' learning experiences throughout the course; as such, main emphasis is not on validating whether the students actually learned what they reported in the diaries, but instead to look at the journey they went through during the course. What is more, as extant research on design literacy has focused on empirically exploring how students understand inquiry in connection to design (Christensen et al., 2016), our study extends this body of knowledge by looking at how inquiry – and hence design literacy – emerges over time. To illustrate this, Figure 1 is an excerpt from one of our participant's learning diary.

Figure 1. An excerpt from Participant #5's visual learning diary.

As the participant writes, "[t]he cold call to Shortcut made us see how ignorant we have been on the whole refugee situation - how delicate we have to approach the issue" and "[l]ooking back, the main issue is that as a team, we did not realize how different we operate as everyone has different ways of problem-solving" – both of these descriptions show how interacting with the surrounding society triggers relevant reflections on developing design literacy.

Acknowledging the multisensory nature of design – and nudging our non-design students towards multisensory expression – we framed the learning diary as visual, and as such they were analyzed as multimodal texts (Kress and van Leeuwen, 2006; Rose, 2016) by utilizing the Gioia methodology (e.g. Gioia & Chittipeddi, 1991; Gioia, Corley, & Hamilton, 2012). In short, the Gioia methodology aims at creating transparency and rigor in qualitative research by generating theoretical insights through the respondents' lived experiences. That is to say, first-order concepts in Gioia methodology are directly derived from the data, whereas the second-order themes are crafted by the researcher, and finally the third level constructs are more theory-driven. As of writing this paper, our data analysis is still in the process, and below we will shed light on our initial findings.

Initial findings on developing design literacy

Our initial findings suggest that design literacy for social agency in classroom settings is positively influenced by the following three concepts: interaction with the surrounding environment (Space), multidisciplinarity (Community), and porous learning content (Emotions). Below, we will go through these separately before bringing them together.

First, through deliberate design, we have forged a foundation that supports an individual's learning on several levels – personal, team, community – and dimensions. We have found that this set-up enables reflexion and reflection (Schön, 1983), which contributes considerably to the forecasted denouement of a sense of belonging and establishment of trust amongst peers early on. Furthermore, as one of our guiding principles in designing the course focused on 'taking the university where the students are', we are also interested in seeing how different activities and learning spaces contributed to developing (or hindering) design literacy. In this context, then, porous learning content refers to curating a selection of videos, podcasts, and articles that enable the participants to approach design from diverse perspectives such as technology, teamwork, and management. Based on the participant feedback from the course's 2017 iteration, video episodes were significantly condensed (from sixty to fifteen minutes on average) and more explicitly connected to the design brief, and this seemed to create positive impact towards developing design literacy as criticism towards the episodes this year was significantly reduced. That is to say, the less technology clutters the learning process, the more time and cognitive capacity the participants have to develop their design literacy.

We identified through the compositions, that this intensive course is often an emotional experience for our students as they discover the extents of their capabilities, while forming alliances to tackle tasks beyond their means. This is an important factor in constructing individual perspectives, a determinant between "feeling for" and "feeling with"; made possible as the students display a controlled level of vulnerability that permits them to be more receptive, and in turn, empathic. From design literacy's point of view, this implied a departure from seeing design as a set of tools, but rather as a mindset or a catalyst for socio-political change.

The foundation of design literacy often begins with an introduction to an array of tools and canvases applied to a made up problem within the safe contexts of the university. This allows students to customise their learning by getting acquainted with the design vocabulary, methods and processes, while enabling them to discern from other modes of approaching solutions and problem solving. This increases their metacognition and ability to effectively apply design tools to their work. However, at the same time, the nature of such projects briefs give a false impression of control over the design process as they are usually open to interpretation, without much restriction.

This in turn generates the unavoidable problem of "distortion" as mentioned in discussion with one of our partners, as he voiced difficulties in his past experience of engaging design students for collaborative projects. It often occurs that students who have only had experience in these types of projects end up assuming the same amount of perceived control when "reframing the brief" for these assigned projects, in a way that it goes off tangent from the original intent, rendering the concepts futile for the collaborators.

Thus, it would appear that developing design literacy seems to benefit from blurring the boundaries between the university and the surrounding societal setting as it enables the students to see the consequences of their design actions (Dewey, 1938). Or in other words, design literacy can be practiced in a closed classroom setting, but it is experienced when the classroom blends itself with the surrounding context. Returning to the SCET framework introduced earlier in this paper, it seems that space, community, and emotions serve as triggers for transformation. This seems to be in line with Dewey's (1930, 1938) and hooks's (1994) arguments on reconciling the mind-body separation plaguing our classrooms. Or in other words, in order for the students to move from sympathy to empathy, we, as educators, ought to understand the lived world of our students to provide them with courses that reconcile the mind-body separation.

Moreover, IDBM Challenge being the first course many students take in their graduate studies, presents us with the opportunity to instil values and design circumstances best suited to nurture these traits while they are new to the city and undergoing a transition phase in their lives. This course sets the tone for their mind-set and approach towards challenging issues and social awareness that they would carry with them throughout.

Concluding remarks

Extant literature has illustrated positive outcomes in learning contexts when design practices are utilized as a catalyst for providing the students with opportunities to take ownership of their learning (Christensen et al., 2016; Green, 2014), thus highlighting the intertwined relationship between design and politics. That is to say, departure from designing *for* someone to designing *with* someone is a question of agency that has at least two implications: first, by becoming active participants in co-creating the learning experience enables students to shift their mindset from static to transferrable skills (Dewey, 1930; Lin, Schwartz & Bransford, 2007) and second, experiencing this shift in a multidisciplinary team when working on a real life project provides the students with first-hand sensations on how and why one should design with, rather than for, someone (hooks, 1994).

This short paper serves as an introduction to our experimental methods, including a proposed framework for curriculum (re)design. In gist, we suggest that a critical prerequisite for students to truly grasp the notion of relational needs is for educators to set an example by employing empathy in the design of their learning environments; understanding what their concerns, ambitions and interests are, in order to design the right conditions to foster the emergence of care. To this end, the SCET framework introduced in this paper warrants more inquiry and theoretical development to push teaching and research on teaching and learning forward.

Rather than teaching empathy in the sterile manner that we currently adopt (through canvases and readings that serve as prompts) to solicit the "right" type of answers from users to generate actionable insights; we believe that emotions play an instrumental role in learning, especially in eliciting care practices.

Using our initial findings, we will be planning the 2019 edition of the course. Through which, we hope to uncover more insights that could point to a more conclusive set of results enabling us to refine the SCET framework further.

A Framework to Accelerate Universal Design Literacy

PACIONE Christopher

LUMA Institute, USA
chris@luma-institute.com
doi: 10.33114/adim.2019.03.479

Design has historically been a specialty, something practiced exclusively by engineers, architects and all manner of design professionals. This is changing. Just as arithmetic was once a peripheral skill until the industrial age brought about the need for math literacy, the socioeconomic conditions of our current age are heralding the need for millions of people to level up in design. The expanding role innovation and collaboration play in our daily work, combined with the ever-increasing complexity and rate of change of today's products, services, and systems are making the case for design literacy. This paper: 1.) makes the case that design is poised to become the next universal literacy; 2.) argues that in order for such a literacy to arise, there must first exist a framework of agreed-upon skills that are taught and practiced by the masses; and 3.) proposes such a set of skills along with the research and reasoning that support this proposed framework.

Keywords: Design, methods, literacy, taxonomy, framework

Everyone Designs

During a client meeting in London, I said something I believe deeply and share often: "Everyone designs." Immediately, a young professional designer in the group challenged me. "That is not true," she said. "Everyone does not design, and it's an insult to me—a professional designer—to insinuate that 'everyone is a designer.' Not everyone has the expertise and experience to do what my team and I do."

I wasn't taken aback by her remarks. This wasn't the first time I had encountered this perspective, and it's understandable among those who have formal training in design and years of experience. That young designer was simply voicing her frustration with the idea that anyone could assume design competency or the role of a "designer" especially after taking a few "design thinking" workshops, something very much in vogue today. She had earned a professional standing that took years of education and application. And she is not alone. Many professional designers and design educators feel this way. They believe the growing popularity of design among non-designers cheapens the value of design and trivializes their profession.

However, I find this perspective shortsighted, counterproductive and futile, especially as more and more organizations—desperate to get their employees to be more innovative, more customer-centered, and more agile—embrace design and attempt to integrate it into their wider work culture. It's shortsighted because it shortchanges the true power and intent of design. It's counterproductive because it reflects a worldview rooted in an outdated, twentieth-century belief that design is a profession for only the special few, and that it should stay that way. And it's futile, because as I argue later, our times are demanding that everyone level up in design.

The reality is that everyone already designs. No one needs permission. Humans have always lived in a world teeming with millions of tangible and intangible things calling for change, and we are hardwired to pursue

ways to bring about that change. As Nobel Laureate Herb Simon (1969, p. 55) said, *"Everyone designs who devises courses of action aimed at changing existing situations into preferred ones."* As such, products are designed. Services are designed. Policies are designed. Laws and strategies are designed. Business models, negotiations, and curricula are designed. Everything manmade is designed. When something fails, it fails because it is not useful, usable, or desirable for the people and situation it was *designed* to serve. And in a world littered with poor design and in desperate need of change, design professionals, design educators, and leaders in all sectors, have an opportunity — a duty, even — to expand design from the profession that it is now into the liberal art it also needs to become and help as many people as possible hone their natural impulses to *change existing situations into preferred ones.*

Everyone designs who contributes to the creation of something new. To design is to play a role, however big or small, in the creation process of all sorts of intangible and tangible things people rely on every day. Whenever and wherever a person finds themselves collaborating with others in the work of bringing something new into this world — whether it is a new product, a new process, a new plan, a new policy, or a new perfume — they are engaged in the vital and communal act of design.

The Case for Design Literacy

Although math has played an important role throughout the history of mankind, it wasn't until the onset of the Industrial Age (1780 - 1840) that math transformed from a skill taught to and used by very few — scientists, engineers, and bankers — into a universal literacy taught to and used by society at large.

In their *Handbook on the History of Mathematics Education*, Karp & Schubring (2014) wrote:

> *In the eighteenth and nineteenth centuries, economic development, no longer exclusively based on agrarian modes, led to an enormous increase in urban populations. Basic numeracy skills such as the ability to tell the time, count money, and carry out simple arithmetic became essential … Within the new public education systems, mathematics eventually became a central part of the curriculum from an early age.*

While knowledge of the local terrain, agriculture, weather patterns, and various farming technologies was important and widespread, one didn't need math to work the land. That all changed with the arrival of the Industrial Revolution and the human exodus from field to factory that marked the age. This was the cultural tipping point for math because a very real need emerged to better educate millions of agrarians relocating to cities looking for work in factories. Lawmakers, industrialists, and educators — faced with a willing but unskilled labor force — responded accordingly. New education policies and education offerings were designed to teach the basics of mathematics to the general public. Research by Soysal & Strang (1989) suggests that these reformations made school compulsory to the age of 10 and made arithmetic a central part of school curriculum from an early age for the first time in history.

Today, we are entering a new age. The socioeconomic reality of our time is calling for design literacy much in the same way the socioeconomic reality of the industrial age called for widespread literacy in mathematics. Consider the following:

- 88 percent of CEOs are concerned about the loyalty of their customers and 82 percent about the relevance of their products or services. (2016, KPMG)
- Only 27 percent of leaders feel they've mastered the elements needed for innovation success over the next decade. (2014, BCG)
- According to a major IBM survey of more than 1,500 CEOs from 60 countries and 33 industries worldwide, chief executives believe that — more than rigor, management, discipline, integrity or vision — successfully navigating an increasingly complex world will require creativity. (2010, IBM)
- The Partnership for 21st Century Skills, a government-sponsored consortium of state-run and privately-run organizations dedicated to education reform, and authors of the book ***Leading 21st Century Schools,*** Schrum & Levin (2009) believe that *"Learning and innovation skills are what separate students who are prepared for increasingly complex life and work environments in the 21st century and those who are not."*

In the Harvard Business Review article *Design Thinking Comes of Age* (2015) Jon Kolko writes, *"There's a shift under way in large organizations, one that puts design much closer to the center of the enterprise. But the shift*

isn't about aesthetics. It's about applying the principles of design to the way people work." Add to this the growing numbers of Fortune 100 companies investing in designers and design training, and studies by the likes of McKinsey & Company, Forrester Research, and the Design Management Institute, that extol the business benefits of design and the ROI of "design-minded" companies[1], the shift is clear – design is poised to become humankind's next universal literacy.

Creating a Universal Framework of Design Skills

The existence of any literacy, by definition, assumes there is a fundamental and agreed on set of skills that is taught, understood, and practiced by society at large. The approach by which one teaches or learns such skills can vary, but without widespread agreement on what those skills are— and a single framework or taxonomy with which to organize and refer to these skills — technically, there can be no literacy.

According to the U.S. Department of Education, traditional *literacy "is an individual's ability to read, write, speak, compute, and solve problems at a level of proficiency required to be productive workers, family members, and citizens."* (OCTAE, 2018) This advisement suggests another way to frame the challenge: What skills should be taught and learned by the general public so that they can apply design at a level of proficiency required to, *likewise,* be productive workers, family members, and citizens?

Below are the heuristics a small team at LUMA Institute established to guide the research, reasoning, and creation of a proposed framework of skills that could serve as a suitable answer to this question. A proper taxonomy of design skills would need to be:

17. Based on extensive and thorough research of all known design methods
18. Organized in a way that is relevant and timeless
19. Essential; a collection of methods used by a multitude of people for a multitude of design situations
20. A comprehensible and accessible framework for the masses

The First Heuristic: Basing our work on extensive and thorough research

For the most part, I think we can agree on what it means to be math literate as opposed to being a math expert or a mathematician. We are talking about the basic skills of math like arithmetic, algebra, geometry, measurement, and statistics, which we learned in our formative years and find ourselves using on a daily basis and without which we would have a difficult time getting by. We are not talking about mastery of specialized forms of math that a physicist might use such as calculus, or actuaries might use like differential equations. We are talking about basic skills that are well within the full range of everyone's cognitive ability and can be employed in the midst of our everyday challenges.

If we apply this same logic to design literacy, it helps frame what it means to be design literate, as opposed to being a design expert or design professional. We are talking about basic skills such as problem framing, learning about the people we are designing for, and prototyping. We are not talking about mastery of specialized forms of knowledge that an industrial designer might employ, like color theory, or advanced techniques an ergonomist might use, such as a Psychological Workload Assessment. We are talking about basic skills that are well within the full range of everyone's cognitive ability and can be employed to navigate everyday challenges. But what are these basic skills? And how should we go about determining them?

This line of reasoning. and these questions yielded the first of our four heuristics. In order to identify these basic skills, and guard against our own bias as design professionals and educators, we believed strongly that we first must conduct extensive and thorough research of all known design methodologies.

To gain this understanding, we conducted an audit. Initially we spent about six months identifying and familiarizing ourselves with dozens of scholars and practitioners who, throughout history, had ever developed a model or published any sort of method compendium on design, problem solving, engineering, or creativity. We were careful to be inclusive and quite divergent in our pursuit of this knowledge. We considered anyone who had created a collection of tools with the primary intention of helping people design, solve problems, or bring about change and improvement. Our first wave of research yielded more than 200 methods. Our subsequent auditing included everything from classics such as John Chris Jones' book ***Design Methods***, published in 1970, to more recent and well-researched compilations like Vijay Kumar's book, ***101 Design Methods***. Included also are the methods of Six Sigma and Kaizen. In addition, we examined system engineering and design curriculums of top schools like the University of California Berkeley, Carnegie Mellon

University, Domus Academy, and the Illinois Institute of Technology. We also spent considerable time familiarizing ourselves with the favored techniques of dozens of creative consultancies like the UK Design Council and IDEO, as well as innovative product companies like Steelcase and Procter & Gamble.

Overall, we would uncover just over 900 distinct design methods. This collection was, to the best of our knowledge, the largest compilation of design methods ever assembled. While many of the methods were variations on a common theme or differed only in name or protocol, the sheer size of the list surprised and humbled us.

However, during our research, we noted that many of these methods were conceived during specific business eras and for specific industries. As such, while relevant for those times and trades, they are less so in today's business climate. For example, not all, but most methods associated with Six Sigma, while popular in the 90's, and within manufacturing, are no longer in vogue today due to sweeping changes to many facets of business and society.

This got us thinking. If design literacy is the goal, then not only do we need to identify the most fundamental methods, we need an organizing principal for these methods that everyone can relate to, but also stand the test of time. This led to the creation of our second heuristic.

The Second Heuristic: Organizing design methods in a way that is both relevant and timeless

While reviewing the different collections of methods during our first phase of work, we noticed that each group of methods came organized in one of two ways. The first way was by a process. The second way was by skill or ability. Our assumption was that our taxonomy should be based on one or the other of these two schemes. However, we were open to another if such a scheme presented itself.

Design Processes

Design practitioners and educators such as John Chris Jones and Vijay Kumar, as well as many schools and companies like Stanford University and IDEO, chose to organize their compilation of design methods by way of a design process. These processes tended to fall into three categories: linear, like many Stage-Gate and New Product Development Processes; cyclical, like Vijay Kumar's variation on Boehm's Spiral model *(figure 1*); or nonlinear, like Stanford's well known "Honeycomb" Design Thinking process *(figure 2).* Design methods were grouped under each phase or mode of work and recommended in order to become skilled at that phase or mode of work. For example, in the first mode of Stanford's Design Thinking process, which is labeled "Empathize," methods such as *Interviewing* and *What? How? & Why?* are advocated and taught in order to develop the student's capacity for empathy.

Figure 1: Source: Vijay Kumar. 2012

Figure 2: Source: Stanford D-School. 2010

Design Skills or Abilities

In our research, we also learned that some experts and organizations preferred to organize design methods by meta-skill or ability. Clayton Christensen, Jeff Dyer, and Hal Gregersen's book ***The Innovator's DNA***, Tom Kelley's book ***The Ten Faces of Innovation***, and IDEO's***, Method Cards,*** *(figure 3)* epitomize this way of

revealing the underlying discipline of design. All of these resources are well-researched and come to understand the practice of design from either observation and interviews with innovative leaders and organizations, or from the actual practices of a design consultancy. For example, in ***The Innovator's DNA,*** the authors identify "observing" as one of the five key skills an individual needs in seeking to be a disruptive innovator. After sharing the research and case stories that led to this insight, the authors identify a handful of principles and methods individuals and teams can use to develop this innovation "muscle." Principles like "Observing with all your senses" and practicing a method called "Dialog in the Dark" are recommended for each of the key skills.

Figure 3: Covers of three publications that organize design/innovative/creative skills by ability in contrast to process.

When we began to consider both design processes and design skills as ways of organizing design methods, we quickly determined that organizing them by way of a process was suboptimal for several reasons:

- Processes varied from industry to industry.
- People and organizations do not tend to follow one-size-fits-all processes.
- Branded processes are not timeless. They come in and out of vogue.
- Some methods could be used in multiple steps of any process. For example, interviewing as a method could be used at the beginning, middle, and end of any process, design or otherwise.

For these reasons we ruled out organizing methods by way of a process.

Aligning on design skills as an organizing principle

These insights, and our early observations suggested that organizing design methods by "skill", as opposed to "process" might be a better way to construct a framework of design methods that would remain relevant to the general public over the course of time.

While we were certain, skills and abilities already identified by experts such as "observation" and "iteration" would in some way play a significant role in our final assessment, we were careful not to jump to conclusions. After all, we felt it important that our framework be as relevant to millions of people 100 years now, as it would in today's society. To our knowledge, no one had ever undertaken a census of all design methods. And when we considered the rich data-set we had assembled, we saw an opportunity to build a taxonomy from the ground up by analyzing this amazing compendium of ways man had devised to solve problems. Our hypothesis was that if we carefully compared and contrasted these methods, a unifying principle might naturally emerge. So, we began to employ one of these 900 methods, an activity called Affinity Clustering, to see what we would find.

Figure 4 shows an early version of this affinity cluster. After analyzing only about 200 of the methods, the contours of a framework of skills began to emerge.

Figure 4: Early Affinity Cluster of the design methods. At this point we had mapped just over 200 methods, but already n organizing principle had begun to emerge. Source: LUMA Institute

We discovered that these methods could be grouped into three meta-skills everyone can relate to:

- **Looking** — methods for observing human experience by watching people and listening to them.
- **Understanding** — methods for analyzing and synthesizing information, uncovering insights, and framing problems.
- **Making** — methods for envisioning future possibilities through concept ideation, modelling, and prototyping.

As we began to examine subsequent methods, this basic organizing principal remained unchanged — meaning the other 700 or so methods fit easily into the categories we had identified at this early stage.

However, upon further examination of all these methods, we realized that the hundreds of methods under each of these three meta-categories could be organized into related subcategories. (*Figure 5)*

Figure 5: The subcategories. Source: LUMA Institute

While these subcategories represented skills that might not be as familiar to those new to design, they gave our model some necessary structure. Sub-grouping the ways in which people go about **looking**, **understanding,** and **making** helped us understand each practice in more depth, and quite frankly, made our taxonomy feel more like a discipline and less like a cluster of related techniques. After completing a full analysis of all the methods, here is how the taxonomy looked.

Skill 1: Looking — Observing human experience

Subcategories:

- **Ethnographic Research**— studying behavior in its natural setting; methods like Interviewing, Shadowing and Fly-on-the Wall Observation.
- **Participatory Research** — inviting people to participate in cooperative design activities; methods like Journaling and Build-Your-Own exercises
- **Evaluative Research** — examining the usefulness, usability, desirability, and reliability of solutions; methods like User Testing and Focus Groups.

Skill 2: Understanding — Analyzing and synthesizing information

Subcategories:

- **People and Systems** — making sense of relationships and the way things work; methods like Stakeholder Mapping and Experience Diagramming.
- **Patterns and Priorities** — revealing unseen structures, relevance and significance; methods like Affinity Clustering and Importance/Difficulty Matrix.
- **Problem Framing** — characterizing the situation to address; methods like the Five Whys and Root-Cause Analysis.

Skill 3: Making — Envisioning future possibilities

Subcategories:

- **Concept Ideation** — coming up with ideas; methods like Brainstorming and Alternative Worlds.
- **Modeling and Prototyping** — building representations of future solutions; methods like Storyboarding and Business Model Canvas.
- **Design Rationale** — justifying the future that we envision; methods like Concept Poster and Cover Story Mock-up.

As this organizing principle was not tied to a particular era or industry but in fact was informed by analyzing methods used thorough history and across disciplines, and employed labels like **looking**, **understanding** and **making** that everyone can relate to, we felt we had arrived at a taxonomy that held universal promise.

The Third Heuristic: The collection of methods must be essential; able to be used by a multitude of people for a multitude of design situations

We had arrived at a trustworthy taxonomy of design skills, one not influenced by our own biases or current business trends, but rather, from a careful examination of all the design methods we had gathered. The next step was to identify the most essential methods — those that would serve the goal of propagating design literacy.

But how does one go about choosing which methods are the most essential? How do you determine which are going to be the most indispensable to all manner of people and in all manner of design situations? And how many should that be? This proved to be a bit of a puzzle as we had no way of knowing how often each of these 900 methods had ever been used. Nor did it make sense to conduct a survey that asked people to name their go-to methods because we had arrived at a taxonomy that included categories and methods that were unfamiliar to all of the design professionals we had interviewed. The same was true for us. Each of us, having been professors and/or practitioners of design for a combined 60+ years, were familiar with only a few dozen *(a fraction!)* of the methods we had found.

We decided at this point, that the best way to determine what the most essential design methods are, was to create an algorithm — a string of questions or rules that would automate our reasoning. Again, this would guard us against bias and honor this incredible collection of methodologies. Below is the algorithm *(Figure 6*) that we created and used to scrutinize each of the 900-plus methods in order to determine their essentialness.

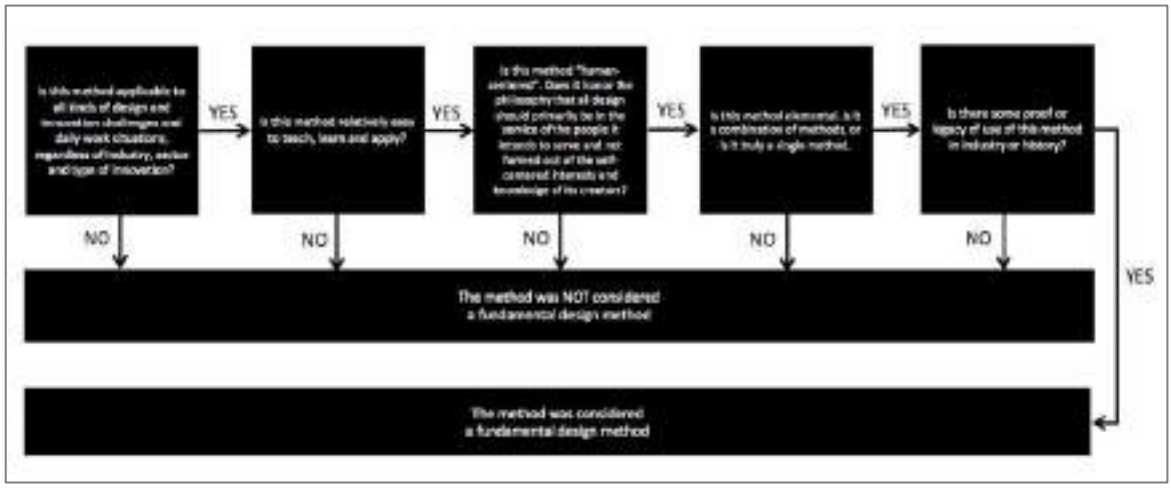

Figure 6: Our algorithm for determining the most essential design methods. Source: LUMA Institute

We used five key tests to evaluate each method. Only if the method passed all five tests was it deemed worthy to be considered an essential method. That is, a method that should be taught to and employed by everyone.

Test 1: Determining the universal applicability of the offering. A method was considered essential only if it could be applied to a wide spectrum of challenges, not just the design of new products but also new processes, programs, policies, etc. We believed that a method that could be used in a variety of contexts, industries, and sectors would appeal to the design specialist and general public alike. For example, Stakeholder Mapping *(Figure 7)* passed this test because this method helps teams gain an understanding of the domain or ecosystem of people who have a "stake" in the solution they are working toward, no matter the challenge or sector. All potential design solutions are intended to serve an ecosystem of specific people and understanding that ecosystem is critical to success.

Figure 7: An example of a Stakeholder Map. Source: LUMA Institute

Compare Stakeholder Mapping to a more specialized method like Wireframing, which creates a two-dimensional illustration of an interactive interface and specifically focuses on layout, navigation and the prioritization of content and functions. Wireframing is a great method, especially for UX designers. But it is not universal enough to be considered an essential method because it was devised to support a particular kind of design — interactive interfaces.

Test 2: Determining the ease by which the method could be taught, learned, and applied. A method was considered essential if it was "portable," meaning its benefit is easily grasped and it is not difficult to perform. This value is quite qualitative and as such we took liberties that might cause a scientist to scoff. However, for the purposes of our exercise, we had to draw a line somewhere. We considered a method easy to teach, learn, and apply if it could be shared through experience. In contrast, if a method required continuous reference to a detailed protocol, it was deemed difficult. If one could share a method by showing it, that method was considered easy. It also helped if the method could be performed effectively in different ways.

Our reasoning behind this test reflected our hypothesis: methods whose purpose and procedure can be quickly grasped will have a higher likelihood of being shared with others and used repeatedly, thus creating the conditions for mastery and therefor literacy. For example, a method like Interviewing passes this test because it is familiar to most people, can be approached in a variety of ways, and is easy to teach and perform. A few well-crafted questions and a notepad, combined with some good listening skills, will produce reasonable results. Over time, one can master Interviewing because the barrier to execute this method is low. Compare this to a more complex method like the Modified Cooper Harper Scale (MCHS) *(Figure 8),* which is a Human Factors technique for assessing mental workload. It is a great method, but it did not pass this test because it is a very specific protocol and requires in-depth explanation and training.

Test 3: Evaluating the method's "human-centered" quality. In order for a method to pass this test, it had to increase the likelihood of an outcome that successfully served people. Our reasoning behind creating this test was the common observation that when a design fails, it's because that design is not useful, usable, desirable,

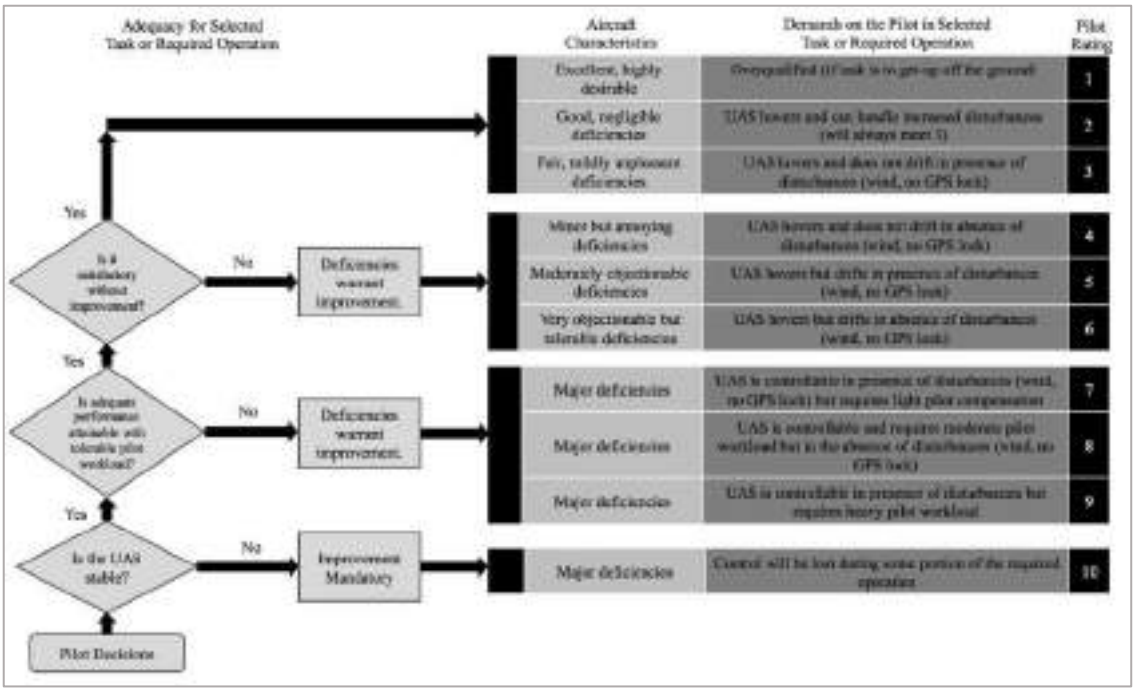

Figure 8: An example of a Modified Cooper Harper Scale. Source: Travis Fields. University of Missouri, Kansas City, Department of Civil and Mechanical Engineering.

or reliable to the people it is intended to serve. For example, a method called Importance/Difficulty Matrix *(Figure 9)* made the cut as a human-centered method. On the surface, it looks like any other "quad" method, of which there are many varieties. But in reality, its protocol helps teams debate and focus on two of the most centrally humane questions about any need, idea, feature, or initiative: How important is it to the key stakeholders? How difficult will it be to deliver it to them? Compare this to more internal or business-centric methods like Break-Even Analysis, which while good for understanding financial risk, puts the needs of the creating-entity first, instead of the people for whom one is be designing. This isn't to imply Break-Even Analysis is a bad method, but only that it didn't pass the human-centered test because it is concerned with understanding profit, instead of people.

Figure 9: Examples of an Important/Difficulty Matrix. source: LUMA Institute

Test 4: Determining if the method was a single method. Many of the methods we gathered were not really individual methods. Instead, they were combinations of methods. For example, the IDEO Method cards include Experience Prototype, which instructs users to "*quickly prototype a concept and use it to learn from a simulation of it."* Upon closer examination, this is actually two methods. The first method is building a prototype using variations such as paper prototyping or click-through prototyping. The second method is simulating use of the prototype in order to learn, using variations such a cognitive walkthrough or a user test.

Experience Prototype is really a compound method, or what we call a method set or a recipe. The distinction is important because we were looking for elemental methods. If a proposed method could be broken down into individual methods, it did not pass the “single method” test.

Test 5: Examining the method’s legacy. It was important that any method we could consider essential have a history of use in industry. We determined this through evidence of use. For example, many books and papers have been written about the method called *Experience Diagramming*, also known as Journey Mapping or Story Mapping. *(Figure 10)* There are numerous case studies and real-world examples of how Experience Diagramming has been used. Compare that with a method called “WWWWWH,” which was included in a number of design method collections we found and consistently defined, but for which we found little evidence of use in pictures of artifacts, books, papers, or case stories. Therefore, it did not pass this test.

Figure 10: Examples of experience mapping in use. The cover of Jeff Patton’s User Story Mapping and an example of an Experience Map courtesy of MAYA Design. sources: Jeff Patton & O’Reilly Publishing (2014), and MAYA Design (2010)

Using this algorithm, we were able to spotlight the most essential methods and thus reduce the number of potential candidates for universal framework from hundreds to dozens. However, we had something of a mess on our hands. For example, there were dozens of ethnographic research techniques still in consideration, but only a handful of design rationale methods. And while quite a few problems framing methods passed the test, some were so similar, like *The Five Whys* and *Abstract Laddering*, that we had to consider if both should be included. When we took a step back and considered what we had, it was uneven and lacked a clear sense of ‘a whole’. What we had, looked a bit random and complex — something the general public might have a hard time comprehending and accessing, which was the very opposite of what we desired.

After presenting our findings to key stakeholders for feedback, it was clear that our collection needed to be curated and designed if it was ever to become a framework the general public might embrace.

The Fourth Heuristic: The Framework should be designed to be comprehendible and accessible by the general public

In cognitive psychology, there is a technique known as “chunking” in which *“individual pieces of information are bound together into a meaningful whole”* (Neath & Surprenant, 2003). It is well studied and understood among psychologists that when this technique is used, the information presented is more easily remembered than when this same information is presented as individual items. It is also understood that in order for chunking to work, the optimal size of the *chunks* generally consists of no more than three-to-five items. For example, when recalling a number such as 4105551367, grouping the numbers as 410, 555, and 1367 creates a mnemonic in the form of a U.S.-based telephone number. Instead of remembering 10 separate digits, which is beyond the "seven plus-or-minus two" heuristic, we recall only three groups of numbers, each containing only a few digits.

With this in mind, we began to edit and iterate. We developed and presented a successive series of candidate frameworks to key stakeholders, who offered us insightful feedback regarding the coherence, relevance, and usability of each version. After several iterations, we arrived at what we called the LUMA System.

The LUMA System *(Figures 11 & 12)* is a collection of 36 methods presented as a simple aphorism that summarizes design into the three fundamental skills of **looking**, **understanding**, and **making**. The simple acrostic **"L-U-M-A"** is offered as a mnemonic for the fundamental skills of design. The final letter, "A," stands for "adapting," which is a synonym for change and is the main concern of design.

Figure 11: The LUMA System. Source: LUMA Institute

Figure 12: An alternate representation of LUMA System. Source: LUMA Institute

To grasp the combinatory power of this system, it's helpful to think of this system like karate or common foods in your kitchen and pantry.

Years ago, a client and colleague of mine, Seth Starner, who today heads up Advanced Development at Steelcase, and is a blackbelt in karate, mused about design and innovation in one of his very thoughtful blog posts. He wrote: "*In the end the martial arts are about a state of mind, yet if you have ever been involved in taking a Karate or Kung-Fu class, you spend a good portion of your time practicing forms called katas (figure 13), over and over and over again. The same moves in the same sequence until you dream about them. We think of design and innovation in the same way. It is a state of mind, but to get there you have to know the tools and approaches and then you need to practice them."*

Figure 13: Sochin is a kata practiced in several styles of karate. Source: https://www.karatedo.asia/shotokan-ryu-katas/sochin/

I've always found Starner's comparison of karate to design and innovation a powerful one. His analogy is a good reminder of how one becomes skilled and fluent in anything. The reason anyone is fluent, whether that be in karate, or reading, writing and arithmetic for that matter, is because at some point that person was taught a system comprised of atomic elements and *how* to combine those elements in a variety of ways for a variety of reasons and contexts. In Starner's karate example, it is the 36 katas which, once you understand them, can be combined in thousands of configurations and used in many offensive and defensive situations. In mathematics, it is just a handful of methods such as addition, multiplication, and simple algebraic formulas that, once you understand them, can be utilized when, where, and how you need them. In reading and writing, once you know the 26 letters of the English alphabet, you can read, comprehend, and utilize any word in the Oxford English Dictionary.

Since publishing the LUMA System in 2012, we've looked for ways to help people understand what it is, and how to use it. One analogy we've found particularly effective is to think of this system of design methods like the common foods you keep in your kitchen and pantry, such as everyday fruits, vegetables, and carbs, plus dairy products, your favorite protein, and go-to seasonings (Figure 14).

Figure 14: Source: LUMA Institute

Just as everyday recipes like Pasta with Cheese and Pepper or Peach Cobbler are made up of these essential food staples, so, too, can all sorts of everyday work experiences be made up of essential design methods used to address challenges such as improving the employee onboarding process or uncovering customer insights. (Figure 15) We have found the recipe metaphor particularly helpful in explaining what the LUMA System is and how to use it, to people without formal design training and who are new to the idea that *they* design.

Figure 15: Source: LUMA Institute

This is a system, not a process, for everyone. No matter what they do or what challenges they might face

Recalling our second heuristic, and the fact that the LUMA system's organizing principle is design skills, not design processes, the system is able to be utilized in all kinds of processes, whether Stage-Gate, Product Innovation Process (Figure 16) or Google Ventures Design Sprints. (Figure 17).

Recalling our third heuristic, and the fact that the LUMA system is comprised of only the most universal and essential design methods, it can also be employed by everyone – from business consultants to human resources managers, to solve common challenges, whether that's coming up with better ideas or working with remote teams. (Figure 18)

Figure 18: Recipes from our SaaS LUMA Workplace, are everyday examples of the combinatory nature of the LUMA system. Source: LUMA Institute.

Even popular design activities such as iteration and empathy are supported by this framework. For example, iteration is a really just a combination of a making method, followed by a looking method, followed by a making method. For example, a popular recipe for iteration might include building a Rough & Ready Prototype, followed by Think-Aloud Testing of that prototype, followed by building a new and improved Rough & Ready Prototype based on the feedback. Empathy is a combination of a looking method, followed by an understanding method. A popular recipe for building empathy might include conducting a Contextual Inquiry, which is a looking method, and then codifying the data collected using the Understanding methods of Rose, Thorn, Bud and Affinity Clustering.

Our goal was to create a design framework that was relevant, timeless and that anyone could learn and apply to all manner of challenges, no matter where they work or what problems they and their teams may face

But how is this system being used? And how effective is it?

The LUMA System: Usage and Impact

We created the LUMA System in response to a clear, unmet need among organizations around the world to elevate design and innovation, and in response to our core belief that the socioeconomic reality of our time is heralding the need for universal design literacy. Since its inception in 2012, the value of our framework has always been measured by its reception, adoption, and efficacy in real-world settings. Here is what we have learned.

Reception

- In 2015, *Harvard Business Review* featured the LUMA System and called it "A Taxonomy of Innovation."
- Our book, Innovating for People, (Figure 19) has a 4.6-star rating on Amazon based on 109 reviews.
- Our workshops and digital platform LUMA Workplace, currently have a Net Promoter Score of 80.

Adoption

- The LUMA System has been used in over 78 countries including mainland China (Figure 20).
- It has been employed at over 600 organizations worldwide, including dozens of Fortune 500 companies. This list includes organizations such as Accenture, Autodesk, Standard Chartered Bank, U.S. Department of Defense, and Knight Foundation.
- About 100,000 people have been introduced to the LUMA System through the book, ***Innovating For People***, in-person and online workshops, and our digital platform, LUMA Workplace®.
- We have certified about 200 instructors worldwide to teach the LUMA System. In addition, hundreds of teachers worldwide are using our system, including K-12 and post-secondary settings. While we would love to include stories of how they are using this system in the classroom, this is outside the frame of this paper.
- Launched in 2016, LUMA Workplace® currently has more than 5,000 monthly active users, a number that has grown more than 60 percent year-over-year.

Efficacy

- The taxonomy is very durable and sound. To date we have received no strong indication or feedback that the organization of the methods is flawed. Also, since our original research, we have uncovered dozens of new methods and each has fit precisely into our framework.
- Not everyone needs 36 methods. In no cases has an individual, team, or organization adopted and used all 36 methods on a regular basis. We have received feedback numerous times that 36 was still too many methods and we have no evidence that all 36 are essential. The data gathered to date indicates that people use a subset of anywhere between nine and 18 of the methods on a semi-regular basis, although not the same ones.
- We are in the process of examining the use of the system and expect to be updating and republishing our framework sometime in 2020. It is likely that a few methods will be removed and/or replaced with more effective candidates.

- We have more than 100 documented case stories shared by users of how they have employed the LUMA System. We assume there are thousands more that our clients have not shared with us.

While we can in no way claim that this framework has produced "universal design literacy," these statistics indicate that the LUMA System is helping to make progress toward this future state. We have much to learn, but we are confident that a system configured such as ours, but not necessarily ours, is necessary to the propagation of design literacy.

Conclusion

Imagine a world in which hundreds of millions of people have mastered basic design skills so they can frame problems, deeply understand people and situations, pull insights from a complex sea of data, generate unconventional ideas, sketch, build prototypes, test assumptions, and iterate quickly — the hallmarks of good designers.

Imagine a world in which everyone is as competent at looking**,** understanding, and making as they are at doing arithmetic, simple forms of algebra and geometry. Imagine that they possess the creative confidence and capability to take on all kinds of opportunities calling for change.

It's hard to see that future clearly. But I predict that it will be a world in which people enjoy their work more, collaborate more, and tackle more of the world's problems, big and small, easy and wicked. I can't help but wonder if that world would be an entirely different place than it is today.

Roles of Design Processes Models as Didactic Materials

We argue that visual representations of design processes contribute toward social and material practices of design(ing). They are used as didactic devices. We will discuss them using metaphors to illustrate that they are active material devices of which circulation, production and consumption are informed and informing perceived complexities, ambiguities and paradoxes associated with design. We propose a follow-up study to investigate how teachers and designers use and interpret visual design process models. The reason is to identify how these models are informing what design is as we are interested to understand how these models are contributing to the development of Design Literacies.

Keywords: visual representations, design education, didactic image, design thinking models

Introduction

More than three decades ago Gather Morgan (1997 [1986]) published a book entitled “Images of Organization”. In his book Morgan explored organisations through lenses of eight metaphors: (i) organizations as machines, (ii) living organisms, (iii) brains, cultures, (iv) political systems, (v) psychic prisons, (vi) flux, (vii) transformation, and (viii) instruments of domination. Wilkes (1989, p. 67), suggested “that metaphor is an especially appropriate tool for assisting us to appreciate, interpret and understand” complexities, ambiguities and paradoxes associated with organisations. Metaphors contribute towards production of organisational cultures and how we can think of organisations, including their possibilities and limitations (Jermier & Forbes, 2011). We would like to extend this idea to design process models.

The motivation to study the design process models is that they ‘represent’ how design practices are conceived (Wynn & Clarkson, 2005). Chaplin (1994, cited by Banks, 2007, p. 17) suggested that “representation has the following three properties:

1) its form is not dictated solely or even at all by the thing represented but by set of convention codes […] but only [comprehensible] to viewers who understand the convention
2) reflects and constitutes social process
3) the representation has some kind of intentional force behind it (agency)

Representations, including representations of design process models, embody sets of shared values, cultural codes, concepts and “emotions we associate with them” (Hall, 1997, p. xix). According to Hall (1997, p. xvii) “representation is one of the central practices that produces culture”, including professional cultures such as that of design. Holliday (1999) refers to these professional cultures as ‘small cultures’.

Hall (1997) suggests that "in part, we give things meaning by how we represent them – the words we use about them, the stories we tell about them, *the images of them we produce,* the emotions we associate with them, the way we classify and conceptualize them, the values we place on them" (p. xix, our emphases). In this sense the designing is the 'thing' to which a meaning is given by representation through the design process models.

The representations do not have any meaning in themselves, "it is we who fix meaning" (Hall, 1997, p. 7). Therefore, in order to 'translate' and to "read visual images", such as the design process models, the members of the cultural group (e.g. designers) "must share, broadly speaking, the same cultural codes" (p. x), as it is "only viewers who understand the conventions can read these" visual representations (Banks, 2007, p. 1). For example, the visualisation of a time has developed its conventions. The past time might be related to what was 'left behind' and the future time to what 'comes forward'. One can visualise this as if a person is standing with their back turned on the past and facing the future (Meirelles, 2013). In graphic terms, this translates into horizontal lines that can be 'read' from left to right, where the left end represents the 'beginning' and the right represents the 'end'. Thus, in this way of representing a time direction, a situation that happened in the past must be placed to the left of another element that occurred afterwards. However, Kress and van Leeuwen (2006) suggested that direction of reading, including a time, cannot be assumed. For example, Tversky (2001) suggested that those writing/reading right to left also tended to map temporal concepts from right to left. Mijksenaar (1974, p. 19) illustrated how African miners read instructions of a cartoon, which was designed to be read from left to right, from right to left and thus reversing the proposed set of actions. The outcome was that rather than loading stones the miners were off loading them.

The design process models stand for or represent concepts and ideas about design. The representations are constructed by those producing (inscribing) as well by those using (consuming) and interpreting these models (Bowker & Star, 2000).[1] The circulation, production and consumption of these visual design process models are constituting and sustaining the 'cultures of designing'. They act as a focal point to initiate the 'uninitiated', the novices, such as students (Bobbe, Krzywinski, & Woelfel, 2016; Howard, Culley, & Dekoninck, 2008), about what design and designing is (the act of designers). According to Dubberly (2005) "models of design process were developed to help […] students to learn to design" (p. 29).

Thus, the design process models act as *didactic materials*, whether it be in classrooms or in offices. According to Díaz Barriga Arceo and Rojas (2002) the use of images, such as the illustrations, concept maps and diagrams, facilitate the processing of information by improving the codification and organisation of information. Therefore, if we understand the design process models as didactic materials then we can reason that they contribute to the development of 'Design Literacies' (e.g. Kolko, 2018; Pacione, 2010).

The Design Literacies can be understood as a set of craft skills such as ability to draw or making a mock-up or producing a prototype (Heller, 2004). However, as design has been increasingly promoted as a creative problem thinking / working / solving activity, we would like to adopt a broader perspective of Design Literacies which can be associated with, for example, creative problem-solving process (Cross, 1982) which in turn has been promoted under the banner of 'Design Thinking' (e.g. Brown, 2009; Buchanan, 1992; Norman & Verganti, 2013; Pacione, 2017). This way of understanding design(ing) enables it to be increasingly promoted and appropriated well beyond the design disciplines (Glen, Suciu, Baughn, & Anson, 2015; Razzouk & Shute, 2012; Riverdale Country School & IDEO, 2012; Stigliani, 2017) as a method of creative problem solving for professionals of other disciplines under the term of 'Design Thinking' (Liedtka & Ogilvie, 2011; Martin, 2009). Dorst (2011) identified 'Design Thinking' as a new paradigm for dealing with problems in many professions such as Information Technology and Business. It has been suggested that the 'Design Thinking' encourages creative thinking through supporting identification of problems and development of more diverse and user centred solutions (Dorst, 2011; Hassi & Laakso, 2011; Johansson-Sköldberg, Woodilla, & Çetinkaya, 2013). We would like further to extend the application of Design Literacies beyond 'production' to encompass practices of consumption of goods and services (Ingram, Shove, & Watson, 2007) and development of citizenship (Nielsen, 2013).

[1] This separation between production and consumptions is not as clear cut. The reason is that designers and design educators who 'inscribe' design practices into design processes for benefits of their colleagues, clients and students may be using these models themselves.

Visual Representations of Design Processes

Many authors have tried to visually represent the design process[2]. The visual design processes models are recurrent representation of proposed 'fundamental' elements such as steps and types of thinking and feedback loops that take place during the design process (see Table 1). However, each emphasises different aspect and incorporates elements of their own professional or academic context. Given the diversity of authors, their careers and disciplinary linkages, the representations of design process models are diverse, both in their structures such as number of different activities, steps and phases as well as the naming of these. For example, Wölfel , Debitz, Krzywinski, and Stelzer (2012) interviewed 50 designers (15 Industrial and 35 Engineering Designers) who together provided 701 named methods! (p. 1400) The large number which was collected represents 14 different named methods per each of the interviewed person.

These visual representations can range from very precise tasks, starting and ending with defined tasks, with phases which bring together various activities which may overlap with each other. The type of activities involved, also vary including practical procedures (e.g. prototype and test), cognitive skills (e.g. analyse, synthesize) and attitudes required (e.g. empathy). The elements involved, are so many and so varied, that it is impossible to reunite them all in a single diagram. For example, the consider complexity associated with transition between the 'problem' and the 'solution': the process moves from a 'current' to a 'future' situation, from 'analytical thinking' to 'creative synthesis', from 'divergence' to 'convergence', from 'knowing' to 'making', from a 'concrete situation' to the 'abstraction of the ideas and concepts', to finally return to the 'concrete' through the implementation of a proposal. The overwhelming diversity has been noted by scholars trying to examine design process models (Bobbe et al., 2016; Gericke & Blessing, 2012; Wynn & Clarkson, 2005).

Dubberly (2005), who collected over 100 design process models, suggests that just recording a design process does not necessarily represents what took place and why. He provides an analogy of recoding the design process to that of recording a photograph. It is "the author [who] chooses where to point the camera—where to begin mapping the process, where to end, and what to put in, what to leave out, how much detail to include." (p. 13) He argues, that "one risk in using this framework is that it neatens a messy world. It may promote an illusion of linearity and mechanism of case and effect." (p. 12) Howard et al. (2008, p. 168) research suggests that the design processes are more erratic than most design process model representations suggest.

Similarly, in the field of school education, there are also many variations of the design processes, such as: the diagrams by the Design Thinking for Educators (Riverdale Country School & IDEO, 2012), Design for Change (Allende, 2016; DFC Global Inc., 2019), and Index (INDEX: Design to Improve Life, 2019; Stenlev & Boegeskov, 2016). Specific questions we might ask are: What are the characteristics of these visual representations? What elements of the design process are maintained across the models and which are different? What elements inherent to the field of education are incorporated into these design models?

Díaz Barriga Arceo and Rojas (2002) identified five types of illustrations, according to their main function in the teaching-learning process: descriptive, expressive, constructional, functional and algorithmic. These categories are not exclusive of each other rather they are part of a continuum:

1) The *descriptive* images show what an object is like and what are its most relevant physical characteristics, for example atlases of the human body or the double helix of DNA.
2) The *expressive* images seek to generate an emotional impact that mobilizes an attitude toward some phenomenon. For example, a photograph of sea turtles trapped by plastic bags, to promote the non-use of plastic.
3) The *constructional* images are used to explain the components or elements of an object or system, emphasizing the structural aspects.

[2] For the purposes of this article, thought and process are used indistinctly to refer to the set of activities, stages, abilities, skills and attitudes deployed by designers in the development of their projects. It is not the objective to focus on analysing the meanings and emphasis associated with each term, although it may be an interesting challenge to address in the future.

4) *Functional* images show processes and interrelationships that occur between the elements that make up a system, for example the illustration of the water cycle, the food chain or the communication scheme
5) *Algorithmic* images allow to describe procedures, visualizing possible actions, routes or steps of an activity. They are used to teach procedures to solve problems, for example flow charts.

Most of the design process representations would fall into the algorithmic category, as generally they define steps to solve problems. Some however include functional elements, which try to characterize thought forms (divergent thinking / convergent thinking), axes or dimensions involved in the process design (understanding - doing, concrete, abstract).

Cross (2005 [1999]), Lawson (2004), Wynn and Clarkson (2005), Dubberly (2005) and others have made a useful contribution in keeping record and analysing different models. For example, Dubberly (2005) classified over 100 models according to their formal characteristics — linear (Figure 1) or cyclical (Figure 2) — or by the context from which they are elaborated: academia, professional consulting, software development.

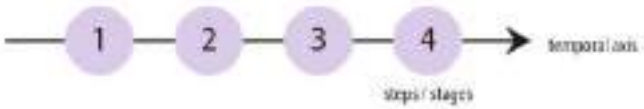

Figure 1 A linear Design Process with Specific Steps

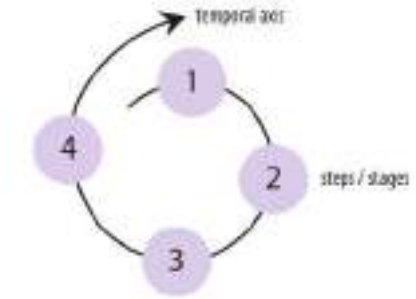

Figure 2 A Cyclical Design Process with Specific Steps

Our interest is to view these design process models using metaphors. During our research we have identified the following metaphors which might be useful for exploring design process models:

- Design Process as Problem Eradication
- Design Process as a Rational Order (e.g. Simon, 1988)
- Design Process as a 'Thinking Journey' (e.g. Alexander, 1973 [1964])
- Design Process as a Co-Evolution (Maher, Poon, & Boulanger, 1996)
- Design Process as an 'Mental State'
- Design processes as a Learning

Design Process as a Problem Eradication

Generally, a design process starts with a problem and ends in a solution (see Figure 3). But this is a fairly schematic way to define it because a design process can also be activated with the detection of a need or an opportunity (Ulrich & Eppinger, 2000). If the design process starts with a 'problem' then it is referring to a 'problematization' of an aspect of reality, and the interpretation of the reality is that there is a 'fault' or a deficiency.

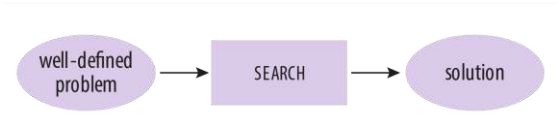

Figure 3 A Design Process Models with a 'well-defined' problem
source: Maher et al. (1996, p. 4)

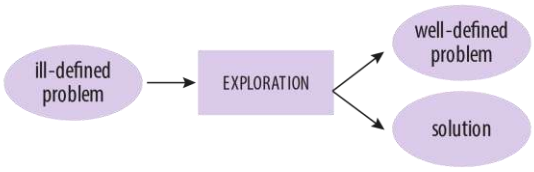

Figure 4 A Design Process model with 'ill-defined' problem
source: Maher et al. (1996, p. 4)

However, Dorst and Cross (2001) suggested that designers do not consider the problem as an objective element—on the contrary—they interpret and construct it from their own contexts, experiences, capabilities and resources, manipulating it during almost the whole process. Implication is, that in this context the problem is never fixed but rather it is continuously 're-moulded' throughout the whole design process. Prior to Dorst's and Cross' article, Rittel and Webber (1973) outlined that "every textbook of systems engineering starts with an enumeration of these phases: 'understand the problems or the mission,' 'gather information,' 'analyse information,' 'synthesize information and wait for the creative leap,' 'work out solution,' or the like. For wicked problems, however, this type of scheme does not work. One cannot understand the problem without knowing about its context; one cannot meaningfully search for information without the orientation of a solution concept; one cannot first understand, then solve." (p. 162) However, we would like to consider that this issue is not much related the wicked problems, but rather to a desire to develop a demand. Mol (2008, p. 27) suggested that "advertising agencies are not at all inclined to 'treat demand' as something that is given. For them 'what people want' is not rational phenomenon, they try to create demand. Not with arguments, but through seduction." (p. 27) We can extend these very qualities onto designers who with professionals such as advertisers, reporters and journalists, are part of the cultural mediators (du Gay, Hall, Janes, Mackay, & Negus, 1997). It is these professions who are in the business of producing seductive 'meanings' for the consumers to consume (Berger, 2010; Fry, 2011).

Design Process as a Rational Order

The design process models developed under the influence of engineering, focus on identifying the main stages of the process. They tend to be linear representations, which are organized in a temporal axis (representing a transition of time, from left to right and from top to bottom) — vertical or horizontal—on which activities or stages are deployed. Some include tasks, objectives, results and feedback loops. 'Synthesised' models identify only the main phases. The green rice by Munari (1989 [1981]) also reflects a linear logic, although clearly the invitation to cook is friendlier and in general well received by design students.

Lawson (2005) stated that these sorts of design process models suggest that transitions will take place during the design process. He used RIBA's sequential design process (see Figure 5) to examine how it might be interpreted by a designer. On a practical level, he observed that it might be difficult for a designer to complete phase 1 before the problem is investigated in phase 2. However, more importantly, relying on his teaching experience, he suggested that students might step over the transition process between phase 1 and phase 2. Implication of this design process representation is that it might "encourage unproductive procrastination!" (p. 34) Further on, in his analyses he outlined that the model does not indicate how the transition (a jump from one of the phases to the next) will take place or how a designer should gather the "information about problem, study it, devise a solution and draw it" (p. 35). In addition, it is not clear how often and what will trigger these jumps.

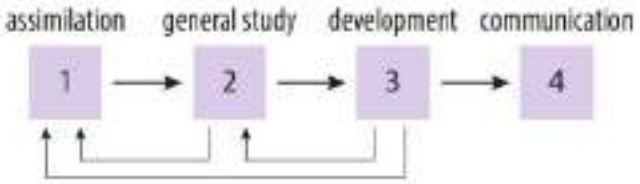

Figure 5 A map of design process according to the RIBA plan of work
source: Lawson (2005, p. 35)

Design Process as a Co-Evolution

Maher et al. (1996) characterised the design process as an exploratory activity, aimed at defining a problem and searching for possible solutions. They suggest that the design process represents into discreet phases "is not good (or correct) description of design" (Maher et al., 1996, p. 3). Unlike the search process, which starts with a well-defined problem (see Figure 3), exploration begins with an open and poorly defined problem. So, that in addition to generating a solution, a designer must shape and define the problem itself (see Figure 4). They suggest that problem and solution are interrelated rather than separate entities. For example, producing a prototype (solution space) might redefine a problem space (Dubberly, 2005), "which in turn will generate a new design space" (solution space) (Maher et al., 1996, p. 4). Thus, the problem space and solution space co-evolve (p. 7), see Figure 6 and Figure 7. To advance their thinking they used analogy of gene mutation.

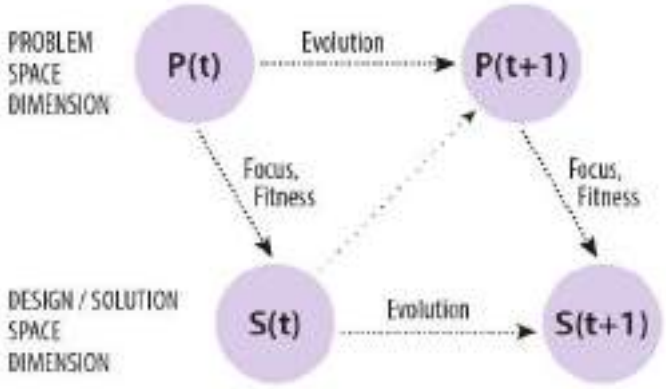

Figure 6 Co-evolution of a problem and a solution (based on the genetic mutation metaphor)
source: Maher et al. (1996, p. 7)

The understanding of the problem and the solution affect each other (Rittel & Webber, 1973). The information needed to understand the problem, depends on the idea that a person has to resolve it and the characteristics and constraints of a possible solution affect and contribute to redefine the problem. The issue is even more complicated, as according to Cross (2011) designers do not interpret the design brief as a specification for a solution, but as a starting point to explore and to define the problem. Thus, the problem definition is one of the results of the design process.

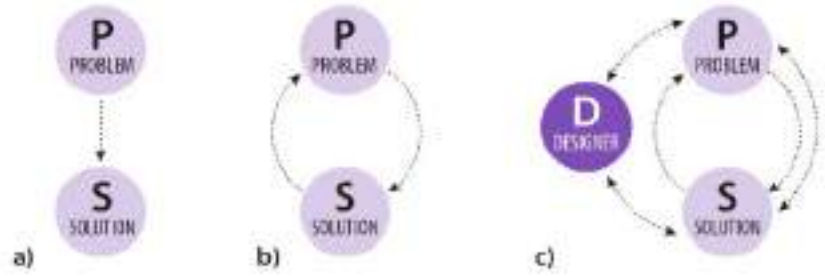

Figure 7 From linear positivism (a), to constructivism (b), to phenomenological (c) design process conception

Design Process as a 'Thinking Journey'

The diagrams of Alexander (1973 [1964]), Dubberly, Evenson, and Robinson (2008) and Kumar (2012), emphasize ways of thinking. Alexander (1973 [1964]) distinguishes the context of the form and explains that the complexity of the process is due to the successive mental and formal interpretations that the designer makes of the context and the form, see Figure 8. Kumar (2012) establishes two axis that intersect forming four quadrants. The vertical axis goes from the 'real' to the 'abstract' and the horizontal, from 'knowing' to 'doing'. Each quadrant is associated with a type of thinking (analysis and synthesis) or procedure (research and realization), see Figure 9.

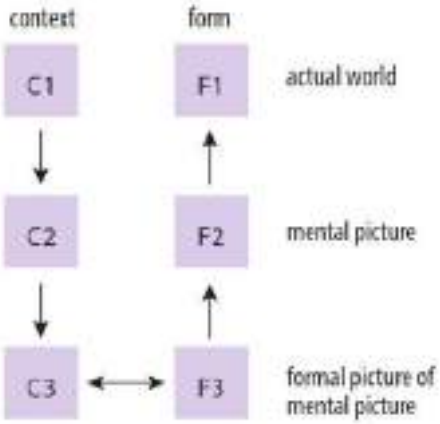

Figure 8 Mediated Design Process model
source: Alexander (1973 [1964], p. 76)

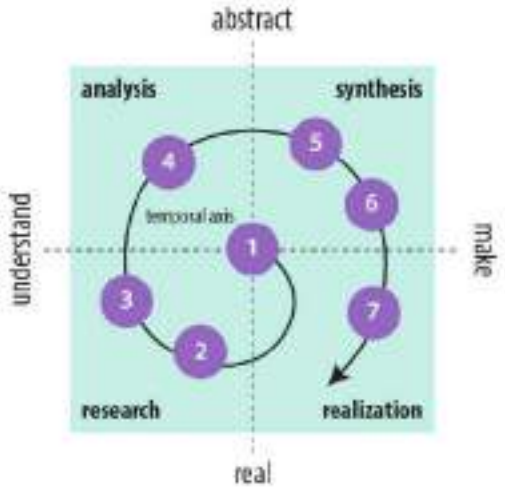

Figure 9 A Model of the Design Innovation Process
source: Kumar (2012, p. 8)

The Double Diamond Model (see Figure 10) proposed by the Design Council (Design Council et al., 2015); which resembles Banathy (1996) 'Dynamics of Divergence and Convergence' model, see Figure 11 (Dubberly, 2005, p. 24); combines a temporal linear structure, with the representation of two main cycles of divergent and convergent thinking, culminating respectively with the definition of the problem and the solution. This model is based on the mnemonic[3] resource of the 4D: **D**iscover, **D**efine, **D**evelop, **D**eliver (Figure 10) (Dubberly, 2005, p. 6). Both models incorporate two key phases which are made of two steps. The diagrams suggest that as the design progresses during the first step problem finding grows exponentially (discovery/divergence). Then, during the subsequent step (define/convergence) the designs are reduced into a 'single problem'. This is then followed with developing many divergent solutions to address the identified problem in the previous

[3] Mnemonic is a device such as a pattern of letters, ideas, or associations that assists in remembering something.

step. Once again, the next step (delivery/convergence) is to reduce these divergent solutions into a 'single solution'.

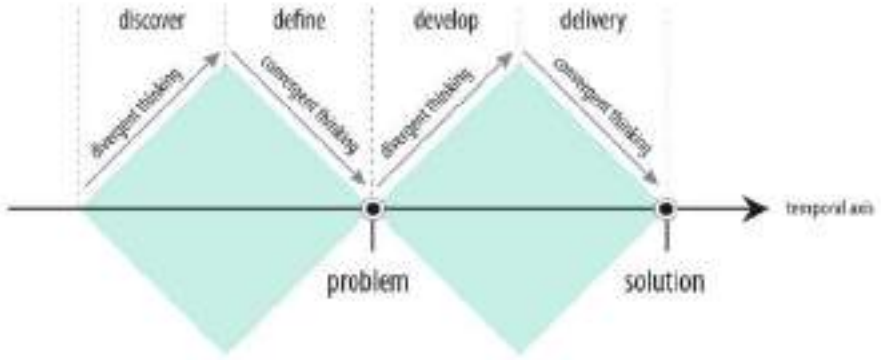

Figure 10 Double Diamond model
source: Design Council et al. (2015)

The key difference between the Design Council's and Banathy (1996) 'Dynamics of Divergence and Convergence' models is that Banathy (1996) attributes the divergent to involvement of members from different disciplinary backgrounds and it is these disciplinary differences which enable to generate the divergence in thinking. What is not clear, is how the use of same elements which facilitate generating the divergence in the prior step will also achieve the convergence.

McComb, Cagan, and Kotovsky (2014, 2015) suggested that as expert designers select a 'good' direction for solution quickly they will generate low levels of divergence, which means that they will consider fewer solutions in comparison to novice designers. The implication is that convergence takes place much earlier in the process then the model might indicate.

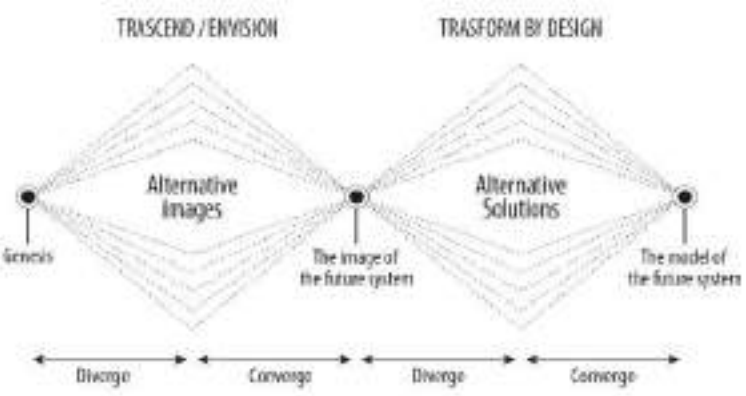

Figure 11 Dynamics of Divergence and Convergence
source: Banathy (1996)

The separation of analysis and synthesis can be observed in many design process models (e.g. Double Diamond, see Figure 10). The influence comes from understanding cognitive thinking skills having analysis (divergence) and synthesis (convergence) as separate thinking activities, see Figure 12, even though research suggests otherwise. For example, Koberg and Bagnall (1981 [1972]) suggested that both analysis and synthesis continue through a project. This is supported by Eastman (1970, cited by Lawson, 2004) and Akin (1986) that analysis (understanding the problem) is much more integrated with synthesis (generating a solution). For example, Akin (1986) concluded that designers were constantly generating new goals and redefining constraints. Thus, Akin (1986) suggested that analysis is part of all phases of design and synthesis is found very early in the process.

The implication of understanding these as separate activities results in, for example, forcing design team members delaying making solution for as long as possible (Bason & Austin, 2019).

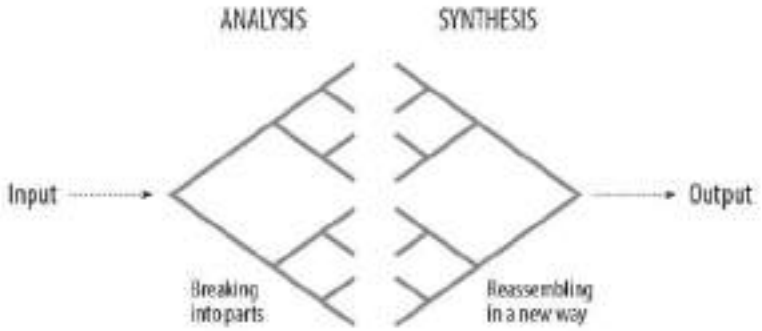

Figure 12 Separation of Analysis and Synthetic
based on: Dubberly (2005, p. 22)

Design Process as a Continuous Improvement

Popularised within the Total Quality Metagaming (TQM) movement the Continuous Improvement cycle also known as the Shewhart-Deming Plan-Do-Study-Act[4] Cycle (see Figure 13) was developed for problem solving and it was used in manufacturing to eliminate a waste (1997):

- PLAN (Approach) means to avoid MURI, or [waste caused by] unreasonableness
- DO (Deployment) means to avoid MURA, or to control [waste caused by] inconsistencies
- CHECK (Study/Results) means to avoid MUDA, or to find waste in outcomes[5]
- ACTION (Act/Improvement) indicates the will, motivation, and determination of the Management

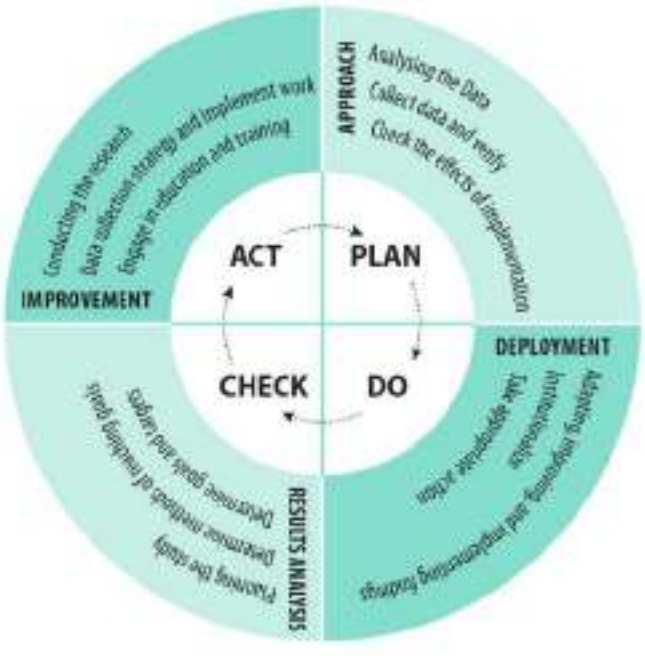

Figure 13 The Shewhart-Deming Plan-Do-Study-Act Cycle for problem solving
adapted from: G. H. Watson (1993, p. 4), Ishikawa (1985, p. 85), Dubberly (2008, p. 31), (Hamson, 2003, p. 239) and Chestnut (1997, p. 52)

[4] There are many variations on how these steps are named.

The cycle was adopted as a cyclical design process model to illustrate the 'never ending' cycle of the design improvement. One of the implications of this model is that any development is done in relation to the existing solution which most likely might prohibit a radical innovation and most likely entrench exiting practices.

Design Process as a 'Mental State'

Some of the most popular models are those of the Institute of Design at Stanford University (d.school). They have been developed to teach design thinking to students from various academic undergraduate and graduate programs in Stanford, as well as executives and young professionals who take their courses and workshops.

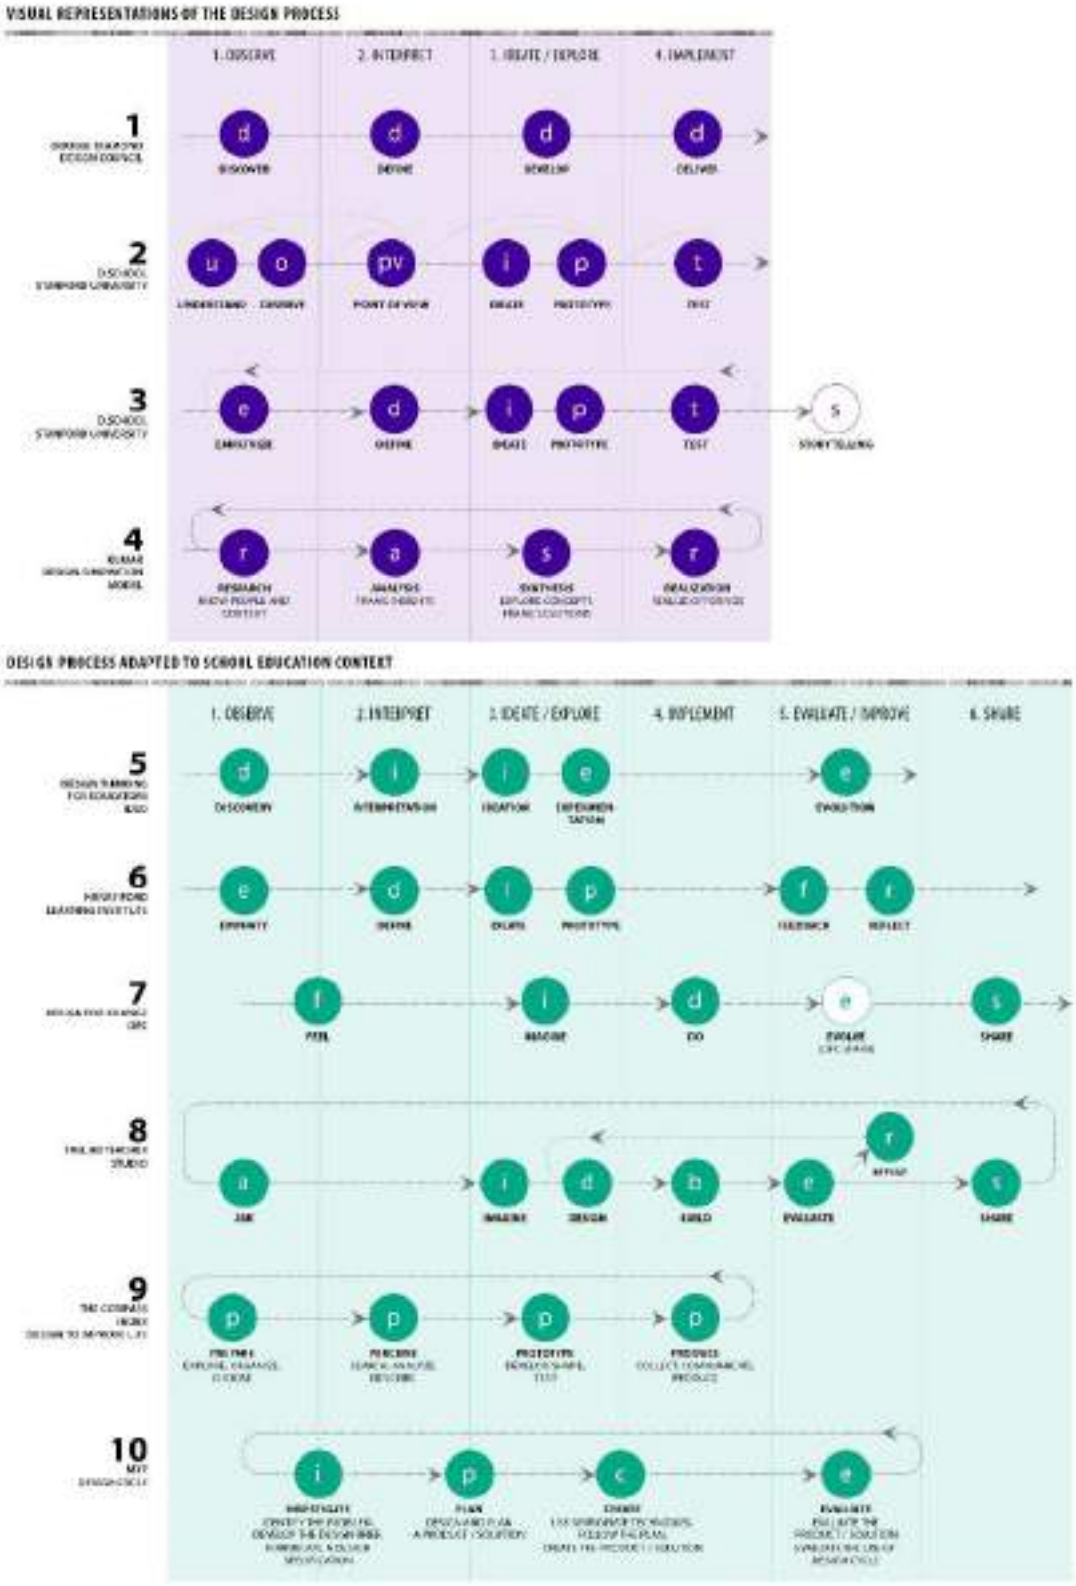
There are many d.school design process models in circulation (see Table 1 and Table 2). However, perhaps the most widespread is the (i) model composed of six stages—understanding, observing, point of view, ideate, prototype and test—represented by coloured circles, from which curved lines display alluding to the iterations. In addition, (ii) the model consisting of five hexagons where empathizing and defining stand out. (iii) A third model includes the same hexagons arranged in a circular shape and adds a final stage of storytelling.

Design Thinking refers to the process that designers 'follow' to address problems and develop proposals with a purpose of solving those problems. As the process includes both cognitive processes and concrete actions, we will refer to those as processes. The differentiators of the d.school models are empathy and prototyping. These are not only considered as stages, but as a 'mental state' or disposition towards innovation. Empathy seeks to identify motivations, needs and wishes of the people, with the purpose of anticipating behaviours that allow the introduction of innovations that are highly significant and relevant to the users. Prototyping is not a stage at the end of the creative process, which enables to make adjustments before starting the production, as was conceived in the traditional models (see for example Ulrich & Eppinger, 2004); on the contrary, it is a way of materialising ideas from a very early stage, with the purpose of communicating and validating them with various stakeholders, as the team members or the users themselves.

Storytelling is another of the additional elements included in one of the d.school's models. It is different from the stages of communication of the traditional models, because it is not geared to describe the proposal for subsequent production, but to build a persuasive story to support the launch of a product or service.

The leaders of IDEO, Kelley and Kelley (2013) and Brown (2009) do not adhere to rigid models, but identify fundamental phases. They proclaim that the processes are not linear and that several iterations are necessary before completing the process. Using the acronym HCD (Human-Centred Design), the manual for social innovation developed by IDEO proposes three phases: Hear, Create and Deliver. In synthesis, it is possible to identify the following stages with their characteristics listed in the Table 1.

Table 1 A List of Design Process models
adoped from the following sources: Brown (2009), Design Council et al. (2015), d.school, Both, and Baggereor (2013), Kelley and Kelley (2013), IDEO (2009) and Kumar (2012)



Design processes as a Learning

The adaptations of the design process to the educational context also vary in structure, naming and number of stages. In general, the first phases aim is to observe contexts and people, identify and define a problem to develop and explore solutions. However, the testing and implementation stages—that respond to the logic of the productive processes where professional designers operates—are replaced by stages of *reflection* and *evaluation*, seeking to promote meta-cognition processes. In some cases, *improve* and *share,* are added, enriching the proposals and facilitating their application in other contexts to promote collaborative work between the students. Some models use pictograms that facilitate the identification of each stage. As in the representations of the design process, it is possible to identify linear and cyclical models.

Henry Ford Learning Institute (HFLI)[6] and *Design Thinking for Educators*[7] adjusted the models developed by the d.school. HFLI seeks to develop creative thinking and collaborative work, promote empathy, critical thinking and the resolution of problems through learning by doing. The model was developed in conjunction with d.school with the purpose of transferring design thinking to their students. It maintains the stages of *empathy, definition, ideation* and *prototyping*, and incorporates *feedback* and *reflection*. Each phase is represented using abstract arrows as symbology.

The *Design Thinking for Educators* manual for teachers—undertaken by IDEO and Riverdale Country School—describes design thinking as a mental ability and is characterized by being collaborative, optimistic, human-centred and oriented towards experimentation. It includes a description of the process, working guides, testimonies and cases in which it has been applied to problems of diverse scale and level of complexity. Testing is replaced by a stage of *evolution*, oriented to develop the proposal in time; either looking for the necessary support to carry it out, documenting the process, defining criteria for success, sharing the experience or planning future stages (Riverdale Country School & IDEO, 2012).

The international *Design for Change* (DFC) movement[8] proposes a methodology of four steps, for children and young people to develop creative proposals to solve problems of their communities. It seeks to develop leadership, empathy, collaboration, and promote analytical thinking and creativity. The stages have pictograms and motivating names as *feel, imagine, do* and *share*. DFC Spain[9] adds "*evolúa*" (a term that mixes the words evaluate and evolve). The organization has developed an illustrated manual that invites the children to be super heroes: explains the activities of each stage, proposes questions, promotes reflection and makes suggestions.

FabLab Teacher Studio (DiGiorgio, 2013) proposes a spiral structure of seven steps: *question, imagine, design, build, evaluate, refine* and *share*. They have developed a canvas named *Project Planning Doc* that includes the visual representation of the process, questions that guide the conduction of the different stages, a definition of criteria for assessing results, a list of challenges to improve the proposal and a stage to share results, conclusions and suggestions. It does not include explicitly the observation of users in the initial stage and focuses on manufacture and promotion of collaboration and the transfer of learning. Developed under the influence of the MIT, the model has been used to strengthen critical and creative thinking and the resolution of problems and the integration of content (A. D. Watson, 2015).

The design cycle of the MYP[10] has a circular structure composed of different stages that are grouped into four main phases: *investigate, ideate or plan, create and evaluate*. There are numerous versions of this model published online. The shape and structure are maintained, but the names and the number of stages vary. This mode is based on the 'Continuous Improvement' model: Plan, Do, Check and Act (see Figure 13).

[8] https://www.dfcworld.com/SITE

[9] https://www.dfcspain.org/

[10] MYP It is the English acronym for Middle Years Program, corresponding to the intermediate cycle—from 11 to 16 years—of the IB or International Baccalaureate.

Table 2 A list of various design process models

Reference / Main stages	Observe	Interpret	Ideate / Explore	Implement
Brown (2009)	Inspiration	Ideation		Implementation
Design Council et al. (2005)	Discover	Define	Develop	Deliver
d.school et al. (2013)	Empathize	Define	Ideate / Prototype	Test
d.school by Carroll (2010)	Understand / Observe	Point of view	Ideate / Prototype	Test
Kelly and Kelly (2013)	Inspiration	Synthesis	Ideation	Implementation
IDEO, 2009	Hear	Create		Deliver
Kumar (2012)	Research	Analysis	Synthesis	Realization
Synthesis of the authors	Know and understand the context that is going to be intervened. It is necessary to collect data related to persons (customs, beliefs, motivations, etc.) and the context (economic, productive, technological, political, commercial, institutional aspects, etc.). The product of this stage is a set of quantitative and qualitative data, images, recordings, testimonies, etc. It is a divergent process, because collected data, generates the need to collect more data.	Analyze, relate and interpret data. Categorize, classify, and possibly collect new information. The product is a vision or particular problematization of the context and translates into a hypothesis or definition of the problem. It is an analytical, abstract and progressive convergence process.	Generation and exploration of ideas. Includes drawings, diagrams, fast prototyping, exploration with materials, mental maps, etc. Initially is a divergent and abstract process. Prototyping facilitates communicating ideas and validating them with users. Make decisions, and move towards a concrete result.	Final testing, specifications for production, implementation and subsequent evaluation. It can include the communication strategy, to support launching or deployment. Can include the final evaluation and feedback for the complete process.

The Compass model by Index, also with a circular structure, proposes four main phases— *prepare, perceive, prototype and produce*—, each one composed by actions or activities. The system incorporates the three dimensions of sustainability—social, environmental and economic —and sets parameters of evaluation—form, impact and context—. In addition, it defines learning objectives of each phase, describes the activities and proposes techniques to facilitate its implementation. It is a very interesting proposal, which manages to articulate elements from design, education and sustainability.

The enthusiasm generated by Design Thinking in the field of education can be perhaps attributed to their common need to understand people, fundamental for both disciplines: their particularities and motivations; making diagnoses and proposing strategies of intervention and applying creativity, in both diagnosis and troubleshooting. Understanding how designers address these issues are seemed to be valuable for educators, in the light of current methodological requirements and curricula.

Conclusion

Becoming professional entails developing and refining embodied understanding of professional practice that integrates knowing, acting and being in the world (Dall'Alba, 2009). We argue that design process models act as didactic tools by mediating between the aims of instruction (the models) and the outcomes (how to do) (Gellert, 2004). The representations of design process models contribute towards production of the design professional culture. It is through the production, circulations and consumptions of these design process models which contribute to 'shared values' amongst the designers and others who are wishing to adopt this way of working. Images of the design process models, in part, give a meaning to what it means to design (act) and to be a designer (identity).

The representations of the design process vary according to the economic and productive context in which they were developed and the disciplinary and professional influences that generate them. The representations originated in the context of the industrial boom, differ from those developed under the influence of emerging technologies and digital economy. The difficulty of graphically representing the design process lies in its

complexity and adaptation capacity. They are complex, because they seek to propose solutions to 'open' problems that 'shift' throughout the process. Feedback processes defy assumed certainties, which require high levels of flexibility. There are cognitive skills, practical procedures, attitudes and productive variables involved, and can be applied to different contexts and address problems of varying complexity.

The design process models do not have any meanings themselves, they signify, it is us who 'read' the meaning. The meaning is constructed by system of representation, which is fixed by the code (Bowker & Star, 2000). It is the code which makes it possible to establish the 'translation' between those producing representation and those consuming (reading) them. This means that the readers need to have access to both the code and mental maps in order to read the design process models. The design process models are not passive objects. Thus, as with maps representing geographies, the design process models do not fully capture all of the design process 'terrain', they are nevertheless "powerful technologies" (Becker, 1986 cited by Bowker & Star, 2000, p. 54). The importance of the design process model representations is their 'doing' (agency).

Even though the representations of the process are not formulas or recipes as they are visual analogies that indicate certain milestones that occur during the process and not a path to follow in a strictly linear way, they privilege certain ways of understanding design practices such a separation of doing and thinking.

As design process models are increasingly taken up within the field of education, the understating of their 'doing' as significant didactic resource is becoming imperative. Therefore, we propose a follow-up study to investigate how design process models are used by teachers and by designers, and their interpretation of these in the used context. The reason is to identify how these models are informing what design is as these design process models are one of the vital components which are contributing to the development of Design Literacies.

Working Together: Cooperation or Collaboration?

KVELLESTAD Randi Veiteberg*; STANA Ingeborg and VATN Gunhild

Oslo Metropolitan University, Oslo
* randivk@online.no
doi: 10.33114/adim.2019.05.259

Teamwork involves different types of interactions—specifically cooperation and collaboration—that are necessary in education and many other professions. The differences between cooperation and collaboration underline the teacher's role in influencing group dynamics, which represent both a foundation for professional design education and a prequalification for students' competences as teachers and for critical evaluation. As a test case, we focused on the Working Together action-research project in design education for specialised teacher training in design, arts, and crafts at the Oslo Metropolitan University, which included three student groups in the material areas of drawing, ceramics, and textiles. The project developed the participants' patience, manual skills, creativity, and abilities, which are important personal qualities for design education and innovation and represent cornerstones in almost every design literacy and business environment. The hope is that students will transform these competences to teaching pupils of all ages in their future careers.

Keywords: art and design education, cooperative and collaborative learning, drawing, ceramics, textiles

Introduction

Is teamwork a necessary premise for success in design environments or in creative entrepreneurship? How can we facilitate innovative pedagogic models for individuals working in a group in order to achieve higher goals? To answer these questions, we consider teamwork and small communities of practice (Wenger, 1998) as important parts of training and preparing for the teaching profession, specifically design education, where dialogue, discussion, co-working, co-exploring, and the building process itself play central roles. Small communities occur when students discuss design, materials, methods, and function and when they experiment with materials and tools to develop manual skills. Building community in teacher education has several features common to teamwork, where students discuss, work, and look for new possibilities. Dialogues between lecturers and students and amongst students play an important role in creating a positive environment.

This article focusses primarily on learning processes in a wider context. In a typical situation, teamwork allows individuals to explore the best ideas for addressing a given issue in a company. Likewise, the lecturer's role in a learning institution is to guide students towards understanding new concepts. Teachers have the opportunity to support critical innovation and raise awareness about sustainable perspectives. Instructors can offer potent insights to their students, enabling students to accomplish their objectives in the classroom context. Hence, individuals should embrace teamwork and work closely with those in charge to pursue their assigned tasks and meet set standards.

Different working methods will influence student community, develop design literacy, and stimulate innovation. Through the assignment of professional tasks in the drawing, ceramics, and textiles fields, students can gain experience from the beginning of their studies, which will increase confidence in their own ideas and develop students' abilities to communicate their intentions to others. In particular, at Working Together—an action-research project in design education within the bachelor-level Specialised Teacher Training in Design, Arts and Crafts at the Department of Art, Design and Drama at Oslo Metropolitan University (OsloMet)—students participated in teamwork by cooperating and collaborating on the assignments.

Using reflections based on Etienne Wenger's work (1998), the groups developed a shared repertoire of resources within the project, including experiences, designs, tools, and ways of addressing recurring problems; other important factors included having mutual trust and respect for each other's differences. The dialogue amongst the participants played a central role. The importance of dialogue is based on the tradition of practical knowledge and knowledge in action (Molander, 2015), which in turn is based on Schön's *The Reflective Practitioner* (1983).

It might be helpful to note how research-based teaching relates to the idea that both education and research are required for design and education. Following Norway's introduction of a common law for universities and colleges in late 1990`s, research requirements became clearer.[1] The term 'research-based teaching' was generally emphasised to stimulate quality and diversity in Norwegian higher education. The term is multifaceted, and the form it should take depends on the subject area in which it is being applied (Hyllseth, 2001). OsloMet's strategy is to develop and stimulate interaction amongst education, research, professional practice, and innovation (Havnes, 2011), but it is important to determine how this strategy can be implemented practically and which materials and techniques are most suitable.

The Working Together project was a type of action research conducted in a practical course, which stimulated design literacy. The students were the main actors; their knowledge development helped to create concrete solutions for the tasks at hand. The lecturer's role as facilitator and tutor was important for academic debate and for research related to the project. Niedderer (2013) discusses which research questions are important to ask in the creative practice of art and design, noting a distinction between art knowledge and design knowledge, which require different questions. This article's questions are related to teamwork in three material cases. Retrospective reflection linked to teamwork about what and how the students designed and improved their performances was a cyclical process of concrete experimentation and learning (Levin, 2017). We will use the reflections of the students and the lecturers as the basis for professional development and discussion throughout this article.

The value of cooperation and collaboration in higher education

In the autumn of 2018, the research project started as an introductory programme for a large 'herd' of 62 students, so they would become known to each other, and to OsloMet in generel, work together, and gain professional knowledge.

A thorough analysis of an earlier teamwork project with first-year students showed a difference in participation in the design tasks (Kvellestad, 2017). In the healthcare field, Ness (2016) distinguishes between cooperation and collaboration to create better outcomes for patients and their families. This distinction has also opened new analyses of teamwork in education. Both cooperation and collaboration have goals that participants should achieve, but the process for reaching those goals is different.

Researchers agree that distinguishing between cooperation and collaboration is important. Roschelle and Teasley (1995), for example, describe *cooperation* on a task that is achieved as a situation 'where each person is responsible for a portion of the problem solving', whereas *collaboration* is 'the mutual engagement of participants in a coordinated effort to solve the problem together' (p. 70). Cooperation can seemingly be successful as long as one individual in the group is up to the task; collaboration, however, is largely based on each individual exchanging his or her perspective.

The definitions for cooperation and collaboration, as they relate to design, clearly describe communicative and relational processes (Kvellestad, 2017). A lecturer's communication with the students plays an important role by initiating activities and precisely articulating tasks. Students are users and designers in the completion of

[1] Retrieved from: https://www.regjeringen.no/no/dokumenter/stmeld-nr-39-1999-/id192405/sec3?q=forskningsbasert%20undervisning#match_0

the teamwork as a whole. In a didactic context and in education, relational processes are based on dialogue between the actors and on making progress in the design work. The lecturer provides the students with the thesis (i.e. the keystone) along with certain guidelines; the students must then communicate, plan, and distribute the work (figure 1). To attain helpful strategies for creating a positive psychosocial environment in education, tasks must be equally understood by all parties. In a creative process, it is common to stop and discuss the work completed at that point, change and perhaps add new strategies, and then continue. In design education or in a company, it is important for leaders to take responsibility, correct and clarify tasks, and ensure participants' involvement. In Sennett's (2009) *The Craftsman*, he emphasises and elevates crafts by discussing them with great respect and insight. He mentions targeted work as an important part of crafts. According to Sennett (2009), targeting is something that is achieved, not something that is set in advance.

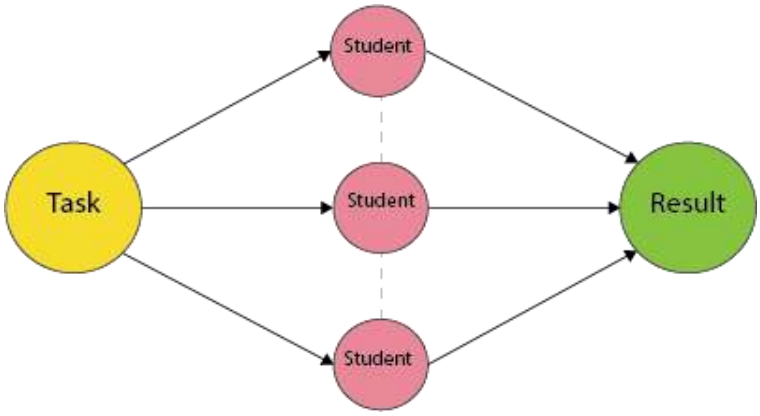

Figure 1: Cooperation in the relational process: the start of the project. The lecturer's introduction of the task (the whole) activates the students (the parts) who solve the task jointly. Illustration: authors and Peter Haakonsen, © 2019 OsloMet

According to figures 1 and 2, this process is similar to Riis's (2016) creative dialogue, which is characterised by openness, complexity, and a dynamic nature. A creative dialogue contains sketches, form studies, solutions, and changes. Knowledge in design emerges through application, challenges, and the development of experiences, as well as through knowledge and action rules (Riis 2016). Ensuring that everyone is involved in teamwork is often a challenge—even in higher education. Cooperative efforts where everyone has tasks usually proceed smoothly because all participants know what to do. In collaboration, however, participants should work and discuss more, listen to and understand each other's points of view, and interact with those with whom they disagree or with those who do not have an opinion (figure 2).

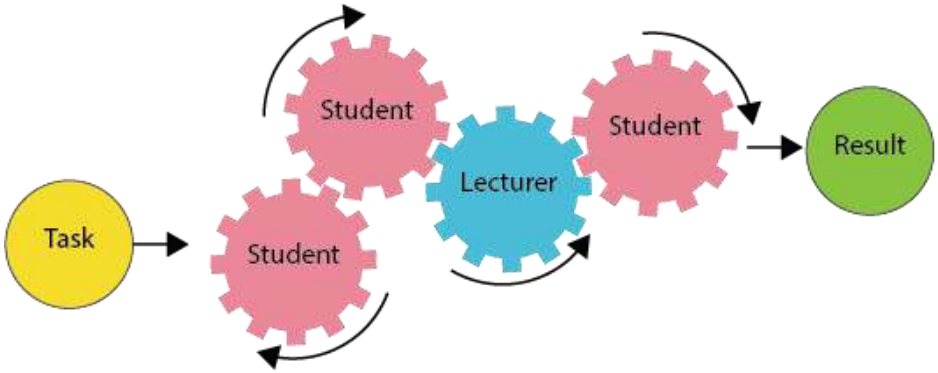

Figure 2: *Collaboration in the relational process that eventually unfolds; dialogues develop the process. Illustration: authors and Peter Haakonsen, © 2019 OsloMet*

Molander (2015) is a pragmatic philosopher who reflects on the main case Schön presents in *The Reflective Practitioner* (1983): the communication between an architecture student (Petra) and her teacher (Quist) in design learning. Petra is a novice at the University of Architecture, and she listens to an experienced practitioner. Their communication includes switching between Petra arguing for her own knowledge and being open to Quist's (the lecturer) coaching. Molander (2015) mentions four tensions that characterise the action in the dialogic structure: part-whole, commitment/involvement-detachment, criticism-confidence, and action-reflection (p. 286). In the Working Together project, the dialogue between the participants went back and

forth between individual parts and the whole task and between practical activities with materials and reflections about those activities. In time, new discussions and new choices became necessary.

In this project, the main goal was to raise awareness of the differences between cooperation and collaboration in higher education (cf. the models).

Cooperation consists of several parts that work towards the same goal. Collaboration is characterised like gears in that it requires closer contact and work amongst all parts along the way towards the goal. After the students become teachers, they will be able to make conscious use of these methods in their own teaching.

Exercises with drawing, ceramics, and hand embroidery

One major advantage in working with students is that they can be included in lecturers' research and development work.[2] Their first year of their bachelor degree studies includes several material-based periods, including a five-week period in drawing, ceramics, and textiles. Students take all three periods in turn. Each group (A, B, and C) consisted of 17–21 students who were required to collaborate on solving challenges related to the task and the practical work. They learned different activities during these periods and studied individually for most activities. To meet the curriculum for these material-based periods, the research-based training on cooperation and collaboration included the introduction of techniques and materials. They learned the craft, including artistic and formal issues; were able to be creative; and were able to test new ideas on short notice.

The lecturer's role in the project switched between facilitator/observer and designer/researcher. The study was an introductory task for the students to become familiar with OsloMet and to become known at OsloMet. The projects took from two days to three weeks, depending on the material. The main goal was to learn cooperation and collaboration in groups—a professional didactic approach using practical material work.

Drawing together: An exercise

The three-step exercise called Drawing Together was given during the start of the semester. Getting to know each other was therefore an underlying motive for establishing interaction between the students. The purpose of the assignment was twofold. Along with promoting drawing skills in observational drawings, the exercise showed how they could explore and participate in drawing processes where interaction and improvisation were promoted, and how others' drawing skills and ideas could include, inspire, and challenge.

Figure 3: Step 3: Ink and marker on paper. Photo: Ingeborg Stana, © 2018 OsloMet

Working individually

In step 1 of the exercise, the students chose a motif and worked alone. The aim was to draw pictures from the area outside OsloMet's buildings. The teacher's instruction consisted of the practice-based terminology of composition to explain the organisation of visual elements. Each student worked for 30 minutes on individual sketches using graphite pencils and size A5 paper.

[2] Norwegian Centre for Research Data approved the research project.

Working cooperatively

In step 2, the students formed groups. The size of the groups depended on the size of the class, and the teacher determined how students would be arranged in groups as needed. Together with the students, the teacher analysed the drawings, which included naming and discussing the use of visual elements. The students found common topics, mood-creating elements, and a suitable title for the drawings they planned.

Working collaboratively

In step 3, the students drew together on the same piece of paper and created a selection of sketches using pen, ink, and A1 paper (figure 3). The step resulted in a large image created from a selection of sketches. In the summary and review of the students' work, the students analysed the results and examined the pros and cons of using graphite and ink. The teacher asked the students to implement instruments through academic language and to compare and explain the difference between cooperation and collaboration, drawing either individually or together.

Challenges (Pros and Cons)

In terms of results, the main differences between steps 1, 2, and 3 of the exercises consisted of two different approaches. In the first phase (steps 1 and 2), the teamwork was focused on working together to create a product; however, doing so required that all participants contribute individual work. In other words, cooperation was initiated if all participants did their assigned tasks and contributed individual drawings. The second phase (step 3) was characterised by collaboration and involved direct interactions between people to produce an end result: a big picture. Being challenged by others' ideas and defending their own ideas made the students vulnerable. In the end, however, the process forced the group of individuals to complement their weaknesses and build on their strengths. The process was a synchronised activity in which the participants continuously tried to develop a drawing; the activity involved negotiating, discussing, and listening to each other's perspectives. The two approaches to collaboration amongst the students had two main effects. First, drawing together on the same piece of paper created new insights into the drawing skills of everyone involved; second, drawing together was a way of capturing creativity. Creativity is often seen as something extremely personal that is done by one person only. While working together on the same picture, the students gained a new understanding of creativity; that is, the final drawing was different from what they could have produced on their own.

Drawing on clay: An exercise with ceramic colours and glazes

In the ceramics portion of the project, the students worked with two-dimensional expressions. Each student made a ceramic tile to be assembled in a common composition. The purpose of this exercise was to improve their ceramic skills by drawing with ceramic colours on a clay tile and then glazing and firing it. In this exercise, sketches from the first drawing task in the OsloMet's buildings served as the starting point for the drawing on clay task. They were encouraged to use other artists as inspiration in their creative process; Keith Haring and Andy Warhol were given as examples. The process started with an introduction in which all the techniques for making the ceramic tiles were demonstrated, including how to use ceramic colours. The various criteria for the design, size (18 × 18 cm), and motif were explained as well.

Working individually

In step 1, the students contributed individually; every student processed his or her motif into a clay tile with ceramic colours (figure 4). They worked individually with their tiles in accordance with commonly agreed-on guidelines and worked towards a common goal.

Figure 4: Examples of individual work in clay. Photo: Gunhild Vatn, © 2018 OsloMet

Working cooperatively

In step 2, to make an interesting composition, the students determined common rules for the design and colour on each tile; a joint strategy for the choice included the use of certain visual elements and colours. Everyone cooperated and made their own tiles for a common purpose, where each student was responsible for his or her own part of the common design (Roschelle & Teasley, 1995). All the students had their tiles ready in time, and they were motivated to do their individual share because those who did not finish in time would be excluded from the rest of the process.

Working collaboratively

In step 3, after the ceramic tiles were finished, the students worked collaboratively to create a common composition of the tiles((figure 5).This phase featured a discussion of various strategies for the common design and the use of visual elements. The students had to listen to and reflect on each other's perspectives in order to complete the composition, which was included in the exhibition at the end of the project.

Figure 5: *Members of the group discussing composition. Photo: Gunhild Vatn © 2018 OsloMet*

Challenges (Pros and Cons)

A challenge concerning group dynamics in the collaboration part was in making the students participate equally, especially in large groups. Disagreements arose about the criteria for the composition, and often the majority decided. Some of the students may have been afraid to raise their voices in discussions. The students also pointed out these challenges in their reflections.

The ceramics field in general evolves through faults. Technical challenges often occur when working with clay. However, through working a great deal, making mistakes, and using different ways of approaching the clay, artists gain new insights and experiences. In this project, the accident occurred when the students received the wrong type of clay, which led to a series of problems, including more than half of the tiles exhibiting large cracks. The accident was useful for learning, however, both professionally and didactically. It was interesting for the students to experience how a mistake became something positive through joint interaction in composition. During the collaborative process, the idea arose of using the crack as a formal element in the artistic process (figure 6). Despite the crack, the creative process led to something new and unexpected, where the negative became a positive impulse. The students found their own tiles to be less valuable because of the cracking, but their attitudes changed during the collaboration part, when they composed a whole out of all the individual tiles. The students experienced that the whole became better than the sum of the parts. In the exhibition (see figure 11 later in this article), the audience and the artists' fellow students expressed great interest in the cracking.

Figure 6: The final composition result from Class B. Photo: Gunhild Vatn, © 2018 OsloMet

Textiles: An exercise in co-design embroidery

During the textile period, the students were given a task in hand embroidery, where the aim was to practice embroidery and make a design via co-embroidery. The thesis was based on similar tasks that were given to

first-year students in 2013–2016 (Kvellestad, 2017) but now with a different task. In a two-step exercise entitled 'Close in Close', each class (A, B, and C) of students was divided into two teams. Team 1 worked cooperatively, and team 2 worked collaboratively. Each class was provided with one piece of off-white wool and different black threads.

Working individually

The students had drawn individual sketches of objects in OsloMet's building that served as the starting point for the embroidery.

Working cooperatively

In step 1, team 1 discussed, picked out sketches, and made a joint composition of the figures. They cooperated on the selection of sketches, composition, and stitches. Each member of the team then embroidered each figure from the composition (figure 7). Everyone used black thread, but they varied the stitches and thread types.

Working collaboratively

In step 2, team 2 discussed, chose, assembled, and embroidered flat patterns between the figures; the goal was to make the characters appear tied together. Team 2 had to collaborate on and embroider the same pattern (figure 8). They were very busy because the composition from team 1 had few figures, and they were small. The work of linking the characters together led the students to physically sit together and embroider, paying attention to each other and discussing, changing, and approving the work. Exploration continued via their dialogues about simple stitching and by looking at previous works. As many of the students wrote in their reflections, this process became collaborative (figure 8).

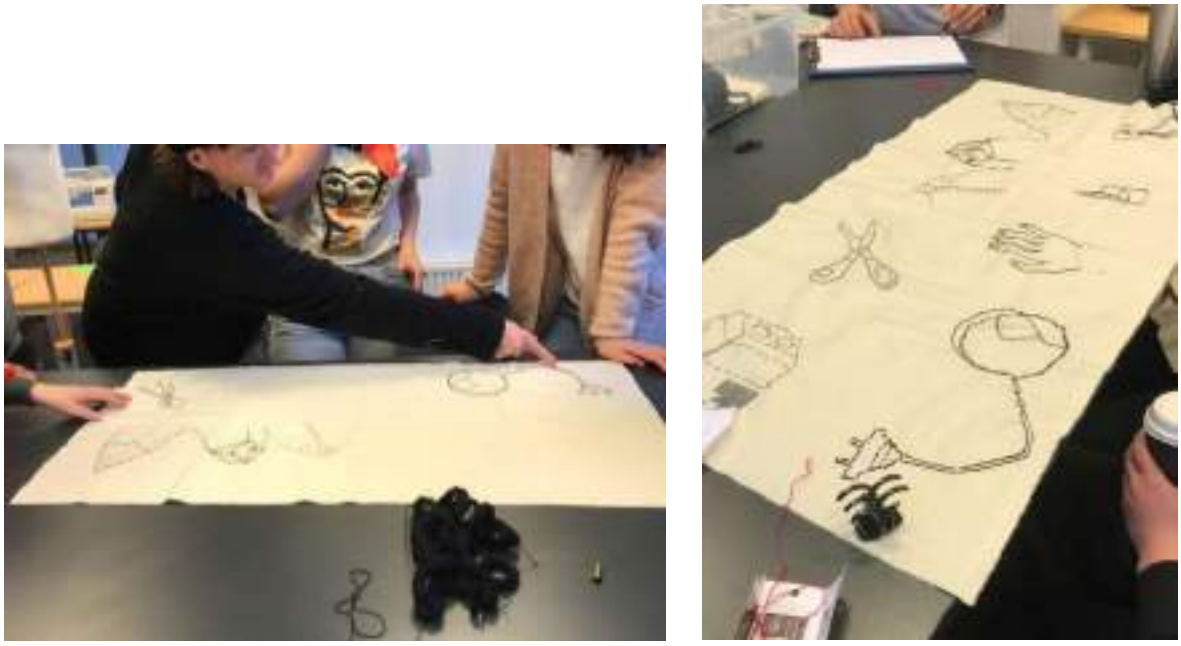

Figure 7: *Members of team 1 cooperating and discussing sketches and composition. Photo: Randi Veiteberg Kvellestad, © 2018 OsloMet*

Figure 8: Members of team 2 collaborating with a flat pattern between the characters. Photo: Randi Veiteberg Kvellestad, © 2018 OsloMet

Challenges (Pros and Cons)

In both teams, the students alternately cooperated and collaborated by either discussing and planning or embroidering individually or together. Figures 9 and 10 show how the teamwork evolved and the results concluded.

The textile exercise had an extended mission to provide the students experience with interaction in embroidery (i.e. co-embroidery). The students were users and designers during the completion of the embroidery as a whole; team 2 worked with a sense of co-owning and sharing of responsibility. The recurring challenges gradually disappeared. The students had collaborative relationships and dialogical conversations about the material and the designs. They interacted with one another in almost mutually responsive ways, and several new possibilities emerged. They experimented extensively with thread and stitch possibilities. To take the material seriously, the students had extensive practice in working patiently and purposefully, which was important for creating quality. Quality is a likely outcome when people spend time and have patience with the embroidery in the design process. The students experienced that the material-based creation process was slow, so courage and patience were important factors (Robach, 2012). The greatest challenge to interaction was the students' time limitation; their evaluations suggested that they would like to have had more time to do a better job. By working practically and physically with materials, the students also achieved a better feeling for touch and a sense of the material and the needle. They may have also remembered the activity better because co-design embroidery is a long-term process (Kvellestad 2018).

Outcomes: The whole becomes better than the sum of the parts

Completion of the Working Together project ended in December 2018 with a collective exhibition at Gallery PP33 at OsloMet (figure 11). The differences between the resulting pictures were obvious. Some of the motifs from the beginning thesis were visible several times throughout the various materials. Both the audience and the students recognised the motifs, which created a connection in the exhibition. Recognising creates affiliation and coherence in a study programme, especially when time is limited. It was a good didactic idea to

have an overall theme over a longer period. Students may bring this experience into their own professions at a later time. A product created by collaboration prepared the students for a synergetic experience in which the whole was greater than the sum of its parts. Differences were notable between cooperation and collaboration, although the role of the lecturers underlines the influence of the group dynamics.

The role of the lecturer

Research context always includes reflection and judgement. During the project, the lecturers' communication with the students played an important role by initiating the activity and precisely articulating the tasks. The role switched among tutor, observer, and researcher. A binding working relationship existed between the tasks and the students. Questions were asked, tests were evaluated, and new tests had to be made, followed by new questions. In this way, the work and research were established. Carnera (2012) writes beautifully about a binding working relationship in the meeting between skill development and experience formation that adds to the learning process an assessment of both poetic and aesthetic judgement. During the project, the students put this lesson into practice with the lecturer; thus, the students' experiences and reflections were an important part of the research material.

The lecturers guided the students towards understanding the concepts that were used to enhance their cognitive abilities. As the interpreters and designers of learning programmes, instructors bridge the gap between learners and the new environment in which students can access learning materials and enhance their knowledge. At the same time, the lecturers were in charge of the administrative process in a class setting where they supervised the students' activities and interactions between learners (Entwistle & Ramsden, 2015).

From this realisation, it is evident that a teacher should use several resources to fill identified gaps by making difficult-to-understand concepts clear. Because students need support when taking in new information, lecturers should assist learners in areas where they experience problems, without demonstrating bias. Students have differing cognitive abilities that require instructors to respond to their varied needs to help them overcome pertinent issues in the learning environment and to participate in entrepreneurship, as one example. As one of the students mentioned, weak communication leads to weak interaction.

To ensure better interaction when the students collaborate, the lecturer's role as leader and supporter is crucial. In this research project, the collaborative phase featured a discussion of various strategies for composition and the use of visual elements, where the students had to reflect and respond to each other's perspectives in order to complete the design. The teacher's influence became especially important in this phase for ensuring proper interaction in which everyone participated equally.

Develop design literacy

Through the students' participation in the project, they learned to compromise and to respect each other's ideas and attitudes. Their professional dialogues about composition and material understanding led to new ideas and design literacy. However, as one of the students said, one of the key challenges in the collaborative tasks was attaining equal participation. Collaborative projects can be both evolving and motivating if the task is well designed, which was confirmed by the students' own reflections related to cooperation and collaboration in a school situation:

> You can get results that turn out to be better than if you'd worked individually. (Student, 1C)
>
> You learn to create something with other people and to work from a common idea, not just your own thoughts and opinions. The result can provide a new and exciting expression that you wouldn't be able to create on your own. (Student, 1B)

The students were encouraged to be critical and to reflect on the challenges of collaborative tasks. These examples critically reflected the disadvantages of collaborative tasks in a school situation:

> There may be conflicts and unfairness, and some of the students may disagree with the common consensus if they feel they're not being heard. (Student, 2B)
>
> It may end up that one or more of the group don't do what they should, so those who remain in the group suddenly end up doing everything. (Student, 3B)
>
> Those who are shy and don't speak loudly don't participate in the discussions. (Student, 2C)

These statements show that a well-functioning collaboration can be stimulated. The students have to be a part of the community, sit together, and contribute in the moment, and then new ideas will arise without being planned. Further, the development of skill-, craft-, or design-related knowledge takes time. All experience and mentorship contributes to insight and understanding. Mentorship enables students to realise their potential and to accomplish specific objectives that will define their careers. In this regard, design education could inspire students to become leaders in society who can formulate good policies and be critically important to addressing problems that affect people's lives.

Løvlie (2011) claims that the foundation of experience is developed within an educational environment when we have a reflective relationship with our own practice. If we participate in a process over time, then innovation and development will occur. The action-research project reaffirms that the teamwork methods stimulate the students' design literacy. However, collaboration helps and inspires the community to achieve a higher result.

Benefits of teamwork in workplace and learning environments

In the design process, practitioners take part in collective creativity applied across the entire span of the process. This collective creativity is one of the strengths of the co-activity method (Anderson, 2012). In this case, company managers should identify the strengths and weaknesses of workers when sharing workloads to ensure that tasks will be completed quickly and effectively (McClellan, 2016). Teamwork also promotes innovation in the workplace, which enables individuals to realise their objectives and to develop viable solutions that a company can use in times of crisis.

Designers and lecturers have ideas and begin a project, but when other users, students, or technicians become involved, those ideas will change. New ideas, materials, and technologies that arise in the process then influence the outcome. Co-activity is not rigid or static but rather is characterised by flexibility and fluidity, which allow for change and a greater appreciation of the product (Anderson, 2012). Through collaboration in educational contexts, lecturers lead the students in their actions, guide them in adapting to changes, and provide support for their creations (Kvellestad, 2018). Such interactions challenge lecturers to ensure that their students take ownership of their tasks and become users and designers in the process.

A good dialogue involves interactions with mutual enquiry—sharing, exploring, discussing, and weaving new ideas—through which newness and possibilities emerge. In responding to one another, a critical aspect of dialogue is by nature an interactive process (Anderson, 2012). Thus, examining the lecturer's influence on the design process is important.

Individuals are more productive in an organisation when their input is recognised. For businesses, creating an enabling environment for employees where they can interact and approach tasks as a team increases the prospects of a company overcoming competition from other industry players. When the workload is shared amongst employees, they accomplish more than they could achieve on their own: a move that results in employee satisfaction (Driskell, Salas, & Driskell, 2018).

Collaboration allows people to help each other and to approach situations from a common point of view in which employees can focus on their goals and their career objectives. The Working Together project had features common to those in Wenger's (1998) social theory of learning, which can be used to describe and understand elements in a partnership. According to Wenger (1998), learning is created by social acts or within processes between people. Learning is characterised by the situation an individual is in and takes place in every practice community. From this realisation, it is imperative to ensure that the application of teamwork in education or business environments promotes harmony and increases an institution's or organisation's productivity regarding accomplishing specific objectives.

In the learning environment, students are typically encouraged to approach problems as a team because doing so will help them explore viable solutions that they can use to solve immediate issues. Compared to their engagement with instructors or teachers, learners can exchange ideas more effectively and improve their communication skills when they interact with their peers. Students can understand issues better when their peers teach them, compared to when they interact with their tutors (McCutcheon, Lohan, Traynor, & Martin, 2015). From this observation, lecturers must create an enabling environment where students can interact amongst themselves and solve various problems that affect their learning process. The student groups in this project had a short deadline, and they had to think and act quickly; they may have found it easier if the design had already been planned and drawn before the work began. Routines and rules streamline a creative process. A good example may be found in the children's education context, where having clear tasks is vital: Pupils must know what they are to do and what is expected of them (Kvellestad, 2018).

Co-activity in the classroom context gives students the responsibility of applying the concepts they learn from their instructors. Lecturers can understand the ethical grey areas that should be explored because of their direct impact on learners' cognitive abilities. Thus, learning institutions should encourage their learners to form groups according to their strengths and weaknesses in order to boost their performance in class. In a school situation, teachers influence their pupils by offering advice and suggesting improvements. The same thing happens amongst students. The students in the Working Together project had to have discussions, make choices, and defend their views with professional arguments, just like Petra in Schön's (1983) *The Reflective Practitioner*. In the project, students had to trust people with whom they did not agree. Knowledge was maintained and even evolved within the dialogue structure (Molander, 2015). The lecturer provided advice, but the students had to make their own choices. They helped each other, made compositions together, combined designs, explored material knowledge, and developed design literacy.

Future views in design education

Further research on the topics discussed in this article could focus on the teacher's role in teamwork, guidelines for interaction, equal participation, or conflict management. Professional education based on both academic study and hands-on practice is closely linked to educational occupations. OsloMet's goal is to develop and stimulate this interaction. Jarning (2011) characterises the educational institution as a knowledge triangle, with education/research/knowledge, sharing, and innovation forming the three sides. The institution will offer education based on research, professional and artistic development, and experience. Professional employees can apply for time to be allocated for research and development work, which then provides opportunities for diverse and non-stagnant work. Jarning (2011) also addresses trends in today's Norwegian education race in which practical work is in the process of being removed from education; he points out that performing more research at the expense of gaining experience leads to practical skills and training becoming less valuable. Even when educators complete their own research and development work, student participation can help in a practical way as well as allow for research-based teaching.

In a larger didactic context, the present project on teamwork supports the three themes that the Norwegian government has promoted in upcoming subject renovations: democratic citizenship, sustainable development, and health and life skills (2016). The last item, health and life skills, will be especially salient in projects such as the Working Together project in which everybody participates, thus stimulating skills and positive attitudes.

This knowledge has both academic and social aspects. Interaction is an important activity in almost all professions. Teamwork and participation characterise political work, education institutions, and health services. The Education 2030 international project is a framework for the qualifications that pupils will need in Organisation for Economic Co-Operation and Development countries by 2030. Some of these skills include professional knowledge, cognitive skills (e.g. creativity, problem solving, critical thinking), and social competences (e.g. interpersonal skills and communication).[3] The project can serve as an example of the type of interaction in which these competences are important to the progress of the task.

OsloMet has started an interdisciplinary project called Interprofessional Interaction with Children and Youth (INTERACT),[4] which has the goal to improve (a) the coordination of services aimed at children and young people, (b) collaboration between professional practitioners, and (c) cooperation between children/youth and professionals. The value of the project discussed in this article will be a practical exercise for students before they participate in INTERACT across the studies.

Concluding remarks

This project has revealed that the factors of cooperation and collaboration in this instance led to successful teamwork and stimulated innovation. Teamwork plays a vital role in the learning environment when students are allowed to experience challenges that can affect their cognitive skills and design literacy. When the lecturers guided students in a structured manner, the students made informed decisions, found innovative solutions, and achieved higher aesthetic goals. Surprisingly, the project also showed that collaboration was noticeably more effective than cooperation for stimulating their creative abilities.

From this realisation, it is evident that instructors can enhance their students' performance by requiring them to work in groups where students explore each other's strengths while they attempt to accomplish their objectives. For this reason, working together has a significant impact on students' class performance. The students who participated in this project learned how to successfully manage and complete a body of work. By applying this knowledge, they will be able to transform the competences they gained and apply them to teaching pupils of all ages, as well as participate in social tasks in general.

Acknowledgements

We would like to express our gratitude to the students.

Social innovation for modified consumption by means of the school subject Art and craft

NEUBERG Anita

Oslo Metropolitan University, Norway
anitaneuberg@gmail.com
doi: 10.33114/adim.2019.06.326

In this paper I will take a look at how one can facilitate the change in consumption through social innovation, based on the subject of art and design in Norwegian general education. This paper will give a presentation of books, featured relevant articles and formal documents put into context to identify different causal mechanisms around our consumption. The discussion will be anchored around the resources and condition that must be provided to achieve and identify opportunities for action under the subject of Art and craft, a subject in Norwegian general education with designing at the core of the subject, ages 6–16. The question that this paper points toward is:

"How can we, based on the subject of Art and craft in primary schools, facilitate the change in consumption through social innovation?"

Keywords: Consumption, production, biology, pedagogy

Introduction

The world's population is expected to flatten out around 10 billion people, and it will, according to Dag O. Hessen, require two planets to provide all an average Norwegian consumption and emissions. It is obvious that we cannot continue with such a consumption. The alternative to saving the planet must be either tomorrow's technology, or that we all take a little less space when it comes to consumption and emissions of greenhouse gases (2010, p. 224,253). In this paper I will take a closer look on how we might take a bit less space, therefore I have ruled out technology optimism, although it is an interesting topic in terms of consumption. To further refine the task, I will introduce some research around the Norwegian clothing consumption. According to Statistics Norway (SSB), the volume of our clothing consumption increased despite the fact that our clothing spending has decreased (1999, 2013, 2014). In Pål Strands' Article *We buy more of the most*, it appears that we have had a quadruple in the consumption of clothes and shoes since the 1980's, and he is putting imports from low-cost countries in Asia to the basis of this development (2014). According Carbon Trust, production and laundry of clothes account for 3% of global emissions, measured in CO2 equivalents (2011). This excludes chemicals, working conditions, energy, and resource usage. Carbon Trust also points out that the longevity and quality of clothes is a major factor for the Environment (Carbon Trust, 2011).

This paper is about people's relationship with their own consumption, what causal mechanisms that affect our consumption, and how we can relate to future challenges. As Matthias Kaiser and Ingrid Louise Ugelvik (2000) writes, we perceive things from our personal assumptions such as life history, experiences, values, attitudes and knowledge. Therefore, it will be natural to me, as an art and design teacher in the subject Art and craft, a

subject in Norwegian general education with Designing at the core of the subject, ages 6–16, to implement the interdisciplinary aspect. I would therefore give an insight into why, and how we can use this in a teaching context. Gunnar Vittersø and Pål Strandbakken (2016, p. 23) points out that knowledge about the environment and climate challenges requires an interdisciplinary approach, which I will try to do here. I will not derive any theories, but present a hypothesis on how we, through the arts and craft, can facilitate social innovation for modified consumption.

> *"How can we, based on the subject of Art and craft in primary schools, facilitate the change in consumption through social innovation?"*

Approach Method

This paper is based on what Runa Patel and Bo Davidson refer to as theoretical anchoring (1999, p. 11). The method I have put to use is a qualitative literature study, in which I have systematic review of selected literature around the issue. One might say that I have worked out from the hermeneutical spiral (Patel & Davidson, 1999, p. 26), where I read and interpret texts, then put them in context to each other, to form an understanding, and we get a new text production, a new interpretation and a new understanding. My empiricism is therefore based on various articles, formal documents and books. Which I attempt to put in context with each other in an effort to identify possible causal mechanisms influencing our consumption and reflecting on what actions that can contribute to change our action patterns. The selection of literature is mainly the book of Dag O. Hessen, professor in biology, *Nature-What are we going to do with it* (2010), a book on the topic of pedagogy and philosophy, as *The anxiety of the upbringing* of associate professor of education and environmental science Per Bjørn Foros and professor of philosophy at the University of Oslo Arne Johan Vetlesen (2015), as well as articles on relevant research related to this topic, and formal documents. This is to achieve the interdisciplinary approach I want.

Causal mechanisms and our consumption

Cultural and social causes of consumption

In the book *The anxiety of the upbringing,* Foros and Vetlesen (2015, p. 144) points out, that we cannot solve climate problems without looking at the cultural and societal causes. Children grows up in a globalized culture, in which there is an asymmetrical power relationship between the individual and global society. They write that consumption has become a key to self-realization, and that self-realization works as a requirement from society. The individual's freedom and the right to choose weigh heavy, and with wrong choices, the individual alone is left with the blame. Foros and Vetlesen points out that this social feature is in the way of political solutions, where interventions can be perceived as a limitation of personal freedom (2015, p. 63). Something like Vittersø and Strandbakken confirms in their article «Consumption and the green shift» (2016, p. 17). Hessen writes that Norwegian politicians avoid pointing at individual responsibility, because they believe it is an impossible political task (2010, p. 246,247). This image of the reluctant politicians is being confirmed by Sjur Kasa (2016), which describes political attitudes toward the consumer; as unable to make environmentally friendly choices without economic intensives. At the same time, Hessen draws a picture of people wanting to contribute to a better environment, but that they want a stronger political will (2010, p.240). This creates an error in politician's argument, who arrange to just continue as before.

Evolution, action patterns, consumption and producers

Why is it important to understand the role of evolution in our actions? Why is it important with an individual focus on consumerism? As I interpret Kaiser and Ugelvik is the individual the most fundamental size in the modern society (2000). According to Hessen (2010), we cannot get away from evolutionary influences on us, but at the same time, modern society requires some rather different characteristics form us, than what was important for survival earlier. We have been hunters and collectors in 99 percent of human history, and these impulses are not easy to change (Hessen, 2010). Hessen points out, among other things that «… We are abundantly equipped with gas pedals, but few brake pedals» (2010, p. 251). We are evolutionary adapted to "Here-and-Now Options" (Hessen, 2010, p. 230), which was beneficial as we lived on the savannah, but that is not as beneficial in a modern society with access to everything we need and desire of goods. As Hessen writes, it is the sum of our individual action patterns which contribute to the state of the globe (2010, p. 222). Foros

and Vetlesen stressed that the problem lies in the volume of commodity production (2015, p. 113). As I interpret Hessen, does increased consumes equals increased waste, increased CO2 emissions and Increased greenhouse gas emissions which threaten our globe.

So why don't we decrease consumption? Could it be that manufacturers are looking to increase our consumption? "It is a market-driven, but unwanted dynamism and business-Darwinism in the society development that makes the current solutions passé before we have grown accustomed to them" (Hessen, 2010, p. 121), with the result that the rate of exchange increases (Hessen, 2010, p. 122). Pål Strandbakken also writes about this theme, with the explanation that when things are cheaper to buy new, than to repair, this affects the consumers choice. It must also be mentioned that according to the article *Product life and product quality that reduced consumption?* (Strandbakken, 2016), it will always pay off for the consumer, both financially and environmentally to emphasize products with good quality.

As mentioned initially, we are on a consumption that is in disparity to natural resources. Vittersø and Strandbakken presents various strategies that can reduce the environmental impact in which the reduction in the actual consumption of goods and services in the household, is identified as the most difficult to implement (2016). The question is, do we have this ability to readjust ourselves to a smaller consumption? As I interpret Hessen, there is an absolute potential for it since we humans have an impressive adaptability (2010, p. 248). We humans have the opportunity to change habits and identity, because we, as human beings are in an interaction between identity and society, as Rune Sarromaa Hausstätter and Sanna Sarromaa (2009) write in their article *A theoretical contribution to an in-law education*. Vittersø and Strandbakken (2016) expresses that the consumer perspective does not get enough focus in the green shift, and that adaptation of our consumption is critical in terms of environment and climate change. They look at social innovations as a prerequisite. I believe that the school can, and should play an important role here.

Abstraction to production

Hessen notes that urbanization leads to a form of abstraction to nature, and writes that the bill for consumption of nature is passed on to future generations (2010, p. 178). But I question whether or not the bill is also sent to the production countries, with a much closer time perspective?

I would think that modernization and our consumption habits to have had a form of abstraction in relation to the resources used. Take for example the production of clothes, with all of the different resource used, including the human labor, the local challenges, and the immediate impact of the environment in the vicinity of emissions of toxins. In order to not forget the use of energy and resources throughout the process of manufacturing the actual product itself, its material and raw materials. As Ingun Grimstad Klepp and Kirsi Laitala points out in the article *Clothes life-LCA on life and death*, these items are difficult to measure (2016). Based on Norwegian conditions, Hessen takes up that protection of land and species should have a local anchoring, ideally, and he points out that the conditions for this framework is changing (2010, p. 121). I am thinking that, yes, the framework for the conditions change, and that today we are responsible for the emissions that occur in other countries on behalf of our consumption, and thus also a responsibility for the protection of areas and species in a global perspective. Which Hessen himself points out, the average Norwegian have the same high Co2 emissions in China, as the average Chinese (2010, p. 229). To change this, we must contribute to these good social innovations such as Vittersø and Strandbakken calls for, previously mentioned in section 3.2.

How about appealing to humanity and empathy? Will we then be able to fight lack of understanding and sympathy for the future generations? Hessen points out that we, as social beings, have empathy that extends beyond ourselves. He is questioning how far this empathy and immersion can be stretched (2010, p. 126, 128), both when it comes to species and the future generations. I think it certainly should be able to stretch to reach living people, and that this can cause upgrowing generations to feel and relate with workers in Bangladesh. The Starting point for biophilia is, as I interpret Hessen (2010, p. 147) that we as human beings are more willing to stand up for someone who is closer to us.

Can we, if we based on biophilia as phenomenon, combined with empathy and immersion, be creating a focus on people's working conditions and different environmental impacts that our consumption provides the local environment? Can knowledge and information on production in other countries Influence the individual's ability to act and work against the biological instincts?

As I understand Kaiser and Ugelvik (2000), our ability to judge situations is about our ability to experience them through different perspectives; If one is introduced to different contexts, one also gets new insights, we understand better and can justify our choices better. Foros and Vetlesen points towards Kant's Distance ethics, that a principle cannot only apply to anyone, it must be able to apply to everyone. So that when we are facing a choice, then we have to imagine that everyone else does the exact same thing, and form that, consider whether we can bear the consequences (2015, s.201).

A look at the future

Future optimism or future determinism?

The location of man at the top of the hierarchy has long traditions from antiquity to the present day (Chalmer, 2013; 4. Kaiser & Ugelvik, 2000; Hessen, 2010). There were little changes at most people in ancient times, but after the renaissance the belief that future generations would get better than previous generations arose (Kaiser & Ugelvik, 2000). Hessen is on to something when he writes that the human cultural project is mainly about cutting the ties to nature (2010, p. 96), but that we must now move from being man against nature, to protect the nature against people (Hessen, 2010, p. 27). This increased focus on the climate crisis is about to take away the belief in the future. This is being replaced with increased concern for the future (Foros & Vetlesen, 2015). Hessen uses the term "meta- concern" about the concerns for the planet's future, and as I interpret him, it is a concern that is difficult to do something about (2010, p. 214). I believe this can contribute to a powerless and hopelessness among up growing generations, which will contribute to a "give damn attitude".

The question is then how children and adolescents can get outlets for these feelings, and how I as an adult person and teacher, can create hope? According to Foros and Vetlesen (2015), all adult persons are responsible for educating and raising children and adolescents, conveying joy of life and faith for the future without concealing the seriousness and urgency of the situation. What seems daunting and incomprehensible needs to be explained, both how it has become so and how it can be better (p. 103). The way I interpret Foros and Vetlesen, it is important that the children get the tools they need to make good decisions on their own. This can prepare the future generations for the life they will live and the Society they will become a part of. Experience of opinion creates greater hope and vigor (2015, s.208). Hausstätter and Sarromaa mention that pedagogy with an environmental focus is an important element in the environmental challenge (2009). They point out that the pedagogy largely puts man in the center, but that the pedagogy must seek away from this starting point with increased focus on the relationship between people and the environment. I think these are important elements for social innovation through the school system.

Tendencies in formal documents

If we take a look at some formal documents, we might see some tendencies presented in the future school. In the white paper *Motivation-Mastery-Possibilities. Lower secondary education* (Kunnskapsdepartementet, 2010, p. 38) they write that Art and Craft subject is one of the subjects the students are most satisfied with, nevertheless it is not embroidered the importance and usefulness of the subject, but is emphasized as a method to use in other subjects. This shows that the subject's specificity is not communicated clearly enough from the field.

According to *Knowledge for a Common Future. Strategic plan*, the Revised Education Strategy for Sustainable Development, education is going to influence people's mindset and attitudes towards more focus on fair and sustainable development (The Ministry of education, 2012). UNESCO, which is the United Nations Organization for education, science, culture and communication, is conducting measures for increased expertise in the field. They emphasize that all subject disciplines support this goal. (Ministry of education, 2012). But I have to point out that subjects such as mathematics, language subjects, social sciences, science, religion and philosophy were mentioned in the strategy plan, but not the Art and craft subject, which I find strange.

In Norwegian public inquiry *School of the future* (NOU 2015:8). They write that the practical aesthetic subjects are carriers of important skills for future workplaces, and for the students' ability to make ethical considerations and good decisions in one's own life, referred to as a life skill and everyday competence (NOU 2015:8, p. 25).

The politicians in *Subjects-Depth-Understanding,* want it to be made easier for individual subjects to be seen in the context of other subjects that have related topics (report. St. 28, 2016, s. 32,37).

In the *General section- values and principals* the overall goals for education in Norwegian primary school are presented. This should be the basis for the education in all subjects. Based on the purpose law of the Education Act (Kunnskapsdepartementet, 2017, p. 2). The values of the education are based on human dignity, culture, identity, diversity, critical thinking and ethical awareness, in addition to creativity, commitment, exploration, democracy and participation. Principles of learning and development is all about the development of students' formations, holistic competence, knowledge about learning and presentation of interdisciplinary topics. It is pointed out that the practical work and the theoretical reasoning is important for understanding, reflecting and thinking critically in subjects (Ministry of education, 2017a, p. 11). One of the points in the value base is about respect for nature. That the students will gain knowledge to learn about nature, developing ethical awareness and develop respect for nature. The school shall facilitate for students to develop a willingness to care for the environment, and the will to make changes in our way of life, and thereby take care of all life on Earth. They Should be made aware of how the human way of life affects the nature, the climate and our society (p. 8.)

As we can see here, the politicians are trying to increase the focus on sustainability in the education system. Still I am afraid that the Art and craft subject's potential in educating upcoming generations within the topic of environment and climate issues will continue to be under communicated. This made me think that my field of expertise needs a greater understanding of the global environmental issues, so that we can more clearly convey our skills and opportunities to contribute to solving parts of the climate problem.

Why the subject of Art and craft?

I will try to show how art and craft subject are important and useful, as more than a method to support other subjects, and try to communicate some of the subject's specificity that lacked in *Motivation-Mastery-Possibilities. Lower secondary education.* At the same time, it is important to show the interdisciplinary related topics that *Subjects-Depth-Understanding* calls for to give the students' knowledge of the environment, the human impact on nature, climate and in a globalized world that *General section- values and principals* expects the school to facilitate. And that the Art and craft subject also can influence people's mindset and attitudes towards more focus on fair and sustainable development, even though not mentioned in Knowledge for a Common Future.

Hessen points out that the curve of life happiness in this country flattened out in the late 60's, while our consumption has continued to grow (2010, p. 229,254). This has been confirmed by Foros and Vetlesen, who points out that the psychological happiness does not follow materialism, but that it rather appears as an obstacle to perceived happiness (2015, p. 21). The western population is increasingly seeking freedom from the materialism (Hessen, 2010, p. 255). At the same time our clothing consumption increases. This shows, as Christine Løkvik and Janne Beate Reitan (2017) points out that sustainability and fashion are important for the general public as critical consumers. According to Monica Shlanbusch Orheim and Liv Merete Nielsen (2017) the conscious consumer needs to be trained, and points out that one of the challenges is "…how to bring these ideas into educational practice in a way that connects to students' choices in their everyday lives." (2017, p.2). Strandbakken (2016) notes that clothing creates identity, and as we have mentioned previously, consumption is a key to self-realization. But are there other, more sustainable alternatives to self- realization through clothes?

«When is life good to Live? » Hessen asks (2010, p. 259) as he continues to ask questions around what gives us people a sense of well-being and what makes life feel meaningful. He explains about the feeling of happiness that occurs in ski tours associated with toil and sees it in the light of both endorphins, moral reward and not to mention the feeling of being alive (2010, p. 79). Hessen writes that nature experiences provide and creates deep emotions and feeling that life is good to live, that the origin of the feeling is not the most important thing, but that the quality of life is the essence (2010, p. 100). If we focus on the feelings and the essence of life quality and moral reward, can this feeling occur within the walls of the classroom? It makes me wonder if this cannot be transferred to students, when they have to produce their own item, such as clothing?

Let us take a starting point in that they must sew or re-design a piece of clothing in the arts and design subject. When the students must spend their time, physically and mentally designing a product, creating, making mistakes and mastering, the question is if this will contribute to a feeling of well-being, a reward after the toil?

Will mastering sowing a garment promote the feeling of life quality? Mia Porko-Hudd, Sinikka Pöllänen and Eila Lindfors (2018) share this point of view as they write that craft is often connected to the concepts of wellbeing and quality of life connected to sustainable crafts. But could this project also contribute to the ownership of their own things, to regain love and the emotional affiliation to things? I wonder if re-design and self-produced clothing can contribute to the garments increased emotional value, that things can have value in virtue of themselves? Hessen specify that empathy, also in the form of sentimentality has a cultural side (2010, p. 137). Something Klepp and Laitala also punctuate in their article (2016). They point out that it appears that the age of clothing is related to frequency of usage and to what extend we like the garment, not to mention the technical durability (the quality, as I interpret it), which does not have the context of price. We take much better care of the things we like. So, will the experience of sowing their own garment, facilitate for an emotional attachment as well as increase its value for the students, which in turn will motivate them to take better care of the garment?

Vittersø And Strandbakken (2016) believes that we can reduce the number of products if we put more emphasis on quality and longevity. One of the solutions for environmental benefit is to reduce the number of garments we own. Furthermore, they write "It is our assertion that if the effort was aimed at increasing the valuation of clothing and other lasting consumables in terms of better quality and longer durability, it would lead to more knowledge and interest in how the things we surround ourselves with are made" (Vittersø & Strandbakken, 2016, p. 19). The way I interpret Vittersø And Strandbakken, they claim that quality and longer durability in clothing will lead to a greater interest and knowledge of how they are made, which in turn contributes to more care and maintenance, with increased lifecycles for the clothes and less consumption as a result. I think we need to turn this around. Whether students get physically aware and master what it is like to create a garment, preferably with conversations around a quality perspective, then I think this will help build up around understanding and knowledge of how clothing is produced, quality and respect for the work that is behind a garment. And this, again, I think can help that they become more conscious of their own consumption. I believe that making a garment, combined with conversations around the quality perspective, will help to build up understanding and knowledge of how clothes are manufactured, quality and respect for the work behind a garment. As Løkvik and Reitan(2017) points out, engaging in a continuous dialogue, the context become clearer and this open up for discussion on the contrast in the mass production of cheap clothes, and "…how rich countries outsource the production to poor countries and consequences this has on us as consumers, environment, economy and health."(2017, p.3). As is evident from Sinikka Pöllänen (2009), art and design subjects are a way to gain an increased understanding of cultural and ecological phenomena, as well as reflect on culture and society, it is about giving the students an individual and balanced relationship between yourself and the world it is part of. Seeing things from others' point of view is important for the ability to reflect and the student's personal growth. And this, again, I think can help to make them more aware of their own consumption and promote for a moral reward, when students can self-realize themselves through clothing without a guilty conscience. This is consistent with the basic values as creativity, identity and human dignity, in General section- values and principles (Kunnskapsdepartementet, 2017).

Orheim and Nielsen (2017) points out that motivation of students is a challenge. On the other hand, real world environmental problems tend to engage students (Løkvik & Reitan, 2017; Pöllänen, 2009). It is important and motivating for the students to explore and find their own answers to what makes things sustainable (Løkvik & Reitan, 2017). As I interpret Løkvik and Reitan (2017), it is important to have different approaches to the topic in order to motivate the students and facilitate the students to make their own reflections and engage them to think for themselves. Introducing craft training that supports the full and versatile development of the student's personalities requires understanding of important features of different pedagogies that models and the ability to draw from them in a conscious manner (Pöllänen, 2009).

Foros and Vetlesen points out that there is not much time for reflection in a busy school day (2015, p. 251). And it is exactly there I believe the arts and design subject is in a special position. Because when you are in the process designing and creating, and you get into a flow where you can work with the products, and let your mind wonder of. Which allow you to reflect in a subtle way. If you facilitate for a short conversation with students in the beginning of the task, or during the process, it creates both space and time to think. Example of conversations that can be conducted with students: How would you feel if you wash this garment that you have spent a long time making, and the fabric turns out to be of por quality, and that the shape of the garment is ruined? How would you feel if someone throw this garment away after using it twice? The question is if the garment they have invested work and time on, will get the increased value for the students, which in turn provides increased care and maintenance that provide longer lifespan mentioned earlier.

Another challenge is that failed projects that fall into the garbage conflict with the environmental focus. (Orheim and Nielsen, 2017; Pölännen, 2009). Løkvik and Reitan(2017) as well as Pöllänen, (2009) raise basic exercises, training and knowledge before the project as an important basis for avoiding this. I believe that exercises in crafts and proper selected materials will give students the skills to see the connections between what they have learned earlier and can affect the quality of the garment. As Orheim and Nielsen (2017) specify it is important that the garment is of good quality, awareness around material use, knowledge and abilities for implementation are important both in terms of production and assessment of quality, therefore the teachers must transfer this knowledge through demonstration and testing. If you give the students a goal that the garment is to be used by themselves, or given as a gift to someone special, the students take the task more seriously and make something they want, not something they need (Orheim & Nielsen, 2017). Granted that students summarize the project in the end, and explain words and concepts such as sustainability, the teacher also receives feedback on what they have learned during the process (Løkvik & Reitan, 2017). However, as Orheim and Nielsen (2017) points out, we do not know if the students will actually use their garments and if they don't, some of the expected learning outcome is not achieved.

As Foros and Vetlesen themselves identify, conversations about consumption are important preconditions for the upbringing. Knowledge and an understanding of the world combined with impressions and experiences, can promote the meaning and actualize value choices are important prerequisites for the upbringing. Experience of choices and opinions creates greater hope and vigor in people (Foros & Vetlesen, 2015). The question is whether such conversations and practical tasks affect how they identify themselves as a consumer in a global community? Will this do something about their consumer perspective, both in terms of relationship to quality, use of materials, time and resources spend use in general. Can this influence their attitudes both to price, quality and their own consumption of mass-produced goods? What experience does the students get through sewing a garment? I think they will get an insight into how demanding it is and how much time it takes as well as a better understanding for the performance of a piece of work. Porko-Hudd, Pöllänen og Lindfors mention that “Craft, design and technology education may help people to see the potentials of sustainable consumption and individual satisfaction of developing one’s skills and accomplishing something concrete with one’s own hands (2018, p.34). This can create a foundation for biophilia, and create a focus on people's working conditions and different environmental impacts that our consumption provides the local environment. The starting point for biophilia is, as I interpret Hessen (2010, p. 147) that we as human beings are more willing to stand up for someone who is closer to us. I think it certainly should be able to stretch to reach living people, and that this can cause upgrowing generations to feel and relate with workers in Bangladesh, which in turn provides a meeting with the basic value in *General section- values and principles* (Kunnskapsdepartementet, 2017), the value of human dignity.

And as Hessen is writing, you also get life's content through what you do (2010, p. 257). "Impression through adolescence will shape the brain, in which much of the human flexibility lies, but it is also where what makes us creatures of habits, lie" (Hessen, 2010 p. 100). Therefore, it is important to lay a good foundation for environmentally conscious reflections and teaching around our consumption into school life. Here, dialogue and reflections important as Løkvik and Reitan(2017), Foros and Vetilesen (2015) as well as Pöllänen, (2009) underlines. I believe this will promote the students' ability to make ethical considerations such as *School of the future* (NOU 2015:8) points out that the practical aesthetic subjects are carriers of. I think this will contribute to the combination of practical and theoretical teaching that, according to *General section- values and principles* (Kunnskapsdepartementet, 2017), facilitates understanding, reflection and critical thinking.

A challenge in the Finnish school Porko-Hudd, Pöllänen og Lindfors (2018) points toward, is lesson hour distribution in craft education to amongst other things influences pedagogical innovation processes, time to develop ideas, design and useful products of good quality. In Norway there is a possibility to do interdisciplinary collaborative projects, thus merging hours with other subjects, but how widespread this is in the Subject of Art and Craft in practice I have not found research on.

Another challenge is that surveys show that a minority of teachers in Norwegian art and craft subject have formal qualifications; in addition, fewer number of teachers being educated with formal qualifications now than in previous years, and continuing education in the subject is minimal (Lagerstrøm, Moafi & Revold, 2014; Espeland, Arnesen, Grønsdal, Holte, Sømoe, Wergwdahl & Aadlamd, 2011; Perduco Kultur, 2008; Opstad, 2013; Neuberg & Digranes, 2017). Formal qualifications and continuing education affect teachers’ focus on concepts, their repetition, and their attitudes toward the subject (Neuberg &Digranes, 2017). I think this can create a challenge for the transfer of knowledge through demonstration and testing, as well as conditions for production and assessment of quality, and not least how the teacher facilitates reflection and dialogue.

As I interpret Hessen (2010), does increased consumes equals increased waste, increased CO2 emissions and increased greenhouse gas emissions which threaten our globe. And as previously mentioned, the framework for the conditions change, and that today we are responsible for the emissions that occur in other countries on behalf of our consumption, and thus also a responsibility for the protection of areas and species in a global perspective. We should present to the students how our way of living affects the nature, the climate and our society, as *General section- values and principles* (Kunnskapsdepartementet, 2017) calls for, presented with the knowledge that humans have the opportunity to change habits and identity, because we, as human beings are in an interaction between identity and society, as Hausstätter and Sarromaa (2009), Hessen (2010) Løkvik and Reitan(2017, as well as Pöllänen (2009) specify.

Summary

What influences our consumption is the culture and society in which we are a part of, as well as the individual's action patterns, that are based on instincts and habits. But we humans have adaptability to change these habits.

Politicians refuse to focus on the individual's responsibility. They can, as we seen, under the direction of their mandate, help to increase the focus on the environment and consumption perspectives in the school trough the white papers. This can provide to bring about a change in attitudes form the bottom up. Social innovation in schools can thus become the key to raising awareness around the topic of consumption. Especially in the subject of Art and craft, which is in a special position for combining knowledge and an understanding of the world, combined with impressions and experiences.

If one assumes that through letting students sew their own garment combined with dialogue around of how the human way of life affects the nature, the climate and our society, one can facilitate for reflection, understanding and empathy in a global perspective, both in terms of human working conditions and an environmental perspective. This can be easier to convey, than a perspective on future generations. But with the climate crisis hanging over our head, it is necessary that we give the students hope for the future. We have to emphasize that there is hope, and that there are choices to be made as well as giving them tools to make them.

These impressions and experiences through sowing a garment can affect attitudes and habits, because students experience a close proximity to the production and will gain new insights and new perspectives. Experiences from sewing a garment will be able to lay a good foundation for environmentally conscious reflections, critical thinking and ethical awareness and can add a basis both when it comes to quality, maintenance and they're own consumption. Sewing a garment is not at least a way to self-realize through clothing without buying clothes. If you make a product, you're proud of, it increases the sentimental value of the garment and can contribute to a heightened desire to care for it. Life should be good to live, and creative processes can contribute to the sense of coping with a difficult situation and facilitate for hope, creativity and identity in a world facing environmental and societal ethical challenges. Therefore, the subject of Art and craft can form an important basis for a multidisciplinary approach to environmental issues around consumerism.

Suggestion for further research is to undertake such projects in practice, investigations of the implementation in such a sowing project with successive interviews or surveys of teachers and students.

Adaptive digital capability development: Professional learning for educators across disciplines

PETERSON J Fiona[a]*; LOCKHART Cathy[b] and RAFFAELE Catherine[b]

doi: 10.33114/adim.2019.07.237

In a cross-university project, a mixed methods approach was adopted to design a learning model for digital work practices in line with evolving industry needs. Drawing upon industry input (*n=50*), developmental learning and technology affordance theory, a model was trialled with Design, Journalism and Engineering students (*n=78*). Workshops were held at five universities with educators (*n=66*) and this paper discusses their perspectives on the model. Their responses indicated a predominantly functional digital capability focus in their current learning and teaching practice; rather than integrating functional, perceptual and adaptive digital capabilities, which are in high demand but short supply in industry. The educators highlighted a need for their own professional learning and we offer practical suggestions for moving beyond a functional digital focus. We argue it is vital for students and educators to learn and use the vocabulary of technology affordances, to strengthen professional learning for digital work futures.

Keywords: digital enterprise learning, adaptive capability, technology affordances, professional learning, academic development

Introduction

At a time of ongoing technological developments and change in the world of work, graduates need enterprise (21st Century) skills spanning communication, collaboration, critical thinking, design thinking, creativity, complex problem solving and entrepreneurship; the ability to select appropriate technology; and data literacy, including analytics, security and the ethics of data use (PriceWaterhouseCoopers, 2018). In this context of rapid technological change, lifelong learning as an attribute of workers is paramount (WEF, 2018). Evolution of the learning continuum concept, including preparation for work and ongoing career learning, is increasingly cited in higher education circles. Examples include the University of the Future Report (Cawood et al., 2018); the University of Queensland discussion paper on higher education trends and implications (Matthews et al., 2018); and re-imagining professional learning models in collaboration with industry (Peterson et al., 2018b). Understanding the digital literacy of entrants to higher education (Coldwell-Neilson, 2017), and shifting the focus of assessment to 21st Century requirements such as teamwork but also resilience (Sonnemann & Goss, 2017), are other examples of ways in which higher education thinking has responded to the changing needs of the workforce.

We, too, argue that enterprise or 21st Century learning, especially digital enterprise learning, needs to be uppermost in the development of curriculum and pedagogy, to ensure that students in higher education are well supported as they prepare for their work futures and ongoing learning. However, there may be a gap

between this aspiration and some current practice in learning and teaching, according to research undertaken in an Australian cross-university project with stakeholders in industry and education. The Digital Work Practices project revealed that adaptive digital capabilities are in high demand yet short supply in industry, where changing workforce needs continue to be exacerbated by technological developments. At the same time, however, a key finding was that the focus of educators and students in higher education may be too much on digital capabilities that are functional, rather than perceptual and adaptive. *Functional* is the 'what and how-to' or operational level; *perceptual* is knowing the 'when and why' i.e. discerning use of technology in *known* contexts; and *adaptive* involves imagining possibilities for the use of technology in new ways or *emerging* contexts (see Peterson, 2018a; Peterson et al., 2018a, c).

The project team suggests that a different approach is needed in higher education, drawing upon affordance theory (e.g., Best, 2009; Evans et al., 2017); as well as deep and transformative learning about technology affordances, where critical engagement and reflection underpins the development of students' understanding of their experiential learning (e.g., Fullan & Langworthy, 2013; Marton & Säljö, 1976; Mezirow, 1997). A Digital Affordance Developmental Learning Model has been developed as a rapid prototype in the project, involving iterative engagement with industry stakeholders, educators and students.

This paper focuses on findings of the five workshops about this Model conducted with educators. Our initial response to the educators' feedback is addressed, including their call for support with professional learning for teaching in relation to the Model. The authors of this paper are the leader and two members of the project team involved. All three authors are experienced educators in Design, Communication and/or Business at different universities.

After explaining the research aim and methodology, we discuss the educator participants' written responses to questions in three broad areas: the key digital capabilities identified by industry participants in the project; the possible strengths and challenges of the proposed Digital Affordance Developmental Learning Model; and ideas for its implementation in teaching practice. Then we outline suggested approaches with examples to enhance teaching capability, for scaled-up implementation and transition to an adaptive digital capability development focus with students. Finally, we discuss some of the wider implications and highlight further research needed.

Research aim and methodology

The aim of the project was to create a useful model for deep and transformative learning and teaching practice to support the development of digital capabilities in Design/Creative Arts, Communication, Business Management, and Engineering, with potential application in other disciplines. The intention was to meet new industry needs, whilst positioning graduates for emerging digital work opportunities in the globalized world of work.

A mixed-methods approach informed the learning model developed in this project from April 2017 to June 2018, including literature reviews and iterative stakeholder interactions. Data analysis was documented initially in a series of six reports available in the project website (https://sites.rmit.edu.au/digitalworkpractices/) and in journal and conference papers focused on different aspects of the research and findings.

Qualitative and quantitative analysis and synthesis in the project spanned employment information; five consecutive industry roundtable discussions in Melbourne, Sydney and Brisbane (*n=50*); the design, implementation and refinement of pilot activities with Journalism and Design students at one university, and Engineering students at another (*n=78*); and teacher reflections from the pilots. Educators at universities in Melbourne, Sydney, Brisbane, Perth and Adelaide were invited to participate in an online survey (*n=91*) to ascertain what digital capabilities were being taught, practised and assessed; then, six months later, face-to-face educator workshops were held (*n=66*) at the same five universities for feedback and further input to the Digital Affordance Developmental Learning Model. Discussions were also held with the project's Critical Friends Group during and at the end of the project. A final symposium involved an Expert Panel responding to the project findings and Model in relation to work futures, institutional strategy and learning futures.

In this paper, the insights gained from the educator workshops underpin our suggestions about professional learning for educators to support their students' adaptive digital capability development. The educator workshop participant input was first documented in the project website in a preliminary report (Peterson, 2018b). This paper draws and builds upon excerpts from that report.

The face-to-face workshops were held at universities in Melbourne, Brisbane, Sydney, Perth and Adelaide in March 2018, following the earlier online survey undertaken at the same universities in September/October 2017. The 66 educators who attended the workshops were from several disciplines: Design/Creative Arts (19); Business Management (15); Education (11); Communication (3); Engineering (3); Science/Health (3); and Information Management (2). Ten participants did not identify their discipline. Project team members designed and facilitated the workshops collaboratively, underpinned by the team's own different disciplinary perspectives from Education, Design, Communication, Business, and Engineering. A common format was used for the workshop presentations and activities, facilitated by different members of the project team.

Workshop participants were introduced to the research, including findings from the online survey of educators six months earlier. Workshop activities and discussion then focused on staff/student capabilities and applying the digital affordance concept, which is integral to the learning model proposed by the research project team. In the final stage of the workshops, participants were invited to provide individual written responses to seven questions, which yielded 320 written responses overall. The questions related to three areas: key themes from the project's industry roundtable discussions on the key digital capabilities needed; possible strengths and challenges of the learning model; and ideas for its implementation in teaching practice.

The educators' written responses from all locations were then grouped under each of the questions to explore any patterns emerging. As a phenomenological method, we used theme identification as a "sense-making tool" to generate meaning and reveal different ways to think about problems and solutions (Dorst, 2011, p. 528). Specifically, a social phenomenological approach was adopted in analyzing the educators' written responses. In this approach, "people living in the world of daily life are able to ascribe meaning to a situation and then make judgments" (Fereday & Muir-Cochrane, 2006, p. 81). As an experienced educator and leader of learning and teaching in higher education, one of us undertook to interpret patterns and initial themes emerging in the subjective data (i.e., in the participating educators' written responses). Reading and re-reading the grouped responses "provided the opportunity to sense and take note of potential themes in the raw data," where both single and repeated comments were important (Fereday & Muir-Cochrane, 2006, p. 86).

The study is limited to the initial themes thus identified; and to the educators who chose to participate in the workshops, providing written responses to our seven questions in the worksheet. Whilst there were some 'early adopters' in teaching for new digital work practices, many participants in the different locations and disciplines said they were less experienced, particularly with technology affordances. Insights to their written comments are provided below, together with sample responses in italics and attributed only to a workshop participant's identified discipline (see also Peterson, 2018b). These insights and participant comments informed our development of resources to support educators, discussed later in the paper.

Educator workshops

Educator responses to industry themes on digital work/capabilities

Prior to the educator workshops, industry participants had highlighted the importance of two key themes: a) analyzing and making sense of data, particularly to inform customer experience and engagement strategy; and b) artificial intelligence (AI) and machine learning (ML), particularly in terms of business and social implications. At the educator workshops, participants were asked to indicate if these industry themes were familiar or surprising, and if they could suggest ideas for addressing the themes with their students. Many educators responded that, although they were familiar with such industry trends, they did not have well developed understanding of AI and/or data sense making for customer or audience experience and engagement, and many were not addressing these themes in their teaching. Some indicated that they had a stronger understanding of these areas and were already addressing them with their students, at least to some extent.

> *The degree I'm teaching, is IT and data analytics. We are just beginning to develop a sense of the true capabilities and business capacities for these. - Business participant*
>
> *Data analysis in Internet of Things is key – so in fact people learning about Internet of Things will learn (hopefully) to understand different types of data, communication of data, data processing, data storage, data services, data visualisation…in other words it's a good carriage for understanding things like data, also machine learning, and even customer experience because it drives you to think about it in an adaptive way. - Communication participant*

Ideas were put forward for maximizing student learning in relation to the industry themes above. Some educator workshop participants encouraged self-directed learning activities and assessment. Many recommended multiple authentic projects for students working with industry to undertake research and problem solving specifically targeting customer or audience engagement. Many also underlined the importance of having such projects throughout the programme of study, rather than 'once only' experiences.

> *Getting students to conduct interviews with customers and their experiences of a product/service and then make recommendations for a solution. - Education participant*
>
> *Engagement data, creating significance and understanding how the creative production is received is a crucial part of the discipline now. These may be addressed whole of course through iteration. - Creative Arts participant*

Learning model

After inviting the educators to respond to the industry themes identified in the project, responses were sought to the learning model proposed. An overview of the model concept had been explained at the workshops, which has also been disseminated in reports in the website (https://sites.rmit.edu.au/digitalworkpractices) and other publications (e.g., Fray et al., 2017; Jollands et al., 2017; Peterson, 2018a, b; Peterson et al., 2018a, b, c). Excerpts are provided below.

Model concept explained

The Digital Affordance Developmental Learning Model integrates technology affordance theory and developmental learning. Affordance theory defines a technology in terms of the uses, interactions and possibilities that the technology affords to its users; and affordances can be categorized – according to their potential for achieving outcomes – as Functional, Perceptual, Maintenance and Contextual (Best, 2009; Evans et al., 2017; Fray et al., 2017). These categories were adapted in the project and re-named as functional, perceptual and adaptive, defined as follows:

- Functional affordances relate to the operation of technology; this includes naming, knowing and operating the features of a technology/technologies to perform tasks.
- Perceptual affordances relate to interpretation and being discerning about technology tools and practices for their suitability and in-context operation for outcomes in known contexts.
- Adaptive affordances relate to imagining, adapting and extending technology use in previously unexplored and emerging contexts for innovative outcomes; this requires some functional knowledge/skills and perceptual experience.

(Source: Peterson et al., 2018c, adapted from Best, 2009; Evans et al., 2017)

As explained in Peterson (2018b), the developmental learning ideas integrated with affordance theory are underpinned by educational theory, including hierarchies and stages of learning with acknowledgement of the learner, environment, outcomes and increasing complexity; and highlighting the importance of reflection-in-action for professional learning and practice in unpredictable and new circumstances (e.g., Piaget, 1936; Bloom, 1956; Biggs & Collis, 1982; Schön, 1983; Gagné, 1984; Anderson et al., 2001; Scott, 2016).

Peterson et al. (2018c) describe a spectrum of capability within the functional, perceptual and adaptive layers, and suggest different emphases as follows. Each affordance layer spans introductory to advanced levels. Realistically, in the adaptive layer, we can emphasise imagination and 'seeing' possibilities, rather than expect that all graduates will be capable of true innovation with technology. We recommend multiple opportunities for students to practise integrating functional, perceptual and adaptive thinking, rather than see these separately forming a linear path. Affordance layers can also be emphasised at different times to suit the needs of students; however, as adaptive digital capability is highly sought after in industry, it would be vital for final year students to focus on this and be able to critically reflect upon and discuss their work accordingly.

Digital Capabilities Descriptors illustrate ways in which affordance theory can be interpreted for scaffolded or developmental learning about industry-relevant digital work practices in different disciplines. Descriptors interpret affordances in sample domains, which are categories of practice and related capabilities for existing and emerging jobs or work roles. In the Digital Capabilities Descriptor for Design, for example, one of the practice domains identified by the project Design team is Persuasion; and within Persuasion, the work activity of 'Storytelling' could be interpreted as follows (see Peterson et al., 2018c):

- Name and define narrative approaches, use software for visualization and interface design to illustrate/present/argue (Functional digital capability for Storytelling).
- Analyze data to tell stories, develop content using techniques appropriate to a range of media, critically evaluate stories (Perceptual digital capability for Storytelling).
- Work with generative systems, artificial intelligence/machine learning to tell stories, developing new tools and platforms (or new uses) to tell and disseminate stories (Adaptive digital capability for Storytelling).

Digital Capabilities Descriptors scaffolded in this way, using disciplinary language in a work context, can guide the design of assessment and learning activities to enhance existing curriculum, or for new programme and unit development. The team deliberately wrote the Descriptors for each sample discipline, as illustrated in the example above, to encourage embedding the scaffold in the curriculum for both existing and new courses/subjects/units with direct relevance to contemporary industry practice.

Educator responses to learning model: strengths and challenges

Applying functional, perceptual and adaptive lenses to using technology was noted by many of the educator workshop participants as a clear strength of the proposed learning model approach, which would address potential gaps in their own teaching practice. Building upon the earlier questions about industry themes, some participants also made further connections here to address industry developments such as artificial intelligence, the interpretation of data for customer experience, or application for social benefit.

> *Useful in qualifying expectations of students and for students. - Engineering participant*

> *I like this model – I think we can use these terms to explain to students where they currently sit on the digital capability spectrum and where they need to be to be employable in 5-10 years; the adaptive affordance can be used to develop creative approaches to problem solving i.e. how can big data be harnessed to map disease prevalence or public health programme take up. - Health participant*

There was wide support for the usefulness of the model, in terms of providing a framework for mapping curriculum in a whole programme of study. Through constructive alignment (see Biggs, 2003), the learning outcomes, learning activities and assessments would be clearly linked, with encouragement for students to make sense of their learning about technology affordances now and in future. Some participants saw the model as a useful way to emphasize the functional, perceptual and adaptive capabilities more at different levels such as first year versus final year, or undergraduate versus postgraduate. The student would move through learning outcomes of increasing complexity over time; for example, move from 'describing' something to 'proposing' as a more sophisticated outcome.

> *Well-structured approach to categorise learning outcomes. Allows alignment of assessment and content. Allows scaffolding across different units. - Business participant*

Some participants were more cautious in their responses, indicating that they saw the model as being necessarily linear and prescriptive. There were clear signals to the team to clarify, for educators and students alike, that the model reflects hierarchical but integrated affordance layers. Adaptive capability requires some functional knowledge/skills and perceptual experience. This may mean knowing enough at the functional level to interact effectively with specialists and imagine the possibilities, rather than having advanced knowledge and skills oneself. Furthermore, encouraging an integrated approach to affordances does not preclude emphasizing different affordances in the hierarchy at different times, depending on the learning situation and learner needs. Several respondents appeared to be more comfortable with the integrated affordance aspect of the model, encouraging other educators and students to be brave. The significance of motivation and positive feelings about learning and teaching in a supportive environment, for students and educators, was evident in several responses.

> *Work on own (and students') fears…move from functional pure focus to integrated focus between the affordances (functional, perceptual, adaptive) - Creative Arts participant*

> *Scaffolding from functional to adaptive. Self-driven experimentation, problem solving and collaborative oriented creative process/activity. - Creative Arts participant*

> *Students as co-creators of engaging assessments; using coding skills to build models that explain physiological processes like insulin's actions, action potential generation - Health participant*

Grappling with assessment surfaced in many of the educators' responses. Some indicated that the Digital Affordance Developmental Learning Model provides a useful way of thinking about scaffolded learning for capability development and assessment.

> *Could be scaffolded over several assessments. Helps us move beyond functional, which is where it mainly sits at the moment. Develops digital fluency, rather than mere skills. - Information Management participant*

However, assessing adaptive digital capabilities was identified by many participants as a real challenge with workload implications, especially where their own and students' adaptive (and other) digital capabilities might currently fall short.

> *Time and effort, staff capability, student acceptance and ability to learn especially adaptive affordance. - Business participant*

> *Students' resistance to move away from conventional 'job readiness' definition based on mastering of functional skills. - Creative Arts participant*

Educator responses to learning model: ideas and recommendations

When participants were invited to suggest the most useful aspects to focus on for student learning, several suggested that data analysis and interpretation should be prominent for perceptual and adaptive digital capability development, although functional cannot be ignored.

> *Adaptive and problem solving. We probably do a lot of 'functional' affordance teaching but need to ensure that digital tech features in our problem solving exercises, such as my capstone project. - Science participant*

Many participant responses underlined the importance of communicating with students about their digital capability development, using the vocabulary of functional, perceptual and adaptive affordances of technology; and of graduates being able to discuss their capabilities for digital work in affordance terms.

> *Opportunities to practice. Connect digital capabilities to job outcomes. - Business participant*

> *Create a matrix to cross check the functional, perceptual, adaptive across subject learning objectives. - Creative Arts participant*

Participants suggested ideas on student/educator interconnections, together with promoting attributes such as lifelong learning and resilience. There was again acknowledgement that educator capabilities need to be developed. Safety for risk-taking – by students and educators – was seen by many as an important consideration in implementing the model.

> *Ensuring that students are rewarded when they want to experiment. - Communication participant*

When asked about the first thing they would need to do, to make the model work for them with their students, many of the educators advocated again for a whole-of-programme action plan. Many intended to look at their curriculum for possible links to the model. They said that revisiting learning outcomes and assessment would need to involve discussion with discipline and industry contacts, for contextualization and identifying core technologies needed. Overall, there were renewed calls for closer connections and collaboration between education and industry, with encouragement for risk-taking raised again.

> *More collaboration between universities and industry i.e. learn about their needs; develop units on data e.g. Design and Big Data. - Business participant*

> *For specific disciplines, show where digital work practices are in the curriculum…how many [work integrated learning] projects relate to the digital future? - Education participant*

> *Find a way to collaborate among academics, students and industry participants that goes beyond current practices. In other words: reward new, daring projects. - Communication participant*

Respondents continued to return to the significance of motivation and positive feelings about learning and teaching in a supportive environment. Time for educator reflection emerged as a common theme. Some also described students as co-creators, and prioritized developing confidence in students.

> *Bring them along on the value of their understanding, and deploying of these affordances e.g. How will these affordances make me more employable? - Creative Arts participant*

Evolve it, i.e. using an action learning context, giving the power to the class/students. Have them as a student-centred approach to digital literacies and competencies - run an evolving development, self-generated learning environment. - Business participant

Incorporating more choice/options for choosing technology to complete assessment tasks. Equipping students with the confidence to explore digital tools to complete tasks and problem solve. - Information Management participant

Finally, we asked the participants how we could build on and improve the model, to help graduates prepare for work and meet industry needs. What should happen next? Several respondents underlined the importance of broad take-up of the model, supported by senior management as a priority. The needs for professional development and adopting a whole-of-programme or whole-of-school/institution approach were often raised. Some also said they were reluctant to engage in yet another 'fad' or university mandated curriculum mapping exercise.

Adaptive affordance area is enormous task. Need whole school approach to teaching. All staff need to know how to incorporate these skills. - Science participant

Developing confidence among educators for motivation is clearly a priority for many respondents, who often said they 'get' the learning model concept but need practical examples for its translation into practice. This need for examples also proved to be a strong common theme in the workshop responses.

More professional development for staff to have confidence to deliver. - Creative Arts participant

Practical example of each i.e. functional, perceptual and adaptive in different disciplines and how assessment is applied. - Communication participant

Enhancing teaching capability

The Design, Journalism, Music Industry and Engineering examples of Digital Capabilities Descriptors developed during the project are provided in the website (https://sites.rmit.edu.au/digitalworkpractices). The website also includes documentation of planning, learning activity and assessment ideas, and teacher reflections from pilot interventions undertaken with students, when elements of the Descriptors were aligned with actual curriculum in action. We believe that these samples of disciplinary contextualization may provide a starting point for colleagues to debate, adopt or adapt in their own teaching practice.

Professional development

A toolkit was created to support facilitators to run their own workshops to help other educators incorporate the Digital Affordance Developmental Learning Model into their teaching. The development of the toolkit built on the resources created for the project team's own educator workshops and incorporated feedback received from those workshops. The toolkit was designed to provide a guide, resources and ideas for running short workshops (1-2 hours). Suggestions were given for structuring a workshop with ideas for discussion and activities. These were supported by further resources and hyperlinks to relevant areas on the research project's website. Sample worksheets and slides that are easily adaptable were also included in the toolkit.

Three main topics were covered in the toolkit: first, an introduction to the learning model; second, selecting and developing digital descriptors for units/subjects; third, using the learning model in teaching.

Topic 1. An Introduction to the Learning Model

The first topic provides an overview of how the learning model was developed and why: a 'walkthrough' for the learning model, broadly exploring how the tools could be used and applied in the participants' own situations. Activities in the toolkit aim not only to introduce what the model is and how others have used it, but also why participants might want to use the model themselves.

Topic 2. Digital Descriptors for Your Unit/Subject

The second topic focuses on using and adapting the existing digital descriptors developed by the project team, with the possibility of extending the workshop to practice in creating new digital descriptors for the educator participants' units/subjects. The toolkit provides resources to guide educators through the process of identifying relevant domains of practice needing digital descriptors, checking the project website for existing

digital descriptors to use or adapt, and practising development of new descriptors if no suitable descriptors already exist in the website.

Topic 3. Using the Learning Model in Your Teaching

The third topic supports educators by developing and sharing ideas for how they might use the learning model in their teaching. The toolkit guide encourages workshop facilitators to ask participants to bring along their subject outlines and learning outcomes/objectives to work on them during the workshop. The toolkit provides resources to 'walk through' how to apply the learning model to the participants' curriculum and lesson planning, including activities to collaboratively develop ideas for using digital descriptors to adapt and create unit/subject learning outcomes/objectives and assessments. The toolkit also provides resources to identify challenges to implementing the model and brainstorm ways to overcome those barriers and constraints.

Encouraging flexible and adaptive uses

As the participants in the project's educator workshops came from a variety of disciplines and were attempting to apply the model to a multitude of different units/subjects, the toolkit aimed to support flexible and adaptive uses to help fit individual needs.

The toolkit was not intended to provide prescriptive direction; rather, it encourages facilitators to view it as a menu from which they could select (and add to) to develop workshops for their own requirements. For example, a workshop could cover all three topics sequentially, or focus on one aspect in depth. Discussion questions and activities could be selected, added to and tailored to the workshop focus and participant needs. The worksheets and slides were unbranded to further support facilitators to make them their own.

Integrated learning process

The investigators who piloted the teaching model in their classes as part of the research project reported how their understanding of the Digital Affordance Developmental Learning Model developed, through applying and shaping the functional, perceptual and adaptive concepts to their actual teaching context and practice (Peterson et al., 2018c).

We recognized that other educators may go through similar learning processes and could be supported by the toolkit and guide. On the functional level, the educators needed to know what the concepts were and how they could be used, so we provided an introduction to the model and core concepts, as well as examples of how the model could be used in teaching and why. On the perceptual level, educators needed to be able to develop the capability to discern and apply the model to known contexts. To support this, we designed activities to work with digital descriptors already developed, which had been tested previously. However, we found that most educators' contexts had differences from the researched cases. Educators needed to be supported in developing adaptive capabilities to be able to shape the model and tools to their own unique and emerging contexts. Thus, we created activities to support educators to devise their own digital descriptors in the workshop and then share and discuss them in the group, along with challenges and opportunities for applying them to their own situation. Just as the learning model encourages real-world projects to develop digital capabilities, so too does the toolkit encourage hands-on practice and reflection-in-action (Schön, 1983) during the workshops. Through use, application and adaptation, educators can develop their capabilities to use the learning model and tools across the functional, perceptual and adaptive layers. While these layers are hierarchical, they are integrated and are not simply linear.

Similarly, we developed the toolkit with the recognition that other educator workshop facilitators may also be learning about digital affordances and the learning model, in the process of designing and delivering these workshops – not just their participants. Teaching has long been acknowledged as an effective way of learning (Cohen et al., 1982, Fiorella & Mayer, 2013), so running workshops provides opportunities for educators to develop their understanding of the concepts and capability to use the model and tools. In undertaking the pilot research studies and developing the toolkit, we observed our own processes of capability development and found that working at the adaptive level further developed our capability at the functional and perceptual levels. We developed more nuance at depth at the functional level through application at the adaptive level, which in turn helped us develop that nuance and depth in perceptual capability for the contexts we already knew!

Hence, we endeavoured to design the toolkit to be simple and easy to understand for those who were new to the concepts, while linking to further resources that could be explored if facilitators and participants wanted to extend their learning. We acknowledged that this is an emerging area where we are all developing our

understanding and capabilities, so we encouraged facilitators and participants to learn from each other as they explore ways to support learners in new contexts. We shared teaching resources, such as lesson slides, from the pilot projects in the research study, as examples of different real-world applications rather than as exemplars. We invited facilitators and educators to share the resources they create back with the community for the project website.

Implications and further research

This paper has focused on the findings of workshops on the Digital Affordance Developmental Learning Model, with our initial responses to the participants' feedback in terms of developing professional learning support for educators. As experienced educators ourselves – in Design, Communication and/or Business at different universities – we have revealed our own team's professional learning journey in the design, development and implementation of the learning model.

The preparation of new graduates for emerging jobs that have new definitions and activity requires a differing approach to how they may have been educated in the past. Graduates need the ability to frame their skills and abilities in industry-relevant terms. What we have explored in this paper has focused on supporting educators with the implementation of a Digital Affordance Developmental Learning Model, designed to support the growing need for explicit incorporation of digital capabilities into subjects/units and mapping across a whole programme/course experience for the student.

Our work with educators highlights an opportunity for programme/course teams or universities to take the lead in shaping emerging practice further with industry, in relation to aligning learning and teaching practice with industry needs. As an example, an ability to interpret data for strategic decision making and customer/audience/user engagement, as well as using artificial intelligence and machine learning, is highly sought after in industry (e.g., CEDA, 2018; WEF, 2018). However, as one educator workshop participant lamented:

> *There doesn't seem to be a sense of urgency in some parts of Higher Education to respond and adapt to these emerging [industry] themes. - Education participant*

Whilst it appeared that not all workshop participants are addressing these trends in their teaching practice, they did suggest ideas such as industry projects based on speculative scenarios. There was also mainly positive feedback about the proposed learning model, with participant suggestions for teaching practice ranging from introducing a functional 'bootcamp', to elevating perceptual and adaptive digital capability development through collaborative 'messy' problem-solving projects related to data, and work integrated learning projects specifically related to digital work futures. Creating 'self-generated learning and development environments' for students, and helping students to learn and use the vocabulary of affordances including their industry relevance, were also seen by the educators as being especially important. Several considered this would strengthen professional learning and counter any student perception of all jobs requiring only functional skills.

Furthermore, the educator workshops revealed the need for professional development and resources to underpin new approaches to preparing graduates for a changing world of work. We found the workshops created a valuable space for educators to reflect on, share and co-create new teaching and leadership practices.

The approaches suggested to enhance teaching capability for transition to an adaptive digital capability focus highlight further research needed. This includes scaled-up implementation of the Model with students. Longitudinal studies would be vital to evaluate outcomes for graduates who have experienced the Model. Further research on the professional development of educators and how they can be supported to apply and adapt the Model in their professional practice is also needed across disciplines. At a time when 'quality' in learning and teaching has different meanings and is under-researched, despite the increased focus on quality and implications of its measurement in higher education (Strang, Bélanger, Manville & Meads, 2016), it is vital that we continue to explore ways in which the actual student learning experience can be enhanced with tangible outcomes, in terms of work futures and digital work practices.

Democratizing Design: Can higher education survive?

KELLY Rebecca

Syracuse University, US
rdkelly@syr.edu
doi: 10.33114/adim.2019.08.402

The tools and techniques of graphic design have become accessible to the public at large to such a degree that the profession itself may be threatened with extinction. At the same time, design literacy — the knowledge and reasoning beyond the use of those techniques — does not seem to be experiencing the same widespread dissemination. In order to re-establish its value, the design profession must introduce a higher level of insight beyond the mere the decoration of artefacts – an ability to understand "big picture" concepts and to work across disciplines to become involved in every step of a project, from concept to completion. Thus, U.S. undergraduate design education must change as well. Educators must be innovative in order to prepare a new generation to evolve quickly and continuously. Programs must be fluid and adaptable, which requires educators to treat their curricula as design problems, to be solved with radical thinking and creativity.

Keywords: design education, design curriculum, graphic design, visual literacy, critical thinking

Introduction

The democratization of design refers to an increased access by the public to graphic design tools and the proliferation of digital venues in which to use them. The software is readily available. Fonts, image manipulation tools, page layouts, ready-made graphics, are all instantly accessible. Herbert Simon suggests that everyone is a designer (1969), but not meaning anyone with a computer and internet access, but in a deeper sense, that anyone who solves problems and improves situations into better, preferred ones. On the social media site, Dribbble.com[1], which promotes itself as a platform for graphic designers, over half of the users describe themselves as having little to no formal training in design, yet they are practicing design (Hemsley, J & Kelly, R. 2019). They have access to the relevant tools and thus identify as designers. However, in *Design Literacy: Understanding Graphic Design*, authors Steven Heller and Rick Poyner highlight the challenges of developing creative proficiencies and conclude that formal aspects such as type and image comprise one small portion of a much larger framework of literacy competencies that includes persuasion, identity, mass media applications, and much more (2004). Yet many people walk through their careers unable to see its influence – and thus unable to harness the power of design to make their work and businesses more effective. By giving non-creative employees the tools needed to improve their design awareness, their ability to explore it in their work, and a structure for collaborating productively with internal and external creative teams, everyone benefits.

Sites such as this reflect a "preoccupation with 'form'" that limits designers to the act of two-dimensional decoration (Welch, 2011). Focused on the treatment of formal elements, they merely regurgitate the known—what has been done before—instead of conceptually reinterpreting the known to create something new. This

[1] https://dribbble.com/

distinction is significant; without context and concept, form becomes far less meaningful and the role of the designer becomes devalued as the boundaries between amateur and professional are blurred (Fleischmann, 2013). The consequences of this practice can be precarious for the profession. “True design literacy requires a practical and theoretical understanding of how design is made and how it functions…which takes years of learning and experience to acquire” (Heller, 2004).

So where does design education factor in the current paradigm? Programs that focus on teaching the technical aspects of design, the tools and techniques and software proficiency, may run the risk of being supplanted by online resources that can offer the same or more up-to-date training at a lower cost and greater convenience. As it becomes more difficult to ignore online learning sites, programs are faced with limited options: acknowledge and incorporate these sites as parallel teaching tools or split entirely from teaching technique and leave that responsibility to the internet. So, the value of a higher education in design may lie in teaching higher-level skills such as the ability to engage in design thinking, build a foundation of visual and design literacy, and direct those skills toward preparing the designer of the future as not just a problem-solver but a problem-seeker proficient in design and critical thinking. What Welch refers to as “creative insight,” the ability to use both associative and analytical thinking, and toggle easily between the two, allows the designer to make new, unexpected connections which leads to novel solutions (2011) that transcend the technique-oriented online resources. In addition, higher education can, and should, emphasize design thinking as a human-centric means of approaching problems from different perspectives, not only in design but as an approach to education in general. In a wider sense, design programs should produce “’critical minds and creative thinkers,’ a skill that cannot be attained from online courses or in self-study mode,” unlike the basic fundamentals. (Fleischmann, 2015a). Technology has altered the way in which we work as designers. Perhaps it has a role in providing instruction up to a point, but design education must find a way to either work alongside (Fleischmann, 2015b) or completely separate from and beyond the online resources to maintain relevance and value.

Background. The relationship between technology and design.

What was once the best friend of the design profession—*technology*, with its essential tools greatly simplifying demands of the job while allowing for boundless excursions into new levels of creativity—is now a challenge to its very existence. In the visual design field, technology has played a supportive role, simplifying a designers’ daily routine tasks and responsibilities — a role it has played so well that in many ways it now appears to be on track to replace the designer entirely. Stock photography, stock illustration, web templates, business cards, billboards, banners, packaging, presentations, publications, animation, logos, layouts—practically all of the artifacts a designer typically creates - can be obtained at little or no cost by anyone with a computer.

The state of traditional design education, as well, is under threat of replacement by technology in the form of workshops and lessons on YouTube, Skillshare, Lynda and inLearning, to name a few. (Fleischmann, 2013) In the early part of the twenty-first century, online learning was already making the traditional education system “extremely uneasy,” with the potential to trigger “evolutionary” changes in the establishment (Singh, O’Donoghue and Betts, 2002). While Massive Open Online Courses (MOOCs) have not yet replaced higher education, their impact is significant enough to warrant a reevaluation of current education practices (Fleischmann, 2015b). It can be assumed that their influence will only increase with technological advances (Fleischmann, 2015a). The rise of these resources, and the fact that there is a legitimate concern over quality control stemming from a lack of skill verification of their “instructors” has led to discussions of certification or accreditation (Karnjanaprakorn, 2012). Were this to happen, it would become even more imperative for university programs to evolve in order to maintain relevance to the profession in order to compete with the entities offering certificates meant to set them apart with more substantial validation. A study of the impact of online resources on the profession and education needs to be pursued, and, in fact, further research into this subject is ongoing and will be included in a subsequent phase of this project.

Due to the revolutionary changes in the industry, design education must evolve, but to what degree (Fleischmann, 2013)? The industry understands that evolution is natural and, in this paper, we are investigating what education is doing to remain relevant. Initially, design was developed as a “trade” in response to the industrial revolution and its alignment with the masses—in this case, communication to the masses. So, what began as an “applied art” during the 1920s moved from a follower of production to a formal

field of study of higher learning with the development of the Bauhaus (Cabianca, 2016)[2]. And design has remained in this position, working with technology, both as leader and as a partner depending on the moment, during which education in the U.S. has generally made small adjustments while many maintain the traditional Bauhaus model. To be sure, the dialogue concerning the need to evolve in response to technological advances has continued for over a decade, (Fleischmann, 2015b) with the issue becoming steady more urgent until there currently exists a "need for radical change in design education" (Fleischmann, 2013). Attempts have been made in the form of experimental program models at various institutions, but a definitive answer in the form of a solid curriculum shift has yet to surface.

According to the *AIGA Designer 2025* report entitled, "Why Design Education Should Pay Attention to Trends," technology is relentlessly reshaping the profession as we know it. Where designers might have once been masters of this technology, "design approaches of the past will struggle in keeping design relevant and…the field risks losing influence to other disciplines" (2017). As technology presents new and revolutionary ways of communicating, the traditional designer risks falling behind and becoming irrelevant. There is a certain danger in following trends; designers can easily become dated and passé as technological, cultural and visual trends cycle more and more quickly. There is a certain danger in not following trends as well. When designers become stagnant and unresponsive to the audience they attempt to reach, they risk being left behind altogether. Trends can be misleading, however, especially when looking at the short-term (within five or even ten years) when programs are producing professionals who plan to stay in the field for several decades (Davis, 2008). Vast, global trends, or paradigm shifts, must be identified within the constant stream of changing ways in which we communicate and interact in order for design—and design education—to once again take the lead.

At one time, designers were the trendsetters, the pioneers who influenced what would become cutting-edge and culturally-defining in the visual landscape. Now, it seems that role is being appropriated by entrepreneurs, engineers, and executives. The designers follow, taking their ideas and beautifying them — however, algorithms may take this away as well. Matías Duarte, VP, Material Design at Google, predicts that "in five years machine learning will enable computers to make the kinds of aesthetic choices that humans make today" (LaBarre, 2016). In fact, it has already happened (Leow, 2018). Where does this leave the designer? It is no wonder that the "prevalent belief in design as a service industry permeates…the culture of design as a whole." (Welch, 2011) This is exemplified in the social media site, Dribbble.com, with its "designer" users "caring only about form" and aesthetic decoration without concept or function being considered (Abehsera, 2013). Where does this leave the educational system that still focuses on this model?

Considering the pace of technological changes in design, how does design education prepare students, in a four-year program, to stay relevant in a networked society (Fleischmann, 2013)? How do we teach them to not only survive but excel as leaders and forward thinkers throughout the commercial sector? As referenced in the AIGA Designer of 2025 report, the traditional curriculum that involves teaching skillsets that build upon each other toward communicating a message to a passive audience no longer reflects the reality the designer will face upon entering the profession, (2017, Flew 2008), and yet colleges still utilize this approach as the basis in their classes. On the other hand, building a curriculum based primarily upon teaching the software *du jour* only compounds the central problem of designers becoming followers of technological trends rather than leaders and forward thinkers. In order to not only maintain design sustainability but regain the leadership role in driving visual communication, something more dramatic, more revolutionary must take place. The curricula developed within serious design programs must address the sea change facing our industry—the speed and efficiency within a university's design curriculum must improve, and not "bury their heads in the sand" (Davis, 2008). To survive, educators must be open-minded about the extent to which the nature and function of classroom must change, dramatically and quickly. It is imperative that educators remain in touch with the industry, through personal work experience or communication with alumni, in order to track the changes as they happen. And it is equally important that they implement changes based on their observations into their teaching methodologies and project development to equip students for the environment they will encounter post-graduation.

A current trend in design education is for universities to focus more heavily on research and theory as a form of validation of their area of focus, as opposed to practice. While this direction is a kind of response to the

[2] The Bauhaus School was developed roughly around 1920. The school was a movement of higher-level thinking about the blending of art and design in response to mass production; a fear of a loss of purpose for art and design. It was founded by Walter Gropius in Weimar, Germany.

evolving field, it may in fact further weaken the impact of education (Werner, 2015), and add greater separation between education and practice for the students ultimately entering the workforce (Friedman, 2016). If professionals in the field largely ignore the research being generated through academic institutions, no matter how applicable or prescient, what value does it bring? Alternatively, professionals who engage in research largely fail to disseminate their work to scholars or collaborate with students in the process (Davis, 2008). This mutual exclusion further exposes the division between the two, as well as the fact that education is potentially losing its relevance to the practice and vice versa. A survey conducted among 35 professionals across the U.S., at different stages in their careers and possessing a variety of design-related job titles, strongly suggests that academic research is not reaching those in professional practice, which is further supported in additional studies (Huber, 2017).

RQ1: How do you stay current within the design industry?

A: Non-academic articles, professional conferences, online training

RQ2: Do you stay current with design research from academic institutions?

A: No (77.14%), Yes (22.86%)

Paradigm Shift. Obsolescence can lead to new opportunities.

So, technology advances, jobs and industries die out. This process makes sense. We no longer need blacksmiths other than at 19th century village reenactments; we no longer require the services of the samurai, except perhaps in Hollywood. However, when the process is occurring right now, with a speed seemingly unmatched in history, the fear of the unknown can easily overpower objective logic and reason. The need to predict what will occur and plan accordingly becomes urgent for those affected by change.

To follow his theory regarding the loss of 50 percent of existing jobs, Erik Brynjolfsson concludes that "hopefully another 50 percent of new jobs will be created at the same time" (What Parts, 2017). Historically speaking, there is reason to be optimistic. As coal and the fossil fuel industry began to decline, entirely new positions surrounding renewable energy have sprung up. According to the 2017 U.S Energy and Employment Report, "nearly one million Americans are working near- or full-time in the energy efficiency, solar, wind, and alternative vehicles sectors…almost five times the current employment in the fossil fuel electric industry" (2017).

In another example, the sharing economy, which has grown out of technological advances, has affected a variety of industries. Ride sharing, for instance, has clearly impacted the income of taxi drivers in urban centers. However, according to Forbes, "Uber has created more jobs than it has destroyed, demonstrated by the staggering expansion of self-employment following its introduction" (Study Explores, 2017).

In the design field, new positions are becoming more and more prevalent. Among them, design researcher, integrated designer, digital designer, UX (user experience), UI (user interface), social media designer, and a continuing stream of emerging titles, such as service designer and usability expert, (Dziobczenski, Person & Meriläinen, 2018) stand out as emerging distinctly from current technological trends. All of these titles surround the same basic responsibilities: developing a targeted profile of a particular user of a specific digital technology, and/or customizing the interface in order to create the most visually and functionally inviting experience. The fundamental principles[3] are the same as they have been since the dawn of design: to communicate a message in the clearest and most visually-interesting way to its audience. There now appears to be a distinct difference in one of the factors affecting this long-standing model: the audience itself. Traditionally, the group which a design was intended to reach has been defined in "broad demographic terms, targeting them as passive consumers of segmented marketing" (AIGA Designer 2025, 2017). But with new technology, the audience is able—and eager—to provide constant feedback, responding in real time to the visual and verbal messages presented to them. They are involved in developing and disseminating those messages as well, and for the designer, there is no longer time to track the results of a campaign, analyze the return-on-investment, or handle unexpected crises when everything is happening live with no down time. The audience is simultaneously huge and solitary, with potentially massive amounts of people on a network and

[3] The fundamentals of design are the proficient use of the principles and elements of design: The elements of design generally include line, value, color, texture, form, space and type. The principles of design – balance, isolation, proximity, contrast, hierarchy, repetition and movement describe how they are employed in a composition, in addition to the communication of the message to a specified audience.

everyone expecting a personally tailored experience.

Further, there is evidence of a shift from design as a service industry, merely answering to specific requests of a client, to a more "cooperative model" in which the designer engages in the process much earlier on, working with the client at the beginning stages of a project to help direct outcomes (Welch, 2011). The T-shaped model for design expertise, in which the designer is familiar with a broad spectrum of related fields, and an expert at one, may be giving way to a "reverse-T," in which designers are rising vertically through a corporate structure to use their problem-solving skills for more than visual design solutions (Baratta, 2017)**.** The skills developed though the process of design thinking become applicable in all facets of an institution's operation and designers are thereby imbued with a unique added value. According to Terbo, a Pi-shaped model described the most effective designer thinkers, who "go deep in two areas and are able to find unexpected connections between the two" (Baratta, 2017). The ability to make novel and unexpected connections can be useful regardless of position and discipline, and truly sets this new designer apart from those of the past.

What skillsets must be taught, then, in order to exist and thrive in this new paradigm? The basic process of developing effective visual imagery that was once at the core of the profession could shift or become secondary to a new mandate. At some point in many programs, the focus on the "why" was replaced with merely teaching the "how" through software and technical skills. High-level thinking, theoretical insight and analytical skills have receded as a consequence. In a survey of 45 students at various stages in their academic careers at multiple universities, the following question was posed:

RQ3: Is it better to understand the "HOW" or "WHY" with respect to design?

Fifty percent of the students named the "how" as the main thrust of design education, while only twenty-five percent thought the "why" was most important. Without experiencing the reality of design responsibilities in the profession, do these answers reflect only what the students are being exposed to in the classroom? A survey of 55 design professionals yielded contrary results. Generally, once in the field, more value was placed on skills that could be derived more from studying the "why."

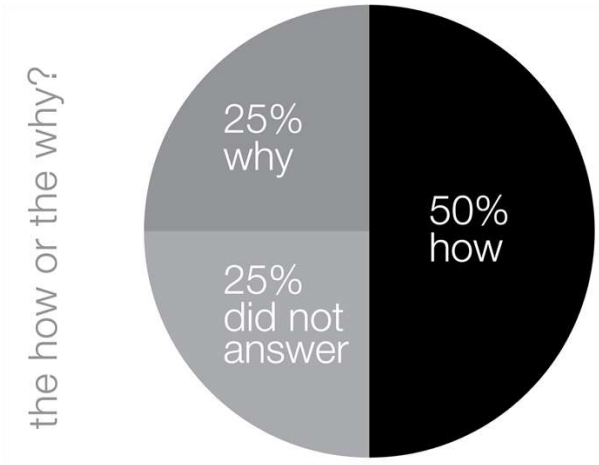

Figure 1. Student survey results: Is it better to understand the "HOW" or the "WHY" with respect to design?

RQ4: What are the qualities the professional world values in new hires?

Answers included "far more than just communications design," (Kelly, 2019) such as critical thinking, active listening, empathy and ethics, storytelling, and co-creative functionality, as well as the ability to face larger, unknown challenges, understand the enterprise user, contribute from a corporate angle, work with experts from multiple fields, demonstrate a global perspective, partner at planning stages—a hybrid professional with skills and formal education in two or more disciplines.

The disparity of what seems to be happening in the classroom and what is currently valued in the workplace is made clear in a comparison of answers to the previous questions. Dating back to the early 2000s, educators have indicated that design education was in danger of becoming outdated or at least threatened by emerging technology, lamenting that digital media had "rendered obsolete what we thought we cared dearly about" as far back as 2001 (Fleischmann, 2013). Without question, a reconsidered approach to teaching a new generation of designers is warranted. Adaptability, collaboration, and a certain affinity for the unknown

(Monahan, 2002) now seem to be the attributes most central to the success and sustainability of the new designer. Would the evolved practitioners of “communication design” even be recognizable to their counterparts a mere 20 years ago?

Starting Points. Preparing the new designer through higher education.

Where does this leave the design educators? How does one teach students to adapt, stay ahead of trends, and maintain relevance in a networked society? According to NPR’s Ari Shapiro, a liberal arts education may provide one of the best chances to keep creative industries such as design from becoming extinct (What Parts, 2017). The classroom experience provides unique opportunities that are notably absent from online learning. In a studio environment, many factors come into play, including an element of chance (Crowther, 2013) and random associations derived from critiques or conversations with faculty and fellow students. The classroom affords a flexible pedagogy (Crowther, 2013) that can be tailored to best suit individuals or groups, and present unplanned lessons in response to classroom dynamics. But finding the most effective approach to educating the new generation is far from guaranteed.

It is the mindset of the entrepreneur that drives technology, not necessarily the other way around, and this mindset can help position designers as leaders and big-picture thinkers in a way that will make the field less threatened by automation. Designers have always been problem solvers, taking the directives and conditions of a client and brainstorming creative visual solutions. But this, too, must be elevated in order to add value to the field at large. Instead of passively waiting for others to present their problems, designers must seek out problems to solve—beyond those which require a logo, a packaging system, website, annual report design, or other typical project staples that remain relatively unchanged. Actively addressing prominent issues with global implications and using their inherent ability to approach them from unique, creative perspectives would help designers secure their role in the emerging economic landscape.

Collaboration—an idea not unfamiliar in agency and studio settings—also becomes a critical concept beyond the traditional designer/art director/account service/copywriter partnership. Collaboration beyond the designer’s inner circle is becoming a key to survival. The founder of Fuseproject, a leader in product experiences and cohesive branding, Yves Béhar emphasizes the key point, “Design is more and more central to the success of the modern business; designers are no longer being brought in at the end of the process to make things look pretty, but rather are providing essential insights from the ground up” (LaBarre, 2016). If it is such an important factor, why does it not play more of a central role within a greater number of university systems? More and more often, designers are expected to understand principles of business, economics, sociology, statistics, psychology, and data science, to name a few. Part of Herbert Simon’s proposed theory of design involves the “organization of complex structures” which necessitates collaboration among participants with diverse experiences to achieve variety within solutions (Simon, 1969, Santos & Tschimmel, 2018). Design itself can connect individuals across disciplines as a “common creative activity” (Simon, 1969), whose processes can be understood to have significance for problem-solving in any context. It breaks down boundaries and provides a common language between professional fields. Therefore, designers who move to a more diffused type of thinking can expand the relevance of their work beyond their immediate discipline. The new designer must embrace understanding and working with disparate areas of an industry whose audience has moved from mass communication to a “networked communication model” (Cardoso, 2008). With the audience more connected than ever, within that realm of new modern demographic mapping, how can tomorrow’s designer begin to truly understand how to reach, speak, and design for this unique market Collaboration (Fleischmann, 2015b)?

Design programs that refuse to acknowledge this reality and continue to focus solely on visual aesthetics may soon find themselves falling behind and unable to catch up. As Tim Brown, CEO of IDEO, explains, “‘Design’ is no longer a discrete stylistic gesture thrown at a project just before it is handed off to marketing. The new approach taking shape in companies and organizations around the world moves design backward to the earliest stages of a product's conception and forward to the last stages of its implementation—and beyond” (2009). Merely concentrating on well-designed typography, eye-catching imagery and clever messaging—even expanding to include the latest technology and trends—may not be enough to sustain undergraduate programs when the designer’s role is becoming much broader. This change in role and the accelerated evolution of the profession presents a difficult situation for design educators. If students are entering a program with increasing amounts of technical knowledge, how is faculty expected to keep up? (Fleischmann, 2013) More so, in college and university programs where curriculum updates can take an average of two to three years from idea to implementation, keeping up with the industry—much less, leading it—seems

practically impossible.

It begins to become apparent that certain steps must be taken to address the obstacles facing design education under the current conditions within the industry. First, based on observations and studies regarding university programs across the U.S., a lack of consistency permeates the naming conventions of course descriptions, course titles and programs themselves. The table below illustrates some of the myriad ways in which facets of visual design are described within higher education.

degrees	program titles	housed with
	Graphic Information Technology	Engineering College
Studio Art: GD Emphasis	Department of Visual Arts and Media	
Bachelor of Design, in GD	Design Department	
GD Programme	School of Art + Design	
BFA GD	School of Art	
BFA Emphasis GD/BFA Visual Art	Department of Art	College of Fine Arts
Bachelor of Design	Visual Comm Design Prog: Div of Design	School of Art, Art History, Design
Bachelor in Graphic Arts	Design Department	
BA, BFA, MA, MFA,	School of Vis Comm Des	College of Comm and Information
	Visual Comm Design	Art, Art History, Arch, L Arch, Urban and Reg Planning, Environmental Design
GD, UX, Game Design	School of Design	College of Comp. and Dig Media
BFA: Communications Design, MFA Exp	Department of Art	College in the Creative Arts
BA	Integrated Media Arts Program	Media and Integrated Arts
BFA concentration GD, Digital Media	Dept of Art and Design	
BFA GD, Interactive Adv, I Print/Screen	School of Design	
AAS, BFA Design	Communications Design	
BA GD, Inter, AAS, Visual Communication		
BFA GD	Department of Art	School of Art
BFA GD		
	Communications Design, School Design	College of Design, Arch, Planning
	Vis Communication Design	Communication
	Vis Communication Design	School of Art and Design

Figure 2. A small pilot sample of differing names of degrees and programs within visual design

Even the departments with which visual design is aligned within colleges can be telling. Some institutions associate design with fine or performing arts, others may combine it with architecture or other design disciplines, while yet others may be aligned with business and marketing schools. This, in itself, demonstrates the identity disconnect with which design has been plagued over the past decades. Further study comparing programs within the U.S. and abroad, including curriculum structure, course content, outcomes, etc. will be conducted in order to gain a broader view of the ways in which design is currently being defined and implemented. For the sake of consistency and clarity, it would benefit the field to consider agreed-upon titles and definitions that would be used to describe itself. If a field which counts branding and identity development among its most basic functions is unable to clearly communicate its own nature to its practitioners, how are others outside the field expected to understand and respect its role?

Once the naming conventions have been established, the dichotomy between the traditional, form- and technique-based model and the newer model dealing with complex interacting systems—what Davis describes as "design as a craft and design as a discipline" (2008)—may be examined. Ultimately, it becomes evident that including everything in a single program's curriculum is unrealistic and the two must diverge as separate paths with trajectories toward building completely different skillsets. As addressed in the *First Things First Manifesto 2000*[4] (Lasn, 1999) the idea of shifting the mindset of designers from simple commercialism toward "broader contexts" with farther-reaching social and cultural goals illustrates a need for this type of philosophical separation (Kelly, 2005), irrespective of technological considerations which were at the time just beginning to be felt. The types of higher-level projects in which some programs may be engaged at the graduate level need

[4] Lasn, Kalman, et al. 1999, URL: http://www.eyemagazine.com/feature/php?id=18&fid=99/

to be provided to undergraduates, as practicing designers typically do not go on to earn graduate degrees, but such skills are becoming more and more vital in the workplace. Of course, there is no proven correct way to approach an education that prepares students for increasing complexities and constant technological advances, but the need for an attempt is more urgent than ever (Fleischmann, 2013). Perhaps changing the mindset of educators and curriculum developers is a place to start (Santos & Tschimmel, 2018).

In order to expect our future designers to be innovators, this new curriculum path must be designed and innovated as an emerging field. So, what might a study to effectively build an undergraduate curriculum for the new design look like? If problem-solving is the act of representing the problem in a new way that makes the solution evident (Simon, 1969) would it not make sense to treat a design program as a design thinking exercise (Santos & Tschimmel, 2018)? With a diverse team of experts asking better questions (Monahan, 2002) challenging existing methodologies, projecting what does not exist, analyzing, comparing and contrasting philosophies, inverting, substituting, poking holes, prototyping, revising and starting over again, a new approach to the curriculum should present itself. A carefully considered series of steps could help narrow the focus on the most relevant skill sets and build a curriculum responsive to the demands of the evolving profession.

Treating curriculum development as a design thinking project, the first step is to define the desired outcomes, i.e. what we want the designers of the future to be able to do. With the formal/technical branch of design more than sufficiently fulfilled through many existing programs and MOOCs, this new direction would focus on the higher-level problem solvers, able to facilitate any wicked challenges, regardless of context, situation or discipline. The new curriculum would begin with a process of deprogramming the students entering the program; un-training them from previous teaching methodologies (Kelly, 2019) that may not have taught them how to adapt, apply knowledge to different situations other than to repeat from rote memory, (Kainose, 2014) and to fail successfully (Sutton, 2007). The tendency to teach to the test in grade school has severely limited students' ability to think *beyond* the test. With all emphasis being placed on coming up with the correct answer, to get the "A" by any means necessary, students have been robbed of the opportunity to experience failure as a teaching tool (Sawyer, 2018), to discover knowledge on their own through trial and error, and, most importantly, to recover from setbacks and adapt their thinking as they receive feedback and data that indicates their first solution is less than perfect. When the world is presented as correct or incorrect, with no gray areas or shades of meaning, and when being correct leads to promises of eternal success, it becomes all-important to avoid being incorrect. Surveys of current design students established that the fear of the unknown is a key factor in their classroom behavior. Additionally, the goal of getting the "A" is the top priority for the majority of students across many programs and grade levels (Kelly, 2019). These results justify the need for further large-scale studies and warrants discussions to begin to address these issues in the overall higher education curriculum conversation.[5] As put by Ken Robinson, international advisor on education in the arts, "If you're not prepared to be wrong, you'll never come up with anything original."

Even more importantly, a deprogramming of the faculty must take place. Faculty behavior, like that of their students (and people in general) shows a psychological reticence to engage in new and innovative processes – even while most acknowledge the changing environment for which they are supposed to be preparing students (Davis, 2008). There is an inherent defensiveness when confronted with the concept of "learning" (Tagg, 2012) and they do not want to appear unprepared to teach; therefore, they fall back on the safe, tried and true curriculum, but their resistance to evolve is amplified through ties to an industry that tends to evolve seismically in short periods of time. "Four-fifths of provosts at doctoral research universities reported greater faculty engagement as their number one challenge" (Kuh, 2009). So, the task of deprogramming and energizing faculty to meet the demands of the new field may be as daunting as it is imperative, but students cannot evolve if their teachers fail to do so.

Success and failure, target audience, visual aesthetics, messaging and idea generation would be redefined and no longer considered in the traditional sense. Student learning and experimentation could actually improve without the distraction of a grade and the fear of failure weighing on them (Flaherty 2019). New forms of project evaluation and grade assessment would be explored. The design process itself would act as a vehicle for assessment (Crowther, 2013), engaging in the steps necessary to invent, test, and reinvent a solution or multiple solutions. Failure along the way would be expected as an "unavoidable part of the creative process"

[5] Of the students studied, 78% said that receiving an "A" was very important to them and 62% commented that their "fear of the unknown" with regard to the potential success of a project or the opportunity of submitting a less creative solution for a guaranteed passing (but not exceptional) grade.

(Santos & Tschimmel, 2018), and rewarded to a certain extent in order to remove it as an obstacle to experimentation. An "A" is not an option. Integrated design teams and interdisciplinary courses with students in revolving roles would be employed, positioning engineers as designers, business students as engineers and designers as business majors. As the "core of all professional training" (Simon, 1969), design offers a common language to the different groups, a starting place for the exchange of ideas on which they can build unexpected solutions. Innovation and entrepreneurial courses, research-driven courses, and adaptability-centered projects would be established, with "What if?" problem-solving curve balls thrown in the mix.

There is much work involved in creating any curriculum; developing one with such revolutionary overtones in an industry that has very strong traditional practices seems extraordinarily challenging, but the profession is undoubtedly changing. More and more responsibilities of the traditional graphic designer are being automated, devalued and digitized. Like it or not, the design survivors are those adapting to the changes, and the educators would require the built-in ability to adapt as well—and adapt quickly. Although design thinking has rarely been used to develop an educational system (Santos & Tschimmel, 2018), it seems particularly appropriate in this case. The process of self-evaluation would be necessary at regular intervals, possibly following each semester. Obsolete or ineffective courses would be removed, and new courses included, based on the trajectory of the field as indicated by professional and graduate feedback. This degree of flexibility is not typical of institutes of higher education, so implementing it in practice would most likely face plenty of hurdles. However, designers are the makers, the trendsetters, the pioneers of an unknown future and as educators, we are responsible for enlightening and inspiring the design thinkers of tomorrow. If successfully preparing our students to survive the ongoing paradigm shift means a separation from stagnant traditions, we should honor our past by celebrating our future.

While knowledge of design thinking (DT) processes and familiarity with its tools can be achieved relatively quickly, few educational programs foster a DT mindset. This study examines the effect of an experiential DT learning environment on the development of a DT mindset. We analyse the extent to which key attributes of a DT mindset are understood, evaluated and assessed. We show that the general value and related challenges of learning a DT mindset are well understood. However, students perceive the importance and value of particular mindset attributes differently; in particular, postgraduate student reflections provide a nuanced and interlinked view of different mindset attributes. We provide a framework for learning objectives and exemplary activities to teach and encourage designerly ways of thinking and doing in business education. We argue that a mindset that embodies DT can address deficits in business school education, better preparing students for future work.

Keywords: Design Thinking, Mindset, MBA, Creative Confidence, Education

Introduction

To help managers develop innovation capability, many business schools have started including design thinking (DT) in their curriculum (Garbuio, Dong, Lin, Tschang, & Lovallo, 2018). The Financial Times describes DT as 'the skill that every MBA students' needs (Stigliani 2017). However, to realise the full benefit of innovation initiatives, educational DT programs have to do more than convey knowledge about DT and its tools; they must also develop creative confidence (Kelley & Kelley, 2013) and foster an innovation mindset. Hence, we wonder how business schools can teach DT to encourage designerly ways of thinking and doing.

DT is as much a mindset as it is a process and set of tools. Both aspects have important implications for the improvement and innovation of businesses. As a process and set of tools, DT informs and shapes practices of dealing with complexity and solving issues. Applying the iterative stages of a typical DT process includes deep empathy with end users, reframing of the problem area, ideation, prototyping and testing. As a mindset, DT refers to the underlying values, cognition and resulting behaviours that, over time, find their way into the beliefs of people and culture of organisations. While individuals and whole organisations can adopt the processes and tools of DT and learn new innovation practices over time, it is the mindset that helps innovation objectives to be achieved at a deeper and more sustainable level.

Micheli et al. (2018) identify key processes, methods and tools of DT. While not explicitly distinguishing these from the cognitive and behavioural attributes of DT, they raise a number of research questions for further study, including 'what constitutes a design thinker and what kind of training and practice is needed to become one?', 'what is the relationship of DT with organizational culture?', 'how can the acquisition and effectiveness of design thinking skills be assessed?' and 'what are the results of introducing design thinking in MBA curricula?' This study explores these research areas through analysis of an experiential learning program that employed instructional methodologies and activities to facilitate the learning of DT.

We explore the value of DT for postgraduate business education—that is, we explore whether and how participation in a DT curriculum affects a student's ability to innovate, and whether a DT mindset can be taught and practised via experiential learning.

Literature Review

Design Thinking as a Mindset

Innovation literature has placed increasing importance on design as an integral capability for innovation and adaptation (Dodgson, Gann, & Salter, 2005). Organisations are trying to integrate the design approach to solve complex social problems and issues of organisational management, and to explore greater synergies between business strategies and product and service innovation (Martin, 2011; Sobel & Groeger, 2013). Design is no longer viewed as a problem-solving activity; rather, it is viewed as a knowledge generation and integration activity (Hatchuel, 2001). The starting point for many scholars looking at design (thinking) within management and organisation studies has been Simon's (1969) assertion that design is an activity undertaken by many professionals.

In recent years, management scholars have recognised and reconceptualised the role of design and DT in business, generating a new sub-field (Carlgren, Rauth, & Elmquist, 2016; Gruber, De Leon, George, & Thompson, 2015; Hobday, Boddington, & Grantham, 2012; Weick, 2004) based on the fact that many organisations achieved positive results using DT (Bevan, Robert, Bate, Maher, & Wells, 2007; Body, 2008; Chang, Kim, & Joo, 2013; Lafley & Charan, 2010; Leavy, 2012; Meyer, 2011). Much of this research has focused on describing DT by means of phases and modes that illustrate the various activities that a team is engaged in. However, these activities are guided by a set of principles or mindsets that recur in many of these modes.

An emerging research stream explores the 'design state of mind' (Beverland, Gemser, & Karpen, 2017; Carlgren et al., 2016). This stream has started to conceptualise the enactment—or the *thinking* and *doing*—of DT on the individual and team level. The underlying assumption is that a DT mindset has a positive influence on individual, team and organisational culture and, ultimately, innovation performance. (Liedtka, 2011) builds on the fixed and growth mindset dichotomy (Dweck, 2012) to explain why some managers succeed and others struggle to innovate based on the differences in mindset. Johansson-Sköldberg et al. (2013) distinguish between the discourse of 'designerly thinking' rooted in the field of design research, which considers DT as a 'practice'—that is, an integrative framework for creative and analytic modes of reasoning supported by a process and set of tools and techniques (Liedtka, 2015)—and the more nascent management discourse on DT. However, fundamental attributes of a DT mindset have been consistently noted in the literature. While definitions may vary, the views are not as inconsistent as they may seem. Various attempts have been made at assimilating knowledge about DT into a general description.

Kimbell (2011) builds on the notion that DT is a cognitive style, a general theory of design and an organisational resource. Hassi and Laakso (2011) make a similar attempt at unifying an understanding of DT, identifying it as a form of practice, thinking style and mentality. Carlgren, Elmquist and Rauth (2016) operationalise DT on three levels: principles, practices, and mindsets and techniques. Summarising 70 articles on DT, Di Russo (2016) identifies 17 commonly cited characteristics and concludes that 'most definitions present design thinking as a mindset, method, process, attitude or a combination of all four' (p. 259).

Schweitzer et al. (2016) identify 11 DT mindsets based on expert DT practitioner interviews: having empathy towards people's needs and context, embracing collaboration and diversity, being inquisitive and open to new perspectives and learning, being mindful of process and thinking modes, embracing experiential intelligence, taking action deliberately and overtly, being consciously creative, accepting uncertainty and being open to risk, modelling behaviour, having the desire and determination to make a difference, and being critically

questioning. These mindsets confirm a set of commonly understood and applied attributes, and reveal organisational constraints on translating cognition into behaviour.

DT practice and research offers many descriptions of design principles, thinking modes, and creative behaviours and postures that are often subsumed under the term 'mindset'. The definition of 'mindset' varies; most authors seem to agree that, while a firm can adopt DT processes and learn new innovation practices over time, it is the DT mindset that enables innovation objectives to be achieved at a deeper and more sustainable level.

Conversely, some authors report that some companies are so fixated on process that DT is turned into a rigid plan, which is implemented like any other efficiency-based process (Nussbaum, 2011). If it is the design state of mind that enables the process and activities that successful practitioners of design thinking employ to create impact and value, more research is required to clarify the specific attributes of the DT mindset as well as the relationships between relevant factors.

Design Thinking Education

The most popular pedagogical model for teaching DT to business students involves project-based learning (Glen, Suciu, Baughn, & Anson, 2015). This is consistent with the increasing use of project and problem-based pedagogical frameworks in other professions, such as engineering, medicine and law (Dym, Agogino, Eris, Frey, & Leifer, 2005). The DT approach reflects the move away from passive teaching approaches towards more engaged and experiential problem-based learning that is taking place in tertiary education (Glen, Suciu, & Baughn, 2014). Teaching DT via experiential problem-based projects entails numerous challenges. For example, providing the experience and iterative practice needed to develop DT skills while accommodating students' desire for structure and predictability of outcomes. DT is not a rigid, predefined series of orderly steps (Brown & Katz, 2009). In practice, DT students gain benefit from going back and forth and in between as understanding of the problem space increases and solutions are refined. While some structure is necessary, DT requires a phased developmental process, enabling multiple cycles of repetitive practice.

Glen et al. (2015) report how reliance on soft skills, such as observation, empathy, intuition and non-linear processes, leave students of DT feeling that the process is more about chaos than technique. Similar concerns have been raised by businesses encountering DT for the first time. Business students, being used to a more ordered and structured learning environment, find the DT process uncomfortable and unfocused (Welsh & Dehler, 2013). Businesses, like faculty, usually focus on the process and tools of DT when starting out; that is, they tend to manage the learning experience via the phases of the DT process (problem finding, observation, sense making, ideation, prototyping and testing) while dealing with any challenges as they arise. This approach helps to alleviate frustration and confusion, provides reassurance, and emphasises how the phases and techniques work towards an outcome. However, it also limits students' opportunity to explore the various principles and mindsets of DT that help achieve innovation objectives at a deeper and more sustainable level.

In a recent study of experiential learning and entrepreneurship in education, Garbuio et al. (2018) emphasise the importance of design cognition, including the cognitive acts of framing, analogical reasoning, abductive reasoning and mental stimulation. They find that teaching thinking modes and mindsets is more effective than teaching processes and demonstrating tools, which are often not easily transferable to other domains. Hence, their study provides some initial support for our proposed emphasis and mindset. The authors recommend teaching design cognition to MBA students in a studio setting and incorporating critical reflection, with lecturers acting as coaches and practising designers supporting the teaching.

Overall, this nascent stream of literature provides valuable insights about how to create active, reflective and engaging programs by combining experiential learning with DT. However, it fails to acknowledge learners' responses to a DT mindset. How do students interpret the different attributes of a mindset? Which attributes are perceived to be relevant and valuable? How should an organisation implement a DT mindset and where should they start? Our research aims to shed light on these questions.

Research Context, Data and Analysis

Research Context

Our exploratory study was conducted on the back of a 10-week postgraduate DT course, comprising 40 hours of face-to-face class time spread across five full days and two block weekends, starting with two consecutive days, followed by field research and a second three-day block. Participants (*n* = 58) were a mix of part-time and full-time MBA students with five to 15 years of professional experience in a wide range of industries, including retail, financial services, manufacturing, pharma, public services and business functions, such as procurement, research and development, production, operations, finance, human resources, marketing and sales. None of the students were already experienced in the application of DT.

During the course, students worked in randomly allocated teams on a living case study with an external partner organisation. The course followed Liedtka and Olgivie's (Liedtka & Ogilvie, 2011) process with students working through the phases of inspiration, ideation, implementation and what works. Accordingly, the course focused primarily on the DT process and corresponding tools and practices. The DT mindset was introduced on the first day—after students had already gone through their first DT experience as part of a two-hour introduction to DT, which involved an exercise called 'the commute challenge'. The course instructor followed Schweitzer et al.'s (2016) classification of 11 DT mindset attributes. However, for purposes of simplicity, the following five key attributes comprised the main focus:

1. Empathetic towards people's needs and context (EMP)
2. Collaboratively geared and embracing diversity (COL)
3. Inquisitive and open to new perspectives and learning (INQ)
4. Optimistic and modelling behaviour
5. Making things tangible (T

Large posters of the symbol attached to each attribute provided a visual reminder in the classroom throughout the course, acting as a reference point or discussion stimulus when a particular attribute was relevant during an activity or project phase. In addition, Schweitzer et al.'s (2016) article was part of the required course readings.

The first three in-class sessions focused on discovery; framing and reframing of the challenge; conducting field research; synthesising data; developing insights; and defining a human-centred problem statement. All teams worked with the same broad design challenge and project partner. However, as part of the learning experience, each team was tasked with defining the scope and focus of their project. Experienced strategic designers from a leading consulting firm coached teams during one of the sessions, providing hands-on advice during analysis and synthesis.

Teams focused on ideation, prototyping and testing solutions during the last two in-class sessions. During the final in-class session, instead of presenting an ultimate solution, teams tested their solution with their project partner, receiving feedback on how they had defined the user and problem statement, and their solution prototype. Teams then had another three weeks to conduct further user research, develop and test prototypes, and run co-creation workshops with stakeholders, before submitting a final prototype and 3,500-word research report. Two weeks after completing the team project, all students submitted an individual reflective journal; these constitute the primary data source for this study.

Reflective Journal

Reflection is used in many fields, including design, architecture, product design and engineering, and is relevant to other professions as well. Drawing on Kolb's (1984) experiential learning theory and Schön's (D.A. Schön, 1983; Donald A Schön, 1987) work regarding reflective practice, we understand experiential learning as a process in which actions result in sensing new information, which stimulates insights and learning. Schön (1983) differentiates between reflection-in-action and reflection-on-action; the former is 'action present', which means reflecting on the incident while it can still benefit that situation. By contrast, the latter involves reflecting on how practices can be developed (changed) after the event.

We designed the assessment for our DT course to encourage and facilitate individual reflection-on-action; specifically, we asked students to think back on their project-based experience and to consider how various attributes of a DT mindset contributed to their project outcomes. Schön (1983, p.76) asserts that, through this

'reflective conversation with the situation', one can come to appreciate consequences and evaluate qualities that would not have been anticipated ahead of time. Consequently, we asked students to evaluate which attributes of a DT mindset were effective and to describe how they were effective. Following the experiential learning cycle of acting, reflecting and conceptualising, we then guided students to envisage future applications of a DT mindset within their own professional practice and organisational context.

The following questions were employed to stimulate student responses:

- Choose two mindset attributes that you believe are most relevant for your organisational context and discuss the behavioural manifestations (i.e., actual doing) of each based on your own experience as part of the design challenge. Be specific and reflect on how you engaged in certain behaviours that represent each mindset component; explain advantages, possible outcomes as well as challenges and pitfalls of each behaviour across the design thinking process.
- Pick one of the two described mindset attributes and justify how and why embracing and fostering such a mindset could be beneficial to your organisation. Discuss the how and why in the context of a very specific starting point (e.g., a particular department, team or process).

Analysis

Thematic analysis (Boyatzis, 1998) was carried out using the software Nvivo 11. Thematic analysis may be based on prior categories or on categories that become clear to the researcher as the analysis proceeds. The five attributes of a DT mindset represented our a priori themes; further codes were added as they emerged from the data, which was closely inspected for recurrent themes, topics and/or relationships. Following an objective research strategy (Marshall & Rossman, 2014), additional starting points for analysis were understanding individual challenges that may arise while practising an attribute of a DT mindset and suggested avenues for implementation.

Findings and Discussion

We review each DT mindset attribute and answer specific research questions before discussing this study's overarching research question: how does participation in a DT curriculum affect a student's ability to innovate, and can a DT mindset can be taught and practised via experiential learning? For the purpose of this article, we present the findings for three mindset attributes only. The examples of student reflections that we provide below are indicative of the total dataset and underscore the general nature of our findings.

Empathy Towards People's Needs and Context (EMP)

Value: Identifying People First, Then Understanding Their Needs

Gaining deep customer empathy—that is, putting people at the centre of the innovation challenge—was the single most valued mindset attribute in this study. Interestingly, the reasons why students chose this attribute varied greatly, indicating that while EMP is viewed as a foundational element of human-centred design, it is seen as having various benefits, challenges and practical implications. Kelley and Kelley (2013, p.85) define empathy as 'the ability to see and experience through another person's eyes, to recognize why people do what they do'. While this interpersonal aspect of DT (Howard, 2015) is understood to be extremely valuable during the research phase, many students saw its value at a much more fundamental level. They explained that being empathetic (or occupying an empathy mindset) forced the project team to focus on external customers and stakeholders rather than internal stakeholders. This was viewed as valuable in itself, and as leading to enhanced business outcomes in the long-term. Without being prompted, the majority of students juxtaposed a DT approach with current practice within their organisation to expose the value of a DT approach. The following excerpt is exemplary:

We are public servants, and we have a fiduciary responsibility to the citizens of NSW to ensure what we do benefits them; not ourselves. All too often, senior managers create policies for the sake of promotion or cost savings, not to fix problems that citizens face.

This respondent felt that a change in perspective would ultimately lead to 'addressing real world problems that citizens face; not our internally driven political issues'. A manager working for a large corporation involved in innovation projects explained that his team took inputs from senior leadership and did not consider the needs of the actual day-to-day users. In such circumstances, occupying an EMP mindset not only goes beyond

the practicalities of working closely together with customers, users and stakeholders through the application of ethnographic methods, but also shifts the focus and subsequent activities, resources and budgets to those relevant (future) customers and users. Notably, understanding customer needs and focusing on selected target segments are common principles taught in numerous core MBA units, which all students in this study had completed prior to taking the DT elective.

One might assume that basic marketing principles, such as 'focus on your customers', are well understood and applied in the corporate context. Yet, our results suggest that the personal experience of focusing on empathy while conducting field work, followed by reflection and evaluation of a related DT mindset attribute, leads to enhanced critical understanding of the value that a human-centred approach can bring to business and business innovation. Therefore, the value that an EMP mindset provides may not come from an intensified human-centred approach alone, but from refocusing activities on relevant external customers. The value of EMP may be less about gaining a deep understanding of users and their needs and more about understanding who to focus on in the first place.

Value: Empathy for Team Members

Unexpectedly, a small number of students viewed EMP as a necessary condition for effective team work, stating that it was not sufficient to be 'empathetic towards our customers' alone, and that it was necessary to be empathetic "also to our peers". This is interesting in the context of this study, as being *collaboratively geared* (COL) was presented as a separate key attribute of a DT mindset, yet students felt that these two mindset attributes were irrevocably connected.

In reflecting on the EMP mindset, students identified a number of challenges that can be categorised under two broad themes: solution mode fallacy and letting go of preconceived assumptions.

Challenge: Solution Mode Fallacy

Differences between the problem and solution space, as well as associated DT processes, tools and activities, were discussed with students during multiple short lectures. At the beginning of an activity that focused on problem space exploration, instructions were given (e.g., sharing field research data and focusing on capturing problems and opportunities) and students were cautioned against jumping into 'solution mode'. Yet, many experienced great difficulties staying within an empathetic 'problem space' mindset and could not resist thinking about and discussing possibilities. Based on previous experience, tools—such as the 'idea parking lot'—were introduced to capture solutions as they emerged without diverting attention away from understanding the problem space. The following statement encapsulates the conflict that many DT novices experience:

Being a senior director at a bank and having a day-to-day environment where we solve problems instinctively it took great personal discipline for me not to jump into solution mode. This ranged from the early steps of interviewing and in being careful not to put the solution in the question but also along the way as we identified an opportunity and developed ideas. I found myself going to an end state too often.

This statement supports the observations of an in-class instructor who reported that students appeared to feel physical pain when they were asked to stop imagining solutions and focus on exploring the problem further. This is not surprising, given the traditional focus in postgraduate management education on problem solving rather than problem definition (Glen et al., 2015).

Application: Setting up Interdisciplinary Teams

When students were asked to reflect on how they saw EMP being implemented within their professional practice and organisation, a number of views were expressed. Many students saw a causal relationship between occupying an empathetic mindset and embracing diversity, describing the latter as a necessary condition to gain deep customer empathy. For example, one student, who works at a leading medical device company, complained that, in her company, 'design teams comprise … scientists and engineers who design products on technical merits alone'. Believing that this decade-old approach was a major barrier to implementing an empathetic mindset, she proposed changing the set-up of teams to 'include people with diverse backgrounds who ideally represent the customer segments but also represent the functional areas of selling, marketing, finance, etc.'.

Collaboratively Geared and Embracing Diversity (COL)

Unlike the EMP attribute, which focuses on designing 'for' people, the COL attribute stresses designing 'with' people. Dunne and Martin (Dunne & Martin, 2006) argue that multidisciplinary teams are required to holistically understand a problem and expand the range of ideas available. Research shows that heterogeneous groups outperform homogenous groups on tasks requiring creative problem solving and innovation (Thompson, 2003). Given the diversity of students' professional backgrounds and their random assignment to team, 'fairly' heterogeneous teams worked on the design challenge in this study.

Value: Multiple Perspectives and Higher Productivity

Based on students' reflections and informal feedback, many found themselves outside their personal comfort zones as they experienced time-pressured, fast-paced activities, and struggled with different working styles in a newly composed teams. However, upon reflection, many acknowledged the value of team diversity for establishing the necessary broad perspective to work with the challenge. The following excerpt is indicative:

Our group had both success and struggles with this concept. We were lucky to have strong team diversity in ethnic background, occupation, personality profiles, gender, geographic living location, industry and life experience. This led to much debate but also varied thinking during our ideation and synthesis phases of our assignment. The advantages by incorporating this mindset were the broad experiences we were able to tap into and ensure that each member was soaring with their strengths.

Coaches encouraged team check-in and check-out sessions and facilitated intra-team feedback aimed at increasing team members' ability to embrace each other's differences, leverage individual strengths and collaborate efficiently. Teams were advised to define roles and responsibilities and openly discuss values and goals at the beginning of the project. Each student completed a FourSight © profile, which was shared and discussed to discover both their own and others' problem-solving preferences, and to leverage each other's strengths. As one student pointed out, sharing the profile was very helpful:

Being aware when someone was playing out of their preferred mindset, e.g., an engineer was having problems with 'wastage' resulting from the prototyping phase, but we turned this mindset into a strength when it came to check the logical flow in the final solution.

Embracing a more collaborative approach increased 'team morale, trust and enthusiasm', 'which led to improved quality of work'. However, this was not evident across all teams. For example, some teams actively sought project specific directions from instructors, trying to transfer a decision to a person outside the team, as they struggled to find common ground. Some students expressed concerns about the relevance of the exercise, pointing out that a truly collaborative, team-centred approach to executing a project was not relevant in their professional life, as there is 'always a manager who makes the final decision'.

Pioneering companies such as Patagonia and Zappos have long since embarked on a journey towards lean, self-managed organisational structures (Groeger, Bruce, & Rolfe, 2019; Laloux, 2014). Others have recently started using DT to become more agile, in the process highlighting the interdisciplinary and collaborative nature of the method. However, student's comments in this study suggest that there is a major gap between understanding the importance of collaboration and acting upon it. Our results suggest that this attribute of a DT mindset requires substantial efforts to ultimately change behaviours. It appears that some students viewed this attribute as a kind of 'necessary evil' that was part of the project, but something they would happily forego once they returned to the classical hierarchical structure of their workplace.

Challenge: Poor Match and Big Egos

A number of students explained that team members were generally motivated to work collaboratively, but incompatible views on what collaboration meant and how it should be implemented resulted in conflict. The following reflection describes two opposing views:

For me, it was about bunkering down in a room, walking through the possible scenarios, building on each other's ideas, and really stress test those ideas against customer needs. Another member felt that this was not a necessary step. They felt that all work could be done independently, with video conferencing to check in at certain stages.

Another student, who referred to a similar situation in which multiple team members 'wanted to break away to work autonomously without team delegation or support', concluded that collaboration could not succeed

unless teams shared the same view of what collaboration meant. For another student, being 'unable to shift our mindset from "I" to "we"' posed a major problem for the team: 'everyone was trying to prove themselves by pitching big ideas rather than collectively thinking together.' While such experiences were frustrating for students, they were also instructive, as they exemplify the problems faced by corporate innovation teams. According to Tuckman's (1965) group forming model, this can interpreted as the 'storming phase'. When, over time, a team overcomes this conflict, it moves into the performing and adjourning stages (Tuckman & Jensen, 1977). As such, blaming a negative collaboration experience on differences in working style misses the point that team conflict is a common and necessary phase that most teams go through. Overall, people struggle to realise that, in solving complexity, no one person is responsible for the final outcome. Given that some authors place collaboration at the centre of DT (Seidel & Fixson, 2013), and that novice learners in this study did not fully embrace this attribute, we conclude that a successful DT journey could be doomed if teams are not provided with sufficient learning and reflection opportunities in relation to collaboration and embracing diversity.

Inquisitive and Open to New Perspectives and Learning (INQ)

Curiosity and an appetite for learning are central to DT (Adams, Daly, Mann, & Dall'Alba, 2011; Kelley & Kelley, 2013). This includes learning about others, challenging existing frames of thinking and seeking out new contexts in which to learn (Cooper, Junginger, & Lockwood, 2009; Jenkins, 2010; Michlewski, 2008). Students saw value in how this mindset attribute helps to overcome cognitive biases but found it difficult to balance the pressure to deliver with the desire to understand and learn more.

Value: Overcoming Assumptions and Biases

Students experienced iteration as part of the DT process, yet many resisted engaging in multiple rounds of field research. This came as no surprise, as many relied upon their established practice of applying historical data-driven approaches to decision-making (Liedtka & Ogilvie, 2012). Repeated hypothesis generation and testing was a new experience for many participants. After an initial period of resistance, many came to appreciate the iterative nature of DT. Students saw how continued inquisitiveness challenged seemingly fact-based assumptions and either proved them wrong or provided validation. The students' reflections about INQ also referred to their evaluation of gaining empathy and the challenge of overcoming their own biases. To this end, some students saw great value and a strong and reinforcing relationship between their growing empathy for others and their openness to learn. This is in line with Liedtka (2014) who suggests that overcoming individual cognitive biases drives DT innovation outcomes. One student, who works in a creative advertising agency, commented that her creative department 'desperately' needed to embrace an INQ mindset:

The creative employees bring their egos to [the] office and assume that they know the consumer, and are designing ad campaigns on the basis of their assumptions and biases. It's surprising how our very own 'ideators' work without actually understanding the customer's needs.

She identified inquisitiveness and the drive for continuous learning as the foundation upon which DT and, ultimately, innovative solutions are built. This confirms Baeck's (2011) view that DT requires a strong desire to dig deeper and a curiosity to develop actionable insights that are beyond superficial observations.

Challenge: Balancing Continuous Learning and Outcome Focus

Throughout the learning experience, students felt that they occupied an inquisitive mindset by personally conducting multiple rounds of field research. Yet, there was also frustration when the project did not move quickly enough towards a final solution. Those students then jumped into 'solution mode' instead of exploring the problem space more rigorously. One student pointed out that, despite 'a deliberate effort to keep learning along the way' and an increased level of focus during a second round of research, the team felt as if they were even more uncertain about what they were looking for. This created tension for outcome-focused students, who felt they 'were overcommitting to the learning stage and underestimating the need for time allocated to implementation. However, despite these tensions, some team members felt that they were able to occupy an ACU mindset by allowing themselves to be uncomfortable with experiencing tension and by exploring different contexts with an open mind. One downside of being inquisitive is that it can cause people to deviate and become distracted, which can be perceived as a waste of time and resources. Yet, it is precisely the cultivation of curiosity and inquisitiveness that makes collecting and analysing data in a rigorous and human-centred way possible.

Application: Inquisitive across Departments

When considering the application of a INQ mindset attribute, students thought of the challenges associated with breaking down departmental boundaries and working across silos. Hence, some saw great potential in fostering inquisitiveness about other peoples' work or other departments. An engineer described this as follows:

Due to the nature of the company every employee was focused on his own work and even though many departments are interlinked for production, the employees never intervened or shared ideas at work. There were often many times where an employee from another department had problems due to the process followed but they never discussed it with the other department to find a solution because they felt that this was out of scope of their working.

She argued that a holistic approach and culture of being open to new perspectives and learning would 'greatly benefit [her] company'. In her view, engineers with expertise and information from 'the client side' would bridge siloed thinking, creating opportunities for innovation and improvement.

Summary of Findings

Overall, we found that the majority of students in the group developed a deep understanding of different DT mindset attributes and the value that each can bring to an innovation project. Yet, those perceptions of value are much more nuanced and interconnected than the current DT literature or instructors of DT courses suggest. While some students remained confused about the nature and purpose of a DT mindset, others came to appreciate the value of occupying a DT mindset for driving tangible business outcomes in their professional practice; these students were able to transfer their experience of living through a DT project in class to their current organisational context.

Our findings are generally in line with other research on DT; however, to the best of our knowledge, this is the first study to report the reflective voice of DT student learners. Previous research on learning has primarily focused on the role of doing (experience) in fostering progress over time. We follow DiStefano et al. (2015) who argue that a key element of learning is reflection—or the intentional attempt to synthesise, abstract and articulate the lessons taught by experience. Based on our reading of student reflections, we believe that their purposeful reflection on their accumulated DT experience led to greater learning, certainly more than any additional accumulation of experience may have achieved.

As they were 'living' through and experiencing the various attributes of a DT mindset, the novice learners in this study shared their personal and team-related challenges. These descriptions were rich and diverse, providing valuable insights for practitioners and educators, highlighting barriers to implementation and learning of a DT mindset. The recorded challenges varied depending on professional and cultural background, personal preferences and previous experiences. Yet, the majority of the challenges mentioned in this study mimic findings of other studies on barriers to innovation in organisational settings. This supports requests to embed DT in MBA curricula more firmly.

Our data suggest that some mindset attributes, such as COL are more difficult to adopt than others. We suspect that this is because experiential learning, by its nature, supports the development of mindset attributes like EMP. From this, we conclude that much more attention could be given to teaching DT with changing behaviours and attitudes in mind rather than by conveying processes, tools and methods alone. To focus on DT mindset learning more explicitly, we present some avenues for future research and learning design, and offer some suggestions on instructional guidance.

Towards a Framework for Learning DT

To facilitate a cognitive learning approach to DT mindset education, we recognise that a DT mindset and its attributes requires a succinct and distinctive definition. This involves assessing desirability and feasibility, as well as setting individual cognitive learning goals in the context of a DT course. Hence, in Table 2, we present three refined and exemplary definitions of DT mindset attributes based on students' reflections, make suggestions about the objectives associated with learning about particular mindset attributes, and describe how learning can be facilitated via specific learning activities. We propose this as a starting point towards designing learning experiences for DT that focus on acquiring a DT mindset in addition to applying the process and tools of DT.

Table 2: Three exemplary DT mindset attributes, learning objectives and instructional guidance

DT Mindset Attributes (Definitions)	**Exemplary Learning Objectives** ***WHAT Should Students Learn?***	**Exemplary Learning Activities** ***HOW to Facilitate Learning?***
Empathetic towards people's needs and context (EMP) The extent to which a person experiences another individual's needs and context from their perspective. The ability to place yourself, your thinking and feeling in the view of another person.	• Apply ethnographic research method to gain user insights • Separate one's own thoughts and assumptions from what one actually observes • Communicate problems and opportunities from a human-centred perspective	• Experience user research using cultural probes (e.g., whose life is it? a day in a life, mystery shopping or immersion) • Experience active listening via interviewing and observation • Make assumptions explicit and derive hypotheses to test them • Create personas and act them out to experience another person's perspective • Create empathy and journey maps to plot current and future user experiences • Involve users in prototyping and testing of solutions
Collaboratively geared and embracing diversity (COL) The extent to which a person buys into working together towards a shared solution and is effective in the service of the team's purpose, believing that no-one person is responsible for the final outcome.	• Recognise the role of self and others in achieving joint outcomes (IQ vs WeQ) • Apply team formation, management and conflict resolution approaches • Appreciate team members' diverse contributions • Create a shared vision for the team and project • Create psychological safety	• Make individual behavioural preferences in team contexts explicit by discussing and reflecting on different working styles and personality traits; setting team goals and defining a common vision • Coach teams with a focus on giving everyone a voice, leaving egos behind via team check-in and check-outs, defining and sharing roles and responsibilities • Facilitate open and transparent feedback within teams; provide external individual and team feedback (coach) • Facilitate team collaboration by focusing on gaining empathy towards peers
Inquisitive and open to new perspectives and learning (INQ) The extent to which a person displays curiosity and a desire to learn new things.	• Appreciate the existence and potential of unknown knowns • Question the status quo and appreciate the importance of continued learning and experimentation • Gain insights through iteration and testing of hypotheses • Create and evaluate low fidelity prototypes and small marketplace experiments	• Demonstrate and experience cognitive biases and practise using tools and techniques to overcome them • Identify and map knowledge, classify facts, opinions, trends and assumptions • Provide curiosity prompts, asking students to look for things that surprise them; double-down to explore the

DT Mindset Attributes (Definitions)	Exemplary Learning Objectives *WHAT Should Students Learn?*	Exemplary Learning Activities *HOW to Facilitate Learning?*
	• Apply system thinking to untangle complexity	issue; share the story within team • Practice creating experiments to test assumptions and gather facts • Use triangulation to critically evaluate information • Explore the value of making learning tangible via prototypes, showing artefacts to receive feedback and not to sell a solution

Conclusion

Our research explored the extent to which key attributes of a DT mindset are understood, evaluated and assessed in terms of their practical value for individuals and organisations. We took a student-centred approach and analysed individual student reflections. Our results indicate that students have a more nuanced and interconnected understanding of different DT mindset attributes than current literature suggests.

Our results also revealed that while some students remained unclear about what constitutes a DT mindset, others felt that occupying a DT mindset could drive tangible business outcomes. Our study introduced a framework for learning a DT mindset based on cognitive psychology, providing guidance for learning objectives and exemplary activities to teach and encourage designerly ways of thinking and doing in education.

We believe that a DT mindset can address deficits in business school education, better preparing students for the future of work. We encourage future research to explore the interconnectedness of DT mindset attributes, especially how these might be quantitatively measured to determine whether an attribute that is lived in the classroom is subsequently lived in practice.

Stressors and creativity in Industrial Design practice

McCARDLE John*; DEMPSEY Samuel and HUMBERSTONE Max

Loughborough University, United Kingdom
* corresponding author e-mail: j.r.mccardle@lboro.ac.uk
doi: 10.33114/adim.2019.10.392

Current literature suggests that stress influences creativity, however further research is required concerning this relationship with a focus on education. Current views are clearly divided on whether any negative effects on creativity are more dictated by environmental stressors or the reactions of individuals whilst under stress. For this study, participants completed a questionnaire comprising of a perceived stress scale and thematic questions, to give an indication of whether they were more influenced by environmental stressors or their individual reactions to stress. Two Torrance tests of creativity were conducted to assess creativity over a two-week period as time pressures increased. The results suggested that participants who identified as being more affected by their own negative reactions to stress displayed a lower calibre of creativity when time-pressure increased, whereas the participants who were suggested to be more influenced by their environment remained at a relatively constant perceived level of creativity.

Keywords: Creativity, Stress, Environment, Reactive, Industrial Design

Introduction

Within educational and professional practice environments, an atmosphere of pressure and stress is commonplace. At a time when innovation and creativity is highly valued, research on the imposed external and internal stressors that may limit this value are highly relevant. The debate continues as whether the effects of stress in relation to creativity are influenced more by the environment, or the individual's possible negative reaction to stress. Many difficulties exist in the study of creativity in design; its definition, protocol observation of action and levels of attainment are highly interpretable and subjective. Nevertheless, while creativity as an innate human propensity is considered to be an emotionally enjoyable act, other external and internal factors are known to depress motivation and drive anxiety, destroy confidence and elevate stress levels.

…artistic activity is a route to human well-being both for people who do not have mental disorders and who want to get the most out of life and for people with minor and major disorders who can find both solace and a way to a satisfying and meaningful life through artistic activity. Maybe those who believe there is a link between mental illness and creative genius are right – though I and others don't think so. But it's for sure that creativity has much to contribute to mental health and human well-being. (Friedman, 2014)

The aim of this small scale study was to investigate the extent to which stress affects creativity within a group of Industrial Design students and to examine whether any adverse effects on creativity are suggested to be driven by environmental stressors or the student's adverse reaction to stress. To gain these insights we

classified students into groups who were identified as having potential to be negatively affected by either a stressful environment or negative reactions to inherent stresses, and measured the extent to which individuals perceived they were stressed during a period of work. Abridged Torrance tests of creativity on these groups were repeated to examine if either group suffered a greater negative effect on their creativity as time pressure increased. By gaining insight into any adverse effects on creativity influenced by environmental stressors or the Design student's possible adverse reaction to stress, we aim to develop support strategies for designers in education and professional practice.

Literature review

According to investment theory, creativity is underpinned by; intellectual abilities, knowledge, styles of thinking, personality, motivation, and environment (Sternberg, 2010). In the last 50 years a large body of work has evolved around the relationship between the characteristics of individuals and their creative performance. Research from Oldham & Cummings (1996) and Shalley, Zhou, & Oldham (2004) for instance, conclude that personality, cognitive style, and knowledge, are positively related to worker inventiveness.

The term *Creative Confidence* has become an important factor in nurturing creativity and understanding a person's belief in their own ability to successfully complete a creative task (Phelan & Young, 2003). As such, *Self-efficacy* provides a foundation for creative confidence as an innate belief in one's own ability to complete a certain task (Bandura, 1993). Individuals with a higher level of self-efficacy have been shown to exhibit greater persistence in overcoming obstacles (*ibid*.), and demonstrate elements of *designerly play* when approaching problem tasks. Designerly play can be considered a form of creative exploration without the fear of getting things wrong. Indeed, risk-taking has been shown to be one of the most significant resultants of play. It is important for any project involving creativity that those involved are prepared to take risks (Kelley, 2001), however in education such risks are often avoided (McCardle, Huskisson & Perry, 2018).

The causes and effects of the factors associated with creativity and its relationship with stress related issues is broad and widely known to be convoluted. But the consequences to and impact upon personal creative growth in HE, and further on into continual professional development for practitioners, should be of more concern. Not only for reasons of achievement, but in safeguarding personal wellbeing. More recently, there has been an acknowledgement of the importance of workload pressures, but an appropriate working environment as a component in supporting and nurturing creativity has also featured strongly.

The Environment

In 1979 Teresa Amabile published work that conveyed how evaluative environments can often lead to diminished creative output from students. Amabile conducted experiments that entailed leading a creativity-based task with two groups of art students. One group's members were told that work would be evaluated, whilst the other was not. Within the context of creativity defined for the work, Amabile concluded that the group members told they were being evaluated displayed significantly less creativity. It was consequently held as an example of where the stress of the environment can directly lead to a negative impact on creativity (Amabile, 1979). In continuing work, Amabile, Hadley, & Kramer (2002) examined in more detail environmental effects on creativity of 177 employees across 22 companies whilst under time pressure and stress. Their findings showed that an environment rich in time pressures resulted in multiple possible outcomes for creativity, both positive and negative. For example, an environment rich in time pressures that had a fragmented schedule, would likely produce a low creative output, surmised as being due to the presence of stress caused by a lack of allocated time available to seriously negotiate a task. The result is summarized in the time pressure/creativity matrix of Figure 1.

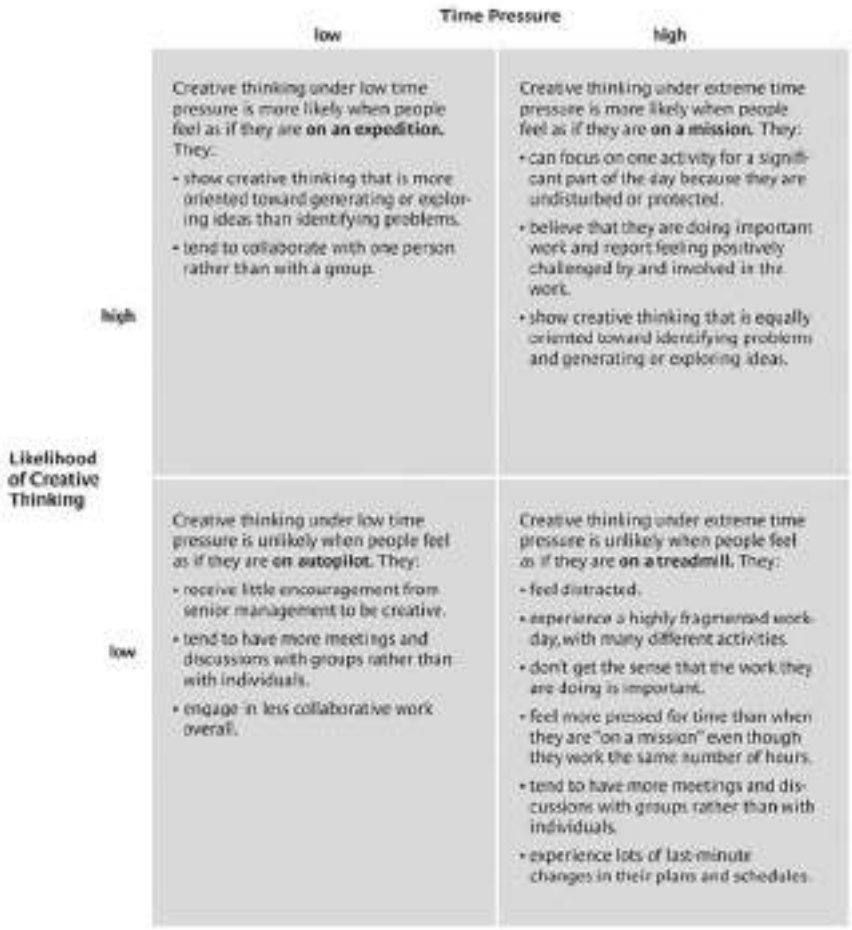

Figure 1: Time Pressure/ Creativity Matrix (T. Amabile et al., 2002)

However, the methodology employed here, whilst relevant, didn't attempt to measure creativity externally but relied on individual's self-perception and peer review.

Byron, Khazanchi, & Nazarian, (2010), have provided a meta-view of creativity and stress research. They concluded that stress is potentially both a contributor and a limit to creativity. Their overview confirms the existing arguments concerning the direct relationship between creativity and stress. The long held view of Wilke, Gmelch, & Lovrich (1985), is that this relationship is an inverted U-shape, in line with the Yerkes-Dodson Law (R. A. Cohen, 2011). That is, low stress results in low creativity, but which increases for a growth in stress, but at some point decreases again as stress continues to grow (see Fig. 2). Some studies however have observed the opposite. In certain disciplines such as engineering, increased pressure beyond that that would be generally acceptable to many, has been observed to increase creativity (Andrews & Farris, 1972). What decides the effect is down to the context of stress; for example, if there is high level of pressure for delivering success then this may produce stress in combination with high levels of anxiety, which was found to be detrimental to creativity. Byron *et al.* (*op.cit*) suggest that the uncontrollable aspects of environmental based stressors, such as deadlines, course requirements and expectations that are perceived to be outside of a person's control are detrimental. Moreover, environments high in external evaluations decrease creativity. Of course, in education or in professional practice, this raises a serious dilemma. The question also remains as to whether any adverse effects on creativity are driven *more* by environmental stressors or personal adverse reaction to stress.

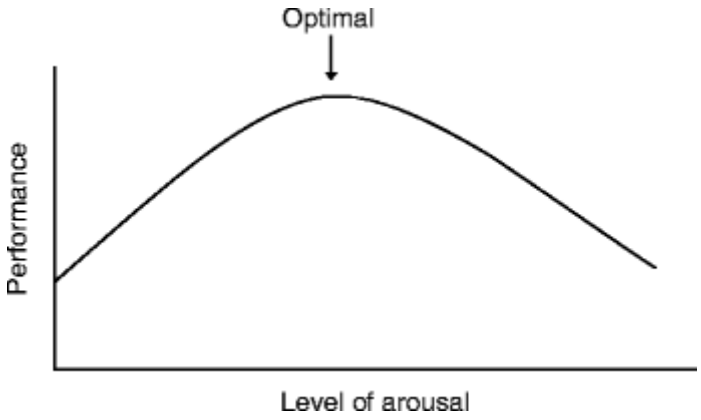

Figure 2: Yerkes & Dodson (1908) cited from (R. A. Cohen, 2011)

Determining a consistent method of assessing creativity is exceptionally difficult as the environmental conditions and cognitive personalities of individuals vary widely. However, the use of the Torrance Test of Creative Thinking (TTCT) (Wallach, 1968) is common. Using this test, the relationship between time pressure and creativity has been investigated by Hsiao, Wang, & Chen (2015), which concluded that long-term environmental stress and pressure induced by high workload and high pressure to succeed in a high evaluation environment, is incompatible with creativity. This is a view further supported by research undertaken by Ding, Tang, Tang, & Posner (2014), again using the TTCT, which found that Integrative Body-Mind Training (IBMT) breathing exercise as part of an environment that promotes calm thinking and removing time pressure, aids creativity, reduces stress and promotes creativity.

The view that the environment is primarily responsible for negative effects of stress on creative ability is, in part, agreed with by Nguyen & Zeng (2012). Their work suggests that mental stresses are directly related to the contextual and environmental workload of the specific design task, ergo, the limit of the creative potential is highly correlated to the size of the design task at hand. Importantly they further suggested that the designer's mental capacity whilst dealing with stress is also crucial in defining the overall effect of stress.

Reactive influence

Perhaps the most prominent counter view to the idea that the environment dictates the effects of stress on creativity is that creativity is more dictated by an individual's internal negative reaction to that stress. Ceci & Kumar (2016) maintain the view that positive and negative *emotions* are at play and unavoidable when engaging with creative tasks and that the key to maintaining a creative output throughout stressful periods lie within the individuals own ability to react to stress positively. With links specifically to motivation, their study used the Griffin and McDermott creativity checklist (Griffin & McDermott, 1998) to assess the creative accomplishments of a group of students self-reporting on motivation, happiness, creativity, and perceived stress. Amabile's 'Work Preference Inventory' (T. M. Amabile, 1983) was also used specifically to determine that motivation was the defining factor. Results suggested that the individual's reaction to stress dictated the influence more so than the environment. For example, two students who were experiencing the same amount of time pressure on a given piece of work reacted differently. The work concluded that an individual who takes the pressure as a motivator may perform more creatively, whereas the other may take the pressure as evaluative and perform less creatively. This work is key in introducing the theme of negative effects on creativity as not being derived entirely from environmental stressors, but also from individual reactions to stress.

This view has been further validated by Gutnick, Walter, Nijstad, & De Dreu (2012) who formed two propositions based on literature surrounding stress and creativity:

1) High work pressure strengthens "threat appraisals" = reducing creativity.
2) High work pressure enhances "challenge appraisals" = enhancing creativity.

Therefore the concept of varying *reactions* to stress, whether positive or negative, plays a major part in defining the resulting effect. This furthers the notion that an individual can feel threatened by work (Liu,

Wang, Ren, & Liu, 2017) and that an undelying motivation commonly falls victim to stress, with the consequential impact on the overall quality of a creative output.

The perception of formality can also contribute to the evaluative perceptions drawn by an individual. An investigation where participants were set tasks in a hypothetical scenario, acting as Human Resources directors, showed that the delivery or presentation of the task to the participants was influential for the motivation in creative tasks. When the delivery was formal and controlling, there was significantly less creativity observed (Shalley & Perry-Smith, 2001). The perception of confrontation or conflict also poses a risk to creativity. Work by (Carnevale & Probst, 1998) concluded that individuals who are expecting conflict rather than cooperation, are less likely to attain a higher level of creativity.

Reactive influence is therefore driven by the key aspect of innate perspective and the personality and behaviour of the individual. Sung & Choi (2009) found that extrinsic motivation contrastingly effected creativity for participants with 'agreeableness' or 'openness' traits. Individuals with high openness to experience seemed to perform better when they were motivated to complete the task through gaining rewards and acknowledgement for their performance. For people who were high in the agreeableness, extrinsic motivation was not beneficial for their creative performance. Given that agreeable individuals care about others and tend to prefer agreeing with other's opinions to avoid confrontation, their creative performance are considered to be further decreased if they are concerned about rewards, compensation, or other's evaluation of their performance. In contrast, agreeableness was positively associated with creativity when the person had low extrinsic motivation, and thus they were less concern about other's opinions. This could possibly indicate that agreeable people are less likely to be influenced by the social or physical elements of a given setting.

A dual-pathway model has been suggested as a way to identify two routes to creative outcomes (Baas & Roskes et al, 2013). Through defining a *flexible information intake* and a *cognitive persistence intake*, observations here indicated that individuals who maintain both these pathways through high pressure periods are less likely to have their creativity limited. In short, having personality traits of open-mindedness and dogged determination is more likely to result in creativity.

Finally, an individual's perception of support in being creative is also an integral factor for defining the relation between stress and creativity. Evidence suggests that innovative performances can be lower when an individual's perception of support in driving innovation is low (Leung et al., 2011). The lack of perceived support for an individual may lead to an apathetic attitude towards their creative tasks, drawing parallels to the motivation argument put forward by Ceci & Kumar (2016).

Methodology

The method for this work was conducted in three sections as shown in Table 1. Ethical clearance was gained before making any contact with participants for the study. An informed consent form was used to ensure participants were willing to take part in the research which also outlined the rules applied around anonymity of data collection and the purpose of the study. Participants were reminded that they were free to remove themselves from the study at any time.

The questionnaire consisted of two sections. The first section utilised the standardised Perceived Stress Scale questionnaire (PSS-14) to indicate the extent to which the participants perceived their current stress levels, (Cohen et al., 1983). The 14 questions asked the user about emotions and scenarios over the previous month, as a 4-point Likert scale format. The direct scoring system was used to determine the level of a participant's stress as ordinal data.

Table 1: Research Method

Methodology	Purpose	Limitations
Questionnaire Part 1 (PSS) (S. Cohen et al., 1983) Q1-14	The Perceived Stress Scale section quantitatively assesses the extent to which students are stressed	The possibility of missing an interesting insight that can potentially be achieved through focus groups or interviews.
Questionnaire Part 2 See Fig. 5 Q15-24	To group participants based on their leaning towards being affected more by environmental stressors or reactive stressors	Small group size. An online questionnaire, with the possibility of participants not fully understanding the questions.
Abridged Figural Torrance Test of Creative Thinking	Picture construction creativity test. Suited to visual creativity of industrial design students.	Preparations are needed. Time consuming to conduct.

The second section comprised 10 questions formed from the references provided in Figure 3. The questions were chosen to characterise the participants to facilitate grouping for the abridged figural TTCT. Five of these questions were linked to environmental stressors affecting creativity, and 5 were linked to negative reactions to stress affecting creativity (See Fig. 3). The responses to these questions determined the group membership, based on leanings towards either environmental or reactive affecters.

Figure 3: Thematic Grouping for Questionnaire

All sections were piloted with undergraduate Design students not participating in the full study. Figural drawing tests were *limited* to 6.5 minutes in the baseline and repeat tests; the duration of which was optimised from the pilot. The researcher was present to explain the test to the participants and answer any questions. The baseline and repeat tests were conducted with the participants over a 3-day duration in week 4 and 6 of a single semester. This was greatest amount of time possible between the baseline and repeat tests to measure the possible effects on creativity defined by time pressures increasing.

The creative task consisted of a simple geometric configuration from which the participants were asked to reconfigure as imaginatively as they could, within the time limit of 6.5 minutes. The output of the creative tasks was assessed on a numerical system whereby a mark between 1 and 5 was awarded for each section, for each participant's response, in line with the following criteria;

- **Fluency:** The number of valid responses offered based on the starting geometry.
- **Flexibility:** The number of dramatic shifts from one theme to another throughout the responses.
- **Originality:** The infrequency of themes offered relative to themes present in the rest of the participants.
- **Elaboration:** The graphical detail in each response.

Results

Seventeen total responses to the two-stage questionnaire from undergraduate Design students were completed. Table 3 shows the participants PSS score and leanings towards either environmental factors or individual reactions negatively affecting their creativity. Participants who were suggested to be more influenced by environmental stressors formed GROUP E and participants who were suggested to be more influenced by their individual negative reactions to stress formed GROUP R.

Of the 17 who participated in the questionnaire, 5 participants chose not to take part in any further stages of the investigation. From the remaining 12 participants, 10 were chosen based on two factors; those who scored highest on the PSS section, and those who sided most strongly with either environmental factors or individual reactions negatively affecting their creativity. Participants 9 and 14 gave an inconclusive result.

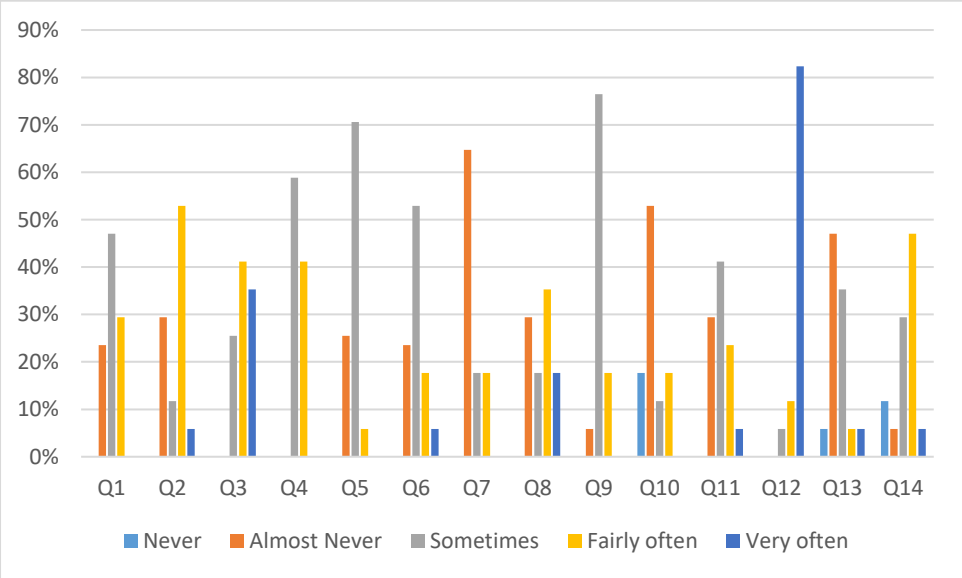

Figure 4: Overall PSS responses to Q1-14

Questions 1-14 for the Perceived Stress Scale:

In the last Month how often have you….

Q1 – been upset because of something that happened unexpectedly?

Q2 – felt that you were unable to control the important things in your life?

Q3 – felt nervous and stressed?

Q4 – dealt successfully with irritating life hassles?

Q5 – felt you were coping well with important changes in your life?

Q6 – felt confident in your ability to handle your personal problems?

Q7 – felt that things were going your way?

Q8 – found that you could cope with all the things you have had to do?

Q9 – been able to control irritations in your life?

Q10 – felt you were on top of things?

Q11 – been angered because of things that were out of your control?

Q12 – found yourself thinking about the things you have to accomplish?

Q13 – been able to control the way you spend your time?

Q14 – felt difficulties were piling up so high that you could not overcome them?

Table 3. Results of PSS Questionnaire

Participant	PSS Score Q1-14	Environment / Reaction Q14-24
1	36	E
2	34	R
3	32	R
4	34	E
5	35	E
6	34	R

14	**35**	**Inconclusive**
15	36	E
16	27	R
17	31	E

The results given in Table 4 illustrate the difference in PSS scores between the two groups across both phases.

Questions 10-24 for Environmental/Reactive response:

Q15 – Do you think you have become more or less creative as the year has gone on?

Q16 – How motivated do you feel to work each day?

Q17 – Has your work often been interrupted by compulsory sessions?

Q18 – How often do you take breaks throughout the day?

Q19 – 'I feel on top of my workload most of the time'?

Q20 – I want to do as well for my degree? Or I want to challenge myself and achieve?

Q21– How often do you have time for personal activities?

Q22 – When do you feel most creative?

Q23 – I am at university to, a) be evaluated or b) learn new skills

Q24 – Do you fell more creative after meetings?

Figures 5 & 6 illustrate the starting geometries and examples of participant's graphical work in response to the request to develop a creative interpretation. Participants were not made aware of the marking criteria.

In the first phase, the results were of a similar standard for both groups, with the differentiation between the two groups overall creativity score being +6 for Group R.

Phase 1 Fluency

The marks for fluency at this stage were relatively uniform across the two groups during the baseline test. The modal score was 3 across both groups with individual high scores recorded on both sides.

Phase 2 Fluency

The marks for fluency showed the largest gap between the two groups in the second round. Group R performed considerably lower than Group E, with the modal score for the Group R = 2, in comparison to Group E = 4.

Phase 1 Originality

Originality showed a slightly higher score within Group R, with common an obvious themes such as human like figures and planets generally being avoided.

Phase 2 Originality

Group E performed at a higher level with regards to originality. Group R showed a pattern of keeping to common themes which surfaced several times; these included birds and cups.

Phase 1 Flexibility

Flexibility scores were relatively uniform with a deviation of marks between the two groups being recorded as 2 in favour of Group R. Group R showed a slightly higher ability to move away from themes they had already presented within their responses. Common themes displayed more by Group E included human like figures and planets.

Phase 2 Flexibility

The marks awarded for flexibility displayed a relatively large difference between the groups. There was a 5 point score difference between the two groups in favour of Group E, with Group R displaying a tendency to stick to a theme they had initial conceived and not stray from it in the rest of their responses.

Phase 1 Elaboration

Elaborative marks were of an average standard across both groups, with Group R attaining a slightly higher score by giving more detail in their responses than Group E.

Phase 2 Elaboration

Elaboration was the only section where Group R displayed a higher level of creative ability, however marks were not dissimilar between the two groups.

Comparative Summary

In Phase 2 the trends were of a notably different standard for both groups, with the differentiation between the two groups overall creativity score being +13 in favour of Group E. Figure 7 shows how Group R scored slightly higher in the first round, but then dropped below Group E's score at the end of the second round.

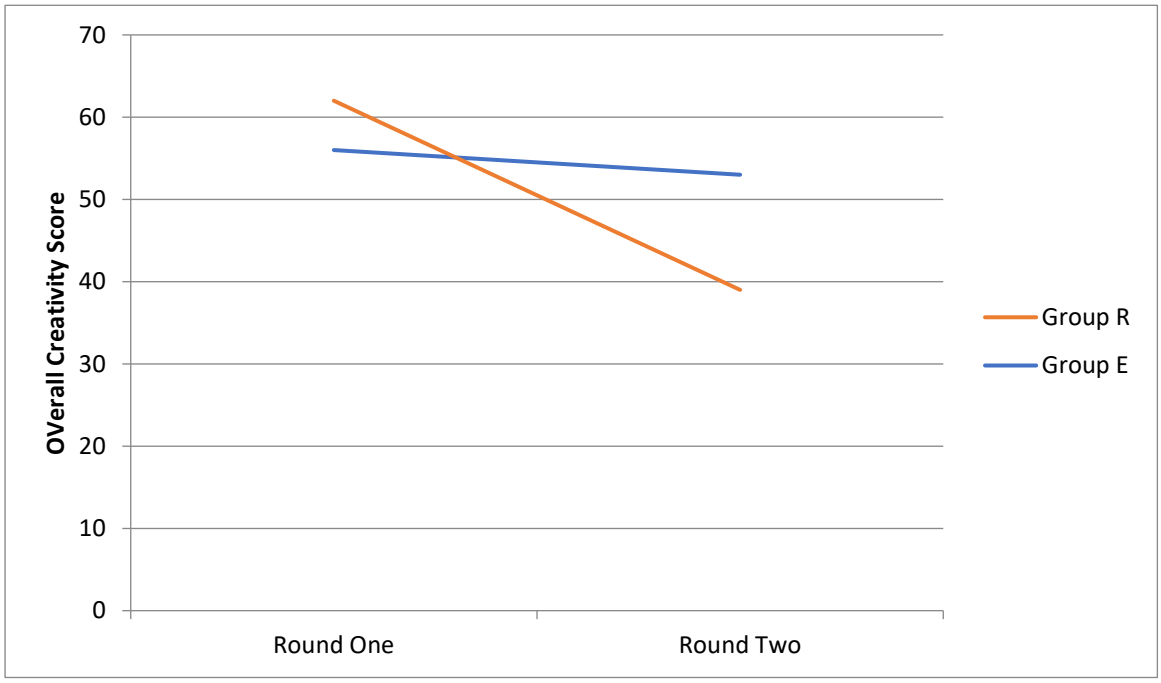

Figure 7: Creativity / Time group performance comparison

Discussion

It is well debated in current literature that stress is a criterion which has the potential to limit creativity, but subject to various factors including environmental and reactive tolerance. The results of the PSS section suggest that the participants may fit into a stressed category, with relatively high PSS scores recorded across all questions by most respondents indicating they were at possible risk of having their creative potential

impacted upon. When examining specific answers to the PSS, a trend is apparent that is consistent with students who are displaying negative psychometric thought patterns. Over 70% of respondents to the survey stated that they felt 'nervous and stressed' either 'fairly often' or 'very often' over the last month. When referring to recent studies such as that conducted by Hsiao et al. (2017), which found that long term stress is incompatible with creativity, the findings from this section of the questionaire alone point towards a situation where students may be at risk having their creativity stifled.

Question 12 (Fig. 3) of the PSS corroborates the theme of high mental stress among the participants. Over 80% of respondants answered that they were thinking about the things they have to accomplish either 'very often' or 'fairly often'. Hoeever, this may be indicative of a high intensity set of activities within a prescribed education programme with numerous concurrent tasks; and it is also arguable that this may not necessarily be negative behaviour, but a display of a proactive approach to time management.

The grouping stage of the questionnaire (Q15-24) was designed to divide respondents into groups who were more negatively affected by either their environment (Group E), or their reaction to stress (Group R). In general, the responses from the questionnaire gave rise to a marginal division in the participants regarding which determining factor they aligned with more closely. However, some responses suggest there is a degree of crossover, where participants indicated they may be affected by both the environmental stressors and their own negative reactions. For example, questions aimed at gaining insight of environmentally negative affect for the respondents yielded inconclusive responses. Eight participants, who identified as being influenced by the environment (Table 3), also responded that they feel they are not on top of their workload most of the time. This suggests that some of the participants who fitted into the bracket of being more influenced by their reactions still felt influenced to an extent by this particular environmental stressor.

This observation was furthered by responses to questions aimed at probing the participant's attitudes towards being more negatively affected by their reaction to stress possibly even threatened (Gutnick et al., 2012). When asked whether participants wanted to do well at university because it a) will determine their degree (environmental stress as a threat) or b) because they want to challenge themselves, nearly 70% of the participants sided with the answer that relates to being affected by their environment, a far higher percentage than the overall percentage of participants who were identified as being more influenced by their reaction.

From the results of the figural TTCT, within the context of this small scale study, both groups experienced a decline in creativity over the time period, however Group R displayed a much steeper drop off in creativity.

Summary of Group E

Although Group E was evaluated as having a drop off in creative output over the time period, it was not perceived to be as pronounced as Group R. A reduction in creativity due to environmental factors may have been logical to expect prior to the results. It is reasonable to suggest that the increase in time pressure may act as a catalyst for the environmental factors limiting the groups creative output. For example, a lack of time to relax, a known key environmental stressor (Ding et al., 2014) would in theory be exacerbated by an increase in time-pressure. Moreover, when considering creativity related to the size of the task at hand, it may be reasonable to expect this group's creativity to diminish as expectations of the students increased over the time period between the two tests.

With environmental stressors, it is possible to experience long term effects rather than purely immediate-reactive. For example, the negative outcome from a long term demand for creativity, as set out by Hsiao et al. (2017), could have been in place for the participant's entire university career. It is possible that over a two-week period alone there may not have been large fluctuations in levels of the participants' creativity at this particular stage. Furthermore, when considering the evaluative nature of Group E's collective diminishing creativity, the participants who were identified as being more influenced by environmental stressors have been in the evaluative environment since the beginning of their university career. Although it is arguable that the evaluative nature has become more important in the final year of their study, it has not changed in format since they started.

Summary of Group R

Regardless of whether or not Group E would perform better outside of their creative constraints, the results here have indicated that Group R appeared to reach a relatively lower standard of creativity overall as time-pressure increased. Superficially the results suggest that participants who identified as being more affected by

their adverse reactions to stress, may suffer more with regards to creative output. Factors such as lack of motivation (Ceci & Kumar, 2016) and viewing work as a threat (Gutnick et al., 2012) are much more dynamic than the environmental factors, and may also be more sporadic and unpredictable. For example, lack of motivation affecting creativity may be described as a phenomenon which is short term and variable rather than a key environmental factor such as long term demand for creativity (Hsiao et al., 2017).

The results of the TTCT lean towards an agreement with various studies that suggest an individual's reactions to stress dictate possible negative effects on creativity more so than environmental stressors. For example, in terms of personality traits and creativity, Baas et al. (2013) describe how individuals who react negatively to stress by losing mental stamina are less likely to attain a high level of creative output. As the participants were under considerable pressure for the weeks before and between the baseline and repeat tests, it may well have reduced the participants' mental stamina.

The results found in the TTCT further add to the suggestion of a lack of motivation leading to a lower calibre of creative output. As to whether or not the students' motivation influenced the results is debatable, however, when referencing both the results of the questionnaire and TTCT, there appears to be some connection between the participants who said they were less motivated, and those who scored lower on the TTCT. From the assessor's view there was a drop off in originality and elaboration in Group R. There were many consistent themes displayed in the answers of this group such as cups and birds, as well as a distinct lack of elaboration in many answers. Lack of motivation could be a logical explanation for this result, as the participants would be required to exert intrinsic motivation to conceptualise original ideas in a reasonable amount of detail.

Further possible explanations for the drop in creativity from Group R may come from the theme of evaluative circumstances impairing an individual's creative abilities as described by Byron et al. (2010). Prior to the tests being completed the participants were given an overview of the research and thus understood that their work would be under scrutiny once they had submitted responses. From the questionnaire it was clear to see that many participants from Group R suggested that they saw university as a system that evaluated them rather than taught and supported them. The results of the TTCT appear to support this argument from Byron (*ibid*.) and provide a further possible explanation as to why Group R appears to have had their creativity limited much more than the Group E as time-pressure increased.

Discussion in context

The relationship between stress and creativity is particularly poignant for educational institutions and professional organisations in the so called 'creative industries'. From the initial observations of this study it could be suggested that at present, practices are failing to enable some Design students to reach their creative potential by not recognising the barriers to creativity.

Some may argue that dealing with stress when creativity is demanded holds the key to being successful in the creative industries. Increasingly, educational establishments are strengthening their industry links, and it is arguable that stress does not dissipate as a student transitions from university life into a career. There are still deadlines to meet, there are professional creative requirements to be met, and there are environments strongly resembling that of university institutions or vice versa.

With that in mind, it is also debatable that whilst the stress within educational institutions may not be conducive to cultivating creativity in students, it is unavoidable. Preparing students for a realistic career in industry may be viewed as being just as important as sharpening their creative talent. This comes with the counter argument that if students are given the optimum circumstances to be able to grow their inherent creativity, this will make them far more employable than simply getting them used to working in high pressure scenarios.

The work here provides the briefest of insights into the link between creativity and induced stress, from environmental and reactive sources. Indications are that at university level, the environment invoke and its students can develop symptoms of these stressors with the inevitable effects on creativity levels. While there are some that maintain universities are a place to learn in a relatively low risk environment, others drive the notion that a university is a proving ground for industry. The Design profession is particularly susceptible to this dichotomy.

Limitations and further work

The limitations of this work relates to timing and scale. The timings in assessing participants may be crucial as there are continual peaks and troughs in demands of work throughout the year. Not all participants will be subject to the same deadlines and there are individual differences in time management skills and organisational ability will skew results, especially where there are low numbers of participants. With regards to the TTCT, it would have been ideal to, a) perform the tests further apart to allow for a higher increase in time pressure and b) to perform the baseline tests when there was a lower level of stress present in the participants. This would have been particularly useful for the Group E as their creative constraints may be less dynamic than Group R.

In terms of scale, the low numbers of participants is less convincing as a quantitative survey. To provide clearer evidence of expected relationships and correlation, work needs to continue to study bigger populations across different design programmes. This would support more generic conclusions on creativity but also facilitate subject specify studies.

The specific work presented in this paper has not dealt in depth with the myriad of issues surrounding creativity, behaviours and performance. There are many additional issues including; subject specificity, risk taking, research and exploratory failure and the nurturing of creative confidence. Personal traits, motivation, learning styles and fear of negative evaluation, are all areas that are open to investigation to gain further insight into the nature of stress related creativity.

Conclusion

The results of the questionnaire suggest that student participants of this survey were generally under a high level of stress, and may be primed to have their creativity limited as a consequence. Although overall there is a suggested divide between individuals who may be more influenced by either the environmental stressors or their own reaction to stress, the points of crossover between the groups suggest the relationship is more complex than previously outlined in the literature. In this case, the TTCT results suggest that individuals who are more affected by their negative reactions to stress are more likely to have their creativity negatively affected than those who are more influenced by the environment.

Complexity, interdisciplinarity and design literacy

RINGVOLD Tore Andre* and NIELSEN Liv Merete

Oslo Metropolitan University, Norway
* torand@oslomet.no
doi: 10.33114/adim.2019.11.244

In today's complex world, a variety of perspectives are needed to better understand and solve challenges. For decades, global organisations and researchers have pointed to interdisciplinarity as a way forward for educational systems. Educational research offers great possibilities and gains for students involved in interdisciplinary teaching and learning processes, and the interdisciplinary nature of design thinking and practice can play a vital role in interdisciplinary general education. This paper explores how future scenario-building, as part of general design education, can serve as a framework for inter-disciplinarity in general education and contribute to a better understanding of complex problems, challenges and design literacy.

Keywords: Interdisciplinarity, general design education, future scenarios, design literacy, design thinking

Introduction

With the world and societies changing rapidly, educational systems are challenged to make future citizens capable of solving increasingly complex problems and to teach them to create new opportunities for themselves and fellow citizens. The tasks ahead are enormous. Battling climate change, unemployment, possible social unrest and other geopolitical challenges demands an ability to understand today's world and the capability to create and innovate solutions.

Design education at both a general educational level and a tertiary level can play an important role in the development of learning necessary for sustainable societal development. We ask how interdisciplinarity in learning processes can contribute to seeing the broader picture and give students a deeper understanding of different phenomena. This paper discusses how the interdisciplinarity of future scenario-building school projects in general design education might contribute to such deeper understanding.

Background

The demand for interdisciplinarity

In the 20th century, education in Europe developed and transformed from a strictly divided disciplinary school system far removed from how individual selves experience the world and its complexity towards a learning ideal promoting a more holistic interdisciplinary explorative approach. In a report on interdisciplinarity, UNESCO stated:

> *From an educational point of view, teaching that is divided into separate disciplines runs counter to the pupil's natural approach to the exploration of his environment, and consequently it provides less incentive for the pupil unless he takes a particular interest in this or that subject. (UNESCO, 1986, p. 16)*

While multidisciplinarity is characterized by its sequential, juxtaposed and coordinated nature, interdisciplinarity (ID) is characterized by integrating, interacting, linking, focusing and blending (Klein, 2010). Most schools in the Western world teach multidisciplinary through subjects taught throughout the day in a sequential fashion and, '…when intentionally aligned, in a *Coordinating* mode' (Burns, 1999; Klein, 2010). A variety of educational research shows that ID teaching increases student learning '…including gains in the ability to recognize bias, think critically, tolerate ambiguity and acknowledge and appreciate ethical concerns' (Science Education Resource Centre, 2017).

Ronald Barnett (2012) argued that there is a need for a pedagogy that focuses on learning not in terms of skills or even generic skills, but in terms of human qualities and dispositions. Learning for an unknown future demands an ontological shift in education, as today's pedagogy does not address the 'supercomplexity' of reality (Barnett, 2012).

In a reality consisting of youth alienation, school drop outs, increasing polarisation and societal fragmentation, there is a need for a more integrated human focus on learning. The way general education in Europe has traditionally been organised does not achieve the ideal of interdisciplinarity. Phenomena descriptions and problem-solving within the framework of isolated school subjects does not necessarily yield the perspectives needed for a deeper understanding. Learning should be increasingly organised and facilitated in a manner that fits the complex reality of today and tomorrow.

The interdisciplinarity of design

The activity of design in the understanding of design as problem-solving can be interdisciplinary or transdisciplinary.

> *In order for the designed artefact to be truly valuable to all those who interact with it, designers have to consider issues of aesthetics, usability, ergonomics, safety, marketability, manufacturability, functionality and sustainability. This requires a wide range of skills and knowledge. Design has therefore been described as science and art, as communication and argumentation, and as thinking and inventing.* (Boradkar, 2010, p. 273)

The interdisciplinary nature of design and design thinking (Darbellay, Moody, & Lubart, 2017) allows us to see general design education as a framework for interdisciplinarity in general education. This is a possible argument for expanding general design education to achieve greater potential for learning outcomes and curricular activity.

Future scenarios, design activism, speculative design and critical design

Within the context of design, the term 'future scenario-building' can be understood as a working method that describes a possible future and provides fertile grounds for innovative and challenging design processes. In the professional design context, the goal is not the scenario itself, but, rather, the design process that follows (Willis, 2005). Scenarios are often narratives, and they follow certain approaches or forms. Future scenarios can help designers to avoid excessively favouring the present (Thorpe, 2007). Through scenarios, designers can free themselves from the idea of what a product is. Thus, scenarios are an important tool in creating a better relation between products and user needs (Willis, 2005). If designers focus more on user needs and detach themselves from existing technologies, they might create possible solutions that are more closely linked to these needs. A specific example is a car: A person does not necessarily need a steel structure with an internal combustion engine and four wheels; rather, he/she needs a method to get from A to B.

Scenarios and design also have common qualities. They are both future-directed and represent attempts at prefiguration (Willis, 2005). Following Willis (2005), we see future scenarios as pre-figurative thought exercises that are similar to design: having an idea about how something should be and actualising it. Through exercises and tools like future scenarios, students can practice pre-figurative thinking and actualising design. In a teaching situation in which students get to work with future scenario-building, opportunities to see products in a larger context might facilitate a greater understanding of such topics as consumption and environmental

impact. Liv Merete Nielsen stated that visualizing ideas and solutions not yet articulated presupposes a competence to visualize these ideas; that is, it does not happen naturally and needs to be trained or developed (Nielsen, 2013). We believe that a good arena for this is the general educational school system, in which citizens can work with a common set of teaching goals.

The concept of design is usually and traditionally thought of as giving form to an object or product for aesthetic and functional purposes. However, the concept of design has changed and is changing. Design is increasingly seen as beneficial to many other aspects of human life: For example, it can promote sustainability through material and manufacturing choices, how designers think and the framework of processes in which they work (Cross, 2011). Fuad-Luke (2009) saw the role of designers as one of an opportunity to change society, and he stated that design can be used as a tool for activism. He described this design activism as creating a counter-narrative that seeks to create and balance positive social, institutional, environmental and economic change, which can be created through fantasy, practice and a design way of thinking. According to Fuad-Luke (2009), design activism can also create a change in the activist him/herself. In this understanding of what design knowledge can be, we see design as an opportunity to actively change society for the better, either through fantasy, design practice or design thinking.

Design can be an opportunity to speculate about how things could be and to try out possible futures to create a ground for discussion and reflection about current society (Dunne & Raby, 2013). Possible futures created should not necessarily be positive ones, as a positive future might not provide the best material for discussion or reflection about today (Dunne & Raby, 2013). A focus on more negative and darker futures might spark more useful reactions, thoughts and reflections about what we see as negative developments in today's society. Scenarios also provide an opportunity to critique and use design to challenge existing paradigms. Matt Malpass (2017) saw design research as having the ability to provoke discussion about an object and to engage a public as an instrumental application. We further see this possibility in future scenario-building and design as a framework in education for insight, reflection and critique.

In this study, we ask: How can the interdisciplinarity of future scenarios in general design education contribute to understanding the complexity of phenomena? Furthermore, we aim to discuss how the interdisciplinarity of future scenarios in a general design education can play a role in students' reflection and critical thinking.

Research method

Action research

The research method used in this study was action research. Action research is a method to improve practice and produce evidence on how such practice can be improved (McNiff, 2013). Through the collection of empirical data, analysis and discussion, we wanted to explore and produce documentation of how scenario-building can contribute to the possible content and development of general design education. The data gathered through the study included participatory observation notes/photos/audiotapes, qualitative research interviews and the students' scenario work. We see the informants as social actors who interact with society on different levels. In this understanding, we saw the scenarios as narrative expressions that, together with interviews, could provide valuable information about students' attitudes regarding their work on the school project.

During the two-week period that the school project lasted, the teacher-researcher (Ringvold) acted together with the students' ordinary teachers. Ringvold had experience and a background in teaching and as a design professional. He did not have any prior knowledge of, or connection to the school or any of the students or teachers involved in the project. To gather data from observation, the classes were audiotaped, and notes and photographs were taken. Student work was photographed, and interviews were audiotaped and transcribed. The student interviews were organised in several focus groups, each consisting of three students. Ethical regulations of individual and parental consent was followed.

The school project 'Build Your Own Future' was conducted with a 7th grade class (age: 12 years) in the fall of 2013 in Norway. The development of the school project was based on an understanding of future scenario-building as a four-phase process (Ringvold, 2014):

21. Finding a focus area.
22. Identifying and describing driving forces.
23. Developing the scenario.
24. Presenting the scenario.

Over the course of two weeks, after choosing between transportation or health and nutrition as a focus area, the students worked on six main tasks. The work resulted in written and visual descriptions of society in the year 2043. The six tasks consisted of:

1. Interviewing an elder. During the interview, both the student and the interviewed elder completed a survey about society today and in the past. The survey covered such areas as technology, health, energy and consumer patterns.
2. Information gathering/context research.
3. Developing a future scenario and creating scenario descriptions.
4. Making a collage presentation of the future scenario containing the written scenario descriptions.
5. Developing design specifications.
6. Drawing and presenting a product design.

The scenario was the setting for future products designed by the students. The school project mainly took place during the students' art and design classes, but the project was interdisciplinary in its approach and framework, as it included an opportunity to work with competences in science and mother tongue classes through the scenario-building activity. This eased the planning of the project by allowing more time for the project. In the work with the scenario-building, the students researched and identified changes and developments within the fields of energy, technology, transport, environment, health and nutrition. The students' work and research interviews formed the empirical basis for the study. The interpretation of the empirical material revealed several types of learning and insights that could contribute to the discussion on the outcome of this study.

Discussion

Seeing and understanding complexity

In today's rapidly changing world, in which reality is described as 'supercomplexity' (Barnett, 2012), general education should help students understand the complex nature of our surroundings. This can be done by identifying what changes are happening, why they are happening and what their consequences may be. In this educational change to better see and understand the complex nature of our world, we see interdisciplinarity as an approach that can help students comprehend the interdisciplinarity of the world itself.

A variety of future stories

The students in the school project 'Build your own future' created different stories (figure 1) about what the future might be like. They based their future scenarios partly on what they identified as changes in society before and today; however, to a great extent, they also integrated their own fantasies and wishes. The futures could describe societies in which we have solved the problems we currently face by changing our consumption patterns and policies; however, they could also describe worlds in which we have not solved our problems and their consequences have been played out. In the interviews, the students reacted to this variety of future versions: 'It made me think of how the world is today and how it can be, and the differences of how it can be in the future' (Student I). Two other students also voiced how the project gave them freedom to speculate. One commented: '2043—there is a lot of ways to imagine it. That's something I have learned. We can imagine it being really good or really bad' (student D). Another commented:

> *What I liked about the project is that there was no right or wrong. That we could see the year 2043. You could see it the way you wanted it. That there was nothing wrong with that. Some had it worse, and some made it better, and that was a good thing.* (student F)

These student reflections of multiple stories and future possibilities indicate, in our view, insight into the complexity of reality and reflections regarding the multiple perspectives needed to understand reality.

Figure 1: Six different future scenarios. Student collage presentations.

The interdisciplinarity of future scenario-building

We see the process of future scenario-building as interdisciplinary in that it is an activity characterised by 'integrating, interacting, linking, focusing and blending' (Klein, 2010). As part of the school project 'Build your own future', the students identified and described driving forces in the world's complexity. Lawrence Wilkinson (2009) described such driving forces as things that move the future in a specific direction, the identification of which can help us make better decisions. Driving forces can be understood as external and internal. Internal driving forces include knowledge and attitudes, while external driving forces can be technological, economic or natural (e.g. globalisation, the increasing greenhouse effect or increased life expectancy).

By identifying driving forces and describing changes that have happened and are happening, the students completed a set of research activities. The first task was to interview an elder and compare present society with society in the year 1983 (figure 2). The questions involved patterns of consumption and issues related to energy, technology, media, waste, transport, health and nutrition. The next task was researching these areas in groups, using web resources and statistics. The class then discussed what they had found out and what consequences their findings might have for future societies. In the variety of this work, the students gained different information about and perspectives on the driving forces described, including the variety of scientific fields, personal experience, society changing over time, global statistical information and group reflections. Through the subsequent scenario development, using visual communication and design thinking and methods, the students showed insight into the challenges we face today and tomorrow. Teaching situations that involve future scenario-building give students opportunities to see products in a larger context, which might facilitate a better understanding of such topics as consumption and environmental impact. In the words of one student: 'I didn't think much about it […] Now that I get all this down on paper, I think it's much more important than that' (Student F). We question whether this approach can provide the students an opportunity to see challenges and problems within a holistic context and whether it can prevent the alienation of such issues as sustainability.

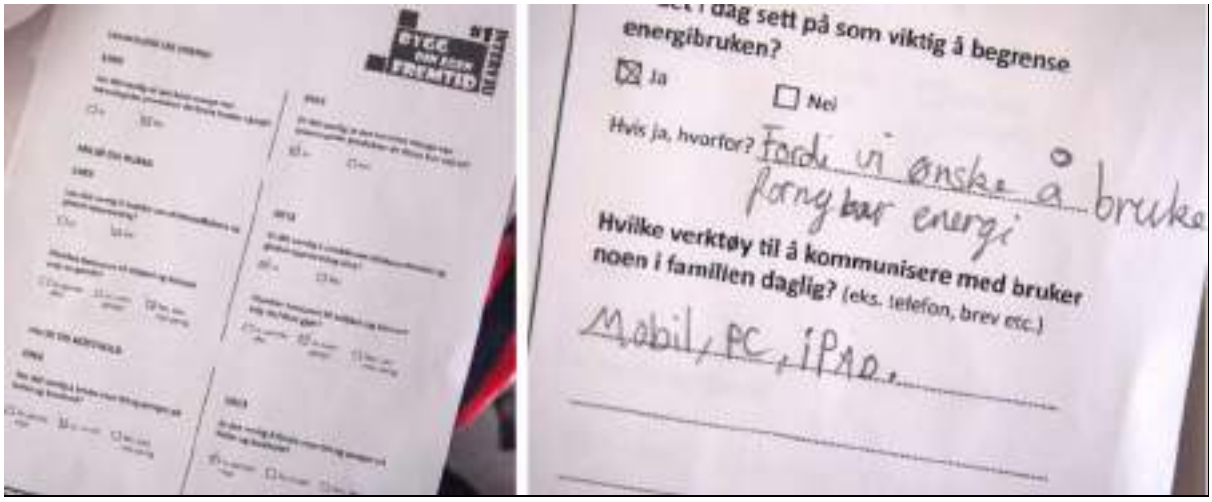

Figure 2: Student work from interviewing an elder.

Design education contributing to reflective and critical thinking

Future scenario-building and design seems to offer the possibility to be an interdisciplinary framework in general education for insight, reflection and critique. The stories provided by the students can engage the students themselves, fellow students and a wider public. It can provide a basis for discussions and reflections concerning ethics, societal and technological developments.

Richard Paul (1993) saw creative and critical thinking as similar. He defined critical thinking as follows:

> *Critical thinking is the intellectually disciplined process of actively and skillfully conceptualizing, applying, analyzing, synthesizing, and/or evaluating information gathered from, or generated by, observation, experience, reflection, reasoning, or communication, as a guide to belief and action.* (Paul, 1993 p. 22)

In light of Paul's (1993) definition, we see the students' project work as an exercise in critical thinking. The students gathered and evaluated information, then analysed and applied the information in their stories and designs, thereby synthesizing it. They accomplished this through reflection, reasoning, communication and conceptualizing.

Early awareness and knowledge of societal challenges might make students more capable citizens in the future. Habits and consumption patterns cannot be changed overnight, and reflection and critique in general education may be key factors in successfully shifting current paradigms. Liv Merete Nielsen and Karen Brænne (2013) argued for design literacy as an important competence for citizens that promotes an understanding of materiality that encourages longer-lasting products and sustainable consumer choices. Stefano Marzano (2005) pointed to studies in brain research showing how consumers are influenced by thoughts of possible futures. We ask whether the insight the students acquired might be considered 'priming memories': an awareness that helps one be observant when meeting the challenges of everyday life and might influence their actions towards making more ethical choices.

Buch-Hansen and Nielsen (2005) have argued that actors do not exist in a structural vacuum, but, rather, can influence and be influenced by the structures around them. Social interaction and collaboration are necessary to change existing structures. One of the aims of education is to give students the tools to interact and collaborate to change existing structures to new ones and mould the future into a more sustainable one. Future scenarios can provide knowledge and serve as interdisciplinary arenas for interaction, collaboration, discussions and reflective thought. As such, they can foster more reflective attitudes towards future actions.

Working with the school project, the students reflected on their learning outcomes. Considering what might be and speculating in their school work was new to some students: 'I have never thought of how it will be in the year 2043. I haven't thought that far ahead before, so I have learned a lot about that and how it can be and such' (student G). In their discussions about the project, it became clear that the students' various stories, dark futures and possible outcomes triggered a diversity of reactions among fellow students*:* 'I don't hope [student name's] version comes true. That's the least I want' (student H). Other students commented: 'He

wanted a third world war' (student G) and 'that cockroaches took over the world' (student H). This dialogue and interchange of reflective thought can be compared to the contributions of speculative design with a focus on more negative and darker futures, according to Dunne and Raby (2013). Specifically, the students' future scenario and speculative design work sparked reactions, thoughts and reflections among their fellow students. Future stories that are negative and scary can help confirm what is positive and what kind of future society students want.

Design processes, tools and ways of thinking can equip youth to 'think outside the box'. However, to accomplish this objective, the students' tasks cannot be fixed or final in form. When the questions youth tackle within these problems are not right or wrong, but deal more with the ethical questions of good or bad solutions or consequences, reflective thoughts will drive the discussions, peer responses and consideration of societal driving forces, while considering how something can be 'good' but have 'bad' overall consequences for the environment or people.

The knowledge formed on basis of the data gathered, experiences and reflections from the school project 'Build your own future' has contributed to transforming the first author's teaching practice. McNiff (2013) emphasized the importance of using action research for transformation, using the knowledge you have earned through action research improving your practice. The first author has in recent teacher practice used the methods of future scenario-building in a wider educational context outside core design subjects. In the school projects 'Media 2046' and 'Media 2047', two newer projects within the Norwegian upper secondary educational programme Media and Communication, students identified media trends of today and tomorrow and created future scenarios through future scenario-building (Ringvold 2019). In this new project the students developed and produced media products and stories that took place within the future scenarios. The stories gave insight into a series of thoughts and reflections about the direction in which our society might move. The projects seemed to provide a framework for critical thinking and reflection. In Figure 3, a student tells a story about a future in which technological developments, robots and automated processes might threaten humanity. In Figure 4, a short film named *twentyfour/seven*, a student tells of a future in which constant pressure causes stress and unhappiness.

Interdisciplinarity, design, creativity and innovation

Interdisciplinary research can discover opportunities that require integrated and collaborative perspectives. Interdisciplinary design thinking can contribute to understanding the complexity or wickedness (Boradkar, 2010) of the problems we face. As Boradkar (2010) argues, '[t]he sheer wickedness and complexity of these issues warrants engagement with other disciplines' (p. 274).

Willis (2005) compared future scenario-building with design, as both are pre-figurative thought exercises. The students' work revealed how this pre-figurative thought process encouraged them to seek new solutions and give shape to something as yet unknown. This ability is seen as a fundamental human capacity and the basis for all design, not just professional design practice (Willis, 2005). Through general design education, this important capacity can be fostered in future generations and can contribute to the development of innovative skills not only among future professional designers, but among all future citizens.

In reflecting on their work with future scenarios, many of the students described a joy of shaping the unknown. They identified problems and described new solutions (Ringvold, 2014). Nigel Cross (2011) argued that good designers have a special way of thinking: 'Rather than solving merely "the problem as given" they apply their intelligence to the wider context and suggest imaginative apposite solutions that resolve conflicts and uncertainties' (p. 136). This description of design thinking is comparable to the students' project work. In their descriptions of the future, they identified problems of today and tomorrow, which they sought to solve with their design solutions. For example, one student designed a *Cloud Bed* (Figure 5), which is not only a hovering bed shaped as a cloud, but also part of photosynthesis. This problem-solving product emerged from the interdisciplinary research phase. The student work shows how interdisciplinarity in general design education can contribute to creative problem-solving. The use of future scenarios and speculative design can help develop human creativity and innovation. Through learning to see the bigger picture and products in a wider interdisciplinary context, students can develop problem-solving skills that support their research capabilities and creativity.

Figure 5. 7th grade student project work: Skyseng (English translation: Cloud Bed).

Obstacles, limitations and challenges

A school project like the one in this study has limitations, and its success is dependent on a series of factors identified during the study. As teaching in schools is not organized in an interdisciplinary manner, but organized in separate subjects, projects like this can be complicated to facilitate and manage. This project was dependent on the goodwill of the school management and teachers. The success of future projects is dependent on general design educators with insight into methods and processes. Ringvold organized and managed this project. Fully understanding the processes and purposes of all the tasks included in the project was considered important to engage the students and tutor them through the different stages and learning processes.

The project success was dependent on providing time for the tasks that needed to be done. In a school day with a tight schedule and minimal available time, projects that are time-consuming might be difficult to organize. On the other hand, by integrating a large set of skills and different subject benchmarks in the same project, an interdisciplinary approach like this can save time by accomplish learning for different subjects within one wider setting.

Summing up

Future scenario-building as part of a design school project can work as an interdisciplinary learning process and framework allowing for perspectives and insights that can contribute to students' ability to better see consequences and grasp the complexity of problems. Through seeing possible futures, be they negative or positive, students can gather and reflect on research and information in a wider context. By playing out the consequences of qualities, trends and changes in today's society, the students raised issues of ethical dilemmas concerning technology and sustainability. This gave them a platform for critical thinking.

The interdisciplinarity of design thinking and general design education projects fosters design literacy including the ability to experience complexity and understand complex problems in a wider context. A design literacy inclusive of design learning can enable students to better understand and reflect upon the challenges of an increasingly complex and rapidly changing society. This kind of design literacy and education for the general public can, in turn, promote sustainable decision-making and critical innovation. The results of these projects are however not generalizable. Time and space influence the outcome. Identifying phenomena and problem-solving through design processes, tools and ways of thinking can be a good interdisciplinarian framework for education because of the nature of the task. To better understand user needs, materials and the environmental consequences of product manufacturing and use, several different disciplines are needed. In light of this, we ask whether general design education can be a natural hub for interdisciplinary education for the general public.

Networking for strengthening design literacy

BRODSHAUG Irene* and REITAN Janne Beate

Oslo Metropolitan University, Norway
*corresponding author e-mail: Irene.Brodshaug@oslomet.no
doi: 10.33114/adim.2019.12.384

This article focuses on design education for the general public and the ways in which students and teachers can become more design literate through the development of networks, such as professional groups for teachers. The aim of professional groups is to create a structure that focuses on design competency among Design, Art and Crafts teachers as well as design education in Norway's primary and secondary schools. Etienne Wenger's theories of community of practice and Unn Stålsett's theory about the development of networking through professional groups are highlighted in this study through the comparison of two municipalities in conjunction with informant interviews. The emphasis of this study is on how each municipality gives time and space for the development of design competence through professional groups. A well-organized professional group will hopefully contribute to a deeper level of expertise in schools and an increased ability for the general public to recognize design education.

Keywords: design literacy, professional groups, strengthening lay people's competence, school development

Introduction

In order to increase general awareness of which choices one must make for a sustainable future, several researchers have agreed that it is important to strengthen lay people's competence in the fields of design and sustainability (Nielsen & Brænne, 2013; Pacione, 2010; Smith & Iversen, 2018). In Norway's primary and lower secondary schools, where design is a primary focus area in the core curriculum, the subject of Art and Crafts is intended to advance design knowledge amongst students. In Norway, Design, Art and Crafts have been combined into one subject since 1960, first named Forming and from 1997 named Kunst og håndverk whereas in other countries these are most often separate subjects (Nielsen, 2008). Design, architecture, art and visual communication are core aspects of Norwegian curricula in Art and Crafts. This paper focuses on the part of the curriculum that deals with the design area in the subject of Art and Crafts. To make the role of deign within this subject, we choose to translate Kunst og håndverk in Norwegian to Design, Art and Crafts in English. We define design and design education broadly, in line with the journal FormAkademisk – research journal og design and design education, which include "fields such as industrial design, visual communication, interaction design, architecture, landscape architecture, urbanism and design education at all levels from kindergarden to the doctoral level" within their scope (FormAkademisk, 2019).

An example taken from the competence aims, stated in Norway's curriculum Kunnskapsløftet [Knowledge Promotion], indicates that students should be able to "design products based on a specification for form and function, describe the life cycle of a product, and assess implications for sustainable development, environmental impacts and utility" (Kunnskapsdepartementet [Ministry of Education], 2006, our translation

from Norwegian). This policy document communicates that it is desirable that the general public receive design education. Its summary describes what students should learn in the field of design:

> *In design, the design of objects is central. Here, the craft tradition continues in the subject. Design includes both working directly with materials and working with sketches and models. The design of ideas, working drawings, products and forms of use are central. Knowledge of materials, problem solving, and production can form the basis for innovation and entrepreneurship. (Kunnskapsdepartementet [Ministry of Education], 2006, our translation from Norwegian)*

In order for students in Norwegian schools to get the best possible education, they must have teachers with a high level of competence in their subject areas. A teacher of a foreign language, for example, is competent if they have a good command of the language, adequate writing skills and an understanding of the current culture. The teacher should also have a grasp of the language's literature. Similarly, a teacher who teaches design within the subject of Design, Art and Crafts must both must both be a competent practitioner and have the ability to teach the subject.

Teachers in Design, Art and Crafts come from different backgrounds. In our opinion, the aims for improving design competence are extensive and can be interpreted differently. There are several questions to ask within the context of this study:

- Does each primary school teacher have the skills necessary to offer their students a good design education?
- How can teachers strengthen their expertise and design literacy in the subject of Design, Art and Crafts?
- How can teachers develop a common understanding of what is important for their students to learn in order to develop competent decision-making and critical innovation skills?
- How should networking in professional groups be organized and managed in order to promote high-quality professional development for teachers?

These are important questions to reflect on in order for future citizens to become design literate.

Previous research

The study of Design, Art and Crafts is facing a number of challenges. Our current educational system focuses strongly on PISA (Programme for International Student Assessment) results in reading, mathematics and science. The Ministry of Education prioritizes funds for certain subject areas, effectively defining what is more or less important regarding the education of students in Norwegian schools (Brodshaug, 2016).

Issues in the field of Design, Art and Crafts education in Norway

- According to Lagerstrøm , Moafi, & Revold's report *Kompetanseprofil i grunnskolen, hovedresultater* [Profile of Skills in Primary Schools, Main Results], based on Norwegian statistics, only half of all teachers who teach Design, Art and Crafts have a specialization in the subject (Lagerstrøm, Moafi, & Revold, 2014; Kunnikoff, 2015).
- It is difficult to get a job as a specialized teacher in Design, Art and Crafts, and it is beneficial to have additional expertise in other subject areas (Kunnikoff, 2015).
- There are challenges with the current classroom framework, such as poorly functioning workshops or large class sizes (Hansen, 2015).
- There are challenges concerning the assessment of students (Lutnæs, 2011).
- The competency requirements in so-called "basic" subjects are promoted by The Ministry of Education but there are no competency requirements for Design, Art and Crafts at the primary level (Ministry of Education, 2015; Kunnikoff, 2015).
- There are fewer opportunities for teachers in Art and Crafts to pursue further education in their subject than there are for teachers in other subjects, like mathematics (Regjeringen [Government], 2015).
- There are few available textbooks and resources in the subject.
- School leaders perceive the subject of Design, Art and Crafts to be less important than other subjects (Lie, 2013).

- School days offer little relevant development time, and educators need to be able to collaborate with each other across subject areas (Garberg, 2014; Lie & Nielsen, 2016).

Research in the area of Design, Art and Crafts highlights challenges involving a lack of cooperation among teachers of the subject, even though other studies illustrate the advantages of managing professional networks and pursuing collaborations (Brodshaug, 2016). Eva Lutnæs discusses collaboration in her doctoral thesis *Standpunktvurdering i grunnskolefaget kunst og håndverk: Læreres forhandlingsreportoar [Final Evaluation Grades in the Subject of Design, Art and Crafts: the Teacher's Negotiation of Repertoire]* (our translation from Norwegian). In her study, she examines two teams of teachers and focuses on how they collaborate while giving students their final grades. There are no requirements from the educational institutions for collaboration while teachers are grading (Lutnæs, 2011), however, Lutnæs's thesis reveals that teachers who collaborate have a more developed response when it comes to clarifying the reasons behind their final grades. Catrine Lie's 2013 master's thesis, *Skolelederes verdsetting av læreres fagkompetanse i kunst og håndverk [School Leadership's Evaluation of Teachers' Subject Proficiency in Design, Art and Crafts]* (our translation from Norwegian), addresses the issue of school leadership prioritising the hiring of teachers educated in the field of Design, Art and Crafts. Lie touches on the teaching loads of Design, Art and Crafts teachers and, specifically, their number of teaching hours, which is greater than the teaching loads of educators who teach other subjects in Norwegian schools (Lie & Nielsen, 2016). She refers to Design, Art and Crafts teachers as a part of a collegium and describes the effects these teachers associate with collaboration and interdisciplinary work. According to Lie, the interviewees emphasised that having at least two teachers within the field of Design, Art and Crafts per school contributes a great deal to their job satisfaction and professional development (Lie, 2013). In her master's thesis, *Formell fagkompetanse i kunst og håndverk, Betydning, prioritering og konsekvenser [Formal Professional Competence in Design, Art and Crafts—Meaning, Prioritizing and Consequences]* (our translation from Norwegian), June Kunnikoff writes that she consciously chooses to not spend very much time developing her professional network; however, she emphasises that networking is important to the participants of her research (Kunnikoff, 2015). Kunnikoff's study begins with statistics cited from Lagerstrøm et al.'s (2014) research, which shows that half of those teaching Design in Art and Crafts have no formal education in the subject (Lagerstrøm et al., 2014).

> *After having spoken with all five informants, I see in the transcripts that everyone speaks warmly about the professional collegium they have at school, and I get the impression that everyone places value on professional networks in different arenas. To varying degrees, collegiality is mentioned in schools, municipality-based professional network meetings, professional conferences, social media groups and the art and design education journal* FORM *as valuable for professional development and teaching. (Kunnikoff, 2015, p. 56, our translation from Norwegian)*

Marit Garberg sheds light on the progress and development of local curricula in her master's thesis, *Planer—hva og hvorfor? En undersøkelse av innholdet i de lokale læreplanene i kunst og håndverksfaget på barneskolens mellomtrinn [Plans—What and Why? An Examination of the Content of the Local Curricula in the Design, Art and Crafts Subject in Primary Schools]* (our translation from Norwegian). She discusses lacklustre collaboration between schools and the lack of a guarantee that further education in the subject will be offered to Design, Art and Crafts teachers like for teachers in other subjects.

> *From my perspective and with my experience in the field, little collaboration exists among and between primary schools and lower secondary schools when it comes to the subject of Design, Art and Crafts, in contrast to other subjects, such as Norwegian and mathematics, in which established collaboration exists between primary and lower secondary schools. Here, I refer to schools that belong to the same school cluster. (Garberg, 2014, p. 15, our translation from Norwegian)*

The Kjosavik report (2003) emphasises that specialized teachers in Design, Art and Crafts in primary and lower secondary schools collaborate less than classroom teachers in primary schools (Kjosavik, Koch, Skjeggestad, & Aakre, 2003). The reasons for this can be complex. Teachers in Design in Design, Art and Crafts are often the solitary instructor at their school. This may be because the total number of class hours required in the subject is low, there are few classes offered in Design, Art and Crafts or the teachers are more focused on their own subject and find it less useful to work with other teachers and subjects (Brodshaug, 2016).

Current research is based on the question of whether there is a need to collaborate across schools in order to strengthen academic environments and heighten competence, as there are often only one or a few teachers in Design, Art and Crafts at each primary and secondary school.

Research questions

This paper discusses the following research questions: what content can academic networking groups for teachers in Design, Art and Crafts include, how can such groups be organized and what benefits does membership entail? In this research, design is both a core area of curriculum in the subject Design, Art and Crafts and a method for creating professional groups. Herbert Simon's definition of design is essential to our understanding of it; “Everyone designs who devises courses of action aimed at changing existing situations into preferred ones” (Simon, 1969, p. 55).

Method

This study is of an exploratory nature. Therefore, the qualitative method has been chosen to better explore how networking through professional groups can be organized for, as Alvesson and Sköldberg (2009) state, “Qualitative research is a contextual activity that places the viewer in the world. It consists of a set of interpretive, material practices that make the world visible” (p. 17).

Various professionals were interviewed for the study and two different municipalities in Norway were compared. Four informants from each of the participating municipalities were interviewed: an adviser of education in the municipality, the manager of the professional group, and two teachers that were members of a professional group. Their statements were then compared. The questions posed to the informants were designed to gain a deeper perspective on the content, organization and utility of professional groups within the field of Design, Art and Crafts. The questions posed to the informants were about the content, organization and utility value of professional groups. The study examined how the two municipalities, and their respective professionals, developed and manage the professional groups. The research explored—in-depth—field work done in Municipality 1, where the municipality systematizes the management of these groups. The manager of the professional groups in Municipality 2 was also interviewed. The manager, who is a teacher, has taken her own initiative concerning the professional groups and organizes meetings without the structure of a municipal model. Municipality 2 is based on a model where enthusiasts drive the groups without the municipality’s involvement, as is the case in Municipality 1. The research discusses Municipality 1's model for professional development through the professional groups and compares it with that of Municipality 2 (Brodshaug, 2016).

This research is based on a reflexive methodology (Alvesson & Sköldberg, 2009), with a focus on a selection of a few theories, and makes use of Etienne Wenger's theory of communities of practice (Wenger, 1998; Wenger, McDermott, & Snyder, 2002) and the theory for the structure of professional groups as described in the book *Guidance in a Learning Organization* (Stålsett, 2006).

Interpretation perspectives

Etienne Wenger

Etienne Wenger (1998) and his older colleague Jean Lave developed the concept of *communities of practice* in their joint projects. They also developed the concept of *situational learning* (Lave & Wenger, 1991). According to these theories, learning is primarily a social phenomenon. Wenger rejects standard, individualized learning, which he believes makes learning dull and too far removed from the context of the world in which we live.

Professional groups meant to improve the teaching of design practices can employ Etienne Wenger and Jean Lave’s theories about communities of practice, as well as their research on the development of schools (Wenger, 1998), as each embraces the characteristics of mutual engagement, common activities and common repertoire.

Wenger stresses the importance of long-term communities of practice. He writes that these communities are not meant to provide quick solutions to problems. They should not replace a team or other aspects of an organisation; rather, they should contribute value to the organisation and its members. Wenger, McDermott and Snyder (2002) classify short- and long-term communities of practice in their own definitions. Short-term communities of practice serve as venues for problem solving. They provide quick answers to questions; help improve the quality of decisions and provide wider perspectives on problems. In contrast, long-term communities of practice require the ability to execute a strategic plan, form knowledge-based alliances and establish a forum that facilitates the expansion of skills and expertise (Wenger et al., 2002).

Wenger et al. (2002) write that time is important for someone who is the leader of an organized community. The most common cause of failure is that the coordinator of such a community simply does not make time to perform the role, even when they have allocated time for this purpose; they too easily let other things take priority over community work (Wenger et al., 2002, p. 83).

Several researchers in the field of design and teaching practices use Wenger's theories about communities of practice and the ways in which people learn in groups (e.g., Reitan, 2007; Lutnæs, 2011). Wenger co-developed the book entitled *Cultivating Communities of Practice*, which focuses on how people can systematically use communities of practice to develop businesses.

Unn Stålsett

Unn Stålsett is a former Associate Professor at Oslo Metropolitan University, where she worked in classroom teacher education. She describes networking teams in her book, *Veiledning i en lærende organisasjon [Guidance in a Learning Organization]* (Stålsett, 2006, our translation from Norwegian), which serve as a venue which serve as communities where members can share experiences, make use of one another's knowledge and be open about the challenges they experience in their disciplines. Such groups are not meant to serve as courses in which the participants are passive recipients; rather, everyone is expected to contribute his or her own knowledge.

Unn Stålsett (2006) relies on Wenger and Lave's concepts to discuss methods of learning in a practice community in her book. Based on three features (mutual engagement, common activities and common repertoire), the professional groups in each municipality can be defined as communities of practice. The groups consist of teachers who teach the same subject. Every teacher works within the same municipality, which has a common proficiency development program for each of its schools. The teachers use similar terminologies.

Starting and managing professional groups in Design, Art and Crafts

Design, Art and Crafts professional groups were started in Municipality 1 in 2003, as a collaboration between a university and the municipality. The collaboration was managed by Unn Stålsett and an adviser in education for the municipality. Municipality 1 has professional groups for every subject taught in its schools; teachers meet in their groups five times a year for three hours per session (1-4pm). Examples of work done in these professional groups include discussions, relevant political work, workshop activities, excursions, evaluations and visits from external professional speakers. The groups also collaborate with the university to provide guidance for newly educated teachers, as was done at Oslo Metropolitan University's Department of Art, Design and Drama, where new teachers were guided through discussions about innovation and professional development around the theme of assessment practices.

While in Municipality 2, one of the Design, Art and Crafts teachers started a professional group in 2012 on her own initiative, without any support from the municipality. These differences will be further discussed in next section.

Points of view from advisers, managers and teachers in Municipalities 1 and 2

In the interviews, the teachers, advisers of the municipalities and managers of the groups had interesting perspectives on the need for collaboration and professional groups.

The adviser of education in Municipality 1 spent approximately half of her interview discussing the subject group managers—she trusts their expertise in their subjects. She could not comment on the actual quality of the groups' content, but she referred to the evaluations done by the professional groups in which it was made clear that the teachers were largely satisfied. In the conversation, she equated Design, Art and Crafts with other subjects and spoke as though it were a matter of course that there was a professional group in Design, Art and Crafts, in line with the other subjects (Brodshaug, 2016).

The adviser of education in Municipality 1 said, "It would have been absolutely crazy if we were to only have professional groups in other school subjects and not in the Design, Art and Crafts subject. We have had that right from the start" (Brodshaug, 2016). She went on to say, "It is important to have a good group manager then, who knows the subject and who is also interested in the development". The interviewer then inquired if a group manager should be able to pull certain strings. The adviser of education replied, "Yes, it is a key role in

being a good group manager. I think so far that, in Design, Art and Crafts especially, we have had very good group managers" (Brodshaug, 2016).

In Municipality 2, the adviser of education had heard of the professional group that was started through the initiative of individuals. She said it was a shame that political guidelines meant that they could not prioritize the organization of these groups. She said that politicians prioritize only subjects such as mathematics, foreign language and science. The manager of the professional group in Municipality 2 was asked why she started this group and why she believed it was important. She said that she had worked nearly ten years as a teacher in Design, Art and Crafts at a secondary school where she often collaborated with two other teachers in the same field. When she began work in Municipality 2 in 2006, she was the only teacher in Design, Art and Crafts at her school. She had little relevant development time and was alone in her pursuit of the subject. She wanted to work more closely with other teachers in order to assure the quality of her teaching, ensure better academic progression for her students and discuss pertinent challenges with other Design, Art and Crafts teachers. She contacted her principal and asked if she could invite colleagues within the municipality to spend some of their development time on professional groups. The principal in her school took this further during the municipal principals' meetings and the other principals responded favourably to the idea (Brodshaug, 2016).

The manager of the professional group in Municipality 1 has received allocated time for group planning from the adviser of education. The manager in Municipality 2 must use her own spare time for pre- and post-group work. The quality of work done in Municipality 1 may not be better simply because more time is allowed for planning, however, groups in Municipality 2 are more vulnerable because they do not have time set aside for group work and they do not have a budget for lecturers or excursions. Wenger et al. highlight the importance that the group manager or coordinator have a good individual relationship with every member of the practice community (Wenger et al., 2002), which also requires time and good organization.

The focus on prepared, sustainable design proficiency

In recent years, a primary focus of the professional group of Design, Art and Crafts teachers in Municipality 1 has been to continuously develop design and crafts courses. The group worked in cooperation with an upper secondary school on a project called *En ny håndverksvei for barn og unge* [A New Pathway to Crafts children and young people]. Together, they designed and made products, such as a chessboard (Figures 1 and 2), from a variety of wood materials. They focused on developing the design process, quality assurance, knowledge of tools, areas of application and an understanding of the best ways to teach students the importance of sustainable materials and techniques. The high dropout rate of students in upper secondary school in Norway is widely known and only a few students choose to study design and crafts. By collaborating with upper secondary schools and focusing on design and crafts in primary and lower secondary schools, the professional group hopes to increase student interest in design and crafts studies in upper secondary schools. It is therefore important to strengthen teaching effectiveness of Design, Art and Crafts from as early as the first grade. The group also wishes to focus on the use of local materials and promote sustainable development. In future years, the professional group will continue to work on these issues in a systematic way (Brodshaug, 2016).

The professional Design, Art and Crafts groups in Municipalities 1 and 2 are organized differently. Municipality 1 has an adviser who has been collaborating with a university, managing the professional groups and taking primary responsibility for all implementation and decisions regarding group managers. She has also been responsible for coordinating group manager meetings, setting aside meeting times and allocating funds. A substantial system has been built around these professional groups, which serve as the municipality's continuing education program for each individual teacher. The professional group for Design, Art and Crafts is equal to the professional groups of other subjects with regard to time and resources allocated when it comes to external course organizers and excursions. There is no similar system in place for these professional groups in Municipality 2. Nevertheless, much of the group content is the same; the groups work on the issues surrounding their subject areas in a similar manner to Municipality 1 (Brodshaug, 2016).

Figures 1 and 2. Designing the chessboard as a team

In 2017, the Norwegian Minister of Education spoke at the Design, Art and Crafts Conference at Oslo Metropolitan University (Isaksen, 2017). He stated that the academic community should be strengthened and systematised for the betterment of Design, Art and Crafts as a field of study. In an interview, Thomas Nordahl, a foremost Norwegian academic on school development, underscored that systematically working with others to address challenges in schools is the most important factor that affects school development (Amundsen, 2015). Erling Lars Dale, another academic on school development, promotes the establishment of a collegial community as a condition that strengthens the professional quality of schools. Dale writes that if teachers want to experience meaningful cooperation, they should have a collective identity that is in accordance with their frame of reference (Dale, 1993). These ideas can be linked to Stålsett's theories on network building and Wegner's theories on communities of practice. Over time, communities of practice – such as professional groups and networks with strategic plans for the development of teachers in, for example, design literacy in primary and lower secondary schools – will be important in strengthening the field of design in general and ensuring both teacher and student competency.

As Kjosavik et al.'s (2003) report demonstrates, and as many others express in different forms on social media, teachers in Design, Art and Crafts often work independently at their schools. Many miss the opportunity to develop themselves professionally alongside others or to obtain help and advice. This situation is related to the fact that only one-half of Design, Art and Crafts teachers are educated in the subject, although many are educated teachers with backgrounds in other subjects. Facebook groups and other social media forums discuss the subject of Design, Art and Crafts and, through them, it is possible to see a demonstration of Wenger's theories on short-term value communities. These groups become venues for providing quick solutions because group members can easily ask for help and advice. These groups are certainly useful, but teachers should still develop themselves over time and should have a plan for sharing and strengthening their knowledge in the context of a group in order to form strong academic communities.

This study focuses on facilitating collaboration among teachers using professional groups. What does a year of networking through professional groups in the subject Design, Art and Crafts look like for teachers? What should the content of these groups be?

In their employment contracts, teachers in Norwegian schools have time designated both for teaching and for proficiency development. The teachers' total work tasks are performed across 1,687.5 hours per year. Good

communication at all levels and systematic collaboration between teachers is important in order to develop processes that meet the individual school's need to organize work hours according to the agreement between Utdanningsforbundet [the Union of Education] and Kommunenes Sentralforbund (KS) [The Federation of Municipalities]. Teachers in Design, Art and Crafts are responsible for 948 lessons (in a full-time equivalent position) per year (SFS 2013, 2015). During the year, municipalities and schools have control over the ways in which teachers organize their teaching time both during and after work, their continuing education and their meeting times.

In a municipality or area containing different schools, there will be teachers who have different skills in different areas. For example, some will have expertise in design literacy and sustainability, while others will have experience working with textiles or wood. If a system can be created that allows teachers to share and learn from each other, then, in a few years, the overall competence of these teachers will increase through collaborations with colleges and professional designers that facilitate development of new skills and expertise.

This study shows that it is important that municipalities organize their subject groups in a structured way based on theory and research. It is important that the groups do not become simply a collection of people who meet to obtain a new course or that the teachers become passive participants. Instead, participants should share knowledge and create alliances (Wenger et al., 2002). It is also important that these networks be firmly rooted within both the schools and the municipality so that the groups do not become vulnerable for permanent existence of groups, which should not have to depend on enthusiasts (Brodshaug, 2016).

Conclusion and the way forward

In order to construct a good foundation for students early on, teachers need sufficient time to become proficient in their subject areas and to develop their field of study in collaboration with other teachers and institutions. If students are to experience progress at their education, and if the quality of teaching design is to be improved, teachers must have a common understanding of teaching standards. In addition to collaboration between schools, teachers in the field of Design, Art and Crafts should work together with colleges and other institutions in order to acquire relevant research insights into the field. Municipality-based professional groups can help a teacher develop competence and can improve design literacy. This is especially true if the municipalities are able to contribute to the organization and structure of these groups.

The research shows that even though teachers can experience greater freedom and influence on networks or professional groups that they have started themselves, municipality involvement is necessary to structure and organize these networks in order to achieve consistent quality and research-based standards over time. The last part of this article will focus on the ways in which this study can be further developed through work in a third municipality.

The design of professional groups in a third municipality in Norway

In a third municipality in Norway – a big city – political leaders agree that design expertise should be strengthened to improve the teaching of practical Art and Crafts.

The municipality’s Education Agency wishes to start professional groups for Design, Art and Crafts teachers according to the methods and models of Unn Stålsett, Municipality 1’s experiences and the research referred to in this article (Brodshaug, 2016). In this context, it is appropriate to consider Wenger's theories on the value of long-term communities of practice. As stated earlier in this paper, these networks should not simply be a collection of people or courses where one can obtain quick answers. These networks should be a place where teachers develop strategies and knowledge-based alliances and where they help to develop their field more broadly.

The goal of each professional group is to strengthen the study of Design, Art and Crafts throughout their municipality, while also improving the design literacy of their teachers. These teachers should be competent in all aspects of the curriculum in order to properly support the learning of their students. Teachers in the municipality have different backgrounds, skills and experiences. Based on a political order, the Education Agency has established a specialist committee and developed proposals designed to strengthen the teaching of certain school subjects, including the creation of professional groups. This step is justified by the findings from different Education Agency surveys, which state that:

- There are few Design, Art and Crafts teachers at each school, and it is therefore challenging to develop professional communities.
- There is a need to increase the competency of teachers, as determined by a mapping of practical subjects completed in spring 2017. In addition to ordinary courses, specialist committees recommend increasing this competence through the exchanging of experiences, the training of one another and the possible hiring of external course organizers. This would be organized and carried out by professional networks.

Both nationally and locally, government agencies and educational departments have stated that both practical and aesthetic school subjects should be strengthened. In Norway, there is a strong focus on professional development in Fagfornyelsen [The curriculum revision] (Utdanningsdirektoratet, 2018, our translation from Norwegian). The subject renewal states:

> *All employees in the school must take an active part in the professional learning community in order to further develop the school. This means that the community reflects on value choices and development needs and uses research, experience-based knowledge and ethical assessments as the basis for targeted measures. Well-developed structures for collaboration, support and guidance between colleagues and across schools promote a sharing and learning culture. (Utdanningsdirektoratet, 2018, our translation from Norwegian)*

Professional groups can contribute to the systematisation of competence development, the structure of a subject's content and the strengthening of the professions and the students' learning in that subject. In order to succeed, these networks must be based on theory and research and they must be structured and managed in a planned manner. In October 2018, an establishment meeting was held with three teachers from different primary and secondary schools in Municipality 3 to launch professional networks. The three teachers had a high level of expertise in art, crafts and design. Their goal is to be the managers of these professional groups and to use different strategies to increase the competency of teachers and strengthen the study of these subjects in their schools. These potential managers work in different schools throughout the city and intend to coordinate teachers from approximately 25 schools, who will meet to develop their competence. In total, there will be three different professional groups involving approximately 75 teachers.

To strengthen the design literacy of teachers and students in Municipality 3, the region should focus on several things referred to in this article. The managers will collaborate on developing an organizational structure and determining desired content in 2019.

The first gathering of Municipality 3's professional groups took place in March 2019. Their goal was to meet the teachers and discuss the importance of both Design, Art and Crafts and good design education. These groups will focus on design and sustainable development. They will eat together, talk together and map out the competence of the group using Stålsett's model (2006). They will ask the teachers which subject areas they are competent in and how they can share that competency with the group. For example, a teacher with a strong design education could lead initiatives and instruct others in the group on that topic.

In the second session, to be held in June 2019, the three professional groups will gather at a university in Municipality 3 where professionals, designers and professors will contribute to the teachers' education. Afterwards, design education and the development of teacher competence will be discussed. In autumn 2019, another gathering will focus on workshops and knowledge sharing; different teaching methods, crafts, materials and skills will be important topics. The new national curriculum, subject renewal and sustainability development will be highlighted. The overarching goal is to engage professional teachers who are passionate about their subject matter, so that students learn more and develop increased curiosity in these areas. These meetings will also focus on working together to recruit others to the field of education. Finally, professions that emphasize design will be an important topic at these meetings.

The goal is to achieve the best possible community of practice to strengthen the teaching profession so that students can receive better design education and become design literate, a skill that will be ever more valuable as we work toward a sustainable future.

Developing design literacy through brand-based artefacts

LELIS Catarina[a] and MEALHA Oscar[b]*

doi: 10.33114/adim.2019.13.358

The brand is a powerful representational and identification-led asset that can be used to engage staff in creative, sustainable and developmental activities. Being a brand the result of, foremost, a design exercise, it is fair to suppose that it can be a relevant resource for the advancement of design literacy within organisational contexts. The main objective of this paper was to test and validate an interaction structure for an informed co-design process on visual brand artefacts. To carry on the empirical study, a university was chosen as case study as these contexts are generally rich in employee diversity. A non-functional prototype was designed, and walkthroughs were performed in five focus groups held with staff. The latter evidenced a need/wish to engage with basic design principles and high willingness to participate in the creation of brand design artefacts, mostly with the purpose of increasing its consistent use and innovate in its representation possibilities, whilst augmenting the brand's socially responsible values.

Keywords: Branding, Participatory Design, Design Literacy, Employees, Higher Education Institutions

Introduction

The brand no longer fits Shannon and Weaver's traditional model of information transmission, mostly because unidirectional branding approaches have been supplanted. This reorientation required from companies a new kind of dominant philosophy, which had to, necessarily, be assimilated by all employees, as individuals. Besides the fact that these must be minimally familiar with the brand identity they represent and with which they commit themselves, they must also realise that their participation in the brand's organic structure means the constant conversion and maintenance of the brand itself. Marty Neumeier states:

> *Unlike the old corporate identity paradigm that prized uniformity and consistency, the new brand paradigm sacrifices those qualities in favour of being alive and dynamic. (…) Brands can afford to be inconsistent — as long as they don't abandon their defining attributes. They're like people. (…) A living brand is a collaborative performance, and every person in the company is an actor (Neumeier, 2006, pp. 133-136).*

The establishment of an institutional philosophy of this nature requires an investment in training collaborative individuals. Employees (being these all the individuals that, as some point, provide institutions with their work and capabilities, either full-time, part-time, no term, casual or voluntary) should, therefore, exploit their own brand knowledge and be confronted with any wrong brand assumptions they potentially have. Neumeier's 'collaborative performance' is only possible when the brand is flexible enough to support the diversity of emerging associations, meanings and artefacts, and as long as these do not turn into instances of infringement

or misappropriation. For employees to experience the brand and collaborate in internal branding activities, brand management efforts must, first of all, be internally-centred, allowing employees to present brand ideas they consider relevant and about which no one has ever thought about (Schultz & Hatch, 2006). Employees that concede themselves to know and align with the brand tend to act in a more consistent way and according to the ideal the company wishes to be perceived by its diverse audiences (Oddie, 2015, Ind, 2017).

This way, the creation of 'brand schools' (Schultz & Hatch, 2006) or 'corporate universities' (Ind, 2007) are interesting benchmarking tactics because they allow the involvement of new groups of individuals, who are expected to be engaged with the brand, whilst enhancing the understanding of what the brand represents (Hatch & Schultz, 2003; Aurand, Gorchels & Bishop, 2005; Schultz, Hatch & Ciccolella, 2006; Ind & Bjerke, 2007; Harris, 2007; Streader & Whitehouse, 2008). However, none of these strategies explore the brand and what it represents from a design perspective, and design literacy (and visual literacy, for that matter) is not part of their curricula. In fact, most of the literature on Branding theorises the brand as a Marketing elaboration and only few consider the design thinking from which a brand should emerge.

Thus, the purpose of this paper is to propose a communication platform for institutions to encourage employees to produce and share their own brand representations and, potentially, select and integrate these artefacts in the brand's identity system, considering the most creative, authentic and appropriate ones – being appropriateness, in this context, understood as a developed sense of design. Such a participatory or co-design approach (Lee, 2008; Fischer, 2012; Oswal, 2014) would contribute to brand equity and to the tangible circulation of intellectual capital but, most of all, to the externalisation of brand knowledge. This research also suggests that computer-mediated communication systems can successfully support this user-generated content logic, whilst increasing inclusion, participation and development. The context of an online community, as defined by Preece (2000) and Preece and Maloney-Krichmar (2003), and the use of Social Web interaction paradigms are considered suitable to support such a participatory internal branding approach. Therefore, the research question that guided this research was '**What participatory design platform can support the development of design literacy by engaging staff in brand artefacts co-creation?'**

Literature review

Brand artefacts are design artefacts

All organisations have a set of rules that allow them to perform their daily activities. These rules are partially codified and, as such, minimally explicit, but not to a lesser extent, they are also hard to articulate as they belong to the realm of *assumptions* – as opposed to the most tangible level, where we would find *artefacts* (Gagliardi, 2017). The study of artefacts takes us back to Schein's work (1984) in which he depicts these levels of organisational culture and their interaction. Several authors followed Schein in exploring nuances of what defines an artefact in an organisational setting: Moingeon and Ramanantsoa (1997) refer to symbolic products (artefacts) as the resources for individuals to understand the governing methods, behaviours and routines that are supposed to be known by the members of an organisation. Masino and Zamarian (2003), state that all artefacts have a set of values:

- *Cognitive*, since they guide the representation of relevant knowledge in the organisation and the identification (or not) with it;
- *Social*, when representing experiences, forms of expression and meanings, shared by individuals who conceive, construct and use them.

Vilnai-Yavetz and Rafaeli (2006) argued on the existence of three dimensions in any organisational artefacts:

- The *Instrumental* dimension refers to the extent to which the artefact contributes to the performance of tasks or to achieving the objectives for which the presence of the artefact was thought for;
- The *Aesthetic* dimension deals with the experience and sensory knowledge that the artefact provides to those who use or contemplate it, enabling the generation of aesthetic judgments that are based on the individual notion of "beautiful";
- The *Symbolic* dimension refers to the meanings or associations – since artefacts, as means of communication, can have symbolic consequences, both desired and unintentional.

These three dimensions seem to be highly relevant in defining satisfaction with imposed artefacts: depending on the adequate functional performance, the aesthetic virtue, and the meanings each individual will read in a specific organisational artefact, an emotional reaction will be determinant as to inform the way individuals will make decisions (Damásio, 1995) and include the artefact in their current and future routines, in a sustainable way. Such value seems to be the one missing in Masino and Zamarian's representation of organisational artefacts and will link to both cognitive and affective constructs – such as identification, belonging and commitment – that historically have been considered essential for values enhancement in internal branding activities (Mahnert & Torres, 2007; Punjaisri, Evanschitzky & Wilson, 2009; Punjaisri & Wilson, 2017), but also behavioural considerations – such as ethics (Dyrud, 2017) – building on awareness of quality, longevity and sustainability (Nielsen, 2017) and that will expectedly increase citizenship at organisational brand level (Burmann & Zeplin, 2005) and beyond.

A brand is a symbolic representation of the organisation's identity, expressed through a diversity of identity-led artefacts (Schultz, Hatch & Ciccolella, 2006):

- *Cultural artefacts*, constructed through the manifestation of perceptions and sensory competences existing in the organisation. Some examples of cultural artefacts can be found in the facilities' decoration style, in the existence or not of more or less rigid dress codes, etc.
- *Strategic artefacts* typically serve to express, communicate, and guide the organisation's purpose through vision, mission and value statements, and consist of the various resources used to make these tangible and operational (such as organisational posters, or enchanted stories filled with metaphors that allow staff to imagine and re-create organisational goals. Logo, signage, slogans and chromatic patterns are used as artefacts that deliberately convey what the organisation stands for and what it aspires to (Balmer & Greyser, 2002).
- *Image artefacts*, functional and aesthetic features that serve to express individuality through the transfer of meanings. Merchandising objects are probably the best example.

Hence, a brand is a whole, made up of symbolic, functional, aesthetic, tangible and intangible elements, grounded on cognitive, social and emotional values, duly articulated and systematised. It is a facilitator in the communication process – thanks to its virtue of stimulating the human ability to retain impressions and linking them to visual or verbal expression (Holsanova, Hedberg & Nilsson, 1998) – and an intellectual capital asset, vehicle of meanings, with which it is possible to establish relationships and create design solutions, through *design artefacts*:

> *"Design can be characterised as an activity where a designing subject shapes the design object by means of some design artefacts. The design object is the artefact formed in design; the outcome that design activity is directed to" (Bertelsen, 2000, p. 17).*

Participatory design and design literacy

Organisational identity and, in this case, the brand as an instrument of identity, are good examples of organisational knowledge made available to all employees within an organisation, and it is true that employees no longer only react: they are interpretive communities and potential sources of innovation. Therefore, some authors argue on the importance of employees to know the brand as much as they should live the brand, participating in its construction, in order to integrate collective knowledge and to make explicit/tangible the abstraction that usually characterises cultural artefacts (Ind, 2007, 2017; Jensen & Beckmann, 2009; Watkiss & Glynn, 2016).

Non-designers' involvement in design processes is a topic under discussion and research since the 1970s (Mambrey, Mark & Pankoke-Babatz, 1998). According to Fischer and Ostwald (2002), participatory design (PD), also known as collaborative design, has been characterised by focusing on the development of systems, more specifically at the design stage, gathering specialists and users in order to better develop new contexts of use and to design, together, the artefacts which the latter shall use. Similarly, co-design helps defining innovative solutions, as much as empowering participants in the solutions that will directly impact their lives (Sanders & Stappers, 2016).

In the PD logic, design is no longer to be practiced in isolation by the designer, but involving a range of other entities in the visualisation of concepts, plans and ideas, and in the production of sketches and models of the design artefact to be achieved. One of the deeper principles of PD is that all individuals can – and should – be designers (Muller, 2003). Some organisations are already involving their audiences (including internal

audiences) in design processes. These entities are aware that supporting and fostering the collective human capital existing in the community they already hold gives them real and creative content. But the strategies of support and development of design literacy are sparse or even non-existent, namely when the contribution of design to the economy is increasingly valued due to the relevance of design skills to the so-called *fourth industrial revolution* (The Design Council, 2018).

From this perspective, a requirement for these contributing audiences would be a minimum sense of design purpose and basic systems of enquiry in the context of design. Hence, as clarified by Pacione (2010), they would have to be design literate, which involves "… basic skills in inquiry, evaluation, ideation, sketching, and prototyping. We are not talking about mastery of more specialised forms of knowledge that a graphic or industrial designer might employ" (p. 9), but also the consideration of production efficiency (time and energy) and efficacy (e.g. sustainability-led artefacts) (Nielsen & Braenne, 2013). Thus, our understanding of design literacy follows Nielsen's (2017, p.2): "a broad concept that encompasses visual literacy, materiality knowledge, ICT literacy, ethics and design education for citizenship. It includes the creation of ideas and technology to create both artefacts and solutions, as well as interpretations and reflections on these designs."

Moreover, brand co-designers can only take part of this if they get to know the brand deeply, and if appropriate infra-structural resources are made available. Currently, much of these communication, skill development-led and co-creation environments have become computer-mediated and follow interaction paradigms common to the Social Web. Cao, Guo, Vogel and Zhang (2016) state that the use of social media in work contexts fosters employees' social capital and, subsequently, furthers knowledge transfer. Hence, the context of an online community, as defined by Preece (2000) and Preece and Maloney-Krichmar (2003), and the use of Social Web interaction paradigms are considered suitable to support the development of design literacy by engaging staff in brand artefacts co-creation.

The proposed system

About a decade ago, the ideals of PD together with the conditions generated by computer-mediated communication (CMC) led to the arousal of user-generated content, defined as interventions on pre-existing content, in a process in which new content is continually being used as the basis for other creations, resulting in constantly under development projects (Bruns, 2008). This is very much aligned with Neumeier's perspective that "A living brand is a collaborative performance, and every person in the company is an actor" (2006: 136) and Schultz, Hatch and Ciccolella's view that the 'perfect artefact' must allow the renewal of perceptions, so as to ensure contemporaneity and the evolution of the entity's interactions (2006).

Lelis and Mealha (2015) developed a supportive procedural model for brand artefacts co-creation which would respond to the needs of employees in service-oriented contexts, to encourage purposeful creativity around the brand. This model proposes three domains of interaction (Figure 1): *Mentoring*, by collaborative brand-related learning experiences, *Co-Design and Transfer*, through opportunities for participation, and *Evaluation* via the creative and sustained brand exploration with the shared responsibility towards both a wealthy and a healthy brand.

Figure 1 — The interaction structure for brand artefacts co-design – adapted from Lelis and Mealha (2015)

Accordingly, a digitally-mediated platform for developing design literacy by engaging staff in brand artefacts co-creation could be governed by these domains of interaction that should be considered in an iterative manner:

- Mentoring towards brand knowledge — staff can interactively experiment the brand's functional visual attributes and applications, exploring and developing basic skills essential for design literacy through, preferably, tangible brand artefacts, as their explicitness and objectified existence facilitate recognition (Watkiss & Glynn, 2016).
- Co-design and transfer of brand artefacts — staff can co-create brand-related ideas (artefacts, associations, meanings) which can be categorised, stored and published, increasing the existing brand knowledge and sense of design.
- Evaluation of brand artefacts — staff can participate in the critical assessment process of these ideas, in an advanced environment where the proposed brand artefacts, subject to open scrutiny, can be further analysed and discussed, considering their design features and functional, aesthetic, symbolic and socially responsible characteristics.

Such an open to participatory design and instructional digital platform, incorporating a three-dimensional approach like the one presented above does not exist. The same authors performed a study covering brand centres' main features (Lelis & Mealha, 2014) which revealed that these include specialised content only, which is previously established or selected by specialists, hence far from the participatory ideology. These researchers also found that critique and evaluation processes are disregarded in most online brand centres. Moreover, this study also states that brand centres tend to be repositories of existing designs and resources, storing standards, guidelines and brand prescriptions and restrictions, not necessarily preoccupied with brand learning, brand tangible experimentation, and design literacy development. With the proposed platform we aim at creating a space where individuals can develop basic design abilities such as ideation, materialisation of ideas and designerly inquiry (Christensen *et al*., 2018).

Methods

This research is grounded on the social constructionist, interpretive paradigm, with greater focus on the way humans interpret their social world in specific contexts. It fits under the 19th century German hermeneutics tradition and symbolic interactionism which, coined in 1969 by Herbert Blumer, is a meta-theory explaining that individuals act before others according to meanings that derive from social interactions, which, in turn, are rooted in shared symbols and language (Putnam & Fairhurt, 2001).

Considering that this research is pertinently supported by employee participation in the design of brand artefacts, only within a real institutional context could a deeper empirical analysis be carried out. A qualitative case study was considered as the most appropriate method, since it allows a holistic view and is more opportune when analysing eclectic and motivational themes, such as participation and identity (Gummesson, 1991). A Higher Education Institution (HEI) seemed to be an appropriate and rich environment, where several domains of knowledge cooperate and cohabit, with high levels of expertise. The University of Aveiro (UA), in Portugal, highly ambidextrous (given it is framed under the new trend of managerialism in HEI), is home to one of the authors and, as an institution not only composed by a great diversity of employees but also holder of a recently redesigned brand, was completely in line with the objective of this research.

In this context, we chose the classic case study that corresponds to the exhaustive analysis of a unique case (Yin, 2014). The objectives of this case study were 1) to illustrate and materialise a communication infra-structure for the design, planning and management of a brand, involving employees (academics and non-academics), offering them opportunities for developing design principles awareness, through creation and co-creation, giving them the shared power and responsibility over the brand they represent, and 2) understand how can a HEI value its brand through the development of their employees' design literacy, grounded on both the creation of new and the appropriation of existing brand design artefacts.

An extensive brand artefacts' audit covering all the existing brand applications was performed, and a set of exploratory semi-structured interviews with 14 specialists (practitioners with academic activity in the fields of branding, design, and communication technologies) was conducted, mostly as means of diagnosis. The information then obtained allowed the identification of:

- the procedural needs that UA's employees face when having to use or appropriate the brand (e.g., via its visual identity) and the difficulties they face;
- the anticipated constraints and advantages of a potential platform for brand artefacts co-design.

Based on the produced insights and results, a prototype for a web-based Participatory Brand Centre (PBC) was designed, considering the definition of a) the essential user interfaces and b) the interaction narratives and main functionalities. The method of prototyping did not resort to any hyperlinks and, for such, it was objectively a non-functional prototype; however, it makes use of careful and detailed visual language features, providing most of the reference system with concrete user narratives.

Finally, five focus groups (FG) were held, with UA's teaching and non-teaching staff (n=32), to whom the PBC prototype was presented for the first time and with whom it was discussed. In order to guarantee impartiality, the invitations for the FGs were sent to a maximum of four employees of different employment categories of each of the 16 departments/schools and six university services.

The sessions had an average duration of 107 minutes. After a brief introduction and review of the topics, the first questions to be discussed were of general character and easy approach, to allow the immediate participation of all (Morgan & Hoffman, 2018). To ease the participants' contextualisation, each one received an *academic chocolate*, a fictitious merchandising brand artefact, composed of a dark chocolate bar and institutional packaging designed on purpose for the research, in which UA's visual identity was clearly adopted. After that, the participants had contact with the prototype via a straightforward walkthrough, using scenarios or recurrent situations, with design and interaction features copied from the institution's website. Hence, a sequence of images representative of the PBC was presented, accompanied by a verbal description of its main functionalities, exemplifying situations of use or representing certain tasks, providing clues of interaction, thus avoiding merely conceptual (sometimes abstract) representations that are, usually, more difficult to share and interpret.

The prototype and its findings

The access to the PBC would have to occur through an initial and public interface, embedded in the internal context of the organisation, and following the current university portal, to ease recognition of major interaction paradigms. It was suggested by some employees that this entry area should include highlights to relevant brand-related ideas and contributions from employees (providing them with public visibility as a means of recognition). This generic and public area, accessible to all audiences, would also make available and explicit what the university brand is, covering all the brand guidelines' topics. Each topic would be described in its own page, with the contents related to it and with links that allow to further expand the information contained therein. As an example, the guidelines for colours are typically described using various colour systems and colour normalisations (CMYK, RGB, Pantone®, etc.). However, as this platform would be incorporating mostly non-specialised people, neither in brands, nor in design jargon, some users may not be able to interpret the technicality underlying this information; still, it was mentioned by several participants that it may be the case that some staff would like to learn what a "Pantone" is. Thus, it should be considered the possibility of broadening the knowledge about the subject through additional resources, e.g. available on the Web.

The access to the staff area would require a staff member login. As a consequence of using the interaction structure for brand artefacts co-design (Lelis & Mealha, 2015), this platform would equally comprise three main areas (Figure 2):

Figure 2 — The overarching structure for a Participatory Brand Centre

Studio

The Studio's main objective (first module in Figure 2) would be the orientation of individuals, providing them with opportunities for experimenting with tangible and visual attributes of the brand's logo, and get an approximate sense of what its standards are, using a context of both simulation and playfulness. In the presented prototype, the Studio area allows the user to click, drag, import, using languages and forms of interaction very close to what they would be accustomed to as regular users of information and communication technologies (Figure 3).

Figure 3 — The Studio area, presenting examples of visual alerts for non-compliance with the brand's standards.

Within the Studio, the user can either create sketches or experiment and exploit the graphic elements of the brand. The free creation and manipulation of own and/or shared sketches, and learning the norms that are inherent to and that govern the brand by trial and error, was very much appreciated by all the participants. This was, in fact, the most popular feature of the entire PBC: the platform would help the user in the process of brand experimentation, allowing the use of basic image editing tools and techniques, managing the constraints associated with the brand's logo, and through a contextual user comprehensible traffic-light metaphor, issuing visual and written explanatory alerts should mistakes be detected (e.g. modified image ratio, lack of readability/contrast, unaccepted typography, etc.). Simultaneously, the user would be presented with the visualisation of correct uses and the options of decision to be made: 'Amend as Suggested', or 'Ignore and Proceed'. Guidelines would, therefore, be provided where any visual elements of the brand logo/symbol were somehow misrepresented. However, the user would be free to follow on and continue their brand artefacts creation process, but already aware (hence, with developed brand design literacy) that their experience is not in compliance.

Community

Community (second module in Figure 2) is an internal and contextual *social network*, through which employees manage and share their contributions, and where they can also see, evaluate, comment and create links to their peers' ideas (Figure 4). In this section, users have access to all artefacts that are published in the Community, by the community. They can filter these by using the PBC predefined categories used to name artefact galleries (such as 'merchandise', 'learning & teaching resources', 'entertainment', 'end-of-year showcase'), or any other labels associated to occasional activities, launched by the institution to promote, for example, participation.

In these circumstances, the PBC would cumulatively be the repository of all unofficial brand artefacts of greater or lesser applicability. The FG participants found it interesting but were intrigued with the purpose of storing "not-in-compliance" cases. It was then clarified that, in this prototype, one of the predefined categories was titled *Pirate*, intended to bring together all the brand artefacts designed by employees and which, deliberately, did not follow the brand standards or brand values. It was further explained to the participants that, depending on the organisation and its culture, it might be interesting to save and retrieve such records, which may, in certain moments, turn out to be great ideas, grounded on the perspective that current standards are not, necessarily, the ones of tomorrow. Users can also participate in the artefact's evaluation process using assessing languages common to Social Media, such as *Like*, *Emoticons*, *Favourites*, five-star rankings, insertion of comments, among others. Interestingly, one of the participants mentioned she would like to have a *Dislike* option available, to allow "a more rigorous evaluation".

Figure 4 —The Community area, presenting the user's published artefacts and the upload of a new artefact to the PBC

Explorer

Finally, the Explorer (third module of Figure 2), allows activity monitoring and analysis according to interest criteria, such as the number of users participating in one's design and evaluation process, the links/interactions established between contributors, the authors involved in a creation, the most recurrent categories, the validation status of their artefacts, among others (Figure 5).

Figure 5 — The Explorer area, presenting analytics and the monitoring interface of artefacts under evaluation

The FGs confirmed that the university brand is highly cherished among staff but there is an apparent inability to understand and relate with the brand guidelines that were made available after its redesign: all participants had experienced compelling situations when using the brand's logo, for not understanding basic design principles. Therefore, participants were very positive mostly regarding the Studio feature that they considered "extremely innovative" and "really helpful". Its perceived playfulness linked to the development of design skills were seen as the most relevant aspects of the entire platform. However, such a system is useless without proper recognition and incentive actions — through which a culture of knowledge development and sharing would be awarded and promoted — as much as a reasonable amount of time dedicated to activities that could easily fall within staff development plans, including, in this case, the development of design literacy.

Discussion

The ultimate intention of this research was to propose a participatory design platform that would integrate, in a multi-directional way, internal branding activities, conceptualised in accordance with participatory design assumptions, providing a context in which design literacy could be developed and where the creation of brand-related and design-informed artefacts could be carried out with the participation of any employee.

A pedagogical dimension is needed to raise employees' brand awareness, which does not happen if investments are limited to unidirectional and imposing communicational approaches, such as through the provision of prescriptive templates. Thus, this instructional informal learning domain should promote and clarify what the brand is – because a brand is, foremost, the result of a design exercise – and the employee would be given the opportunity to embark into an actual design process as an insider.

When employees are invited to assess brand-related ideas provided by other members of their community, these processes must be as transparent as possible, for staff to have a very concrete idea of the value of their own contribution (not only in the design of potentially valuable artefacts, but also in the scrutiny of artefacts designed by others), allowing the community to a) know more and better its brand and how it should be applied in its various contexts of use, and to b) understand the immense design possibilities every brand entails. And, although described in a linear fashion, the interaction structure is always iterative (as depicted in Figure 2).

There is some preliminary evidence of the supporting model's potential, but not enough to completely validate it as a structure to support design literacy. The process of participation, which is, by its very nature, a social and communicational process, enhances, from a cognitive perspective, the flow and use of brand-related information existing in the organisation, hence constantly creating new knowledge, potentially contributing to more design literate individuals: those able to code and decode functional, aesthetic, symbolic and socially responsible artefacts.

It should be noted that a technological resource based on participatory design would demand a) tactics to reduce the perceived effort associated with participation in such a resource, aimed at avoiding frustrations and irreversible withdrawals, and b) a moderator, able to ignore the entropy and noise that will escort some of the contributions, making use of his/her own brand and design -related experience to systematise, (re)categorise and, eventually, validate ideas. A designer would be in the best possible position to assume such job, which would be very much aligned with some of the actions listed on the Report and Recommendations of the European Design Leadership Board (European Commission, 2012), namely:

- *Strategic Design Action 2*, "Positioning design within the European innovation system", namely through "the public procurement of innovative solutions through the recognition, inclusion and implementation of design as a driver of user-centred innovation" (recommendation 9),
- *Strategic Design Action 3*, "Design for innovative and competitive enterprises" by recognising "training for generating world-class specialist and skilled crafts-people in traditional and emerging sectors with an increased awareness of design, as a driver of growth and job creation" (recommendation 15),
- *Strategic Design Action 4*, "Design for an innovative public sector", considering the HE context, by increasing "the use of design/designers in public sector innovation" (recommendation 16) and

- *Strategic Design Action 6*, "Design competencies for the 21st century", by increasing the level of design literacy for all the citizens of Europe by fostering a culture of design learning for all at every level of the education system" (recommendation 20).

Undoubtedly there is a societal challenge involved in this project: as publicly funded institutions, many European Universities do not rely on their low or inexistent fees to keep themselves active. For this reason, one may say that it is ethically correct to conceptualise systems that allow the received public money to be spent more with research and social services and less with outsourced agencies, especially when, sustainability-wise, a design school is one of the institution's faculties. There is also a dilemma, which was addressed by some of the FG participants: freedom to create and to have a voice vs. intellectual property and authorship. The public area and the Community space were thought to, in a way, mitigate this, by providing contributors with full visibility, especially when their ideas were to advance to production stages. Finally, it is a complex problem as it involves multiple stakeholders with different views, potentially leading to conflicts concerning the nature of the platform and its solutions: on one hand, the employees, happy to engage with the suggested activities, on the other, the outsourced agency and designers that may feel their role is being minimised and taken from them.

As major limitation, this research used a single case study approach within the very specific sector of academia, in one country only. Nevertheless, the findings were presented to and discussed with eight communication directors and human resources managers from commercial companies (three of them among the biggest in Portugal and at least five fairly well internationalised). Out of the eight, seven found the approach very relevant for their own staff development context and one wanted to implement it straight away. In addition to this, the Studio area was designed to explore the experimentation of design principles based on interactions with the brand's logo only, which, although permitting a considerable array of applications involving other design specialisms, is in fact only one of the several design resources a brand encompasses, hence, much more can be investigated within the same context and loyal to the same brand-based rationale. A functional prototype and a longitudinal, multi-institutional context study would gauge the implications and possible reciprocity between the development of brand knowledge and design literacy and the proposed platform.

Conclusion

Most of the existing work on internal branding is conceptual and based on small-scale studies grounded on managers' views, rarely shedding light on design as a pivotal activity for brand success. Staff development activities that involve and motivate them to participate in the construction of brand artefacts are not design-led and tend to be individualistic, centred on the result achieved by each individual, without systematically contemplating the possibility of collective creation, nor of sharing. In addition to this, research in PD covering the design process of brands is reduced, if not non-existent.

The number of studies on the introduction of CMC resources to support brand awareness is also limited; online brand centres are typically unidirectional, only allowing the download of brand-associated features, and the completion of forms as means to request further information. Some research has been done on the contextual analysis of online platforms that have been used by big corporations to promote both the collection of brand strategy-led ideas from employees and the appropriate usage of the brand's visual system, but no holistic ecologies were found supporting a combination of these activities. Finally, no studies were found where an explicit combination between a brand's design artefacts and the development of design literacy is established whatsoever.

This research contributed to a better understanding of the potential that brand artefacts may have in the development of design literacy among staff, enhanced by the strong ties these develop with the brand they represent. Moreover, predictably, systems such as the presented can bring 1) a change in participation patterns and shared opportunities to express opinions and make decisions and 2) the democratisation of innovation, capitalising individual or collective brand-related and design-informed user-generated content, which can, potentially, be applied in the official brands' product/service development, communication and marketing throughout, in a sustainable way.

Track 6.c Introduction: Entrepreneurship in Design Education

HOWELL Bryan[a]; ANDERSON Curt[a]; HATCH Nile[a]; TENG Chia-Chi[a]; MATTSON Chris[a]; BANGERTER Neal[b]; SANTAMARIA Laura[c] and WOLFF Fabiane[d]

Over that last few decades there has been a significant rise in interest for design-led entrepreneurship and innovation. This has brought about the need to expand on the principles and methods of human-centred design by incorporating knowledge from multiple disciplines, such as management, business, and entrepreneurship studies. This expansion aids designers, engineers, and marketing practitioners who strive to create innovative, meaningful and relevant services, business models and experiences.

More often than not, ventures operate under very limited resources, and practitioners are often required to fulfil several roles. The concept of 'multidisciplinary teams' widely spread in this sphere often bears little resonance in these contexts. Designers possess valuable competencies that can have a significant impact on the venture, especially driving user and context-centred strategy and processes for the introduction, legitimization and scaling-up stages. However, engaging with these areas of practice requires skills and capacities that overlap traditional disciplinary roles. In doing so, the boundaries between design and engineering, branding and communications, cultural and behavioural insight, marketing and management strategy are blurred.

As educators in design innovation, how do we explore, define and balance interdisciplinary relationships between design, engineering, management, business and entrepreneurship theories, methods, language and models of education? The purpose of the entrepreneurship in design education track is to discuss methods, models, case studies, research, insights and unexpected knowledge in benefits and limitations of design entrepreneurship education. In particular, the three papers presented in this track demonstrate different approaches to entrepreneurship and design education.

The paper, *Design Thinking & Entrepreneurial Opportunities: Visual Case Studies of Chilean Designer/Non-Designer Founders* by Potocnjak-Oxman, Kriz and Nailer explores the rise in both number and diversity of roles played by designers in the global entrepreneurship ecosystem. Be it as consultants, contractors, educators, founders or funding decision-makers, design skills seem to be increasingly attractive to entrepreneurial teams, accelerator programs and venture capital. The study asks whether the practices, cognitive processes and mindsets prevalent in formal design thinking training helps in the formation of entrepreneurial opportunities. The paper highlights the parallels between design thinking traits with established entrepreneurial competencies and points out that while there are significant alignments, there are also gaps, which when identified, could help determine entrepreneurial actions and success. It also explores how "abductive reasoning" which has been said to sit at the core of design thinking could be a potent tool to enable the successful formation of entrepreneurial activities. The study compares the processes of 14 Chilean founders from both design and non-design backgrounds, with the purpose of identifying how design thinking contributes to, or hinders, those processes. Preliminary findings suggest that successful entrepreneurs from

design backgrounds extend the human-centred view to include organisations, industries and societies, use continuous observation and learning-by-doing to develop their ventures, rely on interdisciplinary collaboration and are tolerant of failure. Design thinking does not, however, seem to provide a clear understanding of the importance of value creation and resource leveraging in the formation of entrepreneurial opportunities.

The paper, *Contamination Lab of Turin (CLabTo): how to teach entrepreneurship education to all kinds of university students* by Fiore, Sansone, Remondino, and Tamborrini presents the impact of combining design and entrepreneurial methods to teach entrepreneurship to a variety of university students in three different formats. As demand for entrepreneurship courses increase, new methods of teaching entrepreneurship will be required. This paper explains how instructors at the University of Turin are exploring this. Their study addresses how students from different fields of study and different educational levels can have a positive entrepreneurial experience. The teaching experience combines design and entrepreneurial education methods to create a practical, multi-disciplinary team-based course that addresses real-life projects through a learning-by-doing approach. The courses enlist instructors from multiple disciplines to mentor students. The study relies on programme assessment data, including pre and post-surveys to evaluate educational impact. Overall, they found a positive effect on the students' entrepreneurial skills. However, when the data was broken down according to the students' fields of study and education levels, mixed results emerged.

The paper, *Entrepreneurial Mindset: a longitudinal study of three different teaching approaches to developing it* by Fain, Rod and Bohemia explores the influence of three teaching approaches on entrepreneurial mindset of commerce, design and engineering students across three universities. They measured the entrepreneurial mindset of students at the start of a course and then again at the end. During the course, three different teaching methods were employed; lecture and case based, blended online and class based, and project-based course. They found that the engineering students mindsets grew the most, followed by the commerce students, while the design students grew the least.

Attendance and conversation during this session was strong and focused. A number of participants shared insights and experiences that enriched the conversation beyond the paper topics. Near the end of the session, a sincere interest was shared that session participants should get together more often and discuss opportunities and practices. Clearly, exploring entrepreneurship and design education is of growing interest while a challenge remains on how we develop effective education methods in multi-disciplinary entrepreneurship courses.

Forming Opportunities through Design Thinking: Comparing Visual Narratives of Chilean Designer/Non-Designer Founders

POTOCNJAK-OXMAN Camilo*; KRIZ Anton and NAILER Christopher

Australian National University, Australia
*corresponding author e-mail: camilo.potocnjak-oxman@anu.edu.au
doi: 10.33114/adim.2019.01.404

An interesting development in the entrepreneurial economy is the rise in both number and diversity of roles played by designers. Be it as consultants, contractors, educators, founders or funding decision-makers, design skills seem to be increasingly attractive to entrepreneurial teams, accelerator programs and venture capital. This exploratory study asks whether the practices, cognitive processes and mindsets prevalent in a formal design education help in the formation of entrepreneurial opportunities. Using a visual narrative approach, it compares the processes through which entrepreneurial opportunities were formed by 14 Chilean founders from design and non-design backgrounds, with the purpose of identifying how design thinking contributes to, hinders, or fails to support those processes. Findings suggest that collaborative work styles, thinking by doing and reflective reframing have the greatest positive impacts on opportunity formation, regardless of the disciplinary background of founders. Design thinking does not seem to provide a clear understanding of value creation and resource leveraging. The study finds parallels between design thinking and opportunity formation that can be drawn upon to improve development of entrepreneurial competencies among designers.

Keywords: Entrepreneurship, Entrepreneurial Opportunities, Design Thinking, Entrepreneurial Competencies, Design Entrepreneurship

Introduction

Entrepreneurship has become an important part of the global economy, with close to fifty percent of companies on the Fortune 500 list having been founded in the previous fifteen years (Sarasvathy, 2001, p.44). Early-stage firms have been shown to contribute more to job creation than their larger, older counterparts (Haltiwanger, Jarmin & Miranda, 2013, p. 355-356; Haltiwanger, Jarmin, Kulick & Miranda, 2016, p.29). These early-stage “start-ups” grew by 75.6% in 2016, five percent faster than they did in 2015 (Morelix & Russel-Fritch, 2017, p.6). Increasing access to technology and the emergence of new industries such as artificial intelligence and robotics are also opening new pathways for entrepreneurial activity (Ortmans, 2016). In the United States, participation of women and members of ethnic minorities in entrepreneurial activity is also increasing (Buchanan, 2016).

An interesting development in the entrepreneurial landscape is the growing number of designers who are engaging with entrepreneurship (Grayson, Lee & Dillon, 2016, p.10; Maeda, 2016, p.10; Startup Muster, 2017, p.11; Startup Muster, 2018, p.16). Be it as contractors, consultants, educators, decision-makers, founders or

funding parties, the skillsets present in the design discipline seem to have become attractive to the global entrepreneurship ecosystem.

Entrepreneurship as a field of research is itself evolving, with a growing emphasis not on the creation of firms, but rather the entrepreneurial opportunity and the processes through which these are formed (Suddaby, Bruton and Si, 2015, p.2). A recent theory of "opportunity creation" highlights the importance of creative imagination, social skill, iteration, reflective learning, and interactions with the environment in the process of conceiving a venture (Alvarez & Barney, 2007, p.11-12; Steyaert, 2007, p.453;472; Suddaby et al, 2015, p.3).

This theory of opportunity creation presents numerous parallels with the collection of practices, cognitive processes, and mindsets of the design-driven approach to innovation that the management discourse refers to as "design thinking" (Dunne & Martin, 2006; Hassi & Laakso, 2011; Hehn, Uebernickel & Herterich, 2018).

This exploratory paper seeks to recognise the parallels that may exist between the process of forming an entrepreneurial opportunity and the traits that make up the design thinking toolkit. It aims to gain a better understanding of how design thinking may or may not impact on the formation of opportunities, with the purpose of recognising which of its tools could be most efficacious in enabling entrepreneurial behaviour. Conversely, it also seeks to identify how design thinking is lacking in its ability to support or foster entrepreneurial behaviour. The goal is to contribute to the fields of design thinking and entrepreneurship research by identifying relationships between the two, and exploring whether design thinking can provide frameworks to enable entrepreneurial learning.

RQ1: *How do the practices, cognitive styles and mindsets of design thinking contribute, hinder, or fail to support the formation of entrepreneurial opportunities?*

RQ2: *How could design thinking support development of entrepreneurial competencies among designers?*

The present study took place in Santiago, Chile. The questions were approached by gathering and comparing the entrepreneurial experiences of fourteen founders from the Chilean context. Nine of these had received a formal education in design, whereas five had not. Twelve of the founders perceived themselves to have achieved success with their ventures, while two felt that they were yet to be successful.

Founders' experiences were captured through use of a "visual narrative" approach that combines rich picture diagrams (Avison, Golder & Shah, 1992, p.398; Sutrisna & Barret, 2007, p.168) with Lawson's (2006, p.26-27; 266) concept of "Design by drawing". Participants were asked to visually describe the process through which they formed the entrepreneurial opportunities that led to the conception of their ventures. Individual visual narratives were analysed through flexible pattern matching (Sinkovics, 2018), comparing them with existing frameworks in the design thinking and entrepreneurial competencies literature. The results from all visual narratives were then analysed collectively to identify themes and derive implications for theory and educational purposes.

The paper is structured in three parts. The first provides the research background, describing the lenses and frameworks that provide the theoretical foundation for the study, as well as an overview of the context in which the study took place. The second explains the methodology, briefly describing some of the visual narratives, and includes preliminary data coding and analysis. The third section covers findings, implications and limitations of the study, finishing off with further research that could stem from this work.

Research Background

The Evolving Field of Entrepreneurship Research

Entrepreneurship, as a field of research, is in the process of defining its "core puzzle". Although not thoroughly established, one approach suggests that the discipline should focus not on the entrepreneurial firm, but on the concept of the entrepreneurial opportunity. These are defined as those that "bring into existence new goods, services, raw materials and organising methods that allow outputs to be sold at more than their cost of production" (Shane, 2000, p.451). Special emphasis is placed on the processes and conditions that lead to the formation of these opportunities (Suddaby et al, 2015, p.2).

There are currently two prevailing theories that seek to explain how opportunities are formed. Although these two theories stem from different epistemological, ontological and teleological perspectives, they both focus on the same dependent variable: the actions undertaken by entrepreneurs to form and exploit opportunities

(Alvarez & Barney, 2007, p.12). This focus on a bias for action is present in key definitions of entrepreneurship. These include "[…] the pursuit of opportunity beyond resources controlled" (Professor Howard Stevenson, cited in Eisenmann, 2013), and the way that entrepreneurs' attitudes towards opportunities are described by Steve Blank, one of the pioneers of the "lean start-up", an experimental, feedback-driven and iterative method for innovation that became popular in the mid-2010s (Blank, 2013):

> *[…] everybody has an idea. [...] number one is: do you have curiosity? Number two is: does it translate to imagination? But number three is: did it translate to action? That's the difference between someone with an idea and someone who is an entrepreneur. Are you willing to actually take that action? (Steve Blank, cited in Nickisch, 2017)*

One current theory around the formation of entrepreneurial states that "opportunities are objective realities that exist in the environment and are discovered due to the unique characteristics of individual entrepreneurs", a product of market inefficiencies and only exploitable by individuals who are specifically suited to perceive them (Shane, 2000, p.467; Suddaby et al, 2015, p.3; Venkataraman, 1997, p.121). This is

Another, more recent, theory is that "opportunities are ultimately determined, not in an exogenous fashion by the external environment, but rather in an endogenous way, through the creative imagination and social skill of the entrepreneur (Suddaby et al, 2015, p.3). In other words, rather than being discovered, opportunities are created by entrepreneurs who engage in an iterative learning process based on interactions with the environment (Alvarez & Barney, 2007, p.11-12). This process has also been referred to as 'effectuation', where entrepreneurs "take a set of means as given and focus on selecting between possible effects that can be created with [those] means" (Sarasvathy, 2001, p.245); 'entrepreneuring', where entrepreneurship is described as a verb, a creative social process and "one of the most inventive human activities" (Steyaert, 2007, p.453;472); and 'reflexivity', where "opportunities are generated by reflection on the possibility of new and creative social realities" (Suddaby et al, 2015, p.6).

Table 1: Comparing Two Theories of Entrepreneurial Opportunity, adapted from Suddaby et al, 2015, p.7-8.

	Imprinting Construct - Discovery Thesis	*Reflexivity Construct - Creation Thesis*
Environment	*"The discovery thesis of entrepreneurial opportunity contains an inherent assumption that the external environment is both distinct from and more agentic than the entrepreneur"* (p. 7)	*"In the creation thesis, the boundary between entrepreneur and environment is less distinct and the degree of agency between entrepreneur and environment is more evenly distributed"* (p.7)
Time	*"an isolated episodic influence"* (pp. 7-8)	*"an iterative […]ongoing interaction"* (p. 8)
Epistemological Emphasis	*"Concrete practices and objective experiences"* (p. 8)	*"Subjective and interpretive inner world"* (p.8)
Level of Analysis	*"Individual or group focus"* (p. 8)	*"Industry or organisational field"* (p. 8)

This second, less-developed, "opportunity creation theory" is of specific interest when attempting to identify the possible links and intersections between design and entrepreneurship. In particular due to the strong parallels that exist between its defining characteristics: creative imagination, social skill, iteration, reflective learning, and interactions with the environment; and the defining characteristics of what the management discourse refers to as "design thinking" (Hassi & Laakso, 2011).

Design Promotion and the Rise of Design Thinking

An interesting development in the field of design, specifically design education, is the emergence of schools providing design-related programs beyond the scope of traditional design students (Glen, Suciu, Baughn & Anson, 2015, p.182; Hasso Platner Institute, 2017; Lehtonen, Schilli & Berg, 2018; Melles, Howard & Thompson-Whiteside, 2012, p.163-164; Stanford d.school, 2017). This may stem from a changing perspective on the role of design, which pushes the discipline from the cosmetic, through the tactical, towards its participation in strategic decision-making, including the development of new experiences and design-driven innovation (Montana-Hoyos & Potocnjak-Oxman, 2017; Ramlau & Melander, 2004, p.49; Verganti, 2009). This changing paradigm would require design professionals to take part in clearly articulating the value of design to

business. This activity became known as “design promotion”, and has focused on demonstrating design’s contribution to national competitiveness, increasing demand for the discipline among small businesses, incorporating design in the innovation processes of established firms, and government support for, and acquisition of, design services (Raulik-Murphy, 2010, p.48-49).

Design promotion is not new, and began in earnest during the post-World War II period (Raulik-Murphy, 2010, p.18;101-102). One example is the development of the design discipline at the HfG Ulm (Bonsiepe & Cullars, 1995, p.15), which “championed the insertion of design into the industrial process, and discarded all artistic or decorative speculations about design activity” (Fernandez, 2006, p.4). Another example is the revised definition of industrial design put forward by the World Design Organisation, formerly International Council of Societies of Industrial Design (ICSID) and one of the world’s leading design promotion organisations, which states that:

> *Industrial Design is a strategic problem-solving process that drives innovation, builds business success, and leads to a better quality of life through innovative products, systems, services, and experiences. Industrial Design bridges the gap between what is and what’s possible. It is a trans-disciplinary profession that harnesses creativity to resolve problems and co-create solutions with the intent of making a product, system, service, experience or a business, better. At its heart, [design] provides a more optimistic way of looking at the future by reframing problems as opportunities. It links innovation, technology, research, business, and customers to provide new value and competitive advantage across economic, social, and environmental spheres. (WDO, 2019).*

From the above definition, it seems that the design discipline has made concerted efforts to move beyond the object into the realm of systems and organisations. It seeks to transition from a problem-oriented view to an opportunity-seeking perspective motivated by the desire to create value.

Arguably one of the most successful design promotion initiatives has been the proliferation of design thinking. This suite of methods has recently gained popularity as a way to facilitate adoption of design processes among non-designers. Although this concept was first described fifty years ago (Simon, 1969), it rose to prominence as an approach to innovation during the mid-2000s (Johansson-Sköldberg, Woodilla, & Çetinkaya, 2013, p.123). The concept itself currently holds many definitions, ranging from the generic ‘what designers do’ (Carr, Halliday, King, Liedtka and Lockwood, 2010, p.62); through the strategic ‘approaching management problems as designers approach design problems’ (Dunne and Martin, 2006, p. 512); to the transdisciplinary:

> *Design practice [...] used beyond the design context, for and with people without a scholarly background in design, particularly in management’ (Johansson-Sköldberg et al, 2013, p.123)*

This definition, which does not describe the traits of design thinking, highlights the intended impact of bringing managers and people from the business world into the design process as active participants. Given the growth and contribution of entrepreneurial activity to the global economy, design promotion that inserts design practitioners into the entrepreneurship ecosystem could provide an interesting new horizon for the discipline.

Design Thinking and Entrepreneurial Competencies

A clearer approach to understanding design thinking and the role it can play in entrepreneurship and entrepreneurial opportunities may be to categorise its characteristics. One such categorisation, stemming from the management discourse (Hassi & Laakso, 2011, p.5-10), states that design thinking includes:

- **Practices** closely related to concrete activities and ways of working;
- **Thinking Styles** and methods of processing information cognitive processes; and
- **Mentalities** in individuals and as part of an organisational culture.

For the purposes of this study, Thinking Styles and Mentalities will be referred to as “Cognitive Processes” and “Mindsets” respectively. Collectively, they will be referred to as “traits”. These traits have been described through various lenses (Hassi & Laakso, 2011; Hehn, Uebernickel & Herterich, 2018; Micheli, Wilner, Bhatti, Mura & Beverland, 2018; Razzouk & Shute, 2012; Sanders & Stappers, 2008; Tschimmel, 2012; among others), leading to extensive lists of methods to be used at different stages of an innovation process. Recently, Micheli et al (2018) have synthesised these lists into ten core components. Their synthesis presents traits not explicitly included in Hassi & Laakso (2011). These traits have been integrated with Hassi & Laakso’s (2011) categorisation to develop a list that, although not definitive, provides an overview of the elements of design

thinking that may be present in the formation of entrepreneurial opportunities. The final list of practices (p), cognitive processes (c) and mindsets (m) of design thinking used for this study, with a brief definition and corresponding code for data analysis, is provided below (see Table 2).

Table 2: List of Practices, Cognitive Processes and Mindsets of Design Thinking (adapted from Hassi & Laakso, 2011 and Micheli et al, 2018).

Code	*Component*	*Simplified Definition*
p1	Human-centred Approach	Putting people first, achieving a deep and empathetic understanding of the customer and other key stakeholders.
p2	Thinking by Doing	Creating and developing knowledge iteratively, through practical, rapid and continuous prototyping.
p3	Visualising	Using concrete representations of abstract concepts, models and ideas to make sense of and communicate them.
p4	Divergence/Convergence	Undergoing cycles that broaden and refine scope to explore diverse alternatives and synthesise preferred solutions.
p5	Collaborative Work Style	Interacting with a wide range of stakeholders to include a diversity of perspectives when tackling complex problems.
p6	Innovation	Successfully implementing novel and useful ideas in organisational or social contexts.
c1	Abductive Reasoning	The logical process of moving from what is known to what could be.
c2	Reflective Reframing	Identifying, framing and reframing the problem to be solved.
c3	Holistic View	Perceiving problems as a system of interdependent structures, patterns and events with functional, emotional, social and cultural elements.
c4	Integrative Thinking	Achieving balance between conflicting requirements, such as the technical, commercial and human dimensions of a problem.
c5	Problem-solving	Defining and tackling systemic social issues.
c6	Blend Analysis & Intuition	Combining perceived patterns with rational evaluation.
m1	Experimental/Explorative	Posing questions and exploring constraints in creative ways that push current boundaries and proceed in unexpected directions.
m2	Ambiguity Tolerance	Maintaining an openness to uncertainty and accepting it as a natural part of an emerging design process.
m3	Optimistic	Assuming that the results of the process will be in some way better than the current situation.
m4	Future-Oriented	Anticipating and visualising new scenarios and situations.
m5	Tolerance of Failure	Perceiving failure as a necessary element in the process of learning about the problem that is being addressed.

These traits of design thinking provide an overview of the competencies used in solving design problems. Of note is their parallel with the traits described in the opportunity creation theory and their similarity with entrepreneurial competencies, or those that are used by entrepreneurs "to begin or transform organisations, [adding] value through their organising of resources and opportunities" (Mitchelmore & Rowley, 2009, p.96). These competencies are said to be distinct from those required for business administration or management (Morris, Webb, Fu & Singhal, 2013, p.355). A list of 13 entrepreneurial competencies, developed through a multi-round Delphi study with both academic experts and successful entrepreneurs (Morris et al, 2013), is

provided below (see Table 3). As with the traits of design thinking, these have been given simple codes for later use in data analysis.

Table 3: 13 Entrepreneurial Competencies, adapted from Morris et al, 2013, p.358

Code	*Competency*	*Simplified Definition*
e1	Opportunity Recognition	Perceiving changed conditions or overlooked possibilities in the environment.
e2	Opportunity Assessment	Evaluating opportunities to accurately determine their relative attractiveness.
e3	Risk Management and Mitigation	Taking actions that reduce the probability or impact of a risk.
e4	Conveying a Compelling Vision	Conceiving and articulating an image of the future that empowers followers.
e5	Tenacity/Perseverance	Sustaining goal-directed action in the face of difficulties and obstacles.
e6	Creative Problem-solving	Relating previously unrelated variables to produce novel and useful outcomes.
e7	Resource Leveraging	Accessing resources not owned or controlled to achieve personal goals.
e8	Guerrilla Skills	Employing low-cost tactics not recognised by others to do more with less.
e9	Value Creation	Developing new solutions that generate revenue exceeding their costs.
e10	Maintain Focus yet Adapt	Balancing strategic direction with actions that improve fit with environment.
e11	Resilience	Coping with stresses or disturbances to thrive in the face of adversity.
e12	Self-Efficacy	Maintaining self-confidence regarding one's ability to accomplish a task
e13	Building/Using Networks	Establishing, developing and maintaining relationships with supporters.

It would seem that these entrepreneurial competencies present interesting parallels with the traits of design thinking described in Table 2. Some of these possible parallels are highlighted below (see Table 4).

Table 4: Parallels between Design Thinking Traits and Entrepreneurial Competencies

Design Thinking Traits	*Entrepreneurial Competencies*
Abductive Reasoning; Innovation; Problem-solving	Creative Problem-solving
Thinking by Doing; Experimental/Explorative	Maintain Focus yet Adapt
Collaborative Work Style	Building/Using Networks
Visualising; Future-Oriented	Conveying a Compelling Vision
Ambiguity Tolerance; Tolerance of Failure	Tenacity/Perseverance; Resilience; Self-Efficacy

It is important to note that design thinking does not completely parallel entrepreneurial competencies. This can help in determining where it may be lacking in terms of enabling entrepreneurial action and success.

Design Thinking Impacts on Entrepreneurship

In its attempts to transition from the cosmetic to the strategic, the design discipline and design thinking have had well-established positive impacts on the performance of private enterprise (e.g. Dunne & Martin, 2006, p.512; Hertenstein, Platt & Veryzer, 2005, p.12-17; Kotler & Rath, 1984, p.17; Maeda, 2016, p.8; Sheppard, Kouyoumjian, Sarrazin & Dore, 2018). Similar positive impacts have also been perceived in the public sector (e.g. Laboratorio de Gobierno, 2018; OECD, 2017, p.30-33; Sanders & Stappers, 2008, p.3; The Australian Centre for Social Innovation, 2018). Although these impacts focus on established organisations, the effects of design on the processes associated with entrepreneurship are only recently being explored. There is currently little research into how design thinking may come into play during the process of forming an entrepreneurial opportunity.

This is of interest due to the increasing participation that design and designers have had in the entrepreneurial economy. In 2016, 21% of "unicorn ventures", defined as "entrepreneurial ventures with a valuation of a billion dollars or more" (Fan, 2016), had designers on the founding team (Maeda, 2016, p.10). An example of this is AirBnB, founded in August, 2008 by two designers and a computer scientist. In March of 2017, the company secured over USD1 billion of investment based on a valuation of USD31 billion (Thomas, 2017). To put this in perspective, Marriott International Inc., one of the world's largest hotel chains, founded in 1927 and owning over 4200 hotels, has a market capitalisation of approximately USD35 billion (New York Stock Exchange, 2017), only USD4 billion greater than that of AirBnB. In 2016, a report on the role of designers in the global technology entrepreneurship industry found that 31% of 400+ companies surveyed had a founder with a design background (Grayson, Lee & Dillon, 2016, p.10). In Australia, a study into the state of the local entrepreneurship ecosystem found that 15% of ventures surveyed had graphic design skills present on the founding team, with 20.4% having user experience design skills (Startup Muster, 2017, p.11). A year later, these numbers had increased to 17% and 21.4% respectively (Startup Muster, 2018, p.10).

Designers are not only taking part in the entrepreneurship economy as founders. They are also increasingly sought after as contractors, ranking second only to accounting (Startup Muster, 2018, p.16). They have also been recruited to take on roles in venture capital firms (Maeda, 2016, p.11), and established funds that invest only in entrepreneurial ventures with designers on the founding team, such as The Designer Fund, founded in 2011 by a "guild" of successful design entrepreneurs (Designer Fund, 2016).

Design Thinking and the Formation of Entrepreneurial Opportunities

Why is the design discipline, traditionally associated with product development and visual communication, having such a sizable impact on the entrepreneurial economy? One possible explanation may be that the aforementioned practices, cognitive processes and mindsets that comprise design thinking provide a set of tools that can help in the formation of entrepreneurial opportunities.

One example is "abductive reasoning", which has been said to sit at the core of design thinking (Dorst, 2011, p.522-524). This cognitive style is defined as "the process of forming an explanatory hypothesis […] the only logical operation which introduces any new idea" (Peirce, 1960). People trained in design use complex forms of abduction that has been said to be particularly useful when tackling open-ended or 'wicked' problems (Dorst, 2011, p.523-524), defined as:

> *[…] a class of social system problems which are ill-formulated, where the information is confusing, where there are many clients and decision makers with conflicting values, and where the ramifications in the whole system are thoroughly confusing' (Rittel, cited in Buchanan, 1992, p.15).*

Wicked problems present similar characteristics to the "opportunities as objective phenomena" described in the entrepreneurial opportunity discovery theory (Suddaby et al, 2015, p.3). Additionally, designers' ability to use abductive reasoning and 'framing', or 'the creation of a novel standpoint from which a problematic situation can be tackled' (Dorst, 2011, p.525; Schön, 1984, p.132), among other tools, present similarities to the processes through which entrepreneurial opportunities are formed in the opportunity creation theory, including the use of creative imagination, social skill, iterative interactions with and learning from the external environment (Alvarez & Barney, 2007, p.11-12; Suddaby et al 2015, p.3)

This study aims to explore the possible relationship between design thinking and entrepreneurship, determining how these practices, cognitive styles and mindsets are used by designers and non-designers in the process of forming entrepreneurial opportunities. It also looks at the visual narratives of successful and

unsuccessful founders to gain an insight into which of these tools are beneficial, which have no impact, and which can prove a hindrance to the early stages of an entrepreneurial project. It also seeks to find if there are gaps in the design thinking toolkit, or areas where it is unable to provide support for entrepreneurial action.

Additionally, the project seeks to inform entrepreneurship education with a set of guidelines as to how to better use design thinking frameworks in supporting the formation and development of an entrepreneurial project.

Research Context

The study took place in Chile, which in 2015 had a Total Entrepreneurship Activity (TEA) indicator of 25.9%, putting them in 6th place of countries that participate in the Global Entrepreneurship Monitor (GEM) study (Kelley, Singer & Herrington, 2016, p.65). In 2018, this number fell slightly to 25.1%, but the country rose in ranking to 3rd place (Bosma & Kelley, 2018, p.72). Entrepreneurial Intentions, defined as "the effort that a person will make to carry out entrepreneurial behaviour" (Liñán & Chen, 2009, p.596) are also high, with 50% of Chilean GEM respondents expressing that they believe the conditions to start a business are favourable, placing the country in 3rd place overall. Entrepreneurs in Chile also state that their products are new to their market or to that of their competitors, and Chile ranks 1st in terms of innovation (Kelley et al, 2016). Design however, has a similar situation to Australia, with between 62% and 70% of recent graduates finding employment in the field, and at fourth year of practice are receiving average wages between CLP4.8m and CLP17.7m per annum (Ministerio de Educación, 2018), roughly equivalent to EUR6.4k and EUR23.7k respectively. In 2018, entrepreneurship was seen as an attractive career path by 76.1% of respondents (Bosma & Kelley, 2018, p.72).

This context is of interest as it combines high TEA with low remuneration for design professionals. Given the right mechanisms for designers to access capital, Chile could present a fertile context for opportunity-driven design entrepreneurship to flourish.

Methodology

In seeking to recognise how design thinking may contribute to, hinder, or fail to support the formation of entrepreneurial opportunities, a "visual narrative" approach was taken. This approach aimed to capture descriptions of the sequence of events and activities that took place in the process of forming an entrepreneurial opportunity. The goal of these visual narratives was to allow for the mapping of procedures, methods and specific tasks undertaken by the entrepreneur in the conception of their venture, identifying whether these included any design thinking traits. Based on the nature of the experiences described in the narrative, a qualitative assessment was made to determine whether specific traits had a positive or negative impact on the formation of the opportunity. To determine where design thinking may fail to support this process of forming an entrepreneurial opportunity, the presence or absence of entrepreneurial competencies was also mapped.

Due to the complex and unique nature of each opportunity formation process, this exploratory visual narrative approach drew upon Sutrisna and Barrett's (2007) use of rich picture diagrams to gather case studies in the field of construction projects. Rich picture diagrams are a pictorial representation that surfaces processes, relationships, people, tasks, environmental factors, interests and other aspects of a situation (Avison et al, 1992, p.298). Based on Lawson's (2006, p.26-27; 266) concept of "Design by drawing", which highlights designers' use of visualisation techniques as part of a thinking process, it was assumed that this visual narrative approach would enable entrepreneurs with design backgrounds to effectively describe their experience of conceiving a venture.

Participant Selection

In order to be eligible for the study, participants must have been part of the founding team of a venture that has had at least 2 years of history. For the purpose of this study, ventures are defined as:

> *'a daring undertaking in the public, private or academic context, using resources beyond the immediate control of the founding team, to create value for a range of stakeholders'*
> *(adapted from Oxford Dictionary, n.d.; Shane, 2000; and Stevenson, cited in Eisenmann, 2013).*

Fourteen participants were recruited through the researcher's personal networks. Participants were divided into four categories based on two criteria:

1. *Successful (S) / Unsuccessful (U)*
   This criterion divided participants into those whose ventures were functioning sustainably or had achieved significant growth two or more years after their launch, and those whose ventures had not achieved significant growth or had been discontinued before their third year of activity.
2. *Designer (D) / Non-Designer (N)*
   This criterion divided participants into those with a traditional education in a design discipline – graphic, industrial, product, fashion, game, interior – and those without said education.

In total, eight Successful Designer Founders (coded SD01-SD08), one Unsuccessful Designer Founder (coded UD01), four Successful Non-designer Founders (coded SN01-SN04), and one Unsuccessful Non-designer Founder (coded UN01) participated in the study.

Data Capture

Data collection took place between the 7th and 17th of January, 2019. Data was collected through sixty- to ninety-minute semi-structured interviews. During these, participants were provided with one blank sheet of 110x77cm paper, pencils, pens, markers and highlighters. They were asked to visually describe the process they went through to form the opportunity that led to the venture. The audio component of these interviews was recorded for cross-referencing purposes and to assist in analysis of the visual narratives.

Data Analysis

Data analysis took place over several successive stages. The first stage aimed to identify which design thinking traits were present in each founder's visual narrative. Due to the exploratory nature of the study, these were analysed using flexible pattern matching (Sinkovics, 2018), comparing them to the design thinking traits derived from the literature (see Table 2). This analysis was complemented through review of audio recordings to reduce the risk of misinterpreting the visual narrative.

The second stage sought to discern which design thinking traits may have produced an impact on opportunity formation. In particular, an attempt was made to qualify whether these had a high or low impact, and whether said impact was perceived to be positive or had the potential to be negative. Each of the Design Thinking Practices (p1-p6), Cognitive Processes (c1-c6) Mindsets (m1-m5), and Entrepreneurial Competencies (e1-e13) identified in a participant's visual narrative was assessed based on the events described by the participant. Where these traits were present and perceived to make a minor contribution to the formation of entrepreneurial opportunities, they have been coded as 1. When their contribution is perceived to be significant, they are coded as 2. When the component is absent or does not seem to have supported opportunity formation, they have been coded as 0. Where its absence is perceived to have had a negative impact, it has been coded as -1. Where its use is perceived to have hindered or had an adverse effect on opportunity formation, they have been coded as -2.

The third stage focused on the overall results of the study. A comparison of visual narratives was undertaken to identify which traits of design thinking seem to produce a consistent positive impact across ventures. Traits were given a score between -4 and 28. This score was based on their presence in the narratives of successful and unsuccessful ventures and their code from the previous stage. These were reviewed in relation to entrepreneurial competencies to determine whether there were any clear gaps in design thinking's ability to support opportunity formation.

This third stage of analysis was used to synthesise findings and detect patterns from which themes and implications for theory, education and further research could be derived.

Sample Visual Narratives

Fourteen visual narratives were captured during this study. The following section includes a brief overview of four of these ventures, including one from each participant category. Examples of visual narratives are also provided to give insight into the methodology used. Preliminary observations and the presence of design thinking traits and entrepreneurial competencies are included in the description of the narrative. They are later summarised in the Results section of this paper.

Founder DS02 – Adding Value to Industrial Processes through Design

The narrative begins with emphasis on the role of design in the creation of value *(e9)*. The participant, while working in a manufacturing industry, realised that they could improve upon the processes present in their workplace *(c2)*, and offer a service to their employer that would provide improved returns to both *(e1)*. They describe their entrepreneurial process as "basically the design process", which includes stages of divergent interaction with the external environment and convergent implementation to improve industrial processes *(p4; p6)*. They perceive the client firm as "an individual with needs" *(p1)* and a system *(c3)*. One of the main drivers for entrepreneurial behaviour was the idea of freedom *(e12)*, and being able to control one's own destiny, even if it is a more strenuous career path *(e11)*. Although the venture managed to earn upwards of USD1m per year, it has ceased to operate due to external market conditions. The founder, however, has already started a new venture *(m5; e5)*, and states that their opportunity formation process is both structured and replicable.

Founder DS03 – Recovering Industries through Social Enterprise (Figure 1)

The narrative begins with a discussion of the entrepreneur's own career path, which began with the intention to provide "strategic design" which could deliver value to people, companies and communities *(e9)*. While working with microbusinesses in regional Chile, they realise that improved packaging is not enough to help their clients, and that it is possible to offer design "that solves meaningful problems" *(c2; e10)*. They undertake further studies, and find "lost industries" which could be recovered to improve the quality of life of local communities *(e1)*. Drawing upon the resources of their university *(e7)*, they interact with the community *(p1)* to develop a small-scale experiment *(p2; p3)* to help connect microbusinesses with design capabilities *(c4).* From this experiment they then develop a model that continues to operate and grow, has produced communication material *(e4)* and is expanding into other regions. They highlight the importance of collaboration with other disciplines *(p5)* and the use of learning loops *(p2)* of varying scope *(p4)*.

Founder DU01 – Integrating Traditional Crafts with Digital Technologies

This founder commences by explaining that towards the end of their design degree, they attempted to keep multiple options open, including academic work, employment and entrepreneurship as possible career paths *(m1)*. After careful consideration, they choose entrepreneurship *(c2)*, and begin by tackling an opportunity that takes advantage of burgeoning digital manufacturing technologies *(e1)*. This venture does not achieve a sustainable client base *(-e2)*. This does not deter them from pursuing an entrepreneurial journey *(m5)*. The second venture aims to combine traditional crafts with advanced manufacturing *(c4)*. Their main goal is to "recover appreciation for crafts", and approach the project from an intuitive, explorative mindset *(p2; c6)*, with heavy use of prototyping *(p3)*. The main obstacle they express is a lack of commercial motivation, and it is implied that they have not engaged with other disciplines to facilitate administrative tasks *(-p5)*. They do not pursue capital *(-e7)*, and the venture maintains an informal status. They express that they are yet to experience success or perceive a path forward *(-m3; -m4)*, as they have been unable to dedicate themselves fully to the venture *(-e5)*.

Founder NS04 – Improving User Experience of Environmental Accounting (Figure 2)

The founder, an academic and a practitioner, begins their journey with an interest to participate in the changing industrial landscape that results from increased awareness of sustainability *(e1; m4)*. This did not initially have a commercial incentive, but rather a desire to experiment and "play business" *(p2)*. From initial development of a prototype that could improve user experiences when measuring environmental impact *(p1; p3; e9)*, collaboration with a close tie *(p5)* and their network of clients *(e7)* led them to start a company. During development of the company, a conflict arises within the founding team *(-e13)*, which is promptly overcome *(e5)* and leads to a reframing of both the venture's value proposition and structure *(c2)*. The product is developed continuously *(p2)* and intuitively *(c6)*. The venture has obtained significant funding in the form of government grants, and now represents an opportunity for the founder to extend the reach and impact of their teaching *(c4; e8)*.

Founder NU01 – Rescuing Heritage through Collected Artefacts

This founder's journey begins with a personal family experience that involves the loss of all belongings. This leads them to seek to fill a personal void through collections of historical objects. They then pursue a fine arts degree, and through their creativity *(c1)*, personal vision *(e4; p3)* and a work ethic *(e12)*, are invited to become part of the local film industry. They perceive an opportunity to provide a service to said industry *(e1)*, but have

a difficult time separating the initial need for collecting with the possibility of creating a valuable service *(-c3; -e2; -e9)*. The business becomes reliant on their other sources of income. Although there is a strong desire to make the venture a success, the main struggle is overcoming the need to use it as a vehicle to "construct a personal identity through artefacts" *(-p1; -e5)*.

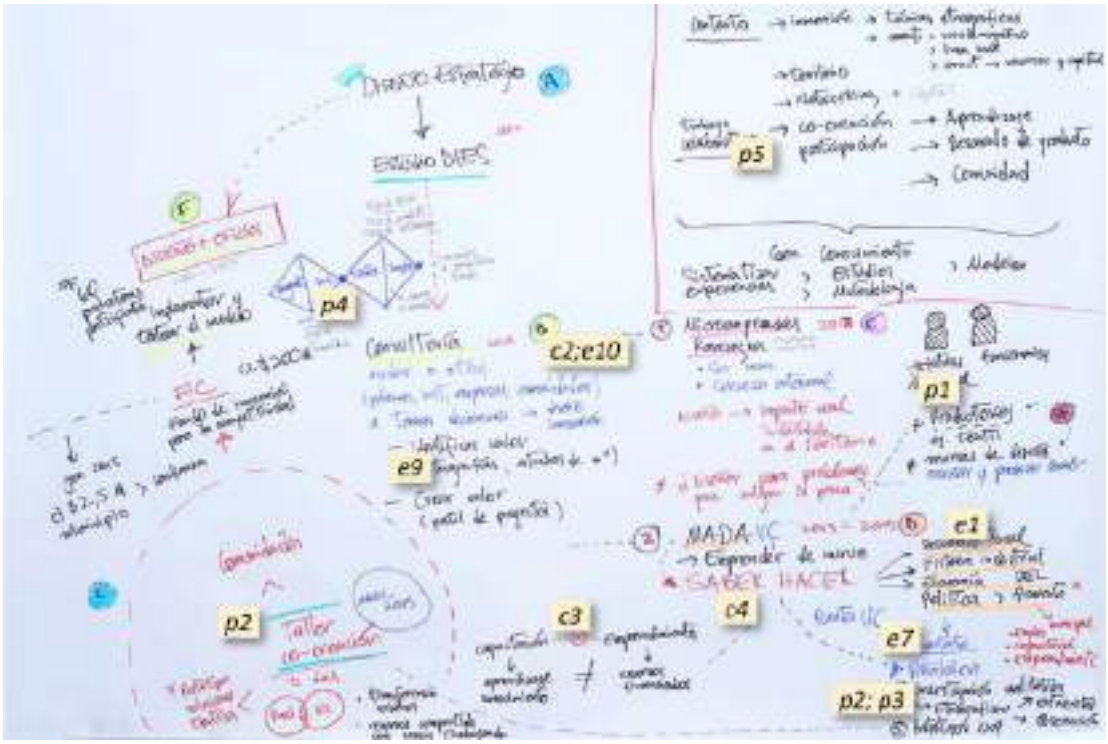

Figure 1: Founder SD03 Visual Narrative with Identified Design Thinking Traits and Entrepreneurial Competencies.

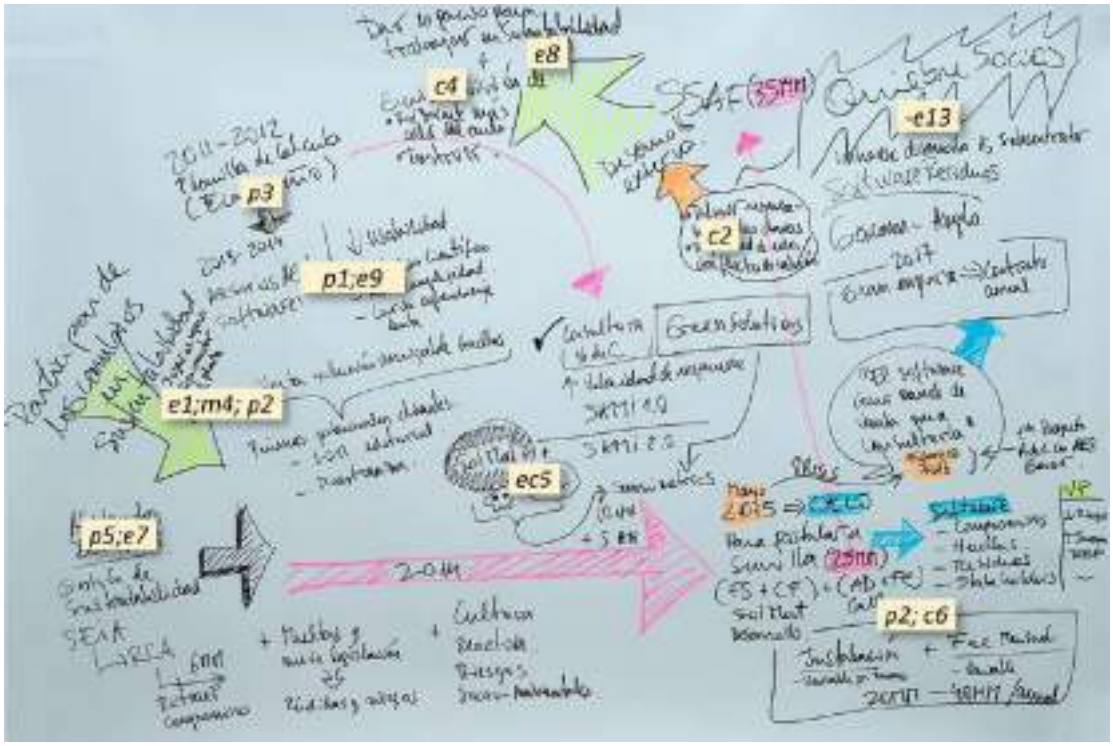

Figure 2: Founder SN04 Visual Narrative with Identified Design Thinking Traits and Entrepreneurial Competencies.

Results

The following section contains findings and observations based on the visual narratives, audio recordings and interview notes. Appendix i provides a summary of the design thinking traits present in participants' visual narratives. The presence of entrepreneurial competencies y available in Appendix ii.

General Findings

Each design thinking trait has been given an indicative score and ranked according to its presence in the narratives of successful founders. Based on this ranking, traits have been attributed a level of impact: high, moderate, low or potentially negative. Traits that were not present in four or more narratives, or whose impact seems negligible, have been omitted. It is important to note that these rankings should not be interpreted as quantitative or predictive. A synthesis of these observations is provided in Table 5.

Table 5: Design Thinking Traits: Presence, Score, Perceived Impact and Observations (S = Successful; U = Unsuccessful; D = Designer Founder; N = Non-designer Founder)

Trait	*S*	*U*	*D*	*N*	*Score*	*Impact*	*Observations*
Collaborative Work Style *(p5)*	11	0	7	4	19	High	Absence hindered success
Thinking by Doing *(p2)*	10	1	7	4	18	High	Overwhelmingly positive
Human-centred Approach *(p1)*	8	0	6	3	16	High	Positive when related to c3
Reflective Reframing *(c2)*	10	1	6	4	14	High	Absence hindered success
Integrative Thinking *(c4)*	8	1	5	4	12	Moderate	Present in S and U
Future-Oriented *(m4)*	8	1	6	3	11	Moderate	Absence hindered success
Holistic View *(c3)*	6	0	5	1	10	Moderate	Absence hindered success
Visualising *(p3)*	6	2	5	3	9	Low	Present in S and U
Divergence/Convergence *(p4)*	5	0	3	2	9	Low	Positive yet rare
Innovation *(p6)*	5	1	3	3	8	Low	Present in S and U

Some interesting outliers include: Tolerance of Failure (m5), which is predominantly represented in designer founders' narratives; and Blending Analysis and Intuition (c6), which has greater representation in the narratives of Non-designer founders.

To identify areas where the traits of design thinking failed to support the formation of opportunities, a similar process was undertaken with the thirteen entrepreneurial competencies. In this case, competencies were highlighted when having a high presence or a low presence. Synthesis of observations is provided in Table 6.

Table 6: Entrepreneurial Competencies, Absence, Score and Observations (S = Successful; U = Unsuccessful; D = Designer Founder; N = Non-designer Founder)

Competency	*S*	*U*	*D*	*N*	*Score*	*Observations*
Value Creation *(e9)*	8	0	5	3	19	Presence increased success
Resource Leveraging *(e7)*	7	0	5	2	14	Absence hindered or delayed success
Guerrilla Skills *(e8)*	6	0	3	3	12	Equal presence among SD and SN
Tenacity/Perseverance *(e5)*	4	1	2	4	8	Potential negative impact without e2
Opportunity Assessment *(e2)*	2	0	1	1	1	Lacking across all categories

Some additional observations include: Building/Using Networks *(e13)* was less present than the presence of Collaborative Work Style (p5) would suggest; Risk Management/Mitigation *(e3)* was also rarely mentioned.

Emerging Themes

From analysis of the visual narratives, it is possible to detect themes and patterns that emerge from the data. These are described below.

1. Interdisciplinary Collaboration is Critical (p5; e13)

Successful entrepreneurs recognise their skill gaps and seek to form collaborative arrangements with people from other disciplinary backgrounds. This occurs early in the opportunity formation process. This seems to contribute to a venture's longevity, as collaborators extend the founder's networks and impact of the project. Unsuccessful founders were either unaware of the possibility of collaboration, unfamiliar with the mechanisms of collaboration, or did not seem willing to engage with the expertise of people from other backgrounds.

2. Opportunities are formed by Doing and Reflecting (p2)

Consistent with the bias for action present in definitions of entrepreneurship, successful entrepreneurs from both categories show high degrees of learning through practice. They highlight successive stages of venture development that are characterised by low cost trials and use of prototypes to refine the venture concept. Sometimes these trials take several years and occur over several distinct entrepreneurial opportunities, with the learnings from each providing the necessary reflection and reframing of the problem for the next.

3. Human-centred Approaches are better when Holistic (p1; c3)

Successful founders from both design and non-design backgrounds highlight their use of continuous observation of the context in which they are executing the venture. This is particularly effective when coupled with a holistic view, including individuals, organisations, industries and regions in their identification of "user groups". Participants whose motivations were centred on personal development tended to have a harder time forming or evaluating opportunities. In these cases, there was little mention of a client, customer or consumer, and the project focused on developing a product or using a particular technology.

4. Tenacity can be a drawback if Opportunity Assessment is lacking (e5; e2)

Data analysis suggests that opportunity assessment is not as common as opportunity recognition. This leads to opportunities being pursued beyond the possibility for them to provide value. Successful entrepreneurs mention failure as part of their process, moving on to other opportunities over time. Unsuccessful entrepreneurs do not seem to have the ability to perceive the point at which a venture should not be continued.

5. Value Creation, when explicitly stated as a goal, is a factor for success (e9)

One of the most consistent aspects of successful founders from both backgrounds was a clear articulation that the purpose of their ventures was to create value, either for themselves, a customer, an industry, or society more generally. Unsuccessful founders did not mention the concept of value, regardless of the depth of their understanding of the concepts and frameworks of design thinking. It would seem that value, although a core component of innovation that is present in definitions of the design discipline, it is not an obvious concept.

6. Guerrilla Skills are widespread; Resource Leveraging is limited (ec8; ec7)

Although guerrilla skills and working in a clandestine manner to access low-cost resources were present in the narratives of entrepreneurs from both design and non-design backgrounds, it seems that designers are less aware of how to leverage resources. Successful design entrepreneurs understand mechanisms to access capital, such as government grants or debt, but the majority were not aware of concepts such as equity or fundraising. There seems to be a negative connotation to the concept of commercialisation, and having an initial profit motive is rarely described.

Discussion, Implications and Limitations

This exploratory study set out to answer the question of how the traits of design thinking may contribute to, hinder, or fail to support the formation of entrepreneurial opportunities, with a specific interest in how design thinking can be used to support development of entrepreneurial competencies among designers. Although the limited sample size and geographic scope of the study prevent a definitive statement on the ability of these traits to predict success, data analysis suggests that some traits have the potential to produce a greater

positive impact than others. This provides an interesting set of directions for further exploration and testing of these finding in other contexts.

Implications for Theory

The study did not find any design thinking traits to have a consistent hindering effect on opportunity formation. On the other hand, Collaborative Work Styles, Thinking by Doing and Reflective Reframing seem to have the greatest positive contribution to the formation of an opportunity. These traits parallel concepts from the entrepreneurial literature, such as bricolage (Fisher, 2012, p.1026-1028) the lean startup (Blank, 2013) and hypothesis-driven entrepreneurship (Eisenmann, Ries & Dillard, 2012).

An empathetic Human-centred Approach, commonly associated with design thinking (e.g. Brown, 2008), is not enough to ensure success. It is when this approach is combined with a Holistic View, perceiving organisations, industries and societies as "human", that it leads to greater outcomes. This is complemented when an Integrative view is present, considering technological and economic requirements alongside human needs. As above, this is also consistent with entrepreneurial literature. In particular, the dynamic systems perspective of an entrepreneurial firm, such as the concept of the business model (Zott, Amit & Massa, 2011; Osterwalder, 2004), and its recognition of customers, partners, activities and revenue streams as interconnected components of a venture's logic-flow (Frow & Payne, 2011; Osterwalder & Pigneur, 2010).

With regards to the shortcomings in design thinking's ability to support opportunity formation, there were several entrepreneurial competencies that were underrepresented, such as Resilience and Opportunity Assessment. Others, such as Value Creation and Resource Leveraging, were not widely present but showed an important contribution to venture success. It may be that Value Creation, abstractly embedded in the Human-centred approach and Innovation, needs to be more concrete and explicit in definitions of design thinking traits. One possible approach, drawing on the field of innovation, is to make the concepts of customer jobs (Bettencourt & Ulwick, 2008), jobs-to-be-done (Christensen, Hall, Dillon & Duncan, 2016), or the value proposition (Kambil, Ginsberg & Bloch, 1996; Osterwalder, Pigneur, Bernarda & Smith, 2014) into the design thinking lexicon.

The parallels between design thinking traits and entrepreneurial competencies are numerous, making it difficult to discern which of the two was present in individual narratives and the overall data set. Examples of this are: Tolerance of Failure (m5) vs Resilience (e11); Abductive Reasoning (c1) and Problem-solving (c5) vs Creative Problem-solving (e6); Future-Oriented (m4) vs Conveying a Compelling Vision (e4).

This leads to perhaps the most meaningful implication from this study: surfacing the overlap between design thinking and opportunity formation. This seems to signal a convergence in theory between the broader disciplines of design and entrepreneurship. This convergence is echoed in practice through the increasing participation of designers in the global entrepreneurship ecosystem.

Could this lead to a further evolution in the field of entrepreneurship, towards an interdisciplinary field of "design entrepreneurship"? Rather than focusing on the entrepreneurial opportunity, perhaps this field could assist in addressing the need for frameworks that enable the transition from opportunity to project (Klein, 2008, p.181). From this, possible avenues for further inquiry could be to explore and define the boundaries of design entrepreneurship as a field of research, and how the traits of successful design entrepreneurs could assist in the development of methods for entrepreneurial action.

Implications for Education

The previously described overlaps between design thinking and the formation of entrepreneurial opportunities provide valuable encouragement for the development of entrepreneurship programs in design education.

There are a several existing conceptual approaches, such as Laukkanen's (2000) Business Generation Model, and practical programs that have done this to achieve positive outcomes, such as Aalto University's IDBM Challenge (Lehtonen et al, 2018). Building on their work, and drawing from the findings and themes that emerged from this study, here are a few basic propositions that focus specifically on using design thinking to develop entrepreneurial competencies:

1. **Foster Interdisciplinary Collaboration:** create contexts that enable designers to begin engaging with representatives of other disciplines or industries early in their studies or careers;
2. **Make Entrepreneurship Continuous:** incorporate the concept of the entrepreneurial opportunity in every project. Include assessment of those opportunities at each stage, ending those with low

chances of success. Celebrate the end of each project as an important chance to reflect on and integrate learnings into the pursuit of a subsequent opportunity.;

3. **From Individuals to Social Systems:** ensure that designers perceive whole systems as their end users. Encourage them to visualise the connections and flow-on effects of designing for each component of those systems;
4. **Value Creation should be a Persistent Message:** coupled with the systems view, designers should be constantly reminded to describe their work not as a collection of features, but as a collection of benefits delivered to a wide range of stakeholders. Designers should be encouraged to measure those benefits in terms that are relevant to said stakeholders.
5. **Pitching for Funding should be part of the Design Process:** incorporate activities that involve acquiring resources from third parties from early on in their training. This could start small, such as B2C sales, but should build up to understanding a range of different funding sources, including crowdfunding, grants and venture capital. As with all design, this will be best learnt by doing.

Limitations & Further Research

Although exploratory in nature, this study possesses many limitations.

The major limitation of the present study is its reduced sample and limited geographic scope. The disparity in the number of successful and unsuccessful founders interviewed is due to both a limited timeframe for data collection and the difficulty in *ex-post* identification of unsuccessful ventures. Additionally, unsuccessful founders who had not initiated a subsequent venture were excluded for ethical reasons. Further research should aim to increase this scope, both geographically and in the number of unsuccessful opportunities whose visual narratives are captured. Of interest would be exploration of different cultural or industrial contexts to identify whether these have an effect on the opportunity formation process. Additionally, it would be of value to look at how design thinking is present in the processes of other specific disciplines, such as engineering, social sciences, art, etc.

The data collected suggests that success is not a binary variable, but rather a spectrum of achievement. Successful entrepreneurs, in particular those that had obtained government funding or revenue through their ventures, did not consider said achievements as measures of success. They were described as means to an end. Failure was similarly described. Success may not be a fixed state, with “successful” entrepreneurs perceiving themselves as being in a constant cycle of achievement and disappointment, with each experience providing insights and lessons to be implemented in the next iteration of the venture. This would require a new categorisation of research participants and a different data analysis technique. One possibility would be to develop a simple survey that could help to characterise the subjective level of success of a venture, complemented with quantitative metrics such as revenue, staff and third party use of intellectual property created by the venture. This could help with comparison and situating participants along the “success spectrum”.

A third limitation is the “visual narrative” and accuracy of data collection and analysis it affords. An unexpected outcome was that no participant, regardless of background, was discouraged by the prospect of visualising their entrepreneurial journey. The overlapping of concepts and interpretive nature of the flexible pattern matching both made it difficult to ensure that design thinking traits were comprehensively identified with an adequate assessment of their positive or negative impacts. Three possible improvements could be made for future studies. The first is further synthesising the design thinking and entrepreneurial competencies, avoiding redundancies that could lead to coding errors. Examples include the nuanced distinctions between Problem-solving (c5) and Innovation (p6) or Optimistic (m3) and Tolerance of Failure (m5). The second would be to structure the interviews in stages from the design thinking literature. For example, Inspiration, Ideation and Implementation (Brown, 2008, p.5). This would help to clarify which design thinking tools are best suited to each of these stages. Finally, limiting the diversity of visualisation materials to improve legibility, and embedding coding tasks in the interview itself through use of colour by the participant would reduce researcher bias in determining positive and negative effects of tools in the study.

Conclusions

The present study set out to contribute to an understanding of the role that design thinking plays in the formation of entrepreneurial opportunities. Through a visual narrative method, it was possible to capture rich picture diagrams about the experiences of fourteen founders from a range of backgrounds and industries.

From this study, it is possible to say that most of the practices, cognitive processes and mindsets of design thinking have the potential to facilitate the formation of entrepreneurial opportunities. The most important impacts were produced through collaborative workstyles, thinking by doing and reflective reframing. The human-centred approach also produced a positive impact when combined with a holistic view of social and industrial systems. A key aspect that could be further emphasised in design thinking is the importance of value creation for stakeholders, including the founders themselves. Designer founders seemed to lose focus of potential returns and as such may be inadvertently limited in the scope of the opportunities they form. This could be addressed by also highlighting the importance of resource leveraging, specifically accessing capital markets, as this could increase the ambition and impact of opportunities formed. The study also finds interesting parallels between the fields of design and entrepreneurship that could lead to interesting interdisciplinary research opportunities.

Acknowledgements

The author would like to thank Dr Vesna Sedoglavich, Dr Ian Elsum and Dr Carlos Montana-Hoyos for their contributions to the theoretical foundations and motivations for the study. They would also like to thank Jennifer Hehn for her inspiring talk at PACIS2018, Claudio Castro for providing access to the space used for interviews in Chile, and Alex Moffatt for their help in photographing the visual case studies. Finally, they would like to thank all of the founders who took time out of their busy schedules to participate in the study.

Contamination Lab of Turin (CLabTo): how to teach entrepreneurship education to all kinds of university students

FIORE Eleonora*; SANSONE Giuliano; REMONDINO Chiara Lorenza and TAMBORRINI Paolo Marco

Politecnico di Torino, Italy

doi: 10.33114/adim.2019.02.359

Interest in offering Entrepreneurship Education (EE) to all kinds of university students is increasing. Therefore, universities are increasing the number of entrepreneurship courses intended for students from different fields of study and with different education levels. Through a single case study of the Contamination Lab of Turin (CLabTo), we suggest how EE may be taught to all kinds of university students. We have combined design methods with EE to create a practical-oriented entrepreneurship course which allows students to work in transdisciplinary teams through a learning-by-doing approach on real-life projects. Professors from different departments have been included to create a multidisciplinary environment. We have drawn on programme assessment data, including pre- and post-surveys. Overall, we have found a positive effect of the programme on the students' entrepreneurial skills. However, when the data was broken down according to the students' fields of study and education levels, mixed results emerged.

Keywords: Entrepreneurship education, design thinking, entrepreneurship, design education

Introduction

The European Commission defined a sense of initiative and entrepreneurship as "key competences [..] which all individuals need for personal fulfilment and development, active citizenship, social inclusion and employment" (EC, 2006, pp. 4). Therefore, local, national and international actors (universities, business incubators, foundations, corporations, policy makers) are working together to promote Entrepreneurship Education (EE) for all kinds of university students (Katz, 2008; do Paço et al., 2011; Duval-Couetil, 2013). This is probably due to the fact that EE increases the students' entrepreneurial competencies (e.g., Man and Lau, 2005; Phan and Siegel, 2006; Pittaway and Edwards, 2012; Duval-Couetil, 2013; Shahab et al., 2019), entrepreneurial intention (e.g., Kolvereid & Moen, 1997; Peterman and Kennedy, 2003; Fayolle, 2005; Shahab et al., 2019) and entrepreneurial activities (e.g., Kolvereid & Moen, 1997; Mueller & Goic, 2003; Florin et al., 2007). Moreover, entrepreneurial competencies can be valuable, not only to create start-ups, but also to work in innovate corporations, since they require entrepreneurial mind-sets and pro-active employees. In addition, universities have increased attention towards EE as part of their 'third-mission' (Siegel and Wright, 2015; Birtchnell et al., 2017) in order to foster the entrepreneurial culture of their students and to develop the local entrepreneurial ecosystem. Therefore, there has been a remarkable expansion in the number of programmes devoted to EE (e.g., Katz, 2008; Fretschner and Weber, 2013), in part because students have expressed a desire to participate in EE programmes (Peterman and Kennedy, 2003).

However, despite its popularity, the vagueness of the EE teaching goals (Hoppe, 2016) and its pedagogical approaches (Thursby et al., 2009; Piperopoulos & Dimov 2015; Nabi et al., 2017), there are still some important weaknesses that future research should try to face. For instance, there is a need to create more practical-oriented entrepreneurship courses (Cooper et al., 2004), and the introduction of design thinking into EE may be a solution to this need (Glen et al., 2014). Moreover, the impact of the entrepreneurial abilities of EE students might vary considerably, according to the students' characteristics (Piperopoulos & Dimov, 2015; Maresch et al., 2016) and the content and pedagogy of the entrepreneurship course (Piperopoulos & Dimov, 2015). Most studies on EE (see Nabi et al., 2017 for a recent literature review) have analysed an EE course offered to a specific field of study (e.g., management) and a specific educational level. Therefore, it is not clear how to teach entrepreneurship to students from different backgrounds and with different levels of education (e.g. bachelor and master), since most of the EE literature refers to a single field of study, which is mainly related to business curricula. However, it is important to teach entrepreneurship to students from different backgrounds in order to create multidisciplinary teams, thus fostering an innovative and entrepreneurial mind-set. Colombo and Grilli (2005), for instance, using the human capital theory, suggested that entrepreneurial teams composed of team members from different backgrounds perform better than others. Moreover, if a student works for an innovative company, he/she will probably work in a multidisciplinary team. This suggests that EE in a multidisciplinary environment is also important for students interested in innovation. In fact, several companies make employees from different backgrounds work together as a strategy to deliver innovative products/services. In addition, companies are increasing their open innovation strategies through the creation of different activities, such as corporation incubation programmes (Becker and Gassmann, 2006; Kohler, 2016). For all these reasons, it is important for students to learn how to work in multidisciplinary teams.

This paper, in order to overcome these drawbacks, is aimed at explaining how it is possible to combine design thinking with EE in order to develop a practical-oriented entrepreneurship course. Moreover, we suggest how entrepreneurship may be taught to students from different fields of study and with different educational levels and help them to work in multidisciplinary teams. In order to do so, we have investigated the entrepreneurship activities developed by the Contamination Lab of Turin (CLabTo) in Italy. We decided to analyse CLabTo because it is a recent programme that was funded by the Ministry of Education, University and Research (MIUR) in Italy in 2016, that is aimed at fostering the entrepreneurial and innovative abilities of all kinds of university students. The aim of CLabTo is to enhance the students' specialised expertise and integrate it with new capabilities to face new, uncertain and complex situations in the real world (e.g. solving real-life/entrepreneurial/societal problems) through learning-by-doing. In CLabTo, we combine EE with design thinking, design methods, cognitive processes, techniques and sensibility for solving problems (Glen et al., 2014).

Following the structure of Thursby et al. 2009, we have drawn on programme assessment data. We administered pre- and post-surveys to the participants to assess the barriers and the obstacles to teaching entrepreneurship in a multidisciplinary environment. Out of 62 participants, 56 participants answered both the pre- and post-surveys, thus yielding an effective response rate of 90.3%. In general, we found a positive effect of the programme on the students' entrepreneurial skills. However, when the data were analysed after breaking them down into the students' fields of study and their education level, mixed impacts emerged for the course on students' entrepreneurial skills. Moreover, on the basis of their answers, it emerged that students liked the multidisciplinary environment of CLabTo and the fact that it is based on real cases and a learning-by-doing approach. However, since our sample was only composed of 56 students and a control sample was not available, our analyses can only be considering qualitative.

We contribute to the theory of literature on entrepreneurship by adding our case study to the structure of Thursby et al. (2009) and by explaining how entrepreneurship may be taught to different levels of university students. Moreover, as suggested by Glen et al., (2014), we suggest how design thinking and EE may be merged in order to develop a practical-oriented entrepreneurship programme, thus contributing to the discussion started by Nielsen and Stovang (2015) by creating knowledge about the cross-over of design thinking and EE. Lastly, this study has a practical implication for scholars, teachers and policymakers interested in how to teach entrepreneurship in a multidisciplinary environment.

This section is intended to frame and introduce the relevance of the topic. The next section will focus on the literature review in order to articulate where this new research is located and how it could add new knowledge. The CLabTO programme is introduced in section 3 as a key study to explain how to integrate EE and design thinking. We show the results obtained on the basis of the Clab teaching model in section 4 and the

answers received from the pre- and post-surveys, including the overall degree of satisfaction with the programme. A discussion on the results is presented in the fifth section, together with the limits and implications for future research.

Literature review

According to Rae & Carswell (2000), a learning-by-doing programme enhances the development of student's entrepreneurial competencies. In fact, Cope and Watts (2000) explained that individuals learn from experiences and failures. Therefore, it is important for students to test and try their hypotheses through real project-work in order to develop their skills. Moreover, such an activity allows students to work in a real-case project on their own ideas, which can help them and teachers to create a more innovative and experimental environment, in part because students are more enthusiastic about working on their own ideas. In addition, the recent social and technological changes that have taken place blur organisational boundaries and emphasise collaboration (Browder et al., 2019). Therefore, it is important for students to know how to collaborate in a multidisciplinary environment. However, collaborating with people from different backgrounds can be complex, and it requires some experience. It is possible to understand, from the literature, that technical students (from engineering and natural science) lack skills in management, communication and team-based problem solving, all of which are critical for decision making in innovation-related careers (Thursby et al., 2009). Moreover, Thursby et al. (2009) suggested that there is a growing need to address this gap without sacrificing specialised and in-depth technical training. In fact, many critiques of Business school education emphasise the need to overcome the rational analytic approach of such curricula, which have been proved to address the complexity of real-life and entrepreneurial problems in an unsatisfactory manner (Glen et al., 2014; Nielsen and Stovang, 2015; Taatila, 2010; Huber et al., 2016). Furthermore, they suggest introducing practical approaches, such as design thinking, to unlock the potential of entrepreneurial and innovative students to deal with practical cases and active learning, in order to help business students develop design skills and mind-sets. On the other hand, another strand of literature points out the need to introduce EE into the curricula of design schools to increase the ability of design candidates to turn product ideas (concepts) into actions and to develop managerial, economic and strategic thinking skills (Gunes, 2012). In fact, EE is expected to allow designers to develop entrepreneurial skills and mind-sets, in order to create new jobs in the future and to become major drivers of economic growth through creativity and innovation (Gunes, 2012).

In this work, we seek to demonstrate that design thinking should play a fundamental role in EE that is complementary with business education (Glen et al., 2014, Nielsen and Stovang, 2015) for any field of study. The two disciplines should coexist in a practice-base new course that is able to encourage students to participate with a learning-by-doing approach centred on action (Joannisson et al., 1998). Several studies have proved that EE, in order to be efficient, must be practical (e.g., Cooper et al., 2004). Thus, we have used design pedagogy to provide the practical approach and stimulate thinking outside the box for any field of study, that is, not just the managerial or design fields.

The CLabTo programme

Introduction to the Contamination Lab (CLab) programme and to CLabTO

The CLab programme is a nationally funded programme that now counts 22 CLabs in Italy. Each of these CLabs is recognised at a ministerial level (Directorial Decree no. 315 of 29 November 2016). This entrepreneurship programme involves two universities in Turin – the Politecnico di Torino and the University of Turin – in which both technical and humanistic disciplines are taught. The CLabTo programme has the aim of developing the students' skills in running their own businesses, as well as in working in highly innovative contexts, by training them through EE and design methods with entrepreneurial and real-life challenges. The goal of CLabTo is twofold. On the one hand, it has the aim of creating the entrepreneurial intention of students to become entrepreneurs or innovators. On the other hand, it seeks to help students to develop skills (such as problem solving, team working, etc.) that are increasingly being requested by companies that operate in innovation fields by introducing design thinking into EE.

Programmes

CLabTo is a sprint-like challenge-based programme that is directed towards innovation. It combines EE and design thinking by allowing students from various backgrounds to apply them to real challenges in the industrial or academic worlds. It includes three different programmes which have three different intents, durations and expected outcomes.

The intention of Type 1 (CLab Workshop) is to generate new ideas in the form of feasible concepts and it lasts 1 or 2 weeks. Type 2 (CLab Sprint) includes prototyping and it lasts from 2 to 4 weeks. Type 3 (CLab Master) has the goal of validating technical, business performances and IP studies to forward the ideas and the prototypes to a more advanced stage, and it lasts from 3 to 6 months. Each of these 3 programmes is divided into courses (training) and team experience (team working). In other words, the first part involves a discussion between students and professors from different research fields. This first part is aimed at filling the theoretical-methodological and entrepreneurial gaps of the students with diverse curricula and from different backgrounds. The professors teach the students the skills necessary to address specific real-life problems and propose coherent and innovative solutions. Professors from different departments and research fields also increase the multidisciplinary aspect of delivering pedagogy. The second part mostly involves team-based work where the students have to face a complex and unpredictable situation within a multidisciplinary environment within which they have to consider several variables. In the second part, professors, experts from industry and entrepreneurs help students by giving feedback on their team-work as mentors/tutors. This second part is aimed at representing a real case as much as possible. CLabTo engages students in tasks, activities and projects that should enable them to acquire key entrepreneurial skills and competences in a real-life situation (Nielsen and Stovang, 2015).

Structure of the challenges

In this paper, we have analysed two types of challenge since, until now, we have organised only three challenges: two type 1 challenges (CLab Workshop) and one type 2 challenge (CLab Sprint). However, the overall duration of both types was limited to two weeks. The structure of these challenges is described hereafter.

The type 1 programme focuses on generating new ideas and exploring alternative solutions in order to allow the students to think beyond technological push solutions, by considering the centrality of the user they are designing for and thus reframing the needs to which they have to respond with different solutions. This type of challenge leads students to develop concepts that are characterised by a certain degree of technical and economic feasibility. Moreover, the solutions are usually iterated with the relevant stakeholders from the local ecosystem during revisions, meetings and intermediate presentations. The type 2 programme, instead, introduces the production of working prototypes, which are developed in a suitable environment for prototyping activities, the Fablab Torino. The students have the chance to experiment with shape and materials through different technologies (Browder et al., 2019), such as 3D Printing, CNC machining, programming on Arduino and Raspberry Pi shields, and are supported by mentors (Figure 1). During these challenges, the focus is more on the process than on the outcome.

Figure 1: Fablab tutoring

As far as the overall structure of the challenge (both type 1 and 2) is concerned, during the first days, the students are required to build their multidisciplinary teams, an activity that is facilitated by team-building exercises. We relied on a team of researchers from the Department of Psychology of the University of Turin, led by professor Cristina Mosso, to perform this activity, settle disputes and balance skills and competencies.

During the first week, we provided the students with short teachings (1-2 hours) on sustainability, entrepreneurship, design thinking, digital innovation and communication, that is, the mandatory modules of our programme, which were delivered by professors from different departments. In the same week, they were also taught challenge-specific contents by university faculty members (both professors and researchers) and industry mentors (entrepreneurs and experts). The organisation of these classes is dealt with in detail in the result section and the students' feedback is commented on. The second week, in the type 1 programme, the students worked in teams to develop their ideas with the support of tutors and mentors, while in the type 2 programme, they worked in teams to develop both their ideas and a working prototype in the FabLab Torino, and on this occasion they were supported by makers, computer engineers and other tutors. On the last day of the challenges, they performed a 10-minute pitch in which they presented their ideas to an audience that included CLab programme members, university faculty members, industry mentors and members of the university incubators.

The first challenge was a type 1 challenge on the specific topic of electric mobility, in cooperation with Iren S.p.A.[1], and it took place in July 2018. The second was a type 2 challenge on the topic of sustainable food conservation, which took place in November 2018, and the third one (type 1) on the potential impact of new technologies (such as AI) on our future life and jobs, which also involved the Visionary association[2], took place in December 2018.

These specific challenges gave the students the opportunity to test their theoretical knowledge in a practical case in multidisciplinary teams and then learn from the others and through mistakes and feedback from the mentors. Each participant provided his/her knowledge and expertise to a programme where there was room to make mistakes, to test and to experiment. In fact, since there was no exam, the students felt free to make errors and to try. They learned more about the specific topics from the tutors, mentors and professors from both industry and academia. CLabTo in fact collects students who are interested in a topic, whatever background they have, provided they have been enrolled in university. The followed teaching model gives rise to the cognitive difference theorised by Reynolds and Lewis (2017). It includes an enhancement of the difference in perspectives and how students elaborate and process information (knowledge processing), as well as how they think about and engage with new and complex situations (Reynolds and Lewis, 2017).

Opportunities

Although multidisciplinary, collaborative learning projects that inspire entrepreneurship are not unusual, the CLabTo programme is extracurricular and it is intended for students from all fields of study and from different university educational levels who are willing to take on a challenge pertaining to a specific topic. Therefore,

CLabTo allows an entrepreneurship programme to be developed for all the enrolled students, albeit outside the university environment, but closely related to it. This is in line with what Thursby et al. (2009) expressed:

> *Introducing entrepreneurship education to graduate programs is challenging because they are typically highly structured and allow little room for courses outside the primary discipline.*

CLabTo was created to solve certain problems (such as credits for different students from different departments, different professors involved in a course), with the intent of being a neutral place where they could conduct experiments. In this way, different types of teaching that could be relevant for EE are now accessible to the various students in a single place. CLabTo adopts teaching methods and space layouts for teaching and team work which stimulate cooperation among the students who work in teams. We witnessed an active role of the participants and a revised the role of the teachers as tutors and facilitators, who were willing to learn from the students and to build the programme with them (Celaschi, 2008). Although this type of approach was originally theorised for design curricula, it should be noted that it is somewhat novel for other types of students who are not used to receiving design pedagogy. On the other hand, students in design schools often discuss and negotiate their ideas with other stakeholders from different fields, but it is not as common for designers to work effectively in transdisciplinary[1] teams, mainly with non-designer students. Combining EE and design thinking, in addition to the previously mentioned characteristics, makes the CLabTo programme different from those that have already been analysed in the literature. This programme includes business and design pedagogies, but it is not intended specifically for business or design students.

According to Yee et al., (2017), the importance of the design process can be summarised as:

1. a cultural catalyst, which promotes both openness and pragmatism;
2. a framework maker, which provides and organises the whole project system (information, spaces, partners, etc.);
3. a humaniser, which encourages empathy in the creative process;
4. a power broker, which tries to break down prejudices and maintain the human-centric focus;
5. a friendly challenger, which encourages an environment of openness and trust and spurs a constructive critique of each-others' work;
6. a technology enabler, which ensures the as fluid as possible transition between physical to digital and the other way around;
7. a community builder, which attracts people (students, mentors, specialists, etc.) with the final goal of enlarging the network of participants to create important impacts.

In addition, another important factor of CLabTo is its focus on sustainability (social, economic and environmental) for all the CLabTo challenges, since there is growing attention on this topic (UN SDGs (2015).

Teaching environment

Since the classroom layouts and University spaces usually dedicated to teaching are unsuitable for these kinds of activities (Nielsen and Stovang, 2015), we provided a physical environment for learning and team work that allows a complete reconfiguration, according to the type of activity that has to be performed. We avoided fixed furniture and opted for wheeled furniture that could be arranged to best satisfy the needs of the students' activities. In this environment, the professors chose the best layout according to the type of lesson, and preferred to sit among the students in circles, or they divided the students into groups for group exercises. Moreover, as mentors, they gave them feedback on their work. In addition, each table was individually cabled and this allowed projection onto a canvas and audio play from any part of the room. This allowed the students and professors to work in a more informal and open environment.

Description of the study population

In this paper, we refer to the study population by reporting data pertaining to all of the participants in the 3 challenges described in the previous section (e-mobility, food conservation and visionary). Overall, from July to

[1] Herein, we refer to transdisciplinary team work, since students from different backgrounds created outputs that are completely new and different from the outputs achieved by means of multidisciplinary cooperation. They integrated their perspectives with a holistic approach that falls outside any disciplinary boundaries.

December 2018, 62 students took part in these 3 challenges and they therefore represent the study population.

The study population was composed of 61% men and 39% women. Of these, 75% were MSc, 25,5% BSc and the remaining students were PhD candidates. It can be noticed, from Figure 2, that 16 students came from humanities, 13 students were engineers, 12 came from management or management engineering, 11 were designers or architects and 10 came from natural sciences. Some of these categories were identified by Thursby et al. (2009) i.e. Engineering, Management and Natural Science, and we added two extra categories, that is, Design&Architecture and Humanities.

This varied and extremely multidisciplinary sample was a good starting point for the creation of 16 heterogeneous teams.

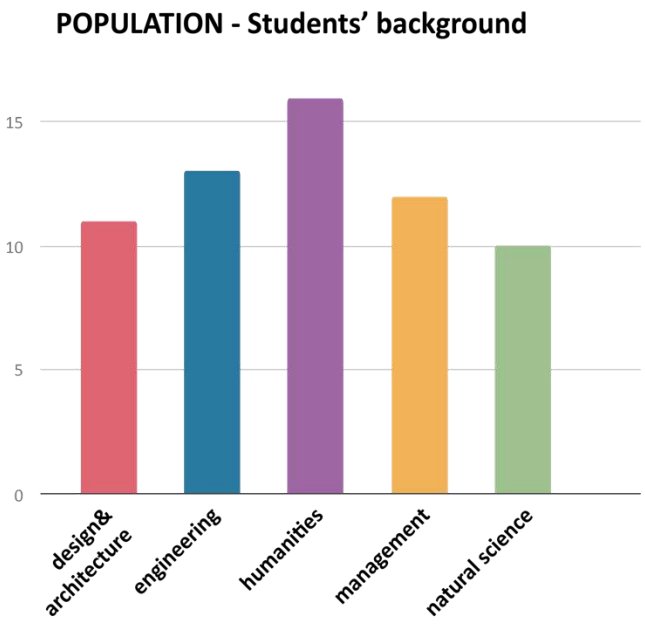

Figure 2: Students' backgrounds divided into categories

The study population of the challenges was generally aged between 20 and 34 years, with an average age of 25 years. The age distribution of the study population showed a peak between 25 and 26 years.

We developed and administered pre- and post-surveys to assess the students' perceptions of their skills or multidisciplinary competencies on entry and exit (Thursby et al., 2009). Data from these surveys allowed us to evaluate the effects of student learning across degree programmes. The assessment goals were both formative and summative, so that the students' feedback and performances could be used to improve the programme (Thursby et al., 2009).

Results

Combining EE with design thinking

As working in innovative sectors and entrepreneurship is increasingly heading towards transdisciplinary collaboration, students will find themselves collaborating with people who have different mind-sets. This EE type of path seems suitable to provide skills that would otherwise not be provided by traditional training. The ability to change their mind-sets in order to communicate effectively and to co-design with people with different curricula will be an essential skill for workers in the coming decades, as indicated by the EU commission (EC, 2006, pp. 4) and by Colombo and Grilli (2005), whether the students decide to start an entrepreneurial path or decide to be employed in stimulating and innovative environments. In fact, even within start-ups when the team is particularly homogeneous, in terms of background and *forma mentis* (in the way to engage with and think about change), this slight cognitive diversity and multidisciplinary reduce their versatility in how to approach a task and their ability to accomplish it (Reynolds and Lewis, 2017). It has been

proved that colleagues usually gravitate towards people who think and express themselves in a similar way (like-minded teams) and have limited ability to see things differently (Reynolds and Lewis, 2017).

For this reason, we tracked the composition of the teams during the proposed challenges in order to make sure a certain degree of cognitive diversity and multidisciplinarity was satisfied. Introducing team building in the first two days of the challenge was appropriate to prompt the students to get to know and compare a small number of people before the onset of friendship or bias among the classmates.

The teams so far have been composed of 3 or 4 people with at least 3 different skills. The winning teams of the three challenges were in fact constituted by four students from three different fields of study, which implies that two students for each team were from the same field of study, as is shown below:

1. E-mobility: two students from Humanities, one from Design&Architecture and one from Engineering;
2. Food conservation: two students from Design&Architecture, one from Management and one from Natural Science;
3. Visionary: two students from Natural Science, one from Engineering and one from Management.

However, it should be noted that the students from the same field of study belonged to different courses and had different levels of education.

Challenge-specific results

During the type 1 challenge on e-mobility, the students were asked to provide a feasible solution to multimodal transport that included all-electric vehicles, that is, from car sharing to scooters and bicycles. The students provided 8 interesting possible solutions, and the winning team focused on a solution that benefited from the historic and well-distributed tram network in the city of Turin, suggesting the provision of multifunctional power stations near the existing junctions.

During the type 2 challenge on food conservation, the students hypothesised alternative food preservation methods. In the prototyping phase, they experimented machine learning, voice recognition and shape recognition of food (Figure 3), as well as temperature/humidity recording and automatic correction measures (Figure 4). The winning team demonstrated, with humidity and temperature sensors, the effectiveness of the pot-in-pot system[2], which consists of two clay containers with wet sand in the cavity, which is able to maintain low humidity and to lower the inner temperature below the environment one. This solution does not require the use of energy and it is suitable for preserving fruit and vegetables. They developed a system of containers that can be integrated in any European domestic environment.

Figure 3: Machine learning, voice recognition and shape recognition of food

[2] Pot-in-pot is a traditional African system that is used to cool the temperature of foodstuffs, which is achieved through direct evaporation generated by exposing the container to the sun.

Figure 4: Temperature and humidity monitoring prototypes

A gaming-based education system which benefited from augmented reality and learning systems won the third challenge (type 1) on Visionary solutions. The students were supported by computer scientists, natural scientists and researchers in the field of Information and Communication Technologies.

Survey results

The results of the two surveys distributed to the CLabTo participants, which resulted in a high response rate of 90.3% (56 students out of 62) were used to form the survey sample. The surveys were given to the participants before and after the challenge, and they are here referred to as the pre-challenge and post-challenge surveys.

To assess the extent to which the CLabTo classes and team experience contributed to fostering the professional development of the students, they were asked. in both the pre- and post-surveys, to provide a self-assessment of their capabilities and perceived expertise in each of the six skills listed in Table 1. These entrepreneurial skills were taken from GUESSS[3].

Table 1: Six skills on which the students were asked to give a self-assessment

Skills					
Creating new products and services	Managing innovation within a firm	Commercialising a new idea or development	Building up a professional network	Identifying new business opportunities	Successfully managing a business

The first three items refer explicitly to the innovation and development of new ideas/products/services. The fourth one is about belonging to a professional network, while the last two refer to vision and management business aspects.

The students' self-declared capabilities were ranked on a 5-point Likert scale, where 1 refers to very low competence, 2 refers to minimally capable, 3 to adequate, 4 expresses good competence and 5 refers to very high competence. The results are shown in Figure 5.

[3] GUESSS is a large, global research project on student entrepreneurship. More information is available on: http://www.guesssurvey.org/.

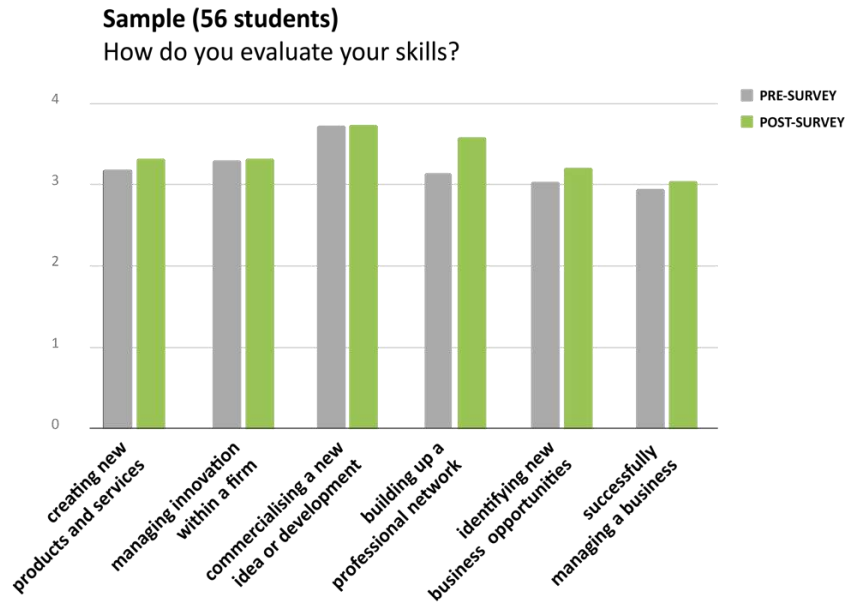

Figure 5: The overall perception of students' pre- and post-challenge skills

At a first glance, it seems that the students' perception of their skills (pre- and post-challenge) increase slightly, which is a good result, considering the limited duration of the programme. However, if the data are analysed by breaking them down into the students' fields of study and their education level, it can be observed that some students benefited more than others from this type of education. The remaining part of this section is dedicated to discussing the obtained data by exploring what happened according to the different education levels of the students (graduate and undergraduate) and the different fields of study (Design&Architecture, Engineering, Humanities, Management, Natural Science).

Differences in results for the BSc and MSc students

On entry to the programme, the BSc students differed from the MSc students for all the capabilities; the results indicate that the MSc students (39 individuals) perceived higher capabilities than the BSc students (16 individuals) (Figure 6). However, at the end of the programme, the situation was completely reversed, with the MSc students feeling they had little or no gains, while the BSc students perceived a greater gain, as shown in Figure 7.

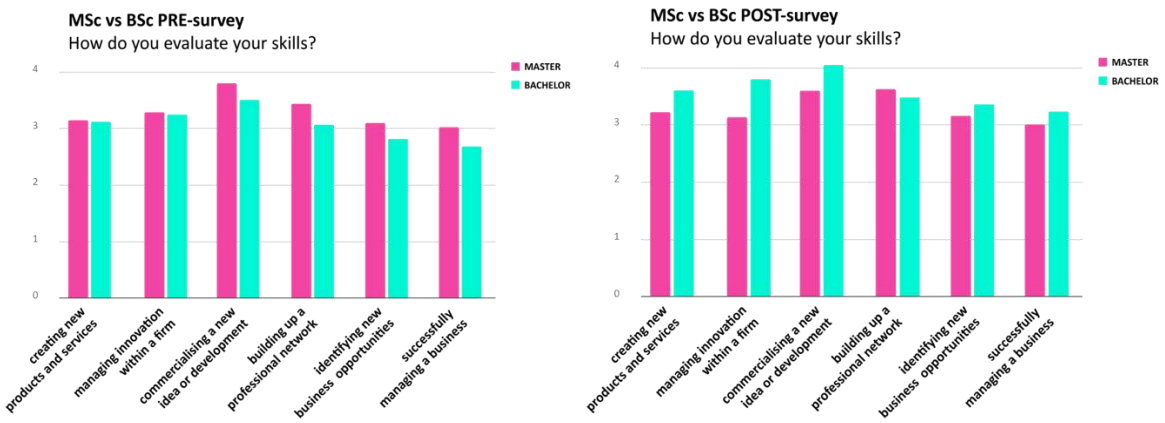

Figure 6: The perception of the MSc and BSc students on entry to the programme and at the end of the programme

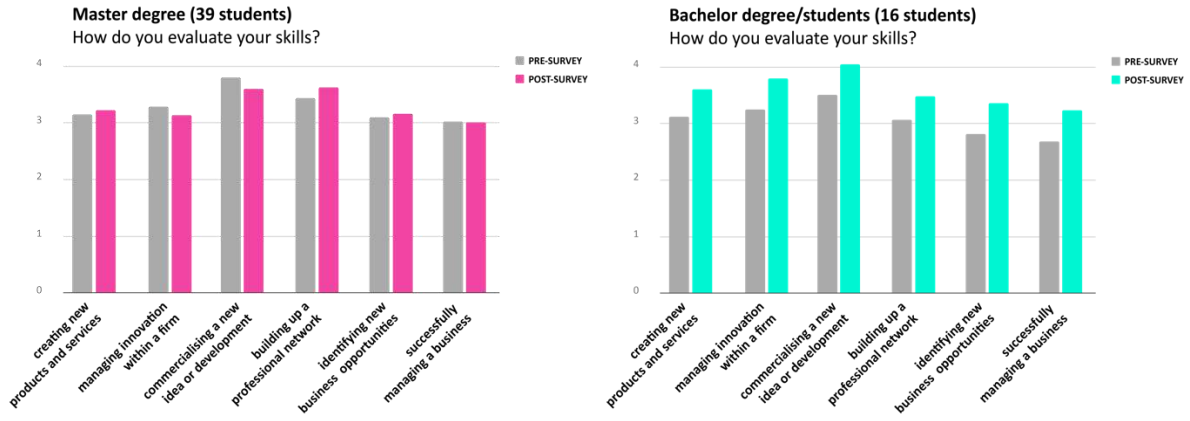

Figure 7: The perception of the MSc and BSc students about their skills (pre- and post-challenge)

Comparing the pre- and the post-challenge perceptions, it emerges that the Bachelor students showed the greatest gain in perceived skills during the course. It also emerges that the MSc students, in some cases, perceived a decline of their skills, such as "managing innovation" and "commercialising a new idea or development". However, since our sample is only composed of 56 students (even though they answered on both the pre- and post-challenge) and no control sample was available, our results can only be considered qualitative.

The results according to the students' backgrounds

In addition to the difference between the MSc and BSc students, the perceived skills of the students are presented in this section, divided according to the fields of study (Figure 8).

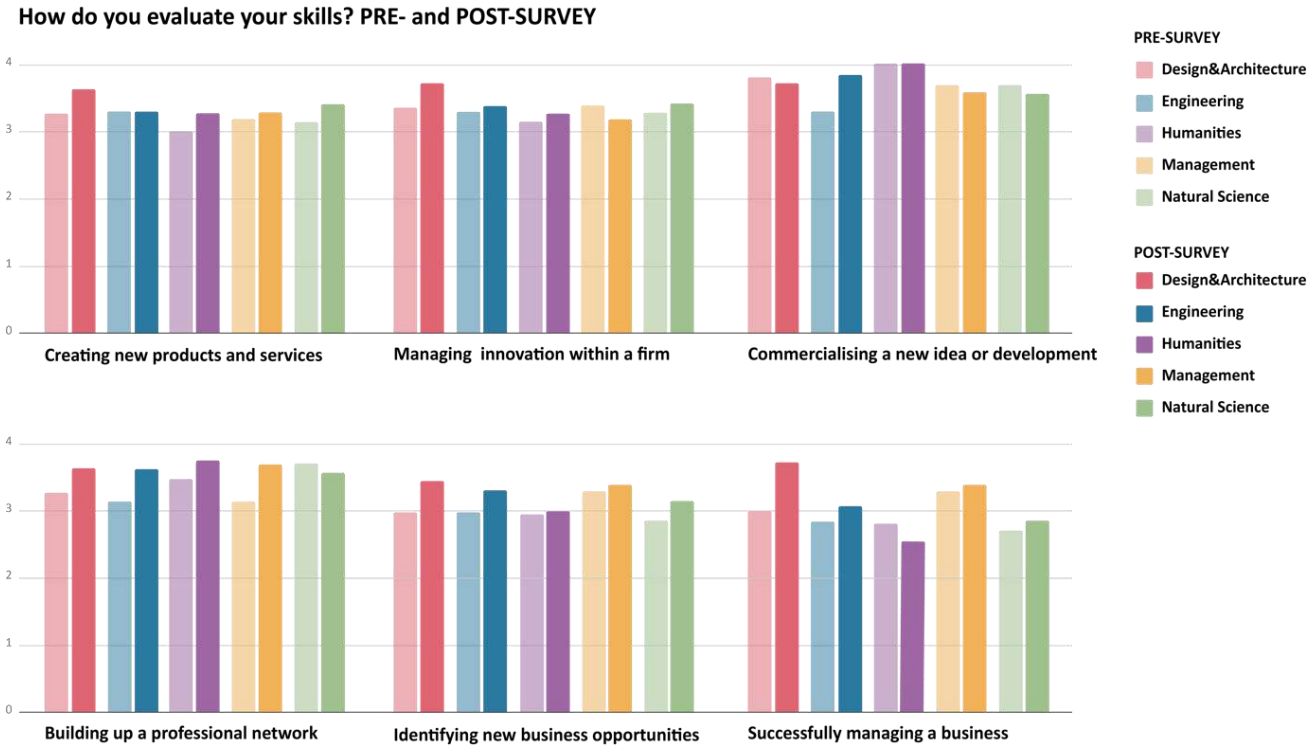

Figure 8: The students' perception of their entrepreneurial skills according to GUESSS.

As far as the two innovation-related aspects, i.e. "Creating new product/services" and "Managing innovation within a firm" are concerned, an increase was observed from the entry to exit levels for all the student categories, except for the management students who declared a decrease in "Managing innovation within a

firm" from the pre- to the post-surveys. Designer students experienced the greatest gain, and they were followed by the natural scientists. This may indicate that this entrepreneurial course and the CLabTo's environment are able to foster these two innovation-related aspects of students from design and natural science. As far as the third innovation-related aspect (Commercialising new ideas or development) is concerned, this entrepreneurial skill decreased for all the students, except for the engineers. We have hypothesised that this is due to the fact that all the students had over-evaluated their capabilities on entry and found themselves facing difficulties during the programme on this topic. The "Building up a professional network" skill increased significantly for all the categories, except for the natural scientists. A satisfying sense of belonging developed during the programme for all the other students. The two entrepreneurial aspects (Identifying new business opportunities and Successfully managing a business) showed a general improvement from the pre- to the post-survey, except for the students of humanities, whose skills remained almost unchanged or were even lower at the end of the programme. This may be a common problem of this category of student, but there was no evidence of it in their comments. The designers, engineers and natural scientists perceived the greatest gain in "Identifying new business opportunities", and the designers also perceived the greatest gain in "Successfully managing a business", and this was followed by the engineers. Those who were more skilled at the beginning of the programme, i.e. the management students, found the programme moderately useful for improving this skill.

Finally, we observed the results for each student category pertaining to each skill (Figure 9).

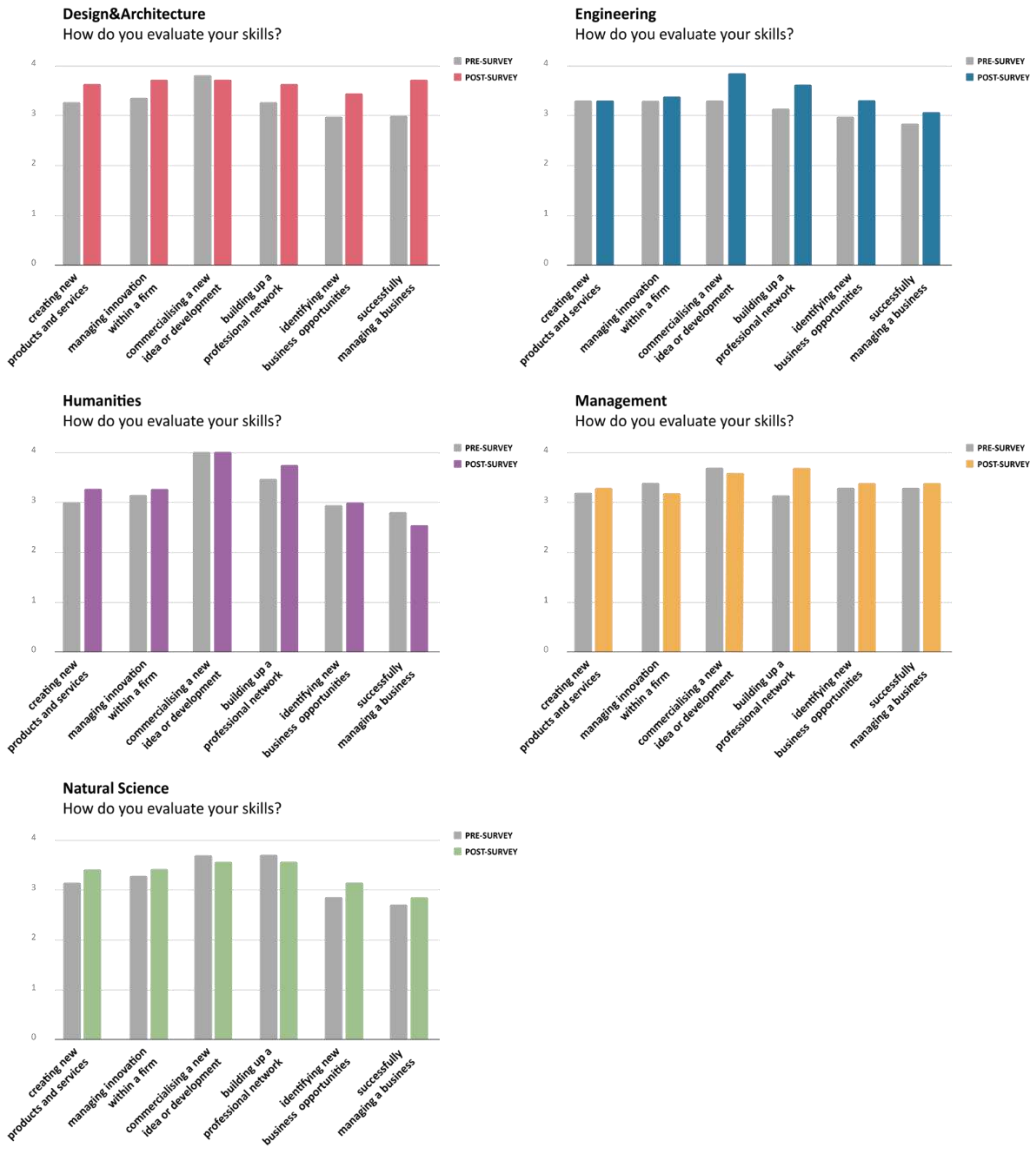

Figure 9: Students' skills divided according to the category of student (pre- and post-survey comparison)

Although our results are qualitative, they show mixed results according to the students' fields of study.

Thus, it can be noted that:

- The Design&Architecture students perceived an increase in 5 items out of 6
- The Engineering students perceived an increase in 5 items out of 6 and one remained unchanged
- The Humanity students perceived an increase in 4 items out of 6 and one remained unchanged
- The Management students perceived an increase in 4 items out of 6
- The Natural science students perceived an increase in 4 items out of 6.

These mixed results indicate how a complex environment with students from different fields of study and different levels of education can have a different impact on the participants.

Results on the degree of satisfaction of the programme

We asked the students if they perceived the programme as being more theoretical (1) or practical (5), and to evaluate this feature over a range of 1 to 5. An average mark of 3.55 was achieved, which means that the programme was perceived as being slightly more practical than theoretical.

Moreover, we also asked the students how they considered the time dedicated to the following topics on a 1 to 5 scale (1=insufficient, 3=adequate, 5=too much):

- Teamwork: 2.77
- Presentations (Pitches): 2.91
- Support received: 2.66
- Classes: 3.11

It emerges that the students' perception about the classes is that the duration is slightly overestimated, while the time spent on team work, presentations and support received should be increased.

Moreover, as far as the overall duration of the challenges (1=insufficient, 3=adequate, 5=too much) is concerned, an average of 2.68 was obtained, which indicates a perception of the programme being slightly shorter than expected. From these results, it can be concluded that the time spent on classes was perceived as a little excessive compared to what the students expected as support for their specific projects.

The students found the material provided satisfactory as a support to develop their ideas. It was evaluated from 1 to 5 (1=insufficient, 3=adequate, 5=too much) in answer to the question "Were the available materials sufficient for the realisation of your idea?" with an average of 3.57/5. Moreover, they were asked to what extent they felt the interdisciplinary experience was useful for their team. Their answers show it was the most appreciated aspect, thus confirming that the multidisciplinary promoted by the CLabTo has been extremely enriching. In this regard, it should be noted that the provided training was also multidisciplinary, as it involved professors and experts from disparate fields. The students indicated they were satisfied with this aspect, and reported it in the free text boxes. Moreover, on the basis of the three categories of teacher presented by Béchard and Grégoire (2005), the students' perception of the teachers was mainly "as tutor and facilitator".

The teachers in the CLabTo programme are in fact encouraged to facilitate debates, share learning, interact and brainstorm. Dziuban et al., (2004 p.3) and Nielsen and Stovang (2015 p 985) suggested a shift from lecture- to students-centred instruction in which the students become active learners, and an increase in interaction between students and teacher is encouraged. One of the questions in the post-survey was related to this aspect, and the perception of the students about their role was mainly that of "active participant with a close interaction with the teachers" (Fiore et al., 2019)

Finally, we asked the students if they thought this programme had overall increased their interest in innovation (evaluated from 1 to 5), and we received positive feedback, with an average mark of 4,45/5.

Discussion and conclusions

In recent years, the focus on the innovative value of design thinking in businesses and business education has increased (Nielsen and Stovang, 2015). In this paper, we provide new insights into how to develop EE through design thinking, teaching methods, teacher-user relations, teaching and team working environment. CLabTo

offers a unique programme for EE as it provides EE for all the different types of university students in the form of a practice-oriented design-led programme. The students faced real-life challenges as well as entrepreneurial ones, and the programme helped the students to acquire communication and networking skills, while working in transdisciplinary teams to develop entrepreneurial tasks (Ball, 2003).

Design is seen as a valuable route to accomplish business goals and new entrepreneurial opportunities (Nielsen and Stovang, 2015; Clark and Smith, 2008; Boland and Collopy 2004). CLabTo has thus allowed design and business pedagogy to be merged for their mutual enrichment, by identifying new business opportunities, and anticipating and creating an unknown future (Nielsen and Stovang, 2015).

We tested our model on students with different educational levels and from different fields of study, and introduced teaching, tutoring and mentoring in which a variety of professors, researchers and experts from different fields were involved. We created a learning environment in which the students and their creativity in delivering innovative solutions were stimulated, with the help of prototyping, visualisation techniques and idea generating support.

As previously noted, a multidisciplinary team approach is a key element of such a programme (Thursby et al., 2009) and it was the aspect that was most appreciated by the students, as shown in some comments to the question "What worked best during the programme?" (Fiore et al., 2019) in which they recognised the role of the Psychologists in the team building phase.

- *"The advice of the group of psychologists for the creation of groups"*
- *"Working in a group with different skills"*
- *"Multidisciplinary allowed us to develop a real project"*
- *"Interacting with different people from different universities. This meant that each of us put his/her own expertise into the project"*
- *"Interdisciplinary groups"*
- *"Being all immersed in something new and unexpected. Regardless of the background, perceiving yourself as similar to others and being able to create in an environment without prejudices and that is only aimed at your growth"*

Teamwork is the students' most commonly mentioned benefit of the programme. For example, in the exit surveys the students were asked "What worked best during the programme?" Of the 56 respondents, 67% of them listed "team" or "teamwork" as one of the most important aspects of the programme. Moreover, the programme has been perceived as being more practical than theoretical, which is in line with our goal. Another relevant result is that the students found that the programme increased their interest in innovation.

As far as teaching is concerned, achieving a pedagogical delivery that simultaneously engaged all the student groups was challenging. We decided to create our own courses and use our own material instead of resorting to those of the two involved universities. The first reason why the programme could not benefit from the teaching of ongoing courses is that they are difficult to access. We in fact needed to cover specific topics on specific days and at specific times, because of the restricted duration of the challenge. The second reason is that the module had to balance the differences in students' background, that is, by trying to keep some parts generic and easily understandable with examples and case studies, while providing some more technical contributions for the students who had the necessary knowledge to understand it and use it during the team work. The key for the class structure is delivery to inform those with limited backgrounds, while avoiding boring those with in-depth knowledge (Thursby et al., 2009). Thus, our classes tended to focus on content for an hour or two, with practical implications on the projects that the students were working on. The teachers became aware of the heterogeneity of the audience and changed their way of explaining to a more interactive and engaging way; this was facilitated by the limited number of participants in each challenge (from 32 to 15). The approach we have undertaken appears to have been successful, as shown by the following comments to the question "What worked best?"

- *"Expert interventions. They have been very useful to approach a new way of assessing the challenge"*
- *"The initial lessons of the various professors allowed us to focus on and study the theme in question in more depth"*

- *"The insights given by the lessons and the mixed groups were good incentives to look for new ideas"*
- *"The multidisciplinary nature of the lessons and the teams"*

The evaluation, by means of pitching instead of written or oral examinations, was also appreciated by the students, as may be seen from two comments to the question "What worked best?"

- *"The final pitch with the jury was a great stimulus"*
- *"Time schedule, pitches, multidisciplinary lessons and teams"*

As already highlighted by Thursby et al., 2009 with another EE programme, although our data are self-reported perceptions, it is clear from our empirical analysis that the described programme had some effects on the students' perceptions of their ability. Both on entry and exit from the programme, we found some differences, according to the fields of study and MSc/BSc background, in the perceived capabilities. Moreover, the greatest gains were shown for the BSc students and designers, followed by the engineers. However, there was an overall increase in each skill, which is a good result, considering the limited duration of the programme (2 weeks).

A better management of time, an extension of the duration of the programme and the need to increase the presence of tutors are some of the aspects that still need to be improved. Moreover, it was noted that some students did not to attend 100% of the classes, probably as a result of a lack of credits. Each aspect of the challenge of developing such an integrative programme is significant, that is, from recruiting students, to planning the teaching activities and the team work, to managing the time of each activity. As far as pedagogy is concerned, the most challenging aspects were finding suitable professors to satisfy the CLabTo approach and the specific teaching delivery required for the challenge. Each challenge in fact required *ad hoc* teaching planning. The CLabTo programme, with its focus on idea generation and transdisciplinarity (pertaining to both the fields of study and the education level), makes an important contribution to EE, as it offers the possibility of working across disciplines. The model may lead students to acquire all the capabilities needed for their future careers in innovation (Thursby et al., 2009). Echoing the hope of Nielsen and Stovang (2015), we hope to have contributed to the discussion by creating knowledge about the cross-over of design thinking and EE.

Limits and future research

In our study, the survey data were based on a limited number of students and no control sample was available, therefore, our analyses can only be considered qualitative. Moreover, we considered a single case study (CLabTo) in Italy and it is therefore not possible to generalise. However, the sample is representative of the population of students who took part in the CLab Torino programmes. Moreover, our results may be different from those of other countries, since different cultures can lead to different results. For example, Mueller and Thomas, (2001) and Giacomin et al., (2011) suggested some variables that should be taken into account in order to study EE in different countries. Therefore, it could be interesting to include students with different cultures and to study the differences in addition to the multidisciplinary nature of their backgrounds, thus creating not only multidisciplinary teams with different educational levels, but also bringing different cultures together.

In addition, since corporations seem interested in employees with entrepreneurial competencies, it could be interesting to analyse whether employees who have taken part in EE classes are more innovative than those who have not participated in EE classes; this could be achieved by introducing control samples.

Given these assumptions and the results of the survey, we believe that the process of creating an entrepreneurial programme for all types of university students, and which would be suitable to fit all the different circumstances, will take from 3 to 5 years of continuous tests and iterations. Thanks to the students' feedback, in the next challenges, we will test new forms of teaching and tutoring during the team work in order to improve the programme and to make it useful for both those students who decide to create their own businesses and those who want to work in multidisciplinary teams in innovative contexts. We believe that this entrepreneurial programme could lead to cooperation with universities outside Italy, but this would require a non-trivial effort to convince different professors and Universities to collaborate in a common project.

Funding

This research was funded by the Ministero dell'Istruzione, dell'Università e della Ricerca (MIUR) PNR 2015/2020 - Directorial Decree no. 3158 of 29 November 2016 n.3158, Prot. CL16JWECRH.

This paper explores the influence of teaching approaches on entrepreneurial mindset of commerce, design and engineering students across 3 universities. The research presented in this paper is an initial study within a larger project looking into building 'entrepreneurial mindsets' of students, and how this might be influenced by their disciplinary studies. The longitudinal survey will measure the entrepreneurial mindset of students at the start of a course and at the end. Three different approaches to teaching the courses were employed – lecture and case based, blended online and class based and fully project-based course. The entrepreneurial mindset growth was surprisingly strongest within the engineering cohort, but was closely followed by the commerce students, whereas the design students were slightly more conservative in their assessments. Future study will focus on establishing what other influencing factors beyond the teaching approaches may relate to the observed change.

Keywords: entrepreneurial mind-set, teaching approaches, longitudinal study

Introduction

The purpose of this paper is to explore the assumption, or essentially 'test' the hypothesis that different approaches to teaching within specific disciplinary fields influence the entrepreneurial mind-set of students and their willingness to pursue their own business ventures after they graduate. We subscribe to the notion that what is foundational in entrepreneurship education is that the disposition, skills and competences of the creators of enterprises are key to enterprise development but that these skills, dispositions and competences can be influenced/shaped by education (Maresch et al., 2016). What we *don't* assume though, is: a) that this entrepreneurial education has the same impact in all contexts, and b) that students in different educational/disciplinary programs view entrepreneurship the same way and that they perceive the importance of and assign the same meaning to the various traits of an entrepreneurial mindset. Although this could introduce some level of 'noise' into the analysis of results, we would simply note that many schools are offering entrepreneurship courses to students as certificates or minors and attract students from across different disciplines (Bilén, Kisenwether, Rzasa and Wise, 2005) and the literature on entrepreneurship does not appear to dig deeply into any possible disciplinary biases that might cause students from different disciplines to view entrepreneurship differently (Levenburg, Lane and Schwarz, 2006).

Entrepreneurship has become one of the driving forces of economies across the world and a variety of disciplines have adopted courses within their curricula to build entrepreneurial skills of students, ranging from commerce programs to design and engineering specializations.

Although much research is currently focusing on exploring different approaches to teaching within and across disciplines, there is no agreed-upon approach to teaching entrepreneurship to students across disciplines and there is also no real evidence of how effective the approaches taken are in building the entrepreneurial mindset of the students – although there would probably be little debate as to the importance of teaching entrepreneurship where it "goes beyond understanding, knowing, and talking and requires using, applying, and acting" (Neck and Greene, 2011).

Changes in the environment through technology advances are driving the students to adapt their approaches to engaging both with school material as well as their interactions in life outside of the University environment. We are trying to assess, if the Universities actually address the environmental changes in preparing students for the workplace, particularly in the face of the new technological trends influencing the way people work and communicate with one another. It seems the new transitions within the socio-cultural, technological and digital environments are requiring the workforce to develop entrepreneurial skills not only for the purposes of launching new ventures, but also for the purposes of better engaging with the new era, to which we are transitioning (Le Merle & Davis, 2017). The students need to develop entrepreneurial skills to be more creative, more tolerant to risk and to make sense of the new content-centric, connected workplaces in which they are entering (Farny, Frederiksen, Hannibal, & Jones, 2016).

It seems that universities are responding by taking a more individualist approaches to student learning, acting as coaches and mentors rather than as the providers of knowledge (Lahn & Erikson, 2016). This shift is particularly evident in business schools, where entrepreneurship has found its home in the past decade. It is however unclear, if this approach brings any further benefits than other, more traditional academic approaches to learning.

To explore this, a study, looking at the influences that teaching approaches have on entrepreneurial mind-sets of students was conducted at 3 different universities, within 3 different educational programs – commerce, design and engineering. This study is the initial component of a much wider research project looking into the effectiveness of teaching entrepreneurship across disciplines.

The study is based on a survey, administered to the students at the start and end of an entrepreneurship course taught at their university. The entrepreneurial mindset traits are taken from well-established and validated measures and include assessments of commitment and determination, courage, tolerance to risk, creativity and ability to adapt, motivation to excel and leadership (Spinelli Jr. & Adams Jr., 2016).

The paper will first look into the theoretical background relevant for the study. The entrepreneurial mindset and different approaches to teaching and delivering content to students will be explored within this section to present the overarching reasoning behind the study. This will be followed by a detailed methodology section to illustrate how the research protocol was developed and administered. The sample and the key variables will be discussed, and key reliability verifications presented. The results will be presented separately for all three universities and conclusions drawn based on the findings presented. The paper will conclude with a brief overview of the future work within the discussed domain.

Theoretical Background

Entrepreneurship has gained increased momentum both in the professional world as well as in education. As Aulet, et al. (2017) point out, a good entrepreneur needs to have the "spirit of a pirate and skills of a navy seal". This clearly indicates, that the skillset the students need to be developing relates on the one hand to creativity, tolerance to risk and opportunity obsession and on the other hand to commitment, determination, motivation to excel and specific leadership skills (Aulet, et al., 2017; Spinelli Jr. & Adams Jr., 2016). All of these skills can often be developed through reflection, learning by doing and continuous drive to develop one-self and the world around us.

At the same time, the changes in the environment, particularly in terms of advances in technology are increasingly changing the way organizations and the business world in general operate. The disruptions that digitalization brings in terms of technological shifts are particularly evident for the so-called generation C – the connected, content-oriented and always clicking population born after 1990. They were born into the digital,

technologically advanced and connected world and have no real understanding of how a world, organization or social environment operated without this connectivity (Le Merle & Davis, 2017). This is the new workforce, entering the job markets currently and in the near future and the way they engage, work, network and behave, is largely connected to the digital world. This means their perceptions of success, development and growth is often very different from established work practices currently employed in organizations. Even the successful entrepreneurs of today are often connected to the advances of the previous era, where different approaches to doing business are still present – they connect traditional way of doing business (structure, governance, process), with the new, connected ways (creativity, drive and interconnectedness). Thus, those entering or already in the workplace need to learn these skills and at the same time foster the ones brought to them innately by the world of connectivity.

All these changes in essence, mean that education is playing catch up in adapting to the new trends within the business environment, no matter whether corporate or venture based (Lahn & Erikson, 2016). New pedagogies, linking to the generation C need to be considered and implemented to develop skills of the students that will enable them to engage on the one hand with the established practices, and on the other to develop their connectivity that comes natural to them to a level that will drive their future growth.

Often, project-based learning has been considered as an approach that bridges the gap between academic knowledge and real-world business skills, but even so, Universities are still not engaging enough to bring the changes to the curricula as they develop in the business world. Academic evidence suggests that project-based learning encourages and supports collaborative work (Christophersen, Coupe, Lenschow, & Townson, 1994); it also improves retention and enhances design thinking (Dym, Agogino, Eris, Frey, & Leifer, 2005) and bridges the gap between theory and practice (Du, De Graaff, & Kolmos, 2009). As the work of de Graaf and Kolmos, (2003; 2007) suggests, project-based learning helps develop collaborative, cognitive and content-related skills, which would in turn mean that the students learn how to collaborate within a particular environment, they understand the key theoretical principles of a particular discipline and they are also able to translate that into practice. Often engineering disciplines are the ones, where project-based approaches are used within the curriculum to advance the skills of the students in a structured, practice-based manner. They solve a particular problem for an industrial partner and learn the processes related to it. This gives them the opportunity to gain an understanding of the processes and practices in the work environment, but at the same time include the safety of the University base, where failure does not have the same magnitude of negative consequences it might have in the work place.

On the opposite end of the spectrum of the learning curve are soft disciplines, like the majority of business studies. As defined by Shulman (2005), the main characteristic of teaching and learning in business would be the absence of routine in the discipline as such – it is an ever-changing practice, jumping from structured to creative approaches of doing things in extremely short periods of time, based predominantly on a critical review and analysis of what is happening in the business and social environment. This is particularly true for the previously mentioned generation C, where their continuous link to technology is speeding up the processes of change, growth and understanding of how things need to be done in that particular timeframe and work framework.

Different approaches in practice and an ever-changing environment therefore demand different approaches in pedagogy. What the students need to learn, understand and acquire is not only the concepts relevant to the practice of business, but also the skills relevant to dealing with constant change in their social, political, technical and economic environments. The business, and in particular entrepreneurship discipline “values insights generated from the variety of different paradigmatic positions to be found in the discipline” (Shankar, 2009), and therefore students need to embrace and understand these positions to be able to become part of the communities of practice in their professional lives. At the same time, they are actively changing the discipline through their engagement with the digital world, where influencers are often the drivers of change and needs that generation C now exhibits.

As Midendorf and Pace (2004) propose, learning to think and work as a business professional is more complex than generally appears to be the case to professionals, and students therefore, need a chance to perfect the skills in order to succeed. This is achieved through active, collaborative and inquiry-based learning. The engagement between students and teachers is significant throughout their time at the University and most of the interaction is case-based, giving the students insight into modern practices and professional approaches towards conducting and managing business. In that sense, the discipline can be classified as pedagogy of uncertainty (Shulman, 2005). The continuous shift in business that the disruptive organizations such as

Amazon, Apple and Facebook (Le Merle & Davis, 2017) have brought to the workplace has however, put the business student at the forefront to develop understanding of this change, and it is uncertain if Universities have adapted fully to the new pace.

This is the reason behind the current study. As the world shifts rapidly, we wanted to explore, if the paradigms and teaching approaches with which students are currently ensconced have the structure and detail to prepare them for the new employment arena.

We are working on the presumption that the skills of an entrepreneur are the ones required to navigate the changing environment (Aulet, et al., 2017; Spinelli Jr. & Adams Jr., 2016) and thus we wanted to test, how different approaches to teaching across various disciplines influences the entrepreneurial mindset of students over the duration of a particular course. The main research question is: will the perceived entrepreneurial mindset of students improve through a particular educational approach?

To test this, three different courses were assessed, and the mindset change measured for the cohort within these courses. The methodological approach employed is presented in the next section.

Research Methodology

As outlined above, the key objective of this initial project was to establish whether and how the entrepreneurial mindset of the students changes throughout their studies and if entrepreneurship courses offered to them actually support the development of the soft skills needed in today's changing environment.

Due to current environmental trends increasingly driving the need for an entrepreneurial mindset in the new workforce, Universities have embraced entrepreneurial courses not only within business schools, but also within engineering and design disciplines, with the key purpose of preparing the students for the new workplace requirements.

From a theoretical perspective, the key traits of an entrepreneurial mindset include the following traits, as outlined by Spinelli Jr. & Adams Jr. (2016):

- Commitment and determination in terms of mission orientation, discipline, decisiveness, tenacity and persistence in solving problems;
- Courage in terms of moral strength, fearless experimentation, tolerance of conflicts and failure and intense curiosity in the face of risk;
- Opportunity obsession in terms of leadership in shaping the opportunity, knowledge of customer needs, market drive and value creation;
- Tolerance to risk, ambiguity and uncertainty in terms of calculated risk, risk minimization and sharing, tolerance to lack of structure, stress and conflict and ability to integrate solutions;
- Creativity, self-reliance and adaptability in terms of open-mindedness, restlessness with status quo, ability to adapt and no fear of failure;
- Motivation to excel in terms of goal orientation, drive to achieve that is self-imposed, ability of support to others and a perspective and sense of humour;
- Leadership in terms of being a self-starter, having internal locus of control, integrity and responsibility and being a team builder/hero maker, with patience.

These key traits of an entrepreneurial mindset were translated into a survey, where each of the mentioned traits was assessed on a 5-point Likert scale, where 1 indicates this trait was perceived as weak by the students and 5 was perceived as strong. The survey also asked the students to qualitatively discuss their key strengths and weaknesses in relation to the entrepreneurial mindset traits to give further depth to understanding where improvements can be made.

Commitment and determination were measured by assessing 6 mindset items, giving a total of 30 possible points for this trait. Courage was measured through 4 items, totalling 20 points. Opportunity obsession was also measured with 4 items, giving a total score of 20. Tolerance of risk, ambiguity and uncertainty consisted of 6 items, giving possible scores of 30, followed by a 5-item measure of creativity, self-reliance and ability to adapt, which gave a total possible score of 25. A final two measures were motivation to excel, measured with 6-items and leadership measured with 5 items. Overall, a full mindset score can be summed to 180 points, indicating a 100% skillset relevant for an entrepreneurial mindset. The full survey is presented in the appendix of this paper.

We tested the mindset of students in three courses that ran in the fall semester of the academic year (all the programmes were located in the Northern hemisphere). The pool of students came from design (N=85), engineering (N=57) and commerce (N=106). The chosen courses were focusing on the soft skills that those entering workforce will require in the changing work environment. The delivery was predominantly lecture-based, with some components occurring online and case studies or projects being the core of the student assignments and assessment.

The design students that participated in this study were Design Innovation students and the course where the mindset was assessed had to do with Communication in an international context. Key theoretical concepts in the course were introduced in lectures and seminars and directed reading and related activities were organized online to support these concepts. There were structured online activities targeted towards supporting the final assessment related to observing and reflecting on communication of peers within an international context.

For the commerce students, the introductory entrepreneurship course followed an application based approach, where student teams were expected to learn how to build high performance entrepreneurial teams, assess the feasibility of innovative opportunities they have originated, develop competitive business models, build a minimum viable product, and test their value propositions with potential customers. This was done through experiential learning, lectures, simulations, videos and interactions with successful entrepreneurs. The format of the course consisted of one 170-minute class meeting per week. The primary role of the course instructor was to lead discussion and experiential learning in practical applications of course concepts. Class sessions entailed a mixture of lecture, videos, problem analysis, guest speakers and class discussion. The content of any lecture presumed and expected that students had carefully studied the assigned reading. Lectures emphasized major topics and readings, yet students were responsible for all assigned materials. This required active learning, where the student was expected to take responsibility for their learning and to ask questions and to stimulate discussion on topics that were of interest to the class.

Engineering students that participated in the survey assessed their entrepreneurial mindset within the New Venture Launch class. The course guides the students through the disciplined entrepreneurship approach towards developing their own idea into a workable business plan with a go-to market strategy. They learn the key entrepreneurial traits by actually engaging with the development of their own venture.

The proportion of design students that completed the survey both times was 44, so all results are based on this sample, although some insight can also be drawn from the larger sample that completed the first survey (N=85) and that which completed the last survey (N=58). 77 Commerce and 27 Engineering students completed both surveys, giving an effective response rate of 72% and 47% respectively.

Preliminary findings

The first survey was administered at the start of the course for each group of students. Figure 1 shows the distribution of perceived mindset traits for all of the students that completed the survey.

Figure 1: entrepreneurial mindset traits of design, engineering and commerce students as perceived at the beginning of the semester

As the figure indicates, the key traits that are perceived as strong by the commerce students have to do with leadership, motivation to excel and opportunity obsession. They seem to perceive themselves as relatively tolerant to risk, which is the trait that is the weakest for design students. The design students assess themselves strongly in terms of courage and creativity. Interestingly, the engineering students assess their entrepreneurial mindset as relatively strong across all of the investigated traits and seem to be strongest at commitment and determination and courage.

Table 1 further dissects the relevant items for each of the entrepreneurship traits, illustrating the average responses for each of the items scored for all 3 groups of students at the start of the semester.

It is interesting to note that the commerce and engineering students seem to perceive themselves as more opportunity obsessed and tolerant to ambiguity than the design students. Similarly, they seem to consider their leadership skills and motivation to excel as stronger entrepreneurial traits than the design students. Overall, the assessment seems to be stronger for commerce and engineering students than for the designers.

Table 1: Average score per entrepreneurial mindset trait as defined by students at the start of the semester

One of the assessed skills where commerce students scored relatively low, was fear of failure, whereas both design and engineering students scored slightly better. They were 1 assessment point stronger on the courage trait than the commerce students. This may be related to the lack of experimentation within business education, where failure is often still considered increasingly bad, whereas within engineering and design domains experimentation is part of the learning process, particularly in project-based environments. This observation goes hand in hand with tolerance of uncertainty and structure, where commerce students were conservative in their assessments, unlike design and engineering students, who seem to be relatively strong in this trait.

It is further observed that the design students don't consider leadership as one of their stronger skills, whereas the engineering and commerce students seem to be more comfortable with these traits. Although statistically significant (t-test;$P<0.05$), differences between the assessed traits of the different disciplines seem to be relatively small, giving an interesting starting point for further study.

Further to the differences between student perceptions across disciplines, we also wanted to assess, if the teaching approach influences the mindset change at all. As a starting point into this exploration, the students completed the same survey again at the end of the course. The assessed mindset at the end of the course is presented in figure 2 for all of the disciplines.

The average mindset has been assessed by the design students at 127/180 points at the start of the course, putting their mindset at about 71% development at the point in time. It rose to 132.6/180, which would bring it to 74%. The key change that the communication course brought, as indicated in Figure 2 has to do with tolerance to risk and opportunity obsession. This would indicate that the approach to teaching within this course, which included both in-class work as well as online work had a positive influence on their mindset. Overall, however, the mindset score is still rather low, particularly in terms of tolerance to risk, ambiguity and uncertainty. This further aligns with the key weaknesses that the students reported within the qualitative part of the survey, where the most cited weaknesses were tolerance to uncertainty (47%) and fearless experimentation (27%). This may have to do with the discipline on the one hand and the cultural background of students on the other. Creativity is one of the key traits of designers; it is overall however, a structured discipline, with processes and best-practices in place. Furthermore, the majority of the students participating in the survey were international (87%), originating form learning cultures with high dependency on their tutors' input (Zhang, Bohemia, & McCardle, 2017).

It is however important to note, that the standard deviation on the results was 16 points on the full score and that out of the 44 students that completed both surveys, 17 in their perception actually marginally decreased their mindset score. Although at this point the results have been isolated to the influences of the course, the pilot study has shown that there is variation on the mindset change that warrants further exploration.

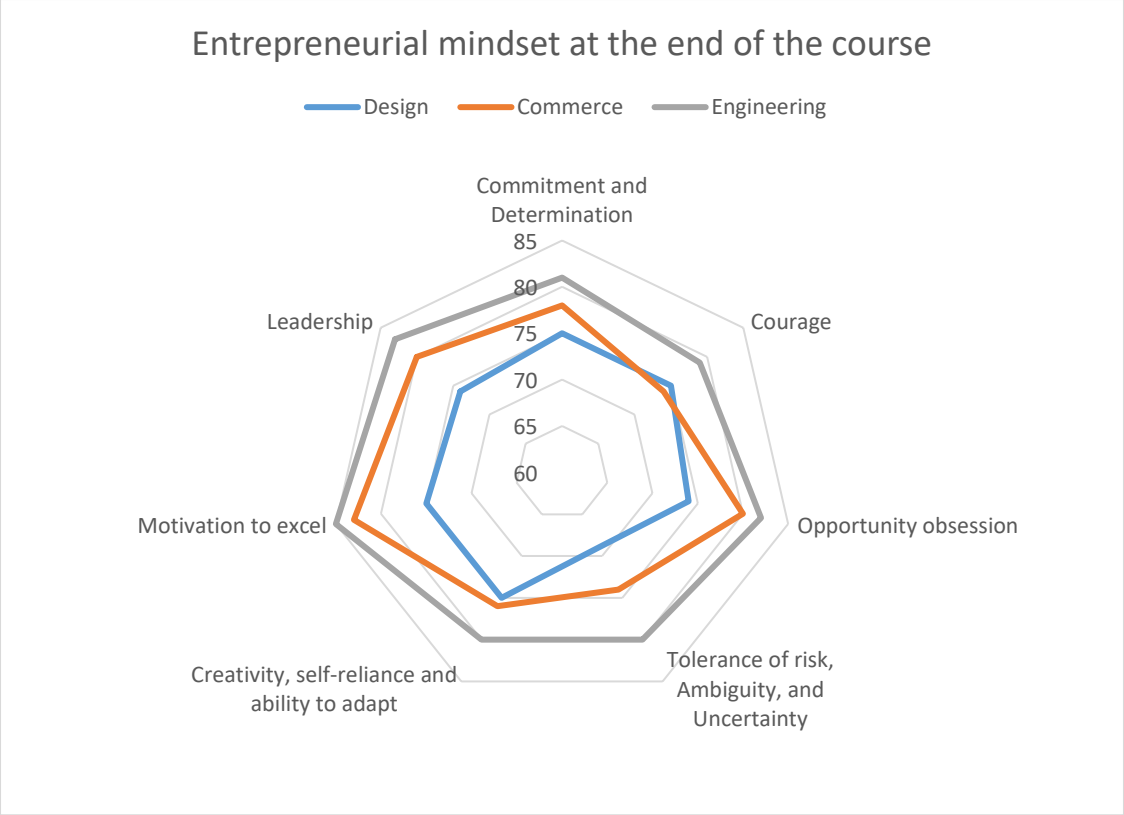

Figure 2: Entrepreneurship mindset traits of design, engineering and commerce students as perceived at the end of the semester

The commerce students' average mindset at the beginning of the course was 133/180, meaning it was at 74% overall and it rose to 140/180. This means overall the commerce students perceived a 4% increase in their entrepreneurial mindset at the end of the course. It seems the course had the most influence on their perceived creativity and the students also assessed their commitment and determination as higher by on average 5%. Although improved, their tolerance to risk and ambiguity still sits below 75%.

As the literature suggests, the students from business backgrounds start their mind-set perception at a higher point due to the fact that they are faced with pedagogies of uncertainty throughout their full educational program. Furthermore, they are actively pursuing this professional path through their education, thus they are more self-aware of the traits they currently possess and the ones they need to improve. Interestingly, the key weaknesses the commerce students highlighted in their qualitative responses at the start of the course had to do with discipline and patience. The course seemed to have helped with the perception of discipline, as it improved on average by 3%, whereas the patience trait of commerce students only improved by 1% at the end of the course. Table 2 further depicts the average score per mindset trait at the end of the course for all the students. The results are statistically significant at 5%.

Table 2: Average score per entrepreneurial mindset trait as defined by students at the end of the semester

On the other hand, the increase in the entrepreneurial mindset of engineering students after completing the New Venture Launch course was surprisingly high, moving from 132.7/180 (73%) to 146.5/180 (81%). The biggest increase within the entrepreneurial mindset of engineering students was assessed for opportunity obsession, followed closely by motivation to excel, tolerance of risk and creativity. The qualitative responses of engineering students supported this notion, as the pointed out that 'there is a structure to launching a venture and I now know I can do it.'

Figure 3 depicts the perceptual change in the mindset across the three disciplines, surprisingly showing the biggest change in engineering students' mindset.

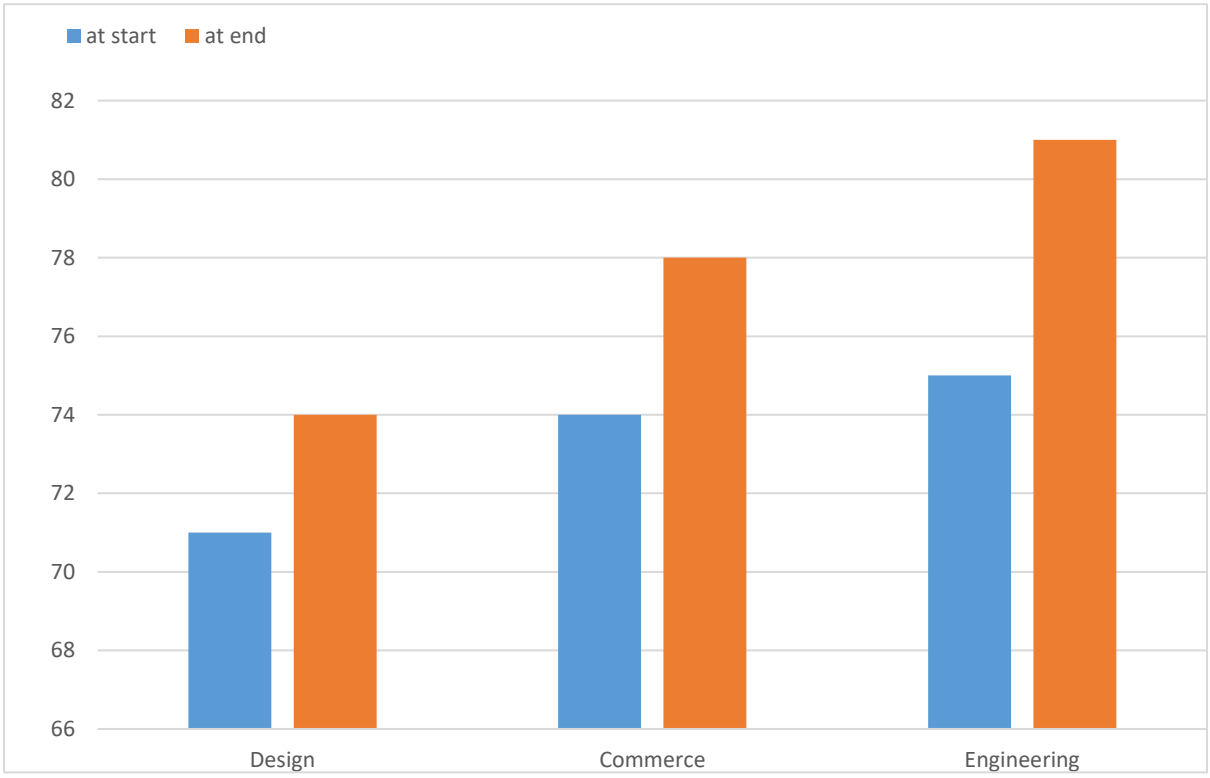

Figure 3: The change in entrepreneurial mindset across disciplines

Conclusions

The results from the longitudinal study of design students highlights that the approach towards teaching the communication skills had a positive influence on the mindset of the students, since on average their assessment of the entrepreneurial mindset increased by 3%. The practical approach to teaching entrepreneurship, where the students were tasked with launching their own venture also showed an increasingly positive effect for engineering students, as well as commerce students.

Overall, the survey showed that a variety of approaches can be beneficial for the development of the entrepreneurial mindset of students, but that the curriculum needs to fully adapt to the new environment the students are faced with and focus on developing the risk mitigating skills in the structured disciplines, such as design and build some of that discipline into the commerce curriculum.

In the context of our study, it is interesting to note that previous research has demonstrated that student self-efficacy beliefs and entrepreneurial intentions are influenced by the extent to which an entrepreneurship course is more theoretically-oriented versus practically-oriented and that in the context of entrepreneurship, theoretically-informed 'learning by doing' is preferable (Fiet, 2000a, b). In drawing on regulatory focus theory, Piperopoulos and Dimov (2015) showed that higher self-efficacy is associated with lower entrepreneurial intentions in theoretically oriented courses and higher entrepreneurial intentions in the practically oriented courses. In our study, we know that the business students and engineering students were being taught entrepreneurship from a very applied/practical perspective. In addition, it is also potentially important to note differences in where/when in each disciplinary program, the entrepreneurship course is taught. In a 4-year undergraduate program, is exposure to entrepreneurship occurring in 1st, 2nd, 3rd, or 4th year – since it has been argued that because entrepreneurship education is not simply about imparting knowledge but instead also involves the manner in which one looks problems and lifestyle which is linked to adolescent development processes (Welsh, Tullar & Nemati, 2016).

The authors used this initial survey as an experiment into the perception of students in relation to their mindset to determine the usefulness of the different approaches that have been taken in building the softer skills across the disciplines but have found an interesting gap in relation to the curriculum delivery and also perceptions of students.

These results will be used as a starting point into developing a full-scale project to determine which traits the students require, how the practice delivers them and how they can be translated into an effective classroom experience. Although beyond the scope of this initial study, it would be interesting to determine the extent to which 'inspiration' is a component of the various disciplinary programs since research has shown that with science and engineering students, between learning, inspiration and resource-utilisation as programme-derived benefits, it is inspiration that has the most significant influence on intention to start a business (Souitaris, Zerbinati & Al-Laham, 2007). The mitigating influences, which in the current study have been isolated to only reflect the teaching approach, will be further explored and relationships amongst the found variables explored. It is expected the full-scale project will spark discussion among the different disciplines as to how entrepreneurial mindset can be grown across the disciplines.

Appendix – the entrepreneurship mindset survey

	Weakest ◄——————————► Strongest					Total
Commitment and Determination						
Decisiveness	1	2	3	4	5	
Tenacity	1	2	3	4	5	
Discipline	1	2	3	4	5	
Persistence in solving problems	1	2	3	4	5	

Willingness to sacrifice	1	2	3	4	5	
Total immersion in the mission	1	2	3	4	5	
						/30
Courage						
Moral strength	1	2	3	4	5	
Fearless experimentation	1	2	3	4	5	
Unafraid of conflicts, failure	1	2	3	4	5	
Intense curiosity in the face of risk	1	2	3	4	5	
						/20
Opportunity obsession						
Leadership in shaping the opportunity	1	2	3	4	5	
Having knowledge of customer needs	1	2	3	4	5	
Being market driven	1	2	3	4	5	
Obsession with value creation and enhancement	1	2	3	4	5	
						/20
Tolerance of risk, Ambiguity, and Uncertainty						
Calculated risk taker	1	2	3	4	5	
Risk minimizer	1	2	3	4	5	
Risk sharer	1	2	3	4	5	
Tolerance of uncertainty and lack of structure	1	2	3	4	5	
Tolerance of stress and conflict	1	2	3	4	5	
Ability to resolve problems and integrate solutions	1	2	3	4	5	
						/30
Creativity, self-reliance and ability to adapt						
Nonconventional, open-minded, lateral thinker	1	2	3	4	5	
Restlessness with status-quo	1	2	3	4	5	
Ability to adapt	1	2	3	4	5	
Lack of fear of failure	1	2	3	4	5	
Ability to conceptualize and “sweat details”	1	2	3	4	5	
						/25
Motivation to excel						
Goal and results orientation	1	2	3	4	5	
Self-imposed drive to achieve and grow	1	2	3	4	5	
Low need for status and power	1	2	3	4	5	
Ability to be inter-personally supporting (vs. competitive)	1	2	3	4	5	
Awareness of weaknesses (and strengths)	1	2	3	4	5	
Having perspective and sense of humor	1	2	3	4	5	
						/30
Leadership						
Being a self-starter	1	2	3	4	5	
Having internal locus of control	1	2	3	4	5	
Having integrity and reliability	1	2	3	4	5	
Having patience	1	2	3	4	5	
Being a team builder and hero maker	1	2	3	4	5

Case Studies

Case Studies Introduction: Case Studies from the Frontlines of Design Innovation Management

FRY Aaron and RANDALL Mark

The New School, USA
doi: 10.33114/adim.2019.c7

When we initially proposed a case study track to Erik Bohemia, the ADIM's 2019 conference chair in London, it was a speculative exercise to ascertain whether an alternate form to the academic paper and the workshop could enrich discourse in the management design community. We are both business-design educators at Parsons School of Design in New York City. Our institution maintains its industry connections principally through our teaching faculty who are drawn from agencies, consultancies and in-house innovation teams globally. Based on our own experience with industry/academic hybridity and through our teaching approach, we developed a hunch that there may be a wide interest in, and applicability [with] this form and we're gratified for the high level of engagement in this initiative, exemplified by the inaugural set of cases in this volume.

We encouraged each case author to use plain descriptive English and empirical observation anchored by specific examples to contribute to applied knowledge in the emergent area of design management and design strategy. We hoped these cases would illuminate for the reader how tools, methods, practices and approaches have performed "on the ground" across cultures and sectors and within diverse organizational and institutional environments. The domain of practical application and integration is one that challenges us as educators and practitioners, we were therefore curious about whether these cases, in the aggregate, may begin to generate new knowledge through a heuristic approach.

The original business case study was developed at Harvard Business School around 1924 and it had a pedagogical function: business cases supported students' [vicarious] experience as they learned lessons from business concepts-in-action. These were (and still are) typically very distilled accounts that can run to fewer than 1000 words and may be three pages or less. Their intention is to provoke debate on the actions taken in the case. In this sense, a business case does not advance an argument, rather it is a simulation; a problem or context for action, an intervention and a reflection on lessons learned. Today business cases may be used internally within companies to sharpen employee engagement with the problems of the organization. Our cases are generally slightly longer in duration and we suggested a three-part structure for each case: i. context and problem/opportunity, ii. the narrative (or what happened) and iii. key learnings. Additionally, we encouraged authors to show rather than tell, through illustrating their cases with visual examples of the specific issues discussed.

The following case studies from the frontlines of design innovation management bring together twenty-six cases with authors from thirteen countries and engage with contexts as diverse as homelessness in Oakland, California, government land surveying practice in Portugal and clinical joint replacement procedures in an Australian hospital. The diverse range of each case found common ground in the application of design thinking and strategy to each.

We have grouped the twenty-seven cases twice into themes or domains of inquiry, these will determine the organization of the proceedings' structure. The following are the themes that were developed by us for the conference after the cases had been submitted through an open call:

- Transformations in methodologies and practices;
- transformations in healthcare/wellness/harm reduction;
- transformations in community empowerment;
- transformations in corporate management and innovation.

Transformations in methodologies and practices

Integrating Business Design through Experiential Learning (New Zealand), explores the challenges and opportunities of a business school educator's application of design into her classroom and culture. The iterative nature of student assessment is highlighted as holding great potential in business education while the challenges of instilling a studio-oriented culture into the conceptual and physical spaces of the business school is also detailed. *Design Thinking in Law School: A Case Study of SoloSuit* (USA), presents a design school-law school collaboration engaging the question of how to redesign a digital legal product to better serve the needs of many of its economically marginalized users. This project highlights how design innovation may support social justice through enhancing literacy and access within specialized legal languages and processes. *Thinking-through-making; physical model-making as a business model education strategy* (USA), discusses a specific example of a student's response to a class project that required her to create a business model or a strategy tool in three-dimensional physical form. The case explores this student's application of the tool she created into client interactions within her consultancy. *Breaking Boundaries: A Unique Inter-University Program Addressing the 21st Century Skills Gap* (USA), discusses an extracurricular program offered to university students from a diverse array of institutions and majors. This program introduced these cohorts to design and business innovation methods. The authors discuss the challenge of measuring results from this experience, and scaling it across comparable programs. *Design Thinking Mindset: Exploring the role of mindsets in building design consulting capability* (Australia), tests the relative utility and value of nine previously-developed design thinking mindset attributes—through interviews and surveys—with several consultancies. The authors share insights gained from this exercise in asserting that mindset may be of greater importance than method in both their own pedagogy and, potentially, in some industry contexts.

Transformations in healthcare/wellness/harm reduction

Community Based Naloxone Kits: Using design methods to transform complex user needs (Canada) details the authors' design-clinical healthcare collaboration to improve the uptake and effectiveness of freely distributed kits to save the lives of those overdosing from opiate drugs. The case demonstrates and tests how innovation in user experience design and communication design of these kits makes them more effective in emergency situations. *Development of JIT patient-specific implants: design-led approach to healthcare and manufacturing transformation in an Australian context* (Australia), examines how human-centered design can improve both patient experience and clinical outcomes in a hospital setting. The case explores how design innovation can streamline the organizational complexities surrounding the use of a JIT (just in time) process to 3D print joint replacement implants. *Discovery – co-designing the software requirements for use in Community Dental Services in the NHS* (UK), details the complex process of transitioning a legacy (paper-based) dental record-keeping system to centralized open-source digital record-keeping. This transition provided an opportunity for the author and her team to involve stakeholders in participatory processes to redesign aspects of the form; enhancing accuracy, salience and the value of data collected. In *Managing Vulnerability and Uncertainty: Developing design competencies within an American healthcare non-profit* (USA), the founder of an American healthcare not-for-profit organization describes how she has used design innovation to train and evaluate her staff. Ensuring consistency, quality and fit are imperative to her service-based organization in which her "product" are facilitators within a system who work closely with the families and caregivers of those suffering from Parkinson's Disease. *Empowering seniors' mobility to maintain a healthy lifestyle: a case study* (Netherlands), explains a plug-in designed for a popular app in the Netherlands. This plug-in facilitates senior citizens to locate like-minded companions and to undertake travel within the country. The case leverages an existing, widely-adopted, platform to support wellness amongst a, sometimes isolated and less physically mobile, population. *System Design for People Dealing with the Liminal Space* (Israel), describes the case of how service design tools and methods were applied to a system that could be implemented between Israeli inter healthcare agencies. This system is designed to support families and caregivers of terminally ill people. The author defines the role of case-facilitator, a type of doula who would assist the person's caregiver(s) to navigate the logistical and emotional pain-points of the journey through a terminal illness, describing the case-

facilitator's function across its liminal space. *Equity Listening and the Transference of Power* (USA), details the class project run through a design strategy consultancy with the American Heart Association as client. The case describes two contexts in which the group worked with a framework (developed with the consultancy), to listen with empathy and agency, to stakeholders experiencing health problems associated with complex systemic issues preventing access to healthcare or discouraging of healthy practices.

Transformations in community empowerment

Designing and Developing Entrepreneurial Culture for a Small UK Based University (UK) presents University of Dundee's work around design innovation management and the development of an outward-facing more networked entreprenurial culture in their city. With a goal of using design to promote cultural change, the University identified and leveraged strategic local cultural and economic resources. *Applying Equity Design to Address Oakland's Homelessness Human Rights Crisis* (USA) describes the work of Reflex Design Collective, an experimental social equity design consultancy based in Oakland, California who facilitated a co-design innovation summit where unhoused Oakland residents led collaborative efforts to alleviate the challenges of homelessness. Their design facilitation approach they propose, will provide managers and designers with an alternative mindset aimed to amplify the voices of marginalized groups and stakeholders. *Design + Social Impact: a Workshop in Cairo* (USA) describes how the case authors were invited by the US Embassy in Cairo, Egypt to give an intensive, five-day workshop on critical areas for those interested in taking a design-strategy approach for entrepreneurial or intrapreneurial ventures addressing complex social challenges. The case outlines their process and insights working with twenty-five Egyptian creative professionals from diverse backgrounds. *Causing a Stir: Co-creating a Crowd-voted Grants Platform for Creative Entrepreneurs* (Australia), presents an overview of the methodology and process used for a crowd-voted grants platform aimed at supporting creative youth in the early stages of their entrepreneurial journey. The author places specific emphasis on the characteristics of programs that target creative youth in Canberra, Australia. *We Need an Internet Connection* (Sweden) outlines a co-design approach addressing the digital transformation of Small-to-Medium Enterprises (SME'S) in the Jönköping region in southern Sweden. The authors describe the tension between proposal-level goals, operation-level goals and the design process which was operatively approached as a co-design activity involving multiple stakeholder groups. *A Design Contribution to the Entrepreneurial Experience* (Colombia) investigates the entrepreneurial environment of Medellín, Colombia. This ecosystem is experiencing recognition and growth but lacks qualitative analysis to fully understand the landscape and how it impacts perceptions and awareness and agency. The author proposes a number of concepts for the local government to improve the experience of establishing a startup in Medellín. *Project Kapıdağ: Locality of Production: A case of research for social design in complex collaboration* (Turkey) addresses the friction between industrialization and localized traditional production in rural Kapıdağ, Turkey. The authors along with a team of students from İstanbul Bilgi University Faculty of Architecture, identified the assets through a range of research methods for the collective wellbeing of the region. Their work revealed potential opportunities to promote and sustain the artisinal practices and traditions of Kapıdağ. *Designing a Coherent Land Registration System for Rural Portugal* (Portugal) presents the work of Lisbon-based "With Company," engaged by the Portuguese government after the launch of a digital platform to address the challenge of their centuries-old problem of rural land registration. The authors executed field research to better understand owners' relationships with their land, map their struggles with the platform and prototype ways to improve the service. In *Applying Design to Gender Equality Programming* (USA), the authors describe their application of design methodologies to the area of women's rights programming and feminist grant making. Working with the "Fund for Gender Equality," a grant-making mechanism of the United Nations Entity for Gender Equality and the Empowerment of Women the case presents proposals for a range of women-led civil society organizations.

Transformations in corporate management and innovation

Business as Unusual: Creative Industries and International Trade in the Era of Brexit (UK) is a survey of "Baltic Creative," a commercial space for creative and digital industries, housing almost 100 SMEs (small and medium sized enterprises). Policy-makers in the UK are concerned that the creative industries are not sufficiently engaged in global markets, however the authors discover that these industries—at least at Baltic Creative—are already very engaged in global markets; the key concern is now around the impact of Brexit on these markets. *Designing a Business Unit and Creating the First Ever Responsive Kitchen* presents a collaboration between Tipic an Italian strategy firm and Marmo Arredo a leading company in quartz surface production. The case outlines the design of a new business unit devoted to the development of innovative products which lead to Tulér, a stone work surface with fully integrated, gesture activated, kitchen technology. *Design Innovation Practices in a Global Supply Chain: A Fung Group case study* (Hong Kong), describes how the Fung Group—a leading Hong Kong-based company whose core businesses operates across the consumer goods global supply

chain—empowers and involves a wide range of stakeholders in in the co-creation of strategies involving absorptive, collaborative, and adaptive practices that aim to challenge or disrupt current company practices. *Towards an Interdisciplinary Knowledge Exchange Model: Uniandes design school helps to transform Avianca into a design driven company in the flight industry* (Colombia), presents a partnership between Design School of Universidad de los Andes and Avianca, the leading airline of Colombia. Students and faculty from the University collaborated with Avianca employees to introduce them to the methodologies of design-driven innovation. Explorations around the traveler experience lead to testing a range of prototypes at Bogotá's international airport. *Transitioning Business for a Circular Economy* (Hong Kong) describes the author's work with Lane Crawford, a retail company with specialty stores selling luxury goods in Hong Kong and Mainland China. Drawing on both academic and professional practice the case explores strategic business opportunities for the company to transition to a circular economy, which in turn can contribute to a regenerative society.In terms of theme, in this round, we were surprised not to have encountered cases from Financial Technology/Cryptocurrencies and banking and finance in general. We also did not see cases dealing with AI and automation technologies or with algorithm design. Just one case (*Empowering seniors' mobility to maintain a healthy lifestyle: a case study*) explicitly addressed aging and retirement, although several implied the existence of an aging population in a public health context. It will be interesting whether we will see these emergent sectors in future case study forums.

Additional to the themes, we discerned several frameworks—or conceptual groupings—that emerged as common threads. The first, using design to optimize or improve project management, outcomes and engagement united cases as diverse as *Equity Listening and the Transference of Power* (USA), *Design Thinking Mindset: Exploring the role of mindsets in building design consulting capability* (Australia) and *A design contribution to the entrepreneurial ecosystem* (Colombia). While Empowering communities through involvement in co-design or other kinds of "bottom-up" input were not exclusively confined to the "Transformations in community empowerment theme," and could be identified in many of the cases presented in the theme we identified as "Transformations in healthcare/wellness/harm reduction." The Application of design innovation to new or underexplored contexts unites any of the cases that may introduce unexpected contexts for intervention such as *Designing a coherent land registration system for rural* Portugal (Portugal), while Mindsets and practices informing new methods, tools and approaches may connect cases clustered in "Transformations in methodologies and practices" with cases nested in other themes that utilize any new or innovate methods of engagement and testing such as *Design + Social Impact: a Workshop in Cairo.*

Finally, we offer our sincere thanks to each of the authors represented here, you have an open invitation to submit cases to future proceedings and to spread the word amongst your colleagues in academia and industry.

We hope you enjoy reading these as much as we did in gathering them up and listening to the presentations.

Research Perspectives IN THE ERA OF Transformations

Community Based Naloxone Kits: Using Design methods to transform complex user needs into innovative community partnerships

HARVEY Gillian[a] and VANDENBERG Stephanie[b]

[a] University of Alberta, Canada
[b] University of Calgary, Canada
* corresponding author e-mail: gharvey@ualberta.ca
doi: 10.33114/adim.2019.c01.161

The opioid crisis in Alberta is a public health crisis. In 2016, more people died from an opioid poisoning than from motor vehicle crashes. Naloxone is an opioid antagonist which means that it can reverse an opioid overdose for a period of 30–60 minutes, at which point, the overdose may return. In December 2015, the Take Home Naloxone (THN) Program was rolled out in response to the opioid crisis. Under the renamed the Community Based Naloxone Kit Program (CBNP), naloxone kits are now available free of cost at many pharmacies and community clinics around Alberta. The wide availability has led to a new challenge—that the kits may be used by people who have received little to no training. Some may encounter the kit instructions for the first time when there is an emergency in which they need to administer an injection urgently to someone who has passed out. Studies have found that most overdoses occur in the presence of another person—this provides an opportunity for someone to intervene. People often die from witnessed opioid poisonings because other people do not know what to do to help. A pilot study conducted through community partnerships involved 30 participants in two different urban centres (Edmonton and Calgary) who self identified as either experienced in substance use or friends/family of people with lived experience has revealed some interesting findings. Qualitative observations and data collected in the initial pilot work show that end users are experiencing unique challenges in accessing opioid education and have challenges using instructions on how to administer naloxone in an overdose setting. User testing and observation of user behavior has great potential to support educational material for opioid awareness.Human-centred design approaches that gather information with and about people using antidote kits are urgently needed in order to mitigate risk and ensure successful administration of first aid and naloxone in an emergency.

Keywords: design research, visual communication design, user centred design, information design, typography, human centred design

Introduction

The opioid crisis in Alberta, Canada is a public health crisis. In 2016 more people died from an opioid poisoning then from motor vehicle crashes. Naloxone (trade name Narcan) is that antidote to an opioid poisoning. Naloxone is an opioid antagonist. This means that it can reverse an opioid overdose for a period of 30 to 60 minutes while medical help arrives. In December of 2015 the Take Home Naloxone (THN) Program was rolled out in response to the opioid crisis. During the first year of the program 9,572 kits were distributed by over

900 sites across Alberta and 973 overdose reversals were reported. Now renamed the Community Based Naloxone (CBN) Program, 83, 286 kits have been distributed by 16,70 registered sites, and 4,505 reversals have been reported. While we usually hear about the overdoses that are due to the use of recreational/street drugs it is important to realize that anyone has the potential to be a victim of an opioid overdose. Studies have found that most overdoses occur in the presence of another person; this provides an opportunity for someone to intervene (Freeman et al., 2017; Davidson, Ochoa, Hahn, Evans, & Moss, 2002; Strang et al, 1999). In an effort to prevent mortality rates due to overdose, Naloxone kits are available at many pharmacies and community clinics around the province. Anyone is able to obtain a kit free of charge and with no questions asked. The person providing the kit (pharmacist, nurse, community support worker, etc.) is expected to provide some basic kit training however it is possible that training may be refused or may be forgotten when it comes time to use the kit. As a result, people are often left to rely solely on the instructions included in the kit.

Context & problem/opportunity area

Health agencies have begun distributing antidote kits widely which has led to a new challenge – that antidote kits may be used by people who have received little or no training. Some may encounter the instructions for the first time when there is an emergency and they need to give an injection urgently to someone who has passed out. Another factor adding to the complexity of the design challenge is the fact that current educational messages for Community Based Naloxone Kits have historically been designed (or "undesigned") *by* healthcare professionals *for* healthcare professionals, without asking people who use drugs or their support networks what information is important for them to have when they or their family/friends experience an opioid poisoning.

In an effort to address the opioid crisis and improve communications strategies around emergency overdose response, we designed, administered and analyzed a pilot study involving 30 participants in Edmonton and Calgary who self-identified as either experienced in substance use, friends/family of people with lived experience or opioid naive participants. Observations gleaned from the initial pilot work demonstrate that end users are experiencing unique challenges in accessing education and using instructions on how to administer naloxone in an overdose setting. The central message of this case study is that, based on our unique and innovative experience, additional human-centred design approaches that gather information with and about people using antidote kits are urgently needed in order to mitigate risk and ensure successful administration of first aid and naloxone in an emergency.

This project is notable because it aims to include individuals and communities affected by opioid poisoning using principles of human centred design in the evaluation of the prototypes. Using a method developed by the Communications Research Institute (CRI), it strives to answer the following research question: What are the perceived barriers to appropriate first aid and naloxone administration in an opioid poisoning and how can the educational and instructional materials surrounding the delivery of the Community Based Naloxone Program improve the end user experience with the aim to reduce deaths from opioid poisoning?

Academic insights came in the form of design methodology and experience from the design experts. Public health nurses and an emergency physician provided real world experience and data, while human factors representatives designed a protocol that tested end user performance measures that were relevant to both the design and public health messaging. Community partners and students relayed important information about the lived experience of opioid overdoses and responding to emergency situations with little preparation or education.

The narrative:

In November 2018 a research team made up of designers, nurse educators, students from the University of Alberta, emergency medicine physicians, a human factors team from Alberta Health Services (AHS) and community partners identified a communication challenge: the instructions included in a life-saving naloxone kit were not easily understood by the general public. This resulted in, at best, confusion and, at worst, a failed attempt to prevent an opioid related death. The research team came to a consensus that the goal of a naloxone kit was to provide specific information to users in an emergency overdose scenario. Through consultation with medical experts we were able to define performance specifications. These performance specifications are goals of the instructions that isolate information that we would like to test with users. User testing allowed us to access what is not working with the designs, set some benchmark goals and then revise

and retest to achieve our desired level of performance. We were able to identify these performance measures/tasks that the instructions in the kit must perform:

1. Define an overdose (OD) (identify what an OD looks like: slow breathing or no breathing at all, unresponsive to voice, lips or nails appear blue, gurgling or snoring sounds, choking or vomiting, cold/clammy skin, constricted pupils, seizure like movement)
2. Know when to call 911 (after an OD has been identified)
3. Know how to do a safety check (assess for hazards)
4. Know how to perform rescue breathing (gloves, mask, airway, rescue breaths, recovery)
5. Know how to inject naloxone
6. Know what to do after administering naloxone

We structured our testing to include 2 days in Calgary, Alberta and 2 days of testing in Edmonton, Alberta, both large urban centers. This allowed us to recruit from two sites, one in each city, that provide care and treatment for people with a history of drug abuse in the community. Both of these sites were stakeholders in the pilot project work. In Calgary we tested 20 participants and in Edmonton we tested 13 participants. We structured each day to reflect a time slot of one hour for each participant. We based our timing on an initial run through to determine how long the protocol would take. There were 4 members of the research team present for each interview: a nurse educator, an information designer, a human factors specialist and a research assistant. When participants arrived they were given information on background to the study, they were given instructions about what they would be asked to do, and they were asked to fill out a consent form. A nurse educator or research assistant went through a pre-questionnaire with them that included demographic information such as:

- Age
- Sex
- Highest level of education
- Occupation
- Can you speak / understand / read English
- Have you used opioids in the past
- Have you seen a naloxone kit
- Have you ever received training on how to use a naloxone kit
- Have you ever administered a dose of naloxone

As the facilitator started the scenario, the observation criteria was noted on a sheet. This sheet contained observation criteria such as:

- Did the participant try to wake their friend (how?)
- Did the participant provide rescue breaths
- Did the participant call 911?
- Did the participant check their friends' airway?
  Did the participant tilt head back, plug nose, and breath 1 breath every second for 2 minutes
- Did the participant reassess their friend?

After we ran through the scenario, we asked participants several questions about their knowledge of the procedure. For example, we asked questions like:

- Were you able to identify all of the contents in the kit?
- What factors would you look for to determine if your friend was experiencing an overdoes
- Did you know how to provide rescue breaths?
- What will happen if you provide Naloxone to someone who is not experiencing an opioid overdose?

We also asked some subjective questions such as:

- Did you find any of the pictures or terminology in the brochure to be confusing?
- What was your impression of the pictures or terminology overall?
- And finally how could the instructions be improved?

We determined through the use of testing, participation and surveying that recording and thematically coding the results that would inform changes to the design work of the insert. Through observation and testing in this way, it allowed us to determine the design strategy and implementation of the following work.

Figure 1: Testing materials

Figure 2: The torso mannequin for simulation of the procedure

Testing Protocol

In order to evaluate the effectiveness and usefulness of the naloxone kit instructions we had participants from the three different user groups take part in a simulated scenario. Upon arrival at the testing locations, the facilitator reviewed the informed consent form with the participant as well as a pre-questionnaire which asked a combination of demographic questions as well as questions about their experience with opioids and naloxone kits. Prior to the beginning of the simulated scenario a standardized verbal protocol was read aloud to participants which outlined what was expected of them. They were asked to imagine that they had entered the room to find their friend collapsed on the floor. Their friend (represented by a torso mannequin) was non-

responsive and was suspected to have overdosed. Participants were instructed to use the naloxone kit and the instructions included to help their friend (Figure 1 and Figure 2).

It was stressed to each participant that the goal of the project was not to evaluate their individual performance but instead to evaluate the usefulness of the instructions provided in the kit. Participants were asked to pretend that they were alone in the room and to avoid asking the facilitator any questions. They were also encouraged to talk-a-loud and say whatever came to their mind so that this information could be captured. At this time the facilitator informed the participant that the scenario was about to start. The facilitator read the following line with a sense of urgency: *"Please someone help, my friend is lying on the floor, I think they've overdosed."*

The participant was expected to use the naloxone kit and the instructions provided to attempt to help their friend. Facilitators used a standardized observation form to record predefined performance specifications. Once the participant had completed the task (used the instructions to provide a dose of naloxone) the facilitator ended the session by informing the participant that *"the ambulance had arrived and the paramedics will take over."* If participants were unable to complete the task or appeared to be too overwhelmed or stressed out the facilitator ended the scenario repeating the same line.

A debrief was administered which asked a series of questions about the kit (i.e. were you able to identify all of the contents in the kit?), the task (i.e. did you know where to inject the Naloxone in your friend's body?) and the design and usefulness of the instructions (i.e. were there any words/pictures provided in the instructions that you did not understand?). Any questions or concerns the participant had were addressed and additional education was provided by a nurse to those who were interested. Participants were thanked and a $20.00 gift card was provided in order to compensate them for their time.

The key learnings:

Many key learnings came from this initial pilot study. These ranged from task uncertainty to product unfamiliarity, compounded by the stress of needing to act in a timely, efficient manner.

First, it is not clear to many what opioids are. Many of our participants, when asked if they had used opioids in the past or if they had responded to an opioid overdose, responded that they did not know what an overdose was. Most participants had knew to refer to these drugs from their "street" names: meth, fentyanyl, etc. In the message strategy going forward, we limited the mention of the word "opioid".

Secondly, we discovered that there were similarities between the target groups that we tested. In particular we found that both used previous knowledge more than the instructions to accurately administer 1 ml of Naloxone. Participants were not able to understand that the package was designed to help in an emergency situation.

Text, Illustration and Layout

There were many differences between the target group as well. In particular, the participants read the pictures and the text equally in the non-experienced group. In the experienced group, however, participants only read the pictures, and rarely read the text.

Through the testing we concluded that it important to use illustration as a way to relate to what the reader already knows. It becomes essential to show what readers expect and recognize. Barnard and Marcel say that when people recognize pictures, "the visual form of objects is related to and invokes spatial, semantic, and other real-world knowledge" (Barnard & Marcel, 1984 p. 44). Pictures need to be able to provide the reader with new information but also need to be able to remind them of the real thing. For example, in the prototype, the illustrations that we used represented how a rescuer and casualty might look if performing artificial respiration. In this step, the rescuer is demonstrating how to clear the airway by performing a "head tilt, chin lift" (Figure 3).

Figure 3: Visual representation of how a rescuer and casualty might look while assessing response and breathing.

We depicted representational, rather than abstract illustrations of people performing Artificial Respiration. Images in these procedural instructions are intended to provide visual information to the reader. This is different than in other publications where they are used to provide pleasure or visual stimulation. How realistic do images have to be? Goldsmith says that "semantic unity requires recognition of the image, and representation adequate for this purpose relies not on slavish imitation of an object, but on the clarity of distinguishing features which give relevant information" (Goldsmith 1980, pg. 207). "The number of distinguishing features that any object possesses controls the extent to which its image can be distorted" (Goldsmith 1980, p. 207). In other words, it may not be necessary to exaggerate every detail of a hand for the reader to recognize it as a hand. In the case of the CBNK instructions, it was important to indicate that the needle should be inserted partly in to the vial containing the medication and that it was important to pull down on the syringe to push extra air out of the needle. It was also important to indicate the correct administration of the injection—in particular what the needle would look like when depressed and which place the on the thigh the syringe should be injected.

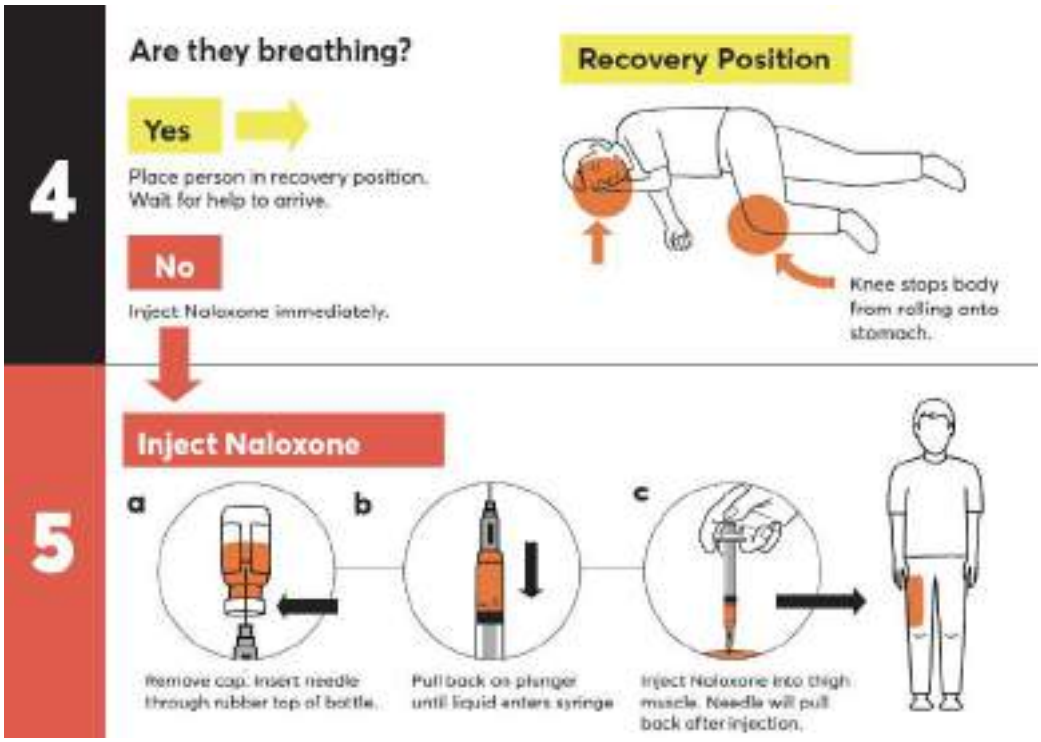

Figure 4: Steps 4 and 5 indicating a decision to be made

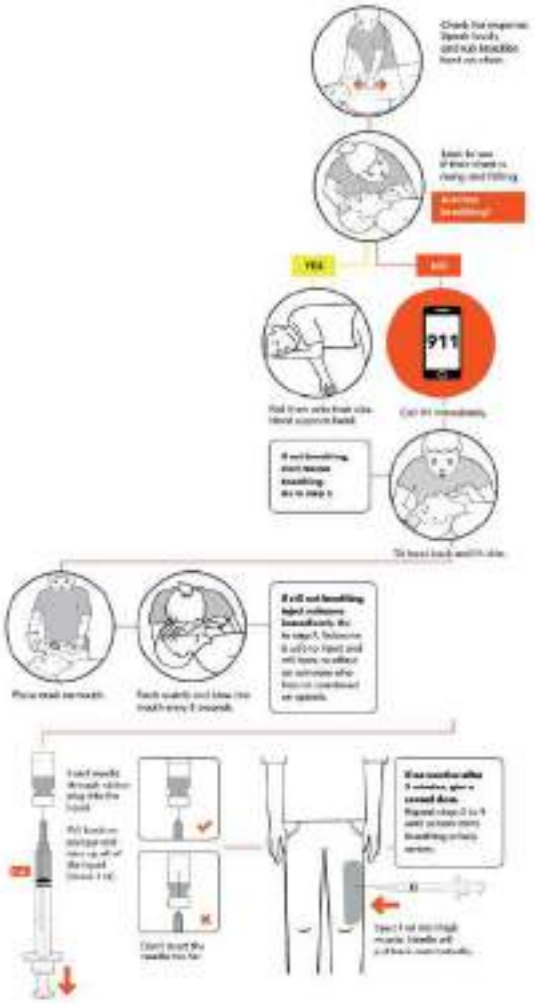

Figure 5: An alternative way of presenting the decision to be made

Evelyn Goldsmith's analysis of how people read illustrations is similar to Marcel and Bernard's analysis of how people relate to instruction. She proposes more of an analytical model that involves three levels of comprehension: syntactic, semantic, and pragmatic. One of the levels of comprehension that is important to these instructions is semantic knowledge – this is the knowledge that involves providing a frame or reference to show size or scale. In these illustrations, hands are an example of a tool that relate the viewer's size of semantic knowledge. The size of the hands shown in the illustrations is an important reference point because not only does it show how to prepare the plunger for injection, but it also provides a visual link to what the user knows, making it easier to explain the procedure of using a needle.

Layout and comprehension

In the participant testing, there was confusion over what to do if the person was discovered to be not breathing. This may have been because the options were not shown side by side in the layout (Figure 4). An alternative presentation to the layout was designed (Figure 5) which depicted the action in a tree diagram or linear branching configuration (Twyman, 1985).

However, we did not choose to test this option because it was felt by the stakeholder team that the layout was too cluttered and that the large steps and headings in the original design helped to provide more of a mental map of the procedure. The layout also meant that we would need to print on a larger sheets of paper, causing additional costs to an already small budget.

As Hartley writes "consistent spacing aids readers' perception of the structure of the document as a whole and thus helps them to understand its organization and structure" (Hartley 1985, p. 27). To this point, Anderson and Armbruster (1985) agree that "visual display, diagrams, and charts can facilitate comprehension presumably because of their ability to portray the 'big picture'' (Anderson & Armbruster 1985, p. 168). In this

insert, all of the steps are labelled consistently on the margin on the left hand side and the decision was made to keep the steps the same height, if possible, as the insert was unfolded.

The design of the insert into a flow chart or tree diagram did not help the reader to see comparisons within the text. As Hartley points out, "psychologists maintain that consistent spacing helps readers to see redundancies in the text, and thus to read faster" (Hartley 1985, p. 27). The use of a grid allows the designer to present ideas so that readers will expect how ideas will be organized (Anderson & Armbruster, 1985). It also "enables comparisons to be made between work produced in different places and at different times; and it leads to an overall approach to the structuring of information which makes it possible to deduce meaning through content and treatment in much the same way that meaning is frequently deduced in verbal language" (Twyman 1975, p. 11). A structured grid, emphasized by the folds of the insert directed the reader's attention and allow the reader to make comparisons between one frame and the next.

Word choice and order of action

The instructions were designed to reflect the way that people would perform the action of the instructions (Figure 5). For example, in order to start rescue breathing, it is essential to put on gloves, then mask, then give one breath every 5 seconds. It would have been possible to phase this operation as "give rescue breathing for 2 minutes by every 5 seconds giving one breath and do not forget to put on your gloves and mask". However, in long instructional sequences, it is helpful to have "the order of mention match the order of action" (Wright 1999, p. 58). Wright points out that in English we usually say things in subject-predicate order. An example of this in overdose first would be: "provide rescue breaths by pinching the nose and blowing into the mouth". However, as Wright points out in the article, when the steps are actually performed, the order becomes reversed: first you need to pinch the nose, then blow into the mouth and then continue providing rescue breaths. This is opposite from the way the instructions are written. Wright suggests that the "writer's choice of word order can slow comprehension but can have a much bigger impact on the ease of creating action plans" (Wright 1999, p. 57). This descriptive order becomes especially important for a procedure with many steps (Wright, 1999).

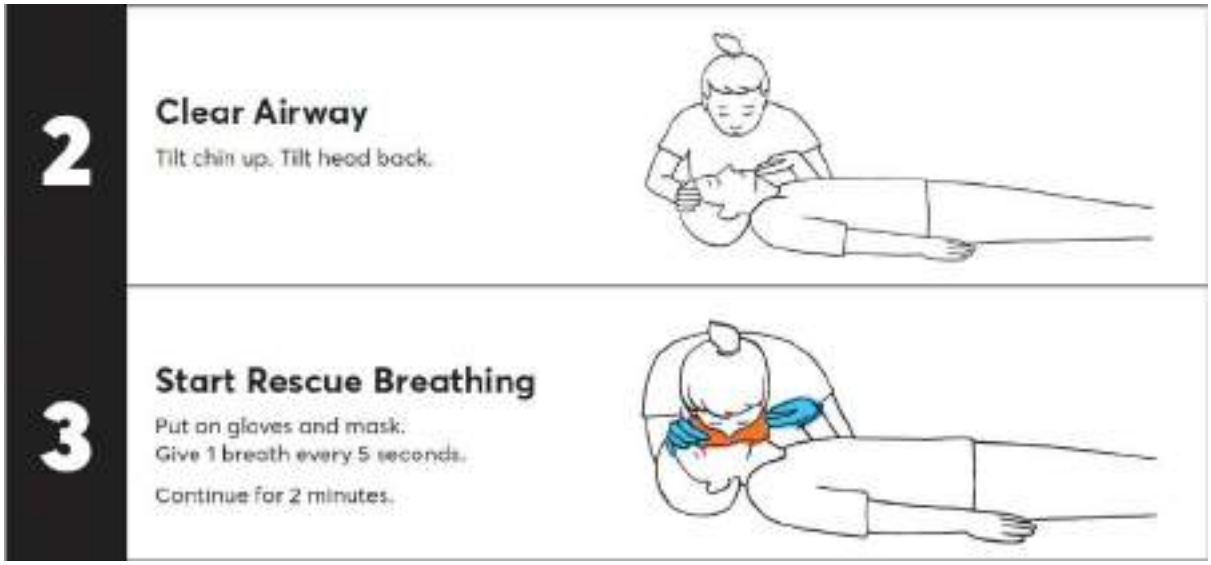

Figure 6: Indicating the sequence for performing rescue breaths

Typography

Short sentences using short phrases with few words and bullets wherever possible were used to aid comprehension. Waller, in his writing about type, emphasizes this point by adding that typography "adds the diagrammatic quality that can make such a structure accessible to the browsing or less committed reader" (Waller 1983, p. 4). Anderson and Armbruster reinforce this point by suggesting that "by simply skimming the text, the reader should be able to determine the author's specific topics, the purposes the author is addressing with respect to these topics, and the structure of the ensuing text" (p. 165-6). Using this logic, the large numbers, and short subheadings should make the steps in the procedure more obvious and easier to read, providing a "typographic roadmap ". The typographic roadmap in these instructions are emphasized by the steps that are in the same place down the left hand side of the insert and the headings which, when read

alone without the detailed instructions, will allow the reader to understand the procedure. Waller writes that "readers who cannot see the wood for the trees may benefit from a map – that typographic and spatial factors can be used to clarify the longer structural relationships in a text, easing the cognitive burden that long, featureless texts impose on the reader" (Waller 198, p. 3). The texts that he is referring to are most likely continuous prose texts in which there is no typographic distinction between different thoughts or ideas. Hartley also writes about the benefits of other formats over continuous prose text. He says that "research suggests that readers prefer text which has lists or numbered sequences spaced out and separated, rather than run-on in continuous text" (Hartley 1985, p. 51). It has been found that when tasks in an examination situation are made more explicit such as by space or typographic cues 'students spend more time and effort reading the relevant segments of text, and learning outcomes generally improve' (Anderson & Armbruster 1985, p. 160).

Conclusion

This collaboration between healthcare providers, information designers, human factors specialists and community members represents a novel approach to addressing a situation where clear communication really matters. Designing a coherent communication strategy for an emergency overdose situation identified unique challenges which required unique design solutions. Lastly, there is no substitute for training. These instructions should be part of a larger educational initiative that includes education and explanation, guided instruction and practice.

Research Perspectives IN THE ERA OF Transformations

Design + Social Impact: a Workshop in Cairo

BRUCE John and RANDALL Mark*

The New School, United States
* randallm@newschool.edu
doi: 10.33114/adim.2019.c02.121

In October 2018, the US Embassy in Cairo, Egypt invited Parsons professors John Bruce and Mark Randall to give an intensive, five-day workshop on critical areas for those interested in taking a design-strategy approach for entrepreneurial or intrapreneurial ventures addressing complex social challenges. This type of cultural exchange, one potentially charged with political issues, was a milestone for the Embassy. From over 200 applications, 25 professionals from diverse backgrounds – NGOs, education, film, design, architecture and performance – were selected to attend. A pre-workshop exercise focused intentions; themes included empowerment, cities, health and culture. All were action-oriented and addressed particular challenges within Egyptian society. The curriculum included innovative design-led research theories and practicable methods. Immediate outcomes revealed positive shifts in perspectives on systems, stakeholder activation, and narrative development for advocacy and implementation. The energy and emotion was palpable over the course of the week, culminating in an event for the public, press and top government officials.

Keywords: social impact, design strategy, Egypt, entrepreneur

"The revolution was the real wake up call, a realization that I also have to work on social projects."

– workshop participant Adham Bakry

Prior to the Arab Spring in January 2011, Adham Bakry was a freelance graphic designer in Alexandria, Egypt with a practice focused on branding for arts and culture. During the upheaval of the revolution he added activist and graffiti artist to his resume and took to the streets, using his creativity to comment on the Mubarak regime (Figure 1).

Figure 1: A protester during the Arab Spring with graffiti art by Adham Bakry. (source Adam Bakry)

Architect and urban planner, Taher Abdel-Ghani said that what inspired him to follow a path of social change was his "previous experience with the revolution" he goes on to say that this period was a "turning point in the way I viewed society and the environment I'm living in." Many of the participants in *Design + Social Impact, a Workshop on Strategies for Creative Intervention* hosted by the US Embassy in Cairo, Egypt expressed similar sentiments. At the Embassy's invitation, John Bruce and Mark Randall from Parsons School of Design in New York developed a five-

day intensive workshop for creative professionals on how to leverage design-led research and strategy to develop interventions to address challenging social issues.

Workshop context

Embassy programs for cultural exchange typically involve more traditional forms of art, film and performance. Dina Hafez Abdelhafez, a Cultural Affairs Specialist from the US Embassy in Cairo was looking for ways in which the Embassy could support the creative economy in Egypt. She was also interested in how design could be leveraged as a tool for social innovation. The open call for applications to the free workshop cast a wide net, with expectations for potential attendees being civic-minded, engaged creative professionals.

Figure 2: Branded materials developed by KMT House promoted the workshop across all forms of media. (source Mark Randall)

The Embassy partnered with urban-tech innovation space KMT House in Cairo to host the workshop. KMT House handled all marketing and outreach, (Figure 2) which attracted over 200 hundred applications prior to the deadline with an additional 100 individuals expressing interest after. The response exceeded expectations, and dramatically indicated a deep desire for this type of engagement.

Participants were early-mid-career professionals covering a wide array of disciplines; from communication and interior design, architecture and urban planning to filmmaking and fine art (Figure 3). In addition, individuals working within established non-profits brought the themes and projects they were exploring into the workshop. Participants were given a detailed assignment in advance to articulate their area of inquiry, which allowed them to engage immediately on the first day. The exercise also gave and Bruce and Randall valuable insight into each individual and an understanding of the emerging themes to better tailor the workshop to meet the needs of the participants.

Theoretical frameworks and approach

The Cairo *Design + Social Impact* case advances an argument for the value of image-oriented practices that embrace cinematic devices and support narrative perspectives during analysis and synthesis of the design-led research and design strategy process. The context addresses learning environments where theories and methods are presented via an intensive workshop format. Our curriculum and pedagogy involved confrontations with narrative artifacts and forms through embodied and multi-directional learning, and relied on a variety of tools and participatory engagements within a design process for rendering images in relation to movements through systems at various scales.

Figure 3: Participants were early-mid career Egyptian creative professionals. (source US Embassy, Cairo)

The term storytelling is thrown about very liberally in design strategy and management contexts. Too many assumptions are made around the potential usefulness of acts of telling stories within a design process. Yet, undeniably, narrative forms and artifacts possess great possibility for catalyzing aspects of design-led research and creative intervention. Stories emanating from events during the Arab spring operated with reflexive potency to disrupt entrenched power and shift system dynamics. The affordances of decentralized information via digital social media – still relatively new in 2011 were put to use during the 18 days of uprising in Egypt in ways beyond reportage, archive, or discourse. Media was used to mobilize people in real time. In the immediate aftermath, trans media projects such as 18daysinegypt.com by Jigar Mehta and Yasmin Elayat attempted to augment media activities with platforms to support generative environments for subsequent collective actions (Mehta and Elayat 2011).

In the years that have followed the major events of the Arab spring uprising of 2011, the socio-political atmosphere of contemporary Egypt continues to pose interesting questions in regard to the potential affect of stories in relation to efforts of design for social innovation. How might the flash points from 2011 continue to influence designers and strategists in their approach to using imagery for investigation and intervention? Memory plays an important role in struggle, and can catalyze energetic gestures for conscious efforts toward change; thus control of people's memory can impact their agency to participate in designing a future (Foucault 1975). In the wake of the 2011 events, alternative press outlets have been suppressed and opportunities for social exchange in public spaces has been atomized through restrictive urban regulations regarding gatherings in Cairo.

Stories in a variety of forms and formats can support vital communication among community members, and thus might serve as the bottom-up currency of exchange for social progress. The infrastructures for such dynamic mixing are often at risk of gentrification, spiritually as well as practically, and gentrifying forces might be motivated not only by market economics but also by desires to control people's ability to share experiences that might spur creative freedom (Schulman 2013). The projects of the Cairo *Design + Social Impact* workshop did not specifically address the politics directly involved with the Arab spring, while many focused on the symptoms of policy that resulted in the wake of the uprising, especially in regard to conditions impacting the potential of social fabric and public space (Figure 4).

In light of the context of Cairo, and in regard to the energetic potential of storytelling, the approach for curricular content and pedagogy of the *Design + Social Impact* workshop was developed in order to privilege stories as active design strategy tools. Our program utilized a dialectic approach to facilitation and visual phenomenon. It relied upon the use of a multiplicity of image-oriented narrative devices (Frølunde, Simonsen 2014). The approach acknowledges an array of players and meanings as operating in dynamic flux within

context, and allows for productive tensions to continuously occur in the construction of meaning (Frølunde, Simonsen 2014) (Bakhtin 2000). Lisbeth Frølunde refers to this methodology as neo-Bakhtinian, referencing Mikhail Bakhtin's theories of hybrid dialogic forms for efforts toward the generation of meaning (Bakhtin 2000).

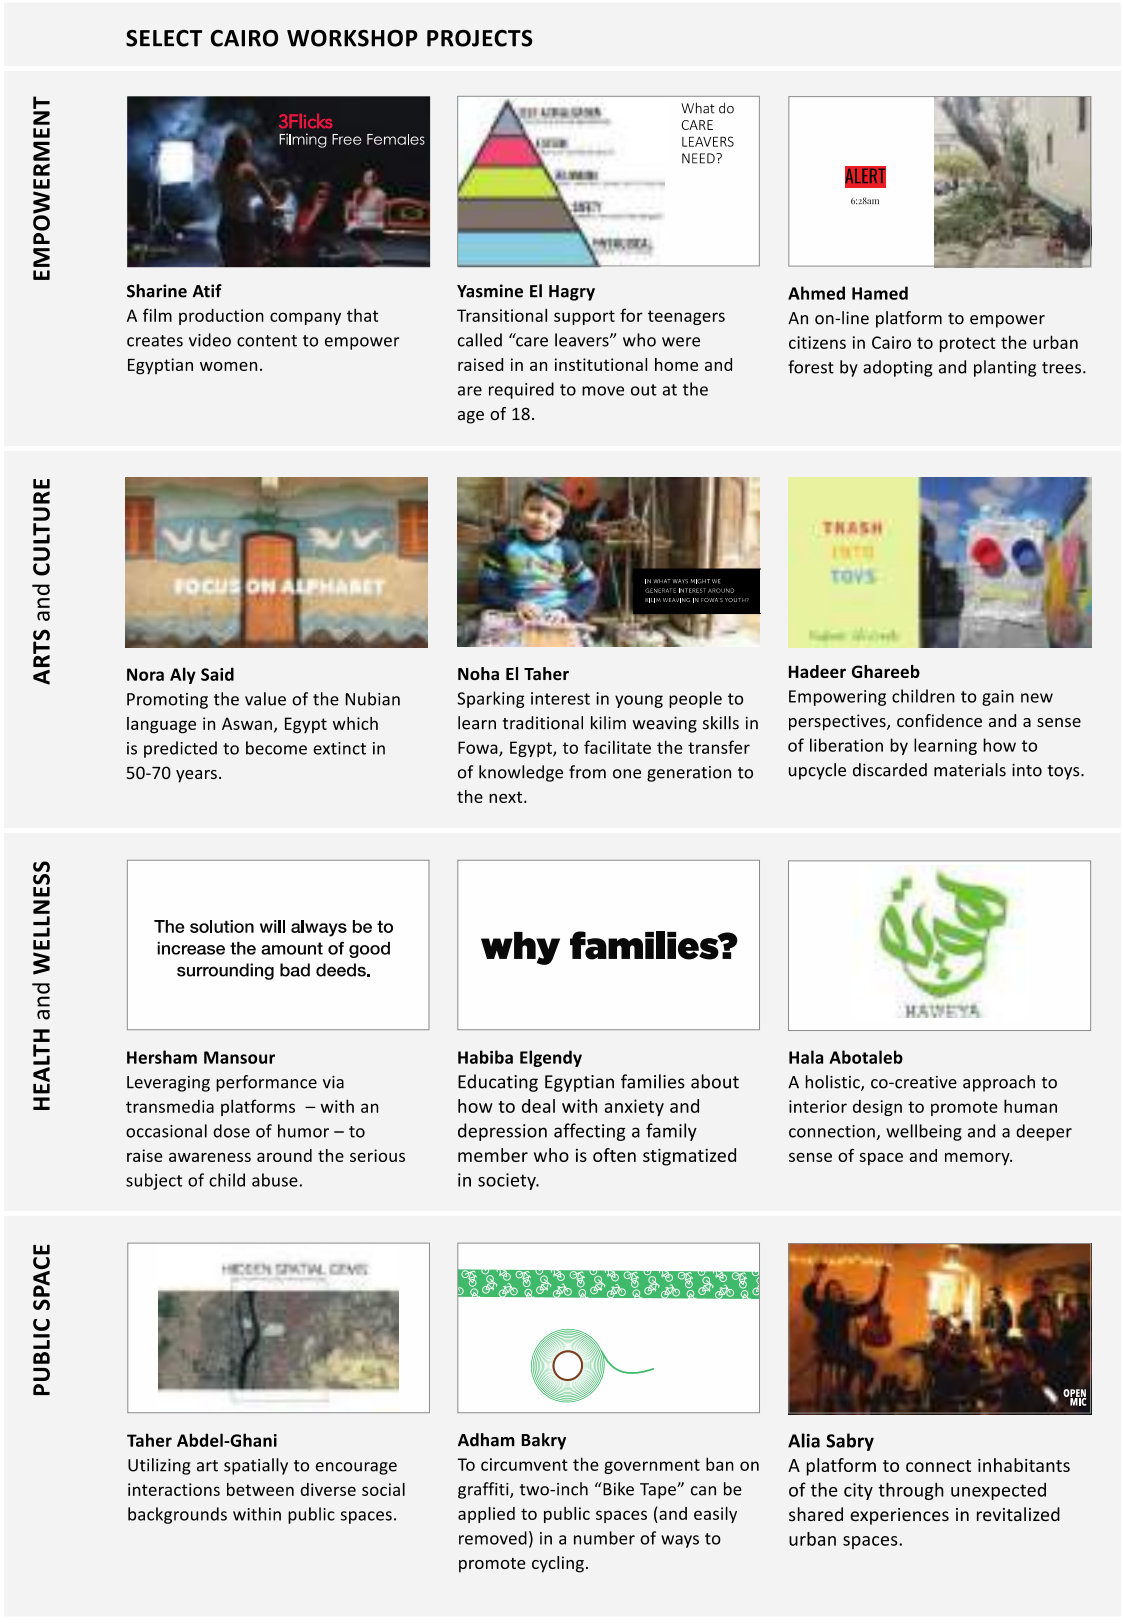

Figure 4: Brief abstracts of select workshop projects. Topics were roughly distributed across four themed areas. (source workshop participants)

Taking cues from design fiction, our attempts were to support iterative activities where narrative elements could be referenced, critiqued, invented, modified, and juxtaposed in order to charge and confuse perspectives within complexity. As such, the framing of the activities leveraged cinematic tropes – bringing to life, through multiple perspectives, the re-creations and speculative creations of situated moments at various scale and temporal junctures of the project ecosystem. In this way, the design process might enable the recognition of new co-creative spaces, counter-intuitive modes for addressing leverage points, and tactical gestures within strategic directions.

Methods: Images of crisis, images of change

The program relied upon a process of creating both reflective and reflexive exercises for workshop participants in order to catalyze narrative fodder and provide organizing infrastructures for sense-making activities leveraging an array of story elements (Schon 1984). Developed by Freedom Lab, the Wheel of Reasoning, (Figure 5) is a tool that maps the relationships of a problem space in order to engage in root cause analysis as well as propose trajectories for positive futures (Freedom Lab 2018). We have modified the original instructions in order to elevate cinematic visualization within the nodes of "crisis" or extreme opportunity, and "change." Instructions indicated that these nodes be articulated as though one were describing a 5-minute scene from a film. What is the moment of crisis in regard to people involved in a situation, in real time, in a particular setting? What are the action, atmosphere, and dynamic energy of this moment? What is immanent? Working in small teams, we tasked participants to craft their "image of crisis" and perform a recitation of these scenes.

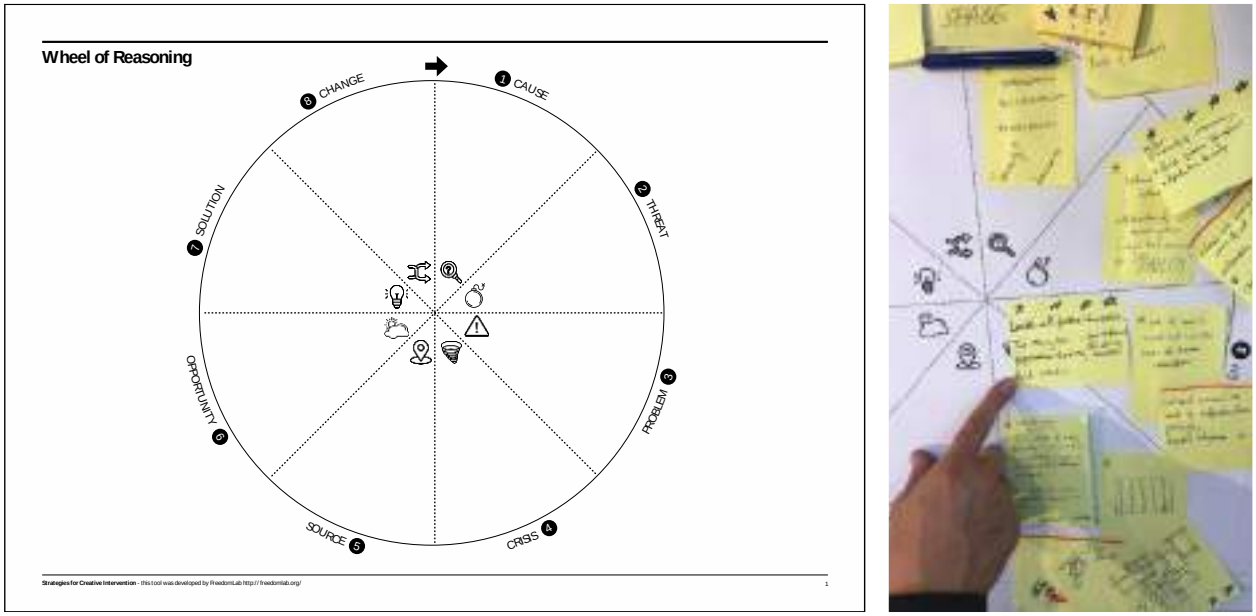

Figure 5: The Wheel of Reasoning maps the relationships of a problem space in order to engage in root cause analysis as well as propose trajectories for positive futures. (source left, Freedom Lab; right Mark Randall)

One participant working with the idea of teaching children how to make toys from trash related her "image of crisis" with the cinematic sophistication of shot/counter-shot vision. Shot: Children watch tourists board a bus, leaving trash behind as they disappear into a strange and unknown place from which they mysteriously had appeared. Counter-shot: View from a tourist bus as it leaves a rest stop in the desert on the way to Luxor, a group of idle children standing on a dusty trash-strewn road watching the bus move away. The "problem" that perhaps brought about this "image of crisis" was cited as: children of this remote and poverty-stricken location have no toys, and their environment is plagued by trash. While this problem is clear, the complexity and resonant possibility of the situation is revealed more profoundly in the "image of crisis." Later in the workshop week, having iterated with the Wheel of Reasoning and other tools, the same participant related that perhaps an even more serious "image of crisis" for her project might be the same children as initially described in the shot/counter-shot scene, but years later as adults who had never benefited from any intervention around this

problem. The visualized insight exposed the participant to notions of generational trauma, thus further informing the nuanced context of the project ecosystem for potential intervention.

Systems and movement: Perspective and reverberation

Workshop activities productively complicated the positionality of the participants, inviting them to alternate between design strategist and narrator. These iterations might involve shifts in scale as perspectives changed, and might demand attention to dynamic movements along relational paths within ecosystems. Movements through systems might be considered as reverberation. Reverb, in acoustics, is the sonic energy that moves through environmental objects, and continues even after the original source of the energy has stopped. Similarly, we might consider moments of intervention and their subsequent energetic movements through system states (Bruce 2017).

Raising narrative elements from the Wheel of Reasoning exercise, we asked participants to transfer these insights into exercises for the mapping of value creation and delivery. Journey mapping and stakeholder activity mapping examine the reverberation of intervention toward impact (Figure 6). These tools were framed to consider the acted out relationships of design value, stakeholder actions, and transformative journey movements in order to support the development of potential design principles.

Figure 6: Mapping and stakeholder tools examine the reverberation of intervention toward impact. (source John Bruce)

Utilizing narrative forms and image-oriented gestures for working through the constellation of stakeholder activities provoked fresh perspectives on leverage points and impact potential.

For example: the *Trash into Toys* project had been up until these mapping exercises focused on value creation in the form of education workshops for children (Figure 7). As the participant sketched stick figures into a journey-mapping template in the form of a graphic novel storyboard, an ancillary narrative emerged revealing upstream opportunities for intervention. Making toys from trash might be augmented if the trash was optimized in advance for the purpose of making toys. This odd notion, as derived through a storyboard image, led to an extended narrative involving the partnership of larger corporate entities producing goods that typically yield certain kinds of waste germane to the project ecosystem – food and beverage packaging, etc. These corporate partners might engage in co-creative sessions with children in order to redesign packaging with an extended life for functioning as toy parts. The formation of such an unlikely partnership might act as the Trojan horse for confrontations around other systemic shifts in production waste, as well as for garnering new attention to communities impacted by socio-economic disadvantages. The evolution of ideas around the *Trash into Toys* project emerged through visceral, narrative extensions.

Figure 7: Images from early Trash into Toys *workshops from the participant's final presentation. (source Hadeer Ghareeb)*

Outcomes

Through the program's cinematic framing for the use with tools of design analysis and synthesis, participants acquired new perspectives on their respective design practices, and projects evolved with actionable next steps around stakeholder engagement.

Participant Adham Bakry was eager to take back state controlled public space and to use it to promote cycling in Egypt. Bakry sees cycling as a way to positively impact the severe traffic congestion and pollution facing cities like Cairo. To combat the government ban on graffiti which carries with it a prison sentence, Bakry had to innovate new ways in which to publicly spread grassroots efforts around alternative transportation and support collective action toward policy change. His solution, *Bike Tape* is a two-inch roll of tape that can be easily applied – and removed – from surfaces such as roadways to create impromptu bike lanes, wrapped around poles to tag a safe place to lock a bike, or on messenger bags to unite the community of bikers – many of them women new to cycling (Figure 8).

Figure 8: Images from the Bike Tape *presentation, sample tape with mockups for an improvised bike lane and identification for a safe place to lock a bike. (source Adham Bakry)*

Recently, Bakry along with colleague Roba Mustafa an Egyptian educator and event planner have translated the tools from the workshop into universal Arabic so they can be engaged with across the Arab world. After the government demolished the Cultural Center in Bakry's hometown of Portsaid, Egypt, Bakry and Mustafa worked on a funding and relocation plan. They have identified a new space and are building a Heritage Museum and Culture Center. Bakry recounts, "the Wheel of Reasoning and Journey Mapping tools

were used in a grand brainstorming session involving 15 people to great success" (Figure 9). This demonstrates that once learned, these tools promote continued use along with an elevated attention to narrative. They are easily adopted and translated for other contexts - an unexpected yet rewarding outcome.

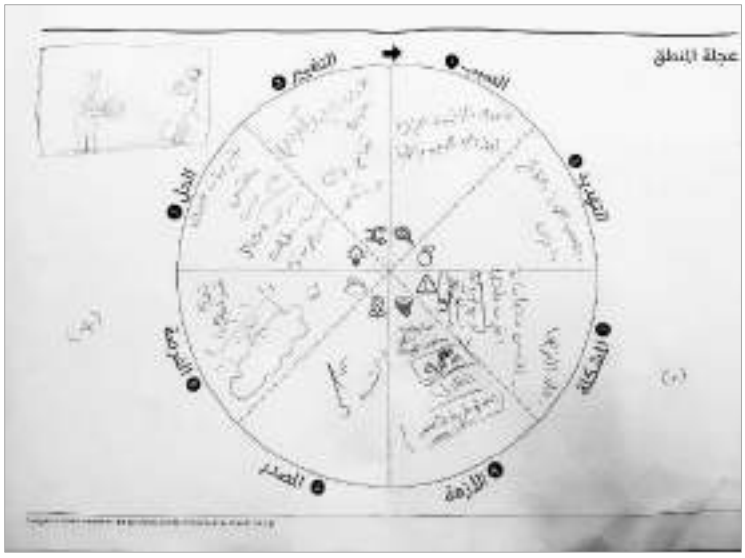

Figure 9: With the Portsaid Heritage Museum and Culture Center's future in mind, Bakry and Mustafa asked each of three groups to pick a moment of "crisis" and finish half of the Wheel of Reasoning. They then rotated the sheets so that each group finished the second half of the wheel for another group. (source Adham Bakry and Roba Mustafa)

Participant Taher Abdel-Ghani, an architect and urban planner, explored ways to utilize art spatially to encourage interactions among diverse social backgrounds within public space. His vision found traction through discovery of the steps necessary to move the project forward through hyper-local pilot programs in co-creation with existing networks of communities of art practice and social hubs operating in public/private pop-ups.

Hadeer Ghareeb shifted her systemic view for approaching the *Trash into Toys* project, re-framing her work to have impacts at the source by taking children into corporations to inform the design process around how packaging was designed. Currently she is developing her project in Zipaquira, Columbia. Over the course of one-year she plans to teach her students about sorting trash, decreasing consumption and making toys that will be distributed to underprivileged kids. Her next step will be at the corporate gates.

The workshop culminated in an evening event for the participants to present their work and reflect upon their experience (Figure 11). In attendance were US Embassy officials, the press and the general public. Dorothy Camille Shea, Deputy Chief of Mission from the US Embassy remarked to the organizers how moved she was with the outcome, and how impressed she was with the passion and commitment of the participants (Figure 10). It allowed her to see the power of design to address social issues on a deeply human level.

Figure 10: Dorothy Camille Shea, Deputy Chief of Mission from the US Embassy at the celebratory closing event. (source US Embassy, Cairo)

All were able to look beyond themselves, and as Nada Salem a filmmaker reflected several months later on her experience "The most transformational aspect of the workshop was realizing that we are not the heroes" She goes on to say, "our social intervention only works if it is truly dictated and driven by the people that we're targeting."

Following the Cairo program, this approach has been applied to an executive education setting where the client company was seeking to discover new innovation practices in order to evolve from their entrenched 20th century mindsets around consumer product offerings. Similarly, the advantages of seeing systems within situated narratives allowed for the revelation of potential new leverage points and approaches for value creation. Process approaches akin to

design fiction, and employing cinematic tropes, revealed relationships from multiple stakeholder perspectives within the value chain, thus elevating the potential for exploration and ideation.

doi: 10.33114/adim.2019.c03.160

Outline

Design thinking currently enjoys public recognition and is increasingly utilized in business consulting and strategic decision-making. It has given rise to university programs while opening up varied careers for design strategists. As design enters mainstream management consulting practice, a critical question being asked of educators, designers and businesses is what *kind* of design is privileged within design thinking-as-business strategy. Moreover, has this version of design thinking delivered additional creativity to business environments centred on process efficiency? Nussbaum (2011) argues that business has embraced a brand of design thinking that is recognizably process-oriented, and this has limited its capacity to deliver on its mission of enhancing business creativity.

This study examines a project delivered in the first semester of Parsons' Master of Science in Strategic Design and Management program, it is called *Understanding-through-making: building new dimensions in the new economy.* This practical studio-based project requires students to physically build a model that exemplifies their understanding of the dynamics defining and driving business in the 21st Century. This project attempts to counter a scientific, process-oriented design thinking with a more beaux arts, craft-oriented, thinking-through-making approach. Currently student outcomes are varied; some exist as pedagogic devices while others are recognizable as tools (e.g., navigators and compasses).

The study analyses these current outcomes, highlights the shortcomings of both the current project and its outcomes and proposes possibilities for future iterations that promise to explore other paradigms in the application of design thinking to business.

Background and context

In recent decades, Parsons School of Design has gained renown for its fashion design program, however, the past few years have seen its BBA (Bachelor of Business Administration) in Strategic Design and Management grow to become its second largest program by volume. In 2004 what was then Design and Management was reimagined (from a program with identifiable origins in fashion merchandizing) into a design thinking/business hybrid. In response to the BBA's growth and profile, and also due to current student demand, the School of Design Strategies (the "school," or sub-faculty in which the BBA is housed), was charged by the Provost of The New School, and the Dean of Parsons, with creating a post graduate-level program with the same strategic business design focus as the BBA. From its inception in 2012, the Master of Science, Strategic Design and Management (MS-SDM), a two-year, 36 credit program, has experienced a rate of growth from a 70 student intake, at the program's inception in 2013, to a peak 110 student intake in 2016 and 17.

The Chase School was founded in 1896 by William Merritt Chase a renowned Impressionist painter, however it was Frank Alvah Parsons, a teacher and subsequent head of school (in 1911), who led the school's transition toward instruction based around art in the service of industry. In 1909, it was renamed The New York School of

Fine and Applied Art to reflect new course offerings such as fashion design, interior design, advertising, and graphic design; the first of their kind in the U.S. It was eventually renamed Parsons in 1940. Even following Parsons' absorption by The New School for Social Research, in 1970, its design DNA retained its origins in a European fine art (or beaux arts) tradition extending from the late 19th Century to the present.

Today, fashion, interior, product, graphic design and architecture are all well-understood and defined as sub-fields within the broader scope of design. In contrast, strategic design and management is less broadly-understood externally, and is an emerging field situated between the domains of design and business. It is currently undergoing further definitional challenges as it is simultaneously developed in more or less different ways by varying institutions all of which have different origin stories. In North America, Stanford University launched their 'D-School' in 2005, while in 2006, the Institute of Design at the Illinois Institute of Technology (IIT) launched a nine-month executive master's program in Design Methods, both were roughly concurrent with Parsons BBA. In 2008 California College of Art (CAA) launched its MBA in Design Strategy and New York's School of the Visual Arts (SVA) launched its MFA in Design for Social Innovation program, graduating their first class in 2014 concurrently Parsons' MS-SDM. My current understanding is that CCA, SVA and Parsons all share beaux arts origins, while strategic design at IIT and Stanford have stronger scientific affinities related to definitions of user research derived from computer science, engineering and product design. This distinction is useful in relation to the status of what we, at Parsons, describe as "studio-based learning."

At Parsons, the MS-SDM program is currently grappling with what "studio-based learning" means in relation to strategic design, specifically what knowledge (or ways of coming-to-know) are integral to studio practices of the "plastic arts:" fine art and design. In their chapter "Design Matters for Management," from Managing as Designing (2004), Boland and Collopy characterized [then recent] management failures (e.g. Enron, Global Crossing, First Capital) as attributable to a 'famine of good ideas,' which were largely the result of managers trained to make choices from among alternatives presented to them, rather than from a training in the design of new alternatives resulting from the generation of new business ideas. Boland and Collopy quote Herbert Simon in making a case for what they arguing was "the manager's professional responsibility [which] is not to discover the laws of the universe but to act responsibly in the world to transform existing situations into more preferred ones," in their quote from Simon, he states, "Engineering, medicine, business, architecture, and painting are concerned not with the necessary but with the contingent — not how things are but how they might be — in short, with design. (Simon, 1996, p. xii).

It is instructive that the Boland and Collopy wrote these words very slightly before the first programs of the kind I described here emerged in North America. Their words are more prescient today as we see "design thinking tools" packaged and utilized in ways that industry voices such as business journalist Bruce Nussbaum summarize in the following way:

> *Design Thinking originally offered the world of big business–which is defined by a culture of process efficiency–a whole new process that promised to deliver creativity. By packaging creativity within a process format, designers were able to expand their engagement, impact, and sales inside the corporate world. Companies were comfortable and welcoming to Design Thinking because it was packaged as a process. There were many successes, but far too many more failures in this endeavor. Why? Companies absorbed the process of Design Thinking all too well, turning it into a linear, gated, by-the-book methodology that delivered, at best, incremental change and innovation.*
> (Nussbaum, 2011)

The project I co-created seeks to address the problem of a studio-based experience within a design-business degree in the following section through describing an attempt to both redress a perceived process-bias in design thinking while grappling with the question of what value a beaux arts tradition in design might offer business strategy in the early 21st Century.

Project 2, Understanding-through-making: building new dimensions in the new economy

Because strategic design is an emerging field and is inherently dynamic (evolving with changes in business conditions), the MS curriculum is re-evaluated and modified on an annual basis. In the late summer of 2017, I was tasked with leading a substantive re-write of three projects, designed to anchor three modules in a course called Strategic Design and Management (SDM) in New Economies. My instructions from former director Rhea Alexander, my co-author on this task, for was to retain and bolster the physical "making" components of the

three projects, keeping in mind that one of the unique (or at least distinctive) value propositions in MS-SDM was the engagement with a Parsons' perspective on studio-based [design] learning.

SDM New Economies is important in establishing the contextual and methodological basis for the subsequent three semester applied strategy and innovation work which is often, (though not exclusively), manifested, by students, within their "studios." Fig 1. shows this course in the context of the four-semester, two-year program, occurring as it does, in the first semester of the first year:

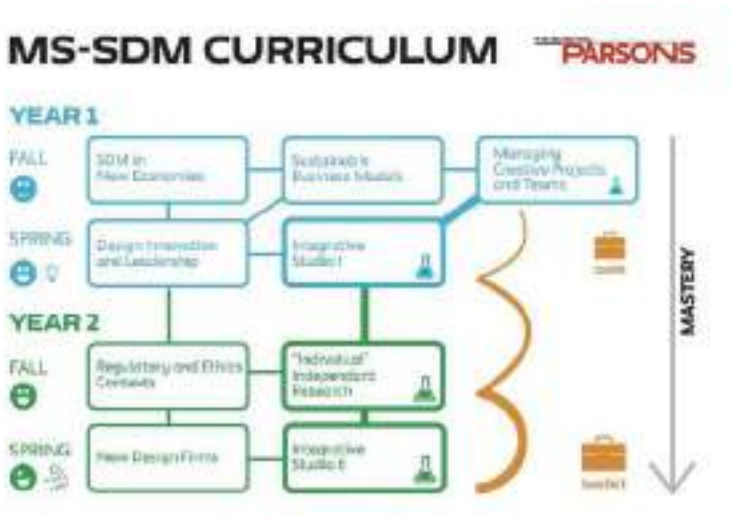

Fig 1. curricula diagram of MS-SDM developed by Rhea Alexander with assistance from Isabel Escobar in 2016 https://www.newschool.edu/parsons/masters-design-management/?show=program-curriculum

My response to this brief was to build upon an existing three-project arc, the emphasis of these three projects are summarized in the following table:

Table 1: The three-project structure in SDM New Economies, redesigned for fall semester, 2017

	Title	*Table heading*
Project 1	Mapping New Economies	Mapping in two-dimensions, using information visualization to communicate complex systems with interdependencies
Project 2	Understanding-through-making: building new dimensions in the new economy	Building models (for business and strategy) in physical three-dimensional form. Figuring out and testing these models using iterative making-thinking-interacting
Project 3	Design Frames and Heuristics	Written reflection on readings and how design tools might be used to address some of the issues raised in the readings. Generate your own game-based tool

Although this three-project structure corresponds to a specific learning progression in SDM New Economies, the single case I discuss here is Project 2: *Understanding-through-making: building new dimensions in the new economy* because this project was my clearest effort to engage with studio-based learning as a function of business modelling and design-inflected strategic business planning. The project brief addresses thinking-through-making by asking students "What bearing does an understanding of the dimensions of the physical world have on our ability to think, and act, in creative ways that may open up new insights[?]" The brief invokes Heidegger in his reflection on craft:

> *A cabinetmaker's apprentice, someone who is learning to build cabinets and the like, will serve as an example. His learning is not mere practice, to gain facility in the use of tools. Nor does he merely gather knowledge about the customary forms of the things he is to build. If he is to become a true cabinetmaker, he makes himself answer and respond above all to the different kinds of wood and to the shapes slumbering within wood—to wood as it enters into man's dwelling with all the hidden riches of its nature. In fact, this relatedness to wood is what maintains the whole craft. Without that relatedness, the craft will never be anything but empty busywork, any occupation with it will be determined exclusively by business concerns. (Heidegger, 1976)*

In the project brief I note that Heidegger contrasts this intelligent engagement with "empty busywork" that will be determined by "business concerns," and I speculate here (not in the brief) that lack of what Heidegger describes as "relatedness" may be have a connection to the "famine of good ideas" referred to by Boland and Collopy.

The case: Janet Hoy's Strategy Clock and Barometer

In fall 2018, Janet Hoy was an online student in my MS-SDM New Economies class, this course is offered in the first semester of the first year of a two-year program making Hoy, then a newly-admitted student. Hoy had spent two decades working since her undergraduate degree making her a more professionally experienced than the majority of her online cohorts. Her company, Janet and Co., currently provides project and design lead consulting on hotel projects internationally. Hoy is based in Sydney, Australia but also works extensively in Europe. For Project 2, it was Hoy's intention both to utilize her professional knowledge as a season project manager and to develop a model or tool that would help her to integrate—in a practical manner—the two hemispheres of her work as a consultant/project manager across the domains of what she describes as the "known" and the "unknown."

In Hoy's words she was "trying to create a tool that gives a framework to think through the challenges presented through having her feet in both more traditional cost/time/quality decision-making while simultaneously managing design teams and therefore engaging with the unknown [the design question] or the not-yet-created." (J. Hoy, personal communication, March 3, 2019). She used Project 2 to create a model, or tool to reconcile these two very different mental processes: traditional project management and designed/speculative (or abductive) practices. For Hoy, a key reading, and inspiration for this project was Nigel Cross' book Design Thinking: Understanding How Designers Think and Work of 2011, which, she says, gave her an "ah-ha moment" of recognition that she had always been involved with abductive reasoning but had experienced difficulties in communicating this aspect of her work to clients in a way that made sense in terms of their grasp of the project as-a-whole. Abductive reasoning is the logical process where one chooses a hypothesis that would best fit the given facts. Cross identified it as a process of inference in which "design develops innate abilities in solving real- world, ill-defined problems" (1982), Hoy identifies these in the right hemisphere of the barometer in Figure 2. below:

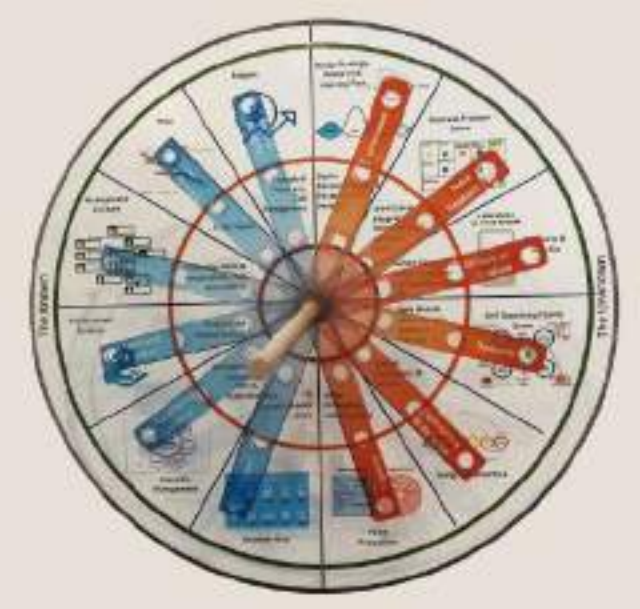

Fig 2. Janet Hoy's Strategy Barometer, 2018.

Hoy stated that abductive and designerly ways of working have frequently put her at odds with traditional project management thinking. In the course of her twenty plus-year career she points to The Project Management Body of Knowledge (PMBOK), a set of terminology and guidelines first published in 1996 by the Project Management Institute, as instigating a mindset she describes as increasingly process-oriented and ever-decreasingly holistic. Hoy's process for making her barometer began with rough prototypes. Hoy stated that she "started by looking at the barometer an instrument for measuring the outside environmental conditions; an idea that can be applied to a project's environmental contexts and conditions." Her barometer has a sliding scale which can be articulated along multiple axes. In her articulation of the known/unknown hemispheres, Hoy's barometer could be compared to a colour wheel in which complementary pairs (of colour) sit on opposite sides of the wheel. These pairings of oppositions (or complements) can be seen in the table below:

Table 1: shows Hoy's oppositional pairings from her barometer, see Fig 2

"Known" hemisphere	*"Unknown" hemisphere*
Budgets	Value proposition
Time (Gantt charts)	Design increments (sprints etc.)
Management structure	Self-organizing teams (scrums etc.)
Products and services	Solutions and benefits
Scientific management	Business problem space
Business plan	Design strategy research and learning plan

Hoy designed her barometer to be used with Plexiglas sticks, each of these corresponded with one of the six oppositional pairings and these were intended to allow the user to play with and reflect upon and then represent the intensity of each aspect of given project in terms of both domain and intensity along the known-to-unknown axis. Blue is more known while the red end of the spectrum is more unknown (e.g., established business vs. new venture), see Fig 3. below:

Fig 3. demonstrates varied intensity along three axes within a single aspect of a project

As she began real-world testing of the barometer, Hoy realized that her own project management experience made the barometer less useful in her client interactions. She felt it was too complicated and somewhat self-evident (to her). Application of the barometer however, enabled her to develop the Strategy Clock; a simpler schema which allowed her to try to hone in on the broader implications of where the value she is creating is derived from. Key attributes of the clock are the same two hemispheres: known and unknown, Hoy states that a stick is chosen on the scale depending on the characteristic it represents which then is placed on clock relative to the management tool or approach that would best manage that project characteristic. See Fig. 4:

Fig 4. Shows Hoy's more simplified Strategy Clock, in this configuration, Hoy states that the clock "Keeps it simple. The hands on the clock face indicate current team focus e.g., this clock shows our current focus is on design research and learning which will be done with our design team through quick sprints over the next month. Concurrently our operations team are establishing our delivery capability by looking at our overall organizational structure."

Hoy elaborates, the face of the clock orients you in relation to the two hemispheres broadly. Then more specifically, it allows you to prioritize your immediate project actions. The clock is your first stop, whereas the barometer is a subtler and more complex tool. As an experienced project manager, Hoy believes that the barometer may be more useful in assisting a junior-level employee, believing it to be overly complex and perhaps of peripheral value (to her) compared with the clock, which, in contrast, "allows the user to locate themselves and then dig deeper in a more focused manner." Hoy generally uses her model indirectly, that is, she generally interfaces with CEOs and founders, therefore the clock "has not been used to build team consensus but rather to formulate her thoughts and understand and create her consulting value via the framework before communicating it to clients." For example, if there is an issue with formulating a global team for a specific project, Hoy may use the model to elicit a recommendation. She does however think it may have value in teambuilding and understanding and focusing collective intent and action.

Summary and next steps

I chose Hoy's Project 2 for this case from a variety of interesting models developed in both this and a concurrent on-campus version of the same course I taught this past fall. I sought out Hoy's work for this case because she almost immediately began beta-testing her model-as-tool in a consulting context, and, in fact, had used the heuristic of client relevance to develop the clock from the initial barometer design. As a new student in the course, Hoy's recognition that her model could be immediately deployed was somewhat of a revelation to her but I believe her success in initial implementation and testing was partly due to her prior professional experience and this rapid real-world deployment, is, at the time of writing, the exception rather than the rule with these class cohorts and their projects.

Project 2 helped Hoy in shifting her own mindset about the role of design in her business as much as it provided specific practical guidance; she stated to me that "the design process of learning-by-doing has been huge in her process and has helped to transform her business currently and her future strategy for the direction of the business."

The case I present here provides one practical example for how one business use of design thinking may evolve and it indicates what a beaux arts pedagogy—fused with a business education—may uniquely offer. Specifically, the case points the way toward achieving two pedagogical objectives that have been partially achieved through Project 2 thus far:

- Encouraging students to be the makers (as well as the users) of strategy tools;
- encouraging students to develop and test models, tools, maps, methodologies etc. using a thinking-through-making heuristic rather than a pre-determined abstract framework that lends itself to a process-understanding of a given business problem.
  My next steps as an educator are to better articulate and more deeply embed characteristics of thinking-through-making (from my education and practice in fine art) into projects supporting the creation of new tools, methods and frameworks in business education broadly and specifically in design strategy. I aim to investigate whether, and how, these tools may scale and work in practice, within a variety of applied business and consulting contexts.

Research Perspectives IN THE ERA OF Transformations

Managing Vulnerability and Uncertainty: Developing design competencies within an American healthcare non-profit

ALEXANDER Rhea; JONES Sarah and MYSORE Vinay Kumar*

The New School, USA
* mysov916@newschool.edu
doi: 10.33114/adim.2019.c04.139

This case study explores building design competencies and a design-driven organizational culture within an American healthcare non-profit. With a staff are primarily from the healthcare space, as well as some in banking and sales, we look at how the staff has adapted to working within a design-driven organization. By applying iterative design methods and embracing innovation and uncertainty we observe how the organization's founder has helped guide team members through a process of discomfort and vulnerability within an experimentally-driven and human-centered organization.Using interviews with employees and the founder at various points in new employee on-boarding processes we chart a transformational arc over six months. The learnings to share include both the universal and the particular: what are the core competencies to develop in all organizational members, and what are the specific and different ways competencies can take form. From building explicitly shared languages to facilitated sensemaking this case study offers an opportunity to share new and developing practices for embedding design-driven innovation and management practices in new fields and contexts.

Context & Problem/Opportunity Area

Parkinson & Movement Disorder Alliance, PMDalliance, offers opportunities for people impacted by Parkinson's and other movement disorders to learn, live more fully and connect to a support community by including the often neglected spouse or loved one that is the primary caregiver, support group leaders and adult children. Through an inclusive, human-centered design approach, they fill a gap in the American healthcare system, by addressing the needs of caregivers providing critical opportunities for connection, support, and community. Their business model is a non-profit service and network. Facilitating workshops and meetups for the groups they serve, PMDAlliance offers not only an opportunity to connect with others in similar situations but an opportunity to learn management tools and coping mechanisms to help them better manage their responsibilities and quality of life. They also offer emotional support opportunities for self-care for caregivers an often neglected group that suffer alongside the afflicted. PMDalliance's staff is distributed, with team members operating from different parts of the country who travel to other parts of the U.S. to help support PMDAlliance activation hubs.

Design-driven practices are critical to PMDalliance's success. By regularly attending to the needs of their constituents, PMDAlliance continues to innovate and prototype new approaches. In the words of their founder, Sarah Jones: "Our prototypes are our programs." PMDAlliance relies on this model to ensure that they consistently can deliver value to members, nimbly and with low overhead. Team members need to be adaptive, quick-footed, emotionally available to hear unmet needs, and able to operate within uncertainty and ambiguity as they continually test, learn, assess the impact and try again to improve.

This process is all within the context of highly rigid and structured medical and healthcare systems. With a staff all trained outside the design field, including healthcare backgrounds, team members come in with high comfort for rules, and familiarity with approaches grounded in didactic, non-user centered methods, typically framed in the language of 'best practices. While often viewed as a design opportunity, many interventions are limited to realms of physical space and equipment, and not addressing underlying cultural norms at play (Bown et al, 2010). While strategic design could be seen as a point of high leverage, to date its impact has been somewhat limited (Taylor et al, 2011).

The three authors connected through Parsons ELab, a design-driven academic incubator at The New School. The founder of PMDAlliance, a contributing author, was a 2016 Fellow, and the remaining two authors at Parsons ELab, including its founder, have been advisors and mentors to her work since then. The authors are drawn to collaborate in this case study because of its application in extending of design into new fields. They find the approach of PMDAlliance, and its focus on the underlying mental models and emotional competencies necessary for design innovation to be novel and generalizable to other similar organizations.

This case study explores the ways by which PMDAlliance, through their hiring and onboarding process, help facilitate the development of designerly competencies, comfort within the design process, and embed design-driven innovation throughout their organization.

Narrative

PMDAlliance views their goal as having new team members able to facilitate a conference within 4-6 months of joining. This goal is seen as the culmination of an onboarding process steeped in a designerly approach that begins with the pre-hiring phase. (see figure 1, PMDAlliances Roadmap for Onboarding)

Figure 1: PMDAlliances Roadmap for Onboarding and Design Training. Source: PMDAlliance

Potential employees for PMDAlliance are screened and interviewed, but also are assessed on their ability to complete a values and position based exercise in the second round and an interactive project brief in the third round. These tests are not just about competency, but more for the ways, they can assess potential employees' openness to risk-taking, capacity to engage in vulnerable work and empathically engage with PMDAlliance members. An example might be a project brief around a new artifact to help support a member, but also simulated communications with members. These soft skill assessments are PMDalliance's way of understanding if there is good culture fit, and also if there is potential to develop, within these non-designers, the designerly competencies needed to be a self-starting innovator within PMDAlliance's distributed network model.

Once hired, a critical artifact given out in the onboarding process is their ecosystem map. Developing a systems-level understanding of the interdependencies within the lives of those impacted by Parkinson's and

other muscular disorders, their caregivers, support networks and touchpoints throughout the health and medical system. This map is used as an anchor for staff and members. This phase is the initial 'knowledge transfer' phase of the on-boarding process. Formally, it takes place over a 2-week process, with once per day lessons and introductions to the variety of tools and operational practices of the organization (see figure 2, PMDAlliance Support Ecosystem Map).

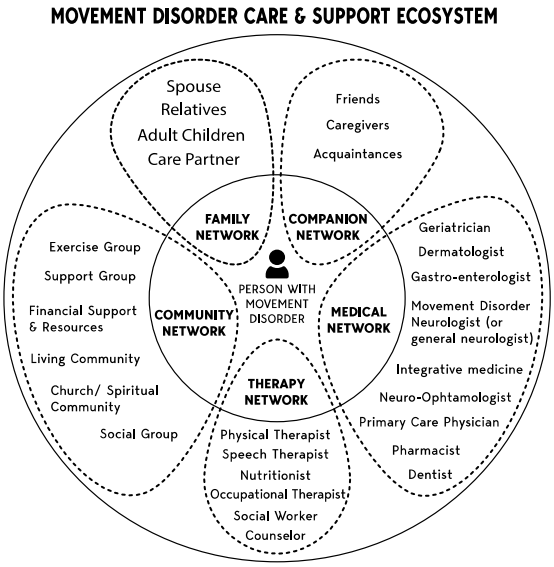

Figure 2: PMDAlliance Movement Disorder Care and Support Ecosystem. Source: PMDAlliance

One design-driven skill at the core of the PMDalliance process is empathy. Empathy not only is a critical person-to-person service skill that builds trust for the organization, but also a foundational skill for other competencies, including design research and also for building comfort with vulnerability and uncertainty as members constantly prototype and test new models of service delivery.

Empathy begins with personal storytelling and modeling from within the entire organization. Staff share and show their own vulnerability, and engage in open and honest discussions about where they are in their own lives during their quarterly meetups, zoom video meetings and even their day-to-day communications over Voxer. They share videos and readings, from Brene Brown and her writing on vulnerability and openness to enneagrams as models of behavioural motivations to help build confidence, comfort, and attentiveness to their own emotional states in preparation for, and as part of the work, they do with others. Crucially this is modeled from the beginning of employees interactions with PMDAlliance, so by the end of this 2-week on-boarding process, they are immersed and enmeshed in a culture that values and prioritizes emotional attunement and intelligence.

From here, curriculums become more personalized and individualized based on the needs and capacities of each member of the team.

One element that all team members will engage in is design research. Typically taking the form of fly-on-the-wall observations and design ethnography, new members are instructed to undertake their own process of discovery. This research is a facilitated learning experience. After observation of a support group, PMDAlliance will debrief with the new team member, discussing observations and understanding key takeaways. This process of facilitated research allows for new members to slowly build a more embodied sense of what PMDalliances' work truly entails, and allows the team to understand and see where their new hire is struggling and thriving. This reflection also begins a practice of deep listening, as they guide new hires into understanding the underlying pain points being expressed by participants and helps build intuition and skill to identify and start creating design hypotheses around the needs of PMDalliance's constituents.

If a particular challenge is emerging, Sarah and the team may use other design research methods to help new members. One example was a new hire struggling with the lack of clear directives and operating procedures for each conference and event. PMDAlliance needs to be nimble and reactive to the needs of its constituents, but this member, a former healthcare (Director of Surgical Services) professional, continued to express deep

discomfort with this approach. Using analogous research to surgery department operations, wherein the best-laid plans of the morning are scuttled within minutes, their team member had an 'aha!' moment. The use of analogous research, this time in a context more familiar to the team member, facilitated discovery and development of competency and capacity within the new hire and helped bring them along this journey of becoming a more design-driven practitioner in PMDalliance's work.

The second element that needs to be developed, and draws from the combination of vulnerability and empathy work started on day one, with the facilitated design research and discovery process, is a capacity to prototype. Prototyping involves being able to identify unmet needs, combining the observation skills of design research with the emotional attunement to meet their constituents. It also involves a belief in one's own skills and a comfort with discomfort and uncertainty as not all prototypes can succeed. In a caregiving environment and context, there is much discomfort with possibly failing, and prototyping necessitates both an emotional and practical element of facilitation.

For PMDAlliance, testing is an existential necessity. It is continuously in an experimental state, iterating endlessly, and also evaluating the efficacy of its work. Prototyping is how they build and develop programs. There are no scripts or similar organizations for the kind of work PMDalliance does, and that means that they must continuously be in dialogue and engagement with participants in order to serve their community best.

By building these successive competencies, PMDalliance arrives at their target goal, which is a hosting or facilitation of an event by a new hire within 4-6 months. For employees to do so, requires many operational and organizational competencies. They must be able to manage the event logistics, and deliver on critical parts of the PMDalliance experience. They will need to appropriately document, track and report on the event using the variety of platforms that PMDAlliance uses in their operations.

However, it also demands numerous designerly competencies. They must be attentive, aware, and attuned to their own emotional needs and the needs of those around them. As care partners and support group leaders share their personal stories and seek support within this community, the new team member must be able to meet them emphatically and empathetically at their level. They need to pair that capacity with a design research lens allowing them to identify opportunities for alternative methods. They need a caring vision in order to see where PMDAlliance could be offering more, and how exactly it helps. These then must also be combined with a capacity and familiarity with a prototyping process and iterative mindset. They must be able to adjust quickly, find new ways of testing new possibilities, and embrace the uncertainty and risk involved in that process. They must be able to test nimbly and learn quickly, and embody the kind of agile approach that PMDalliance uses as the foundation of its value proposition.

Key Learnings

PMDAlliance's experience of developing design-competencies maps the second arc of capacity building and transformation in the onboarding of new employees. They show how a facilitated design-education process can help build critical competencies and an organizational competitive advantage for, in this case, a distributed not-for-profit.

Within a healthcare system that struggles with innovation, PMDAlliance's approach is exciting and promising. Their success in building high-level design competencies and a design-driven innovation mindset within their team highlights an opportunity for other healthcare organizations. As the call for a more human-centered approach to healthcare continues to be heard, they offer a practical study on how to address the underlying human and cultural problem in the implementation of design innovation.

A key learning for the authors are the many subtle ways that these competencies are developed. As opposed to a singular process, the journey of each employee is distinct, with its own educational inflection points. It is notable that as opposed to experiencing a series of design workshops or design sprints, these competencies were developed through a more collaborative and coached model of education.

The authors observe that an approach grounded in a design research and empathy development process could allow for a more bottoms-up approach to developing design capacity within organizations. By creating mechanisms and opportunities for staff to safely practice design as a form of learning and doing, teams have the space for growing a design approach that is reflective of, and responsive to, the needs of the team and organization.

In many sectors, and particularly in healthcare, calls for innovation are often heard and left unaddressed. This case study begins to look at ways to approach the underlying mental models within the practice of healthcare and suggests ways by which design processes can themselves help transition an organization to become more design-driven in its practices. A process that builds comfort with uncertainty and vulnerability and that creates space for prototyping and testing, can help build a muscle and capacity for design innovation. Such approaches must be contextualized for the specific work being done by the organization, by the individual and by the competencies and capacities of all participants involved. That said, the authors believe that the core principles that are exposed through this case study offer avenues for other organizations to find similar success in bridging design innovation and management in challenging and novel sectors of the new economy.

Research Perspectives IN THE ERA OF Transformations

Transitioning Business for a Circular Economy

EVANS Susan

Hong Kong Polytechnic University, Hong Kong
susan.evans@connect.polyu.hk
doi: 10.33114/adim.2019.c05.137

This case study explores the strategic business opportunities, for Lane Crawford, an iconic luxury department store, to transition in a circular economy towards sustainability. A new experimentation framework was developed and conducted among cross departmental employees, during a Design Lab, with intention to co-create novel Circular Economy business concepts towards a new vision: the later was a reframe of the old system based on the principles of sustainability; to move beyond a linear operational model towards a circular economy that can contribute to a regenerative society. This work draws on both academic and professional experience and was conducted through professional practice. It was found that innovative co-created concepts, output from the Design Lab, can create radical change in a circular economy that is holistically beneficial and financially viable; looking forward to extract greater value a)Internal organization requires remodeling to transform towards a circular economy; b)Requirement for more horizonal teams across departments vs solely vertical; c)New language and relationships are required to be able to transition towards a circular economy; d)Some form of physical and virtual space requirements, for cross-disciplinary teams to come together to co-create; e)Ability to iterate, learn and evolve requires agency across the business

Keywords: Experimentation, Design for Sustainability, Circular-Economy, Business-Transformation, Methodological-Framework

Context and opportunity area

The circular economy model continues to gain attention from global companies (Lewandowski, 2016), yet a recent report, by (PACE, 2019), identified that the linear economy is 'baked in' to the global economy, only 9% is circular, and that progress towards sustainability is in reverse.

From the perspective of business transformation in a circular economy there is a gap in tools and methods as while "Sustainable business model innovation is an emerging topic, … only few tools are currently available to assist companies in sustainable business modelling" (Geissdoerfer, Bocken, & Hultink, 2016) and "To date few if any processes for sustainable and circular business model experimentation have been developed" (Bocken, Schuit, & Kraaijenhagen 2018).

The economic paradigm is shifting, thought to happen at times of revolutionary development, with significant changes in societal and business values, and interrupt periods of continuity, as first discussed by Kuhn (Shapere, 1964); Brand & Rocchi (2011) and Gardien, Djajadiningrat, Hummels and Brombacher (2014) discuss the change to the future economy as the transformation economy.

With paradigm shifts come changes in design processes, methods and tools (Gardien, 2014). The latter argues that by adapting to the new paradigms 'will allow companies to extract more value from the marketplace'. There are four paradigms, spanning from the 1950's to the future, defined by people and business mindsets,

each with a specific economic driver, namely, 1) the industrial economy (mass production), 2) Experience economy (marketing and branding), 3) Knowledge economy (knowledge platforms) 4) Transformation economy (value networks). This study leverages the research method types of the transformation economy described as 'Empathic, in-context experimentation and data collection through living labs', (Gardien, 2014), whereby the design deliverable is imagined to fit beyond the needs of the individual to include society and planet, suggesting that design processes may take place in a circular economy for sustainability.

This case study aims to explore, through the use of action research and a systems and design thinking approach, (The Design Lab), a new methodological framework to co-create novel business concepts to radically change business practices in a circular economy that can be implemented in a business circular economy experiment in the form of a living lab.

Circular economy

The circular economy is used as it presents a 'more targeted focus on resource-related issues to facilitate experimentation' (Bocken, 2018) and contributes to sustainability (Mentink 2014). It was first introduced by Stahel and Reday (1981) as a way to minimize resources impacts, wastes, emissions, energy use and energy loss by slowing, closing and narrowing materials and energy loops. In this way regenerative loops aim to create, Innovation opportunity, Job creation, Economic competitiveness, Resource savings, Waste prevention. There are now various frameworks that highlight the opportunities and ways to integrate and evaluate circular economy concepts, all with their roots in the earlier work of Stahel et al., (1981), built on the looped system theory, these include Resolve (Ellen-MacArthur-Foundation, 2015) and the work by Van Renswoude, Wolde and Joustra (2015) and Laubscher and Merinelli (Lewandowski 2014). Most recently the work of Lüdeke-Freund, Gold, & Bocken (2019) proposes a framework for circular economy business model (CEBM) development, drawn from an assessment of literature of 26 published circular economy business models (CEBM). The framework relates six CEBM patterns, with four design strategies and links the different strategies back to the key circular economy resource strategies of slowing and closing; and value strategies of retain product and material value.

This work is situated at the 'upfront end', of the design process, (Sanders & Stappers, 2008) uses co-creation, through experimentation (Hall, 2011) and in this way, informs and inspires exploration of an open ended question and addresses fundamental and radical challenges, beyond the cutting edge (Hall 2011) to innovate new business concepts in a circular economy. The latter will have wider impacts on the eco-system and so, ideation is initiated through a holistic sustainability lens (Boons & Lüdeke-Freund, 2013) to enable reflection (Schon 1983) on the consequences of any intervention on the system (Cross 1972). Co-create is used as embraced by sustainable development to increase efficacy of interventions (Bell, 2012).

This case study builds on and contributes to the discussion of strategic design methods, tools and processes to transition business from the linear economy to the circular economy; through the exploration of a new methodological framework to co-create, with transdisciplinary dialogues (Banerjee 2008); (Stock & Burton 2011), that seek to propose new business opportunities beyond the leading edge, that can evolve technologies, markets, user expectations and behaviours (Hall 2011) in a circular economy for sustainability (Stegall, 2006). Output concepts are implemented into the business eco-system, the living lab, among suppliers, other stakeholders, customers and employees for experimentation.

The context: Lane Crawford - Iconic Luxury Department Store

Lane Crawford department stores are located in Asia. Awareness and commitment from senior management to transition towards responsible business in a circular economy for sustainability. This company relates most clearly to Paradigm 2,(Brand et al., 2011), 'The Experience Economy', such that the business economic driver, is 'marketing and branding' and the business focus is 'brand experience'. This can be observed both, externally, from the offer that is heavily invested in the physical, an integral and tangible brand touch point; the brands and messaging, and internally from the company operational and siloed set up and the way interactions are organised across the eco-system.

The competitive landscape is fierce and includes well-funded digital first companies and start-ups, such as Net-a-Porter, for example, that tend to operate in paradigm four, the transformation economy; as their technology advances so company learning and iteration accelerate due to leveraging the research and tools of paradigm 4; that includes the use of Living Labs 'which involves users as co-creators and enables

experimentation in real-world settings' (Almirall, 2011). Development is amplified by exponential growth in processing speeds as given by Moore's Law and grounded in the lean start-up methodology (Ries 2011).

By comparison the approaches used in Paradigm 2, operate on much longer developmental time frames and rely on limiting research methods. It is complicated and difficult to transfer from an earlier economic paradigm to another "companies that grew up in an earlier paradigm risk being bogged down by an outdated mindset and ways of working" Gardien et al., 2014, p.137).

Strategically, over the past 18 months, the senior management set new purpose, principles and values with business goals. The latter are aligned with two key global themes as identified by the Sustainable Development Goals (SDG's) one of which targets waste (Figure 1). Measurements for KPI's are in progress and currently driven by specifics from individual projects.

The case study discussed in this paper is the first prototype project to systematically address a move towards a circular business economy with intention to change behaviours and measure impact. To initialize and test this type of change a specific and bounded, controlled event was set up and measured by the internal team. In this way a business experimentation was set up with its employees, including relationships with other stakeholders and their users, over a controlled time period with specific changes.

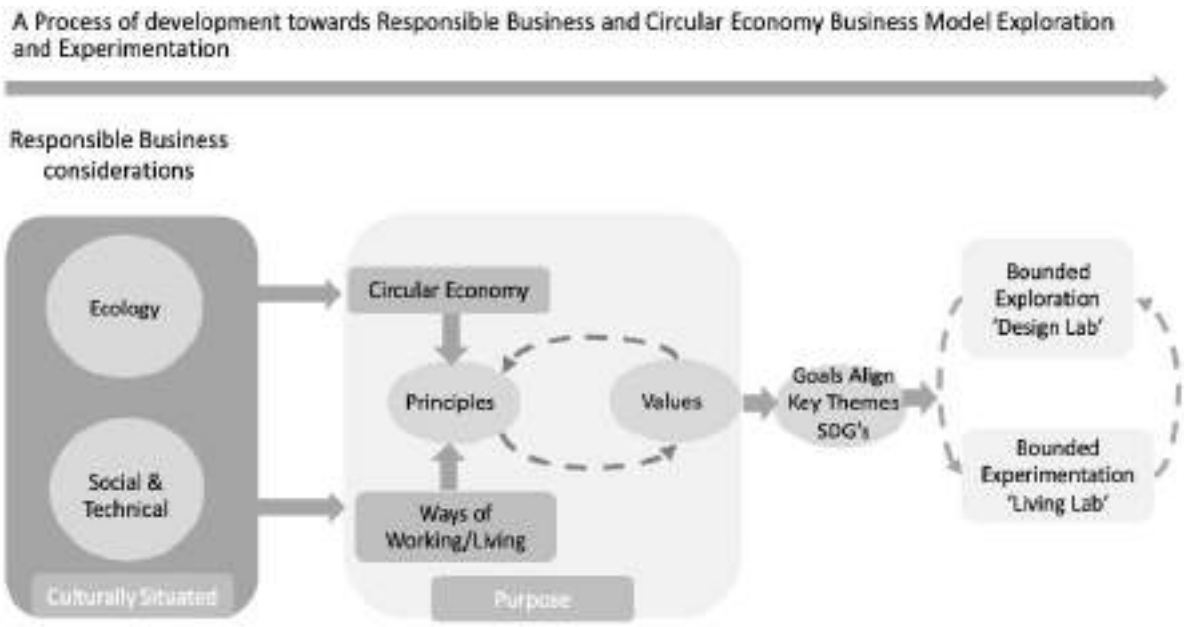

Figure 1: *A Process of development towards Responsible Business and Circular Economy Business Model Exploration and Experimentation*

The Narrative

This research was conducted with the belief that a diverse group of eco-system business stakeholders in a design led co-create environment, using the new methodological framework, could innovate viable, desirable and feasible business concepts in a circular economy.

The research question proposed to kick off the Design lab was 'How might we design responsible Christmas packaging and retain our excellence and luxury offer in a circular economy?

A three-hour Design Lab was conducted among a diverse group of eco-system stakeholders including, store management, communications, design, brand strategy, technology and academia who are involved with the organization and contributions to the implementation and outcomes of the research; to co-create novel concepts that can radically change the business eco-system in a circular economy.

It should be noted that the time frame was extremely short to implement this first experiment in a circular economy, such that concepts moved forward were believed to be feasible in the time frame.

The new methodological framework

The methodological framework (Figure 2) has been developed with intention to explore, support and accelerate novel business and systems scenarios in a circular economy using co-create and a systems and design thinking approach. It has drawn on the behavioural change work of (Dolan, 2012) with intension to change the context from which participants tackle the challenge to raise automatic behavioural responses in a circular economy: specifically resetting norms, raising salience in the potential of the challenge and in this way priming participants prior to co-creation. The work of Schon (1983/4) is leveraged such that the visionary view is changed and, in this way, encourages participants to co-create towards a circular economy rather than the established norm of a linear model.

The framework consists of three parts, namely, Empathize, Ideate and synthesize; the first phase,

Empathize phase, has intention to change the context, through which participants consider the norm, moving their perspective from a linear business model to a circular business model, using a future novel vision, case studies, and facts and in this way changes the context and sets the challenge.

- An alternative supply chain visual is created in several steps; the first considers the core principles of the circular economy (Lewandowski, 2016); secondly social impacts (Boon et al., 2013) and thirdly the concept of data usage. This acts to change the context (Dolan et al., 2012), the norm and so shift the view of the problem with intension for participants to consider alternative solutions (Schon 1983).
- Case studies included leading packaging examples that use renewable resources, non-toxic, design led products to design out waste and design in regenerative behaviours.
- Facts: Included: Relevant changes in policy that fundamentally change the flow of waste and so resources in a production and supply chain, current local and regional facts, State and user perspectives, global goals as defined by the SDG's in the area of consideration.

The second phase, Ideation, invites participants grouped in teams representative from diverse departments, to strategically design concepts that meet the challenge by re-considering, through a holistic and new view the eco-system and supply chain. This allows the co-ideation of new narratives and potential futures in a circular economy.

- Conversation mapping is used at the early stage of a co-create design process as it enables many new themes, through capturing plurality (Fry 2010).
- This is followed by future scenario planning that uses a visual plotting method to identify the business strengths and weaknesses of various new concepts using qualities of desirability (what users want), Feasibility (what is technologically possible) and viability (what is financially possible).

The final phase, Synthesize, summarizes the themes and through decision making dialogues aided by the soft system tools, the team progresses to create conceptual future narratives within the system of interest; with greater clarity of how and what might be and so set project goals the team believes are achievable.

- Participants individually created their own Root definition using the given format as presented as: How might we *(problem to solve*) through/by (*doing something*) so that (*we create an impactful outcome*)?
- Pairwise analysis is conducted, and the top definitions were reconsidered.
- Following this exercise, a stakeholder responsibility road map is created.

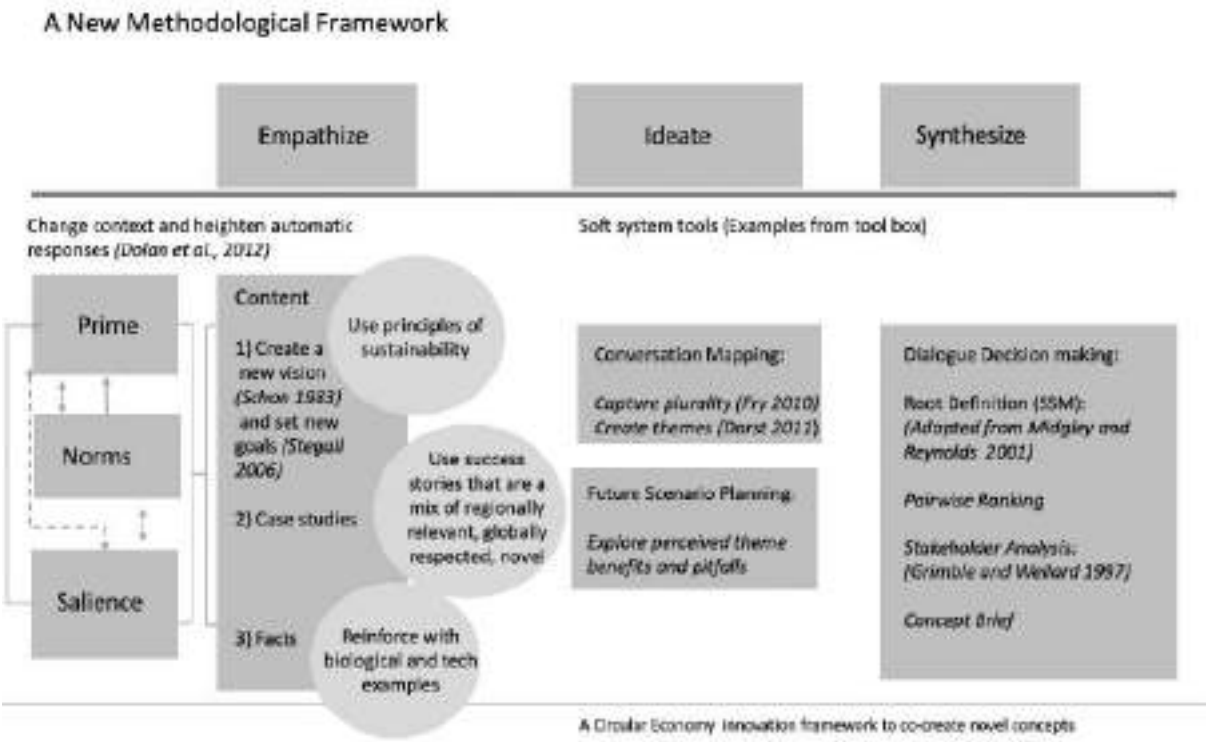

Figure 2: A New Methodological Framework – A Circular Economy Innovation Framework to Co-create Novel Concepts

Key Learnings

Findings from the Design Lab

Overall, we can say that the participants in the Design Lab, using the new methodological framework were able to co-create many innovative business concepts (Sanders et al., 2008) from a different context and view in a circular economy (Dolan et al., 2012); (Schon 1983).

In the following section the concept findings are discussed using an evaluation framework adopted from the Resolve framework (Ellen-MacArthur-Foundation, 2015) with additions from the work of Laubscher and Merinelli (Lewandowski 2015).

Outcomes: These are the first and immediate steps taken to change the Christmas packaging in a circular economy as made during the 2018/2019 season.

Regenerate*:* 'Focuses on the use of renewable energy and materials'. Participants recognized the issues with their product in terms of its non-renewable materials and toxic pollutants prior to the design lab. This contribution was further explored and expanded to understand the full lifecycle and what happens in the afterlife; after use. From this reflection, mixed materials were brought to the forefront as an issue for recycling and so significantly more likely to keep the products in a linear system; also, the lack of infrastructure locally to aptly process biodegradable products led to further thought on how to better manage the product after-use. In turn this led to further discussion and a build through exploration of what can happen further up the chain to reduce materials entering into the system?

Beyond Christmas packaging dialogues explored the increase in packaging due to their online sales and delivery, this provided wider opportunity to redesign packaging for online sales.

Action taken:

- Redesign of Christmas packaging and for online purchases
- Renewable and non-toxic supply chain for packaging
- Removal of mixed materials
- Ongoing discussions on how to better manage after-life

Share: 'Maximize utilization of products through share'. As part of the full lifecycle and extended life of a designed product, seasonal holiday boxes were viewed as limiting for their desirability to re-use due to their colour.

Action taken:

- The team changed the colour as they believed that a more neutral colour would allow for the box to be re-used given its quality, durability and aesthetics.
- Secondly, old stock was donated to local schools for a specific Christmas project.

Optimize: 'Aim to increase performance/efficiency and remove waste'. Once the teams focused on waste, they realized that there were some habits that were consistent and frequent that led to high volumes of waste that could be addressed prior to materials and resources entering the system, for example: double or triple bagging goods; or customers asking for extra wrapping papers and accessories; double use of tissue paper for perceived greater aesthetic effect. Strategies were developed to address minimizing unnecessary product entering into the system with consideration for various relationships, such as, clients, staff usage and also beyond into other types of products, curtesy umbrellas for example. All of which add to inputs to the circular economy loop, energy and resources and potential outputs in terms of waste and again energy to address end of lifecycle.

Action taken:

- New informed strategy and road-show to inform staff of new positioning packaging and perspective on packaging and its contribution to healthier life (self, family, community and planet)

Loop: 'Retain materials and components in the system'. Until now all materials and products were sent to landfill. Raised consciousness on the lack of infrastructure to process appropriately in a circular system

Action taken:

- The team is exploring ways to recover and increase likelihood that biodegradeable products can be treated appropriately so that after use product can naturally biodegrade and so contribute to regenerative systems.

Exchange: 'Replace old items with new technologies'. At the customer level the offer and service experience changes between the customer and the staff. The staff and customer are more actively involved in the transaction. The customer at the moment when interfacing with the sales and packaging staff will actively make a decision based on some new information (Mentink 2014).

Action taken:

- New micro-systems put into place to deliver on new processes and relationships. New language, new considerations, new meaning.

Building trusted partnerships: From the perspective of the team these changes will be exploratory and iterative, the effects will disrupt the eco-system so collaboration and trust to ensure that these changes can be optimized is key

Action taken:

- Changed packaging processes and materials, required new learning and practical applications to use materials that are less agile and less convenient for packaging purposes at time of packing and take longer to apply. Team managed disruption in the eco-system supported by trusted relationships and belief in the purpose stakeholders moved through discomfort and arrived at a circular economy solution.

Incentives and capabilities: Incentives are in discussion with intension to align with responsible business practices and a strategic move towards a circular economy and sustainability. Capabilities there are beginnings of practice and experimentation internally. This Is a time, people, budget balance

Action taken:

- Learning is continually taking place and with this comes iterations.

Participants had short term deadlines to meet and were able to use the scenario planning tools to identify concepts that they felt they could make happen in a relatively short time space. This was based on the ability to collaborate seamlessly and to roll out the road map as they had planned during the synthesize session.

The CEBM according to the framework , Lüdeke-Freund et al., (2019 p54), can be said to place emphasis on a CEBM pattern of 'Recycling'; and a design strategy of 'Design for biological cycles (using biological nutrients e.g., organic, plant-based materials)': a change in material ingredients to improve the potential of recycling, cascading and organic feedstock that can lead to closing loops.

The challenge space to move forward was set by the participants:

'How might we design responsible Christmas packaging, retain our excellence and luxury offer by exploring opportunities among our customers, staff and supply chain to reduce consumption of paper bag and wrapping by 30%, average per customer sale, over the Christmas 2018/2019 compared with 2017/2018.'

Follow up

Following the Design Lab activities further work was conducted on viability to implement biodegradable packaging materials. It was calculated that a 12% reduction in packaging materials, as compared with previous year, would be needed to balance investment in the change. With this knowledge and an absolute minimum goal for change in packaging entering into the system, the project was established, and first steps were made towards a CEBM.

The transition was accomplished over the Christmas period 2018/19. Early feedback indicates that key goals to reduce packaging entering into the eco-system and financial targets were met a) financially accounts were balanced (key to the continuation of this project and next projects) by creatively and strategically reducing resources entering into the system (in the form of packaging) this reduced financial outgoings to compensate for the added financial outgoings associated with a change to renewable and non-toxic resources, materials and production b) Messaging represented a paradigm four value proposition that is appealing to social leaders (beyond the individual inclusive of social and environmental); c) staff were motivated and enthused to be involved in this project d) An alignment with global as well as local goals added more weight to the necessity to act e) the project was highly desirable with real purpose and goals that highlighted the consequences for their personal lives and those of the people around them as expressed by one of the team leaders as "doing something meaningful" f) general raising of consciousness on waste and its impacts throughout the business.

Gaps in the system

Lack of systems technology that can accelerate decision making processes based on circular economy (systems) changes. Operates mostly in paradigm two The Experience Economy: complicated to gain decision making information and takes time as this involves a process of contacting various departments to access data that can then be assessed.

Discussion

We can say that the methodological framework was successful. It aimed through the empathize stage to reset the context, by priming participants, resetting norms and raising salience in the challenge space. The outcomes demonstrated that participants switched thinking into a new context (Dolan et al., 2012) co-creating ideas from a different view in a circular economy (Schon 1983). Participants were able to co-create many innovative concepts (Sanders & Stappers, 2008) that expanded scope and implementation opportunities to apply circular economy practices (Ellen-MacArthur-Foundation, 2015).

During the Design Lab, an introduction to the principles of the circular economy, a wider view of the eco-system and supply chain participants opened up to a greater number of opportunities for circular economy business practices.

Participants considered the full lifecycle from upfront design aspects through to the long cycle which extends the lifetime of existing products and processes (Van Renswoude et al., 2015); (Lewandowski, 2016) and considered reverse logistics and creating relationships with other companies and customers to assure closing of material loops (Mentink 2014). In this way the value proposition, delivery, creation and capture of the CEBM (Lüdeke-Freund et al., 2019), for experimentation in the living lab, was explored through Design Lab dialogues, reflections and the narrative creation of potential Circular economy business concepts.

Finally, the teams settled on changes that they believed they could make in the short term which could have significant impacts on reducing waste, toxic materials, pollution and production as associated with their packaging offer.

Technology

This first step and accomplished change to the supply system represents a fundamental and successful step for a traditional company that is baked in an earlier economical paradigm. It is evident from the process needed to collect and assess KPI data that technology on many levels is not available. Improvements can be made to support measurement of, flow, quantity and types, of materials; the customer and staff feedback systems; the relationships between customers, suppliers and other system influencers, with staff. Reflection on this specific project and how data could be captured and turned into decision making knowledge, relevant to users, staff, suppliers, quantity for example, that can promote better relationships through more informed interfaces and can give guidance for development and for further research using paradigm four methods.

Conclusions

This case study was conducted with Lane Crawford and found that novel, viable, feasible and desirable, concepts co-created in a circular economy, among a diverse group of stakeholders, using a new methodological framework, were able to radically change the specified eco-system from linear to circular practices through experimentation in a living lab. Further, that a shift in thinking happens through use of the new methodological framework such that a greater number of eco-system opportunities in a circular economy are opened up once participants start to view the system differently.

Early feedback from Living Lab Experimentation indicates financial costs associated with changes to materials and products in the system were balanced through creative strategic tactics to reduce materials and energy entering into the system such that both financial and reduction of waste goals were achieved; meaning no extra cost to Lane Crawford with circular economy benefits. It was found that a) the business rallied around the concept and purpose of change; b) a transformational economy positioning was found to be highly desirable by staff and stakeholders; c) the message and action raised behavioural consciousness around waste and materials; d) amplified beyond the specific business goals.

Forward looking: to support further change, Internal organization requires remodeling to transform towards a circular economy, sustainability and responsible business practices; this might include a) Operations to include collaborative project team work with use of physical (and virtual space), for cross-disciplinary teams to come together to co-create as 'future innovation will require intensive collaboration between stakeholders', (Gardien et al., 2014) b)Requirement for more horizonal teams across departments vs vertical; c) New language and supported relationships (to include: customer, other stakeholders and staff); d) Ability to iterate, learn and evolve requires greater and perhaps dedicated agency across the business.

Research Perspectives IN THE ERA OF Transformations

Empowering seniors' mobility to maintain a healthy lifestyle: a case study

TREGLIA Chiara[a]* and LU Yuan[b]

[a] Royal College of Art, Imperial College of London, United Kingdom
[b] Eindhoven University of Technology, The Netherlands
* corresponding author e-mail: Chiara.treglia@network.rca.ac.uk
doi: 10.33114/adim.2019.c06.181

Ageing population is one of the most pressing societal issues that current and future generations will need to face. As part of her graduation research, a student from Industrial Design at University of Technology Eindhoven looked at the Dutch context and researched how empowering independent mobility could intrinsically motivate seniors to maintain a healthy lifestyle. The research culminated in a concept, YouGoIGo, which is the subject of this case study. YouGoIGo is a participatory mobility service that aims to suit the needs of every traveller, regardless of their age, physical abilities or access to technology. The service lets anyone become a "travel buddy", by matching seniors and regular travellers according to their planned routes and providing rewards. In this case study, we will firstly illustrate the steps of the participatory design process used to develop YouGoIGo; secondly, we will discuss which probes have been designed to collect quantitative/qualitative data (from different stakeholders and users) and how they have been deployed. As an example of innovation by intersecting engineering, social sciences and design, this case study aims to contribute towards a body of research that looks at holistic prevention and intervention systems, to engage the elderlies in healthy lifestyles.

Keywords: ageing population, healthy lifestyle, senior mobility, prevention, empowerment

Context

Ageing population is an ill-defined problem. However, its consequences have been researched and outlined: there is an international concern that current social infrastructure will be insufficient to provide care to an always-increasing number of elderly people, whilst carers and taxpayers reduce in number. Ageing makes people's lifestyle less active on a mental and physical level, thus a preventative approach is needed to elicit the behaviour of maintaining healthy habits in later life stages. In light of this societal challenge, multiple disciplines, such as engineering, design and social sciences, are cooperating towards preventative holistic solutions. Physical activities are of great importance to older adults as it can not only help to improve their psychological well-being and overall quality of life, but also enable them to be care-free for a longer period of time (LeRouge, Ma, Sneha, & Tolle, 2013). However, due to ageing, the amount of physical activities taken by older adults naturally reduces.

The first author, referred to as the designer in the following paper, focused on ageing population in the Dutch context, where the rate of elderlies over 65 years old is expected to increase to 26% by 2035 (Smits, 2013).

This reported case study focuses on design for promoting physical activities among older adults, by empowering prolonged efficacy and independent mobility and it illustrates a 'research through design

process'. The designer worked closely with multiple stakeholders and developed a concept that encompassed their insights and addressed their needs. The stakeholders were:

- 40 senior participants from Zuidzorg Extra (a business unit of ZuidZorg, a large home care organization in the southern part of the Netherlands), referred as participants in the following paper.
- 2 students from Summa College (a secondary vocational education) of which one was perspective Zuidzorg caretaker in training, referred to as students and trainee in the following paper;
- an account manager from 9292, the largest and most popular mobility service used in The Netherlands;
- the director of the ZuidZorg Extra unit in Eindhoven, The Netherlands;

The steps of this process are organised as follows:

- 'Problem scoping': probes designed to gather an understanding of seniors' lifestyle;
- 'Design process': probes designed to co-create (Sanders & Stappers, 2007) and validate YouGoIGo, the design solution, with senior participants.

The Narrative

Problem scoping

First experiments

As the design challenge was still broad, the designer studied the role of social influence through a small social experiment with some of her family members. The objective was to understand how social context plays a role in motivating seniors towards positive behaviour and a more active lifestyle. She created a group chat on WhatsApp with 12 members of different ages, from 14 to over 65. She created couples, usually grandchildren with grandparents. The rules of the game were that every member had to challenge their respective partner in a physical challenge twice a week. Everyone had to provide evidence, with a video or photo, of the executed challenge, so all the members of the group chat could see the results. This 'challenges game' was played for two weeks. The insights obtained were in line with social influence, as described by behavioural theories:

- Some of her elderly relatives would not enjoy doing the challenges, as they would openly admit, but would pursue their challenges anyway, in order not to be disliked by the group, as addressed by the principles of social acceptance and rejection (Fogg, 2009).
- Some shared the view that being more in contact with their loved ones was a strong enough motivation to keep up with the challenges. This is in line with the principle of consensus (Kaptein, Markopoulos, Ruyter, & Aarts, 2015), by mimicking other people's good behaviour, participants would perform certain tasks they were not intrinsically motivated to do by themselves.
- Some asked to change their challenge according to their capability to achieve the goal and to make the challenge fit in their routine. For instance, three hours of gardening instead of a half an hour walk. This is in line with Fogg's findings (2009) on simplicity profiles.

Figure 1 Screenshot from WhatsApp group's challenge game, representing a senior performing a physical exercise.

Understanding seniors' experience

The behavioural insights gathered from this experiment inspired the designer to further investigate what intrinsically motivates (Ryan & Deci, 2000) seniors to maintain a healthy lifestyle. Ryan (2000) describes motivation as "the inherent tendency to seek out novelty and challenges, to extend and exercise one's capacities, to explore, and to learn" (p.70). Particularly in group/social settings, this seemed to be a key factor that needed deeper understanding.

In order to do so, the designer adjusted a design probe (developed by a PhD researcher from Eindhoven University of Technology) to have an overview of which everyday activities the Zuidzorg participants already practice as a collective in their everyday, which one they miss out and which to reintegrate in their lifestyle. This probe presents 12 icons with text, in the middle, representing individuals or social groups (e.g. family, volunteers, relatives, neighbours, etc..) and presents two questions on opposite sides of the canvas:

- Which activities do you do already with others?
- Which activities do you wish to do more with others?

The task is to place some activity/hobby icons into either side of the canvas and link the activities to the persons in the middle. During 2 sessions of half an hour at the ZuidZorg centre, the designer gathered canvases filled out by 27 senior participants. After processing the results, the main insight was that the participants wanted to spend more 'dagen uit', days out, as a group activity.

Figure 2 Example of compiled adjusted Canvas. Translated from Dutch, the question on the left is "Which activities do you do with others?", while on the right "Which activities do you wish to do more with others?".

Figure 3 Senior compiling the adjusted canvas and linking activities with people.

Mapping first-hand and literature insights

Research shows that compared to other age groups elderlies do not travel as long in time and as far in distance (Böcker, Amen, & Helbich, 2016). Based on the insights from the culture probe study in the previous step, the designer decided to focus on creating a concept to support older adults to have more days out with their peers. To gain first-hand insights about their 'day out' experience, she created a flyer that was filled out by 13 participants, with the following questions:

- What does your day out look like?
- Where would you go?
- By which means?
- What activities do you do?
- With whom would you go?
- How do you organise it?

- Do you foresee any problems/difficulties?

Figure 4 Example of compiled flyer by two participants (in Dutch).

The main insights were the following:

- Perceived autonomy: the respondents who noted difficulties (e.g. too much walking, health issues, mobility issues (e.g. rollator), checking information online, having to ask for information to strangers), also reported that they go on days out autonomously. Those who did not foresee any problems or difficulties during their journey, also reported that they would rely on others to organise and take care of them during their day out.
- Means of transportation: in line with Böcker's findings (2016), participants expressed a preference for car or private vehicles (e.g. buses from tourism organisations) as transportation means, rather than public transport, because of difficulties in boarding or alighting (Arentze, Timmermans, Jorritsma, Kalter, & Schoemakers, 2008).

Böcker (2016) and Arentze (2008) argue that there is a sustainability concern regarding supplying the mobility needs of a growing segment, such as the older adults market, with private vehicles. They argue that research and efforts should be invested in improving public transport infrastructure, for both its social and environmental benefits. In light of this insight, the designer chose to focus on the systemic challenge of designing a service that would lower the threshold for Dutch seniors to choose public transports over privately owned vehicles.

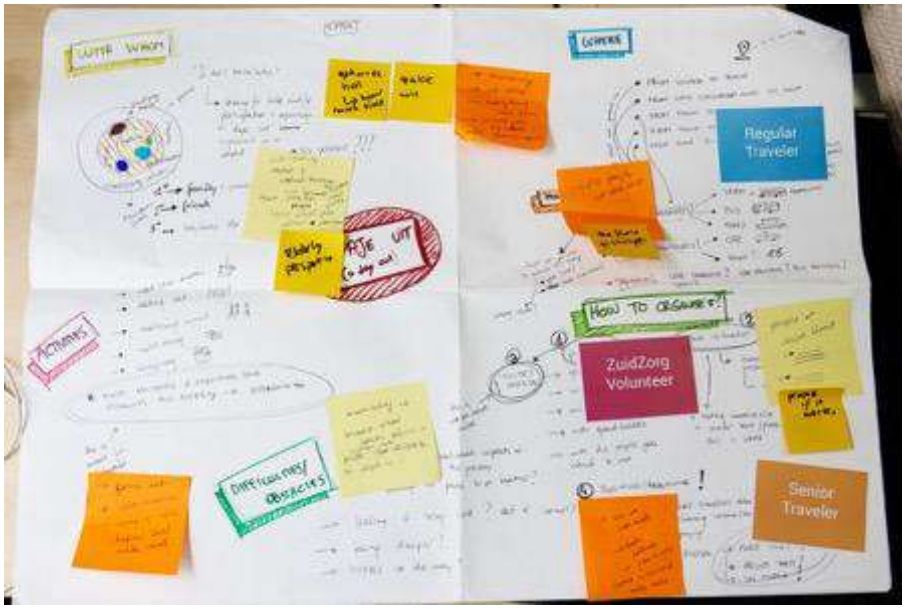

Figure 5 Problem mapping on the topic of 'spending a day out'.

Design Process

In the first ideation phase, the designer came up with the idea of a buddy system that would pair regular travellers with senior travellers, to be able to travel together. Inspired by sharing-economy concepts (BlaBlacar, Uber in early phases) she wanted to design a 'win-win' situation concept, rather than relying on a volunteering buddy, accompanying a more vulnerable and less mobile buddy. Inspired by the Self-Determination Theory, she wanted to address three needs, described in Ryan (2000) as "essential for facilitating optimal functioning of the natural propensities for growth and integration, as well as for constructive social development and personal well-being" (p.68).

- the need for competence, in organising and spending a day out;
- autonomy, in travelling independently;
- relatedness, in relying on a participative support system to spend a day out.

The outcome of this process was YouGoIGo, a participative mobility service that suits the needs of every traveller, regardless of their physical abilities, their age or their access to technology. The concept is a two-ends system and it is built upon the infrastructure of 9292.

Figure 6 Example of YouGoIGo interface.

Each feature of the concept has been co-designed as the final users of the service (the seniors) played the role of 'experts of their experience' (Sanders & Stappers, 2007) whilst the designer iteratively created and deployed probes, as tools to empower the expression of their expertise and knowledge.

Scenario's

The preliminary concept was sketched in two vignette-style scenarios. The task for the participants was to give feedback with sticky notes of different colours on the parts of the canvas they liked and the ones they disliked. The purpose of the exercise was to:

- envision themselves as 'protagonists' of a potential future mobility service;
- empathise with other potential roles in this scenario.

On Scenario 1, the journey of a group of three elderly ladies was described: with the help of a Zuidzorg carer a group of elderly ladies publish on this buddy service their route and requested a buddy to accompany them. After a while, they find one and decide it is a match. On the day of the trip, the senior ladies meet with their buddy and commute together, who supports them at challenging steps (managing tickets, navigating stations and stepping on or off trains and buses). When they arrive at destination, they shout out goodbye.

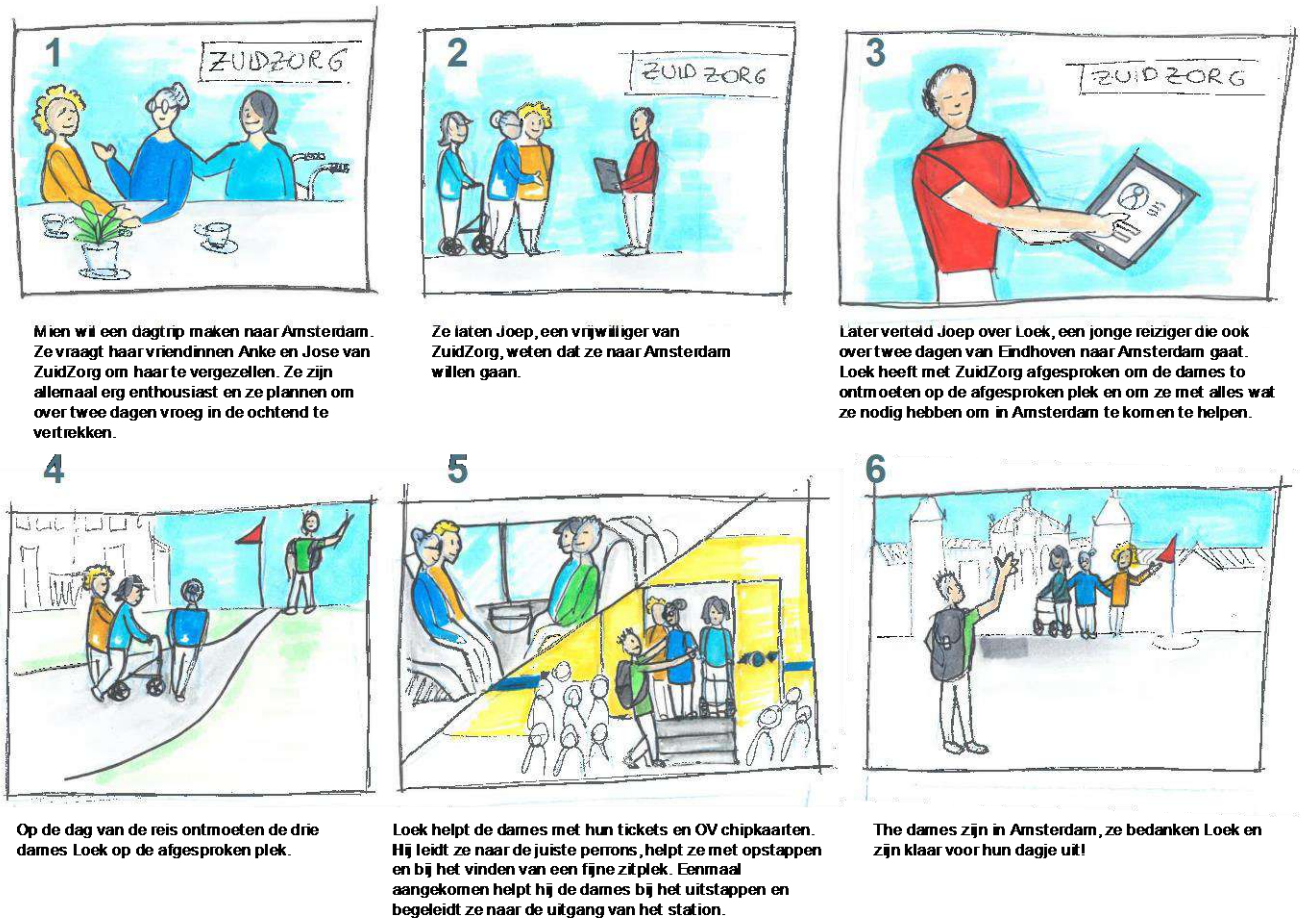

Figure 7 Canavs Scenario 1 (in Dutch).

On Scenario 2, the regular traveller's perspective of the same journey is described: a regular traveller creates a buddy account by using 9292. He checks if there are seniors travelling on the same route. Once a match is made, he meets with the seniors and accompanies them to the set destination. He helps them with all their necessities (like Scenario 1) until they arrive at destination.

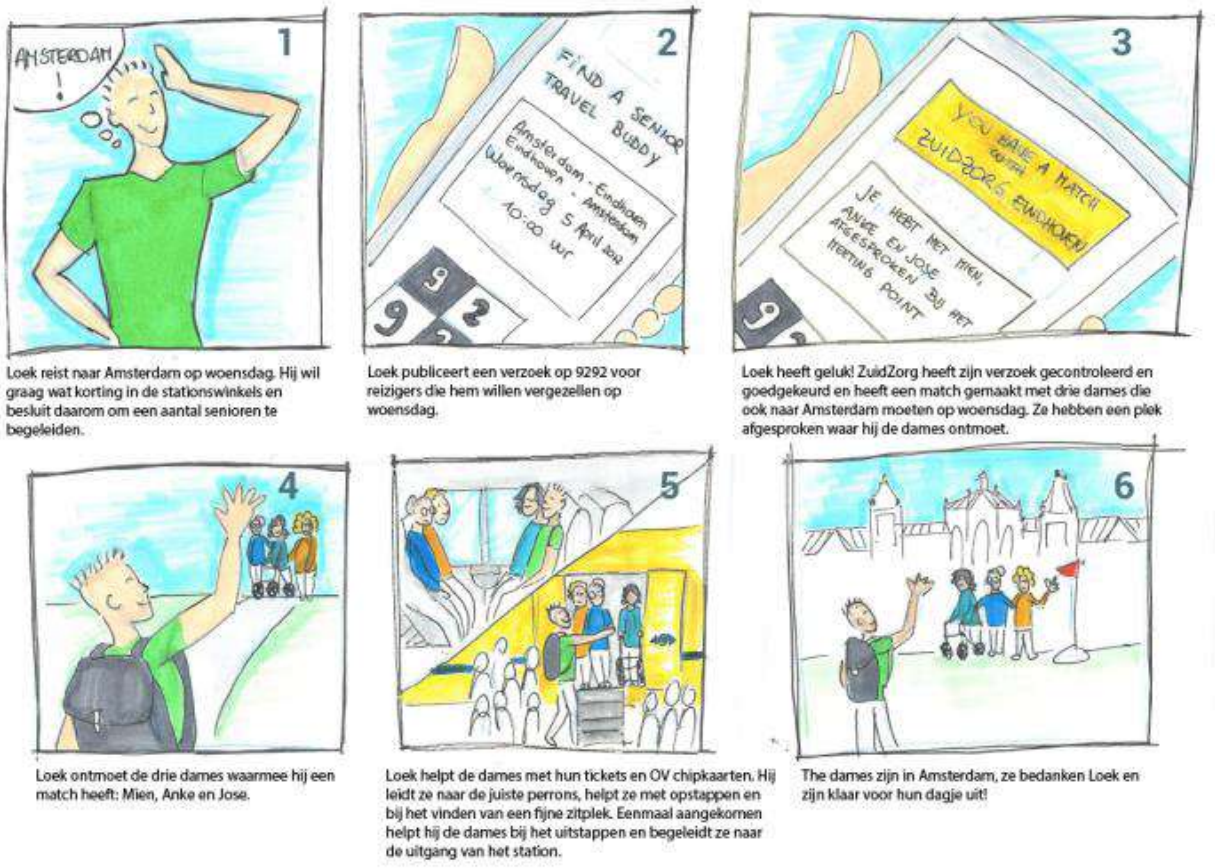

Figure 8 Canvas Scenario 2 (in Dutch).

During 2 sessions of an hour, the designer collected qualitative feedback on both scenarios from 15 senior participants. The two main insights from this exercise were that:

- for some participants, it seemed hard to trust a stranger to accompany them on their journey. Some of them refused to believe that anyone would invest effort in helping senior travellers.
- It seemed hard to find a consensus among participants regarding the purpose and how to reward a regular traveller accompanying seniors on their journey.

Figure 9 Zuidzorg participants giving feedback on Scenario canvases.

Figure 10 Example of participant's feedback (in Dutch).

Role Play

At this stage, the designer conducted further investigation in order to unfold the issue of trust (between regular and senior travellers) that emerged from the previous exercise, as well as to figure out a safe way to reward regular travellers.

She organised four role playing sessions with 6 participants, asking them to 'act-like' one of one the regular travellers' personas that she created. They were asked to build arguments why a senior traveller would choose them and how they would like to be rewarded.

Figure 11 Senior and researcher in a role play session. Persona cards are displayed on the table.

Role play is widely used by design agencies such as IDEO, because it is an effective tool to stimulate empathy and creativity. Inspired by Simsarian's framework (Simsarian, 2003), the goal of the role-playing session was to let participants immerse in a 'what if' context, perform a role and formulate observations from the perspective of the role they played. The main insights of this exercise were the following:

- Seniors travellers want some specific information (picture, phone number and proof of ID) to be able to trust a regular traveller to accompany seniors on their journey. Moreover, the participants expressed they would feel safer if they were represented by an established organisation (e.g. Zuidzorg) within this system.

This insight informed the design feature of YouGoIGo that enables ZuidZorg, or any other elderly centre, to build a company profile on the service. By doing so, they can represent their guests and publish their routes on their behalf. In this way, elderly care centres can function as authorities that guard the seniors' safety and make sure the system runs smoothly.

Figure 12 Example of interface where Zuigzorg publishes routes on behalf of its senior guests.

Figure 13 Example of interface displaying matching routes for senior and regular travellers.

- Participants expressed that they feel unsafe when handling money in public, thus many other proposals arose (e.g. not rewarding at all, offering coffee). A decision regarding reward was therefore not taken yet at this stage.

Semi-structured interviews

Two interviews were held with the student and the trainee in order to understand the perspective of potential regular travellers, as well as of a Zuidzorg carer, on the matters of trust and being rewarded on this developing travel service. The questions were the following:

- what would the impact be of using the company profile of ZuidZorg to publish seniors' routes?
- what would a ZuidZorg caretaker need to know about a regular traveller to confirm a match with him/her?
- how would she/he reward a regular traveller for the support she/he gives in accompanying senior travellers on their journey?

The trainee shared her perspective on the issue of trust: in order to feel safe in matching seniors with strangers, she wanted to know contact details, see a picture and a small biography, to have a complete overview of the other person. Reviews would also be helpful to make a more personalised choice. As Ert, Fleischer & Magen (2015) studied on Airbnb, a popular sharing economy platform in the tourism industry, pictures and reviews might have an important role in building trust between the multiple users of the service.

This insight informed the final 'privacy versus safety' compromise that is featured on YouGoIGo: the users, whether business accounts or personal accounts, have to authenticate by default with a proof of ID. Besides, users have to share a phone number (which can be accessible by different channels e.g. WhatsApp, Messenger or just regular dialing). This information is crucial to allow seniors or carers to contact regular travellers and make arrangements, if needed. However, this information is not stored in the system and is deleted once the trip is over. A phone number associated with a name and surname is the only sensitive information that travellers need to share with other users. Any other profile details are optional to share and reviews from other trips can be hidden. However, regular users are encouraged to share as much info as possible, to increase the chances to be chosen for a match.

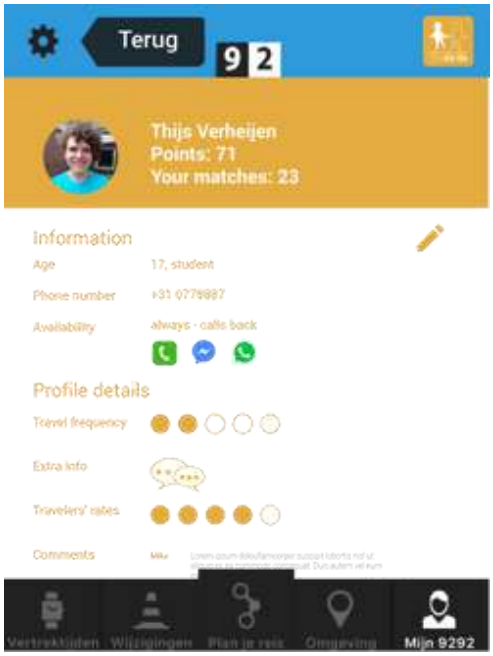

Figure 14 YouGoIGo interface, displaying regular traveller's info.

Regarding the 'how' to reward regular travellers, the student and trainee agreed that a scoring system to gain a discount would be an appropriate way to be rewarded for accompanying the seniors. In this way, cash money would not be needed, by making the system safer for the seniors and more convenient for regular travellers.

This feature has been implemented in the final design of YouGoIGo: a regular traveller gains scores for their service, which can be transformed into discounts. Any shop or promoting enterprise can join the system, by offering their discounts on the interface. The scores gained by the regular traveller double for return trips and for positive reviews by the seniors they accompanied. Next to this, they get to travel for free each time they accompany seniors, by showing the details of the trip to the conductor on the train or bus.

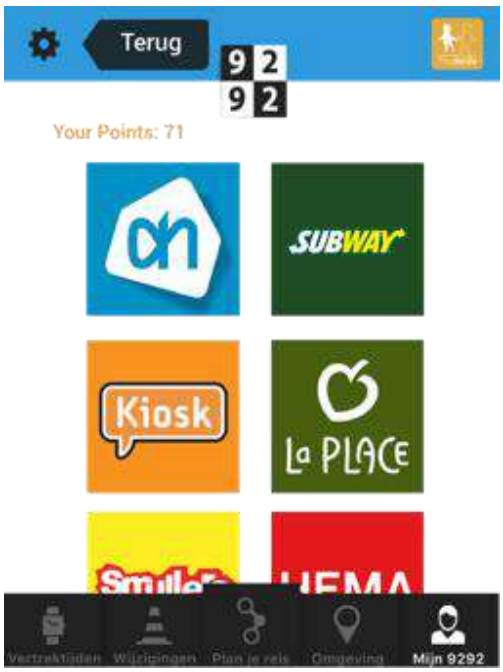

Figure 15 Example of interface through which a regular traveller can use her/his points to get a discount at different shops.

Service simulation

After the main features of the design had been defined, the designer organised a day out to Utrecht. A group of 6 participants, accompanied by the students, experienced the service, finally named YouGoIGo. The students had been instructed to behave as regular travellers using the service: they had to support the seniors in navigating public spaces (such as bus stops and stations), support them with their ticket purchasing and help them physically overcome barriers (such as stepping on and off the train).

The designer behaved as the intermediator (a ZuidZorg caretaker) and she showed the seniors, on a designed interface, that they had a match with two students for their trip to Utrecht. She gave them information about the students and showed them pictures of them. She also asked them if the information provided made them feel more comfortable in trusting the students. Their response was largely positive.

Once they met, the seniors were able to recognise the students and the group travelled back and forth to Utrecht. Simulating the system was effective to test its features and highlighting the potential bottle-necks (e.g. such as potential disruption during rush-hour and the need for further investigation of viability and feasibility of the system at a policy level).

Figure 16 Participants and students simulating YouGoIGo on a day out.

Figure 17 The group of seniors with their travel companions at a train station in The Netherlands.

Key learnings

From a design management perspective, the following key learnings have been found:

- Trust in the design process and by technology: in line with principles of cultures of participation (Fischer, 2011), it can be argued that the systematic democratisation of the design process (by creating probes that empowered users and stakeholders to participate in both the problem definition phase and in the design development phase) enabled a reciprocal feeling of trust and shared responsibility. Signs of this newly established trust could be perceived during the YouGoIGo simulation-day and by the participants' enthusiasm to see the service implemented. However, research on sharing economy services claims that built-in trust (within the app or website) is what makes them so successful (Richardson, 2015). YouGoIGo was developed in a process that entailed shared trust among all stakeholders involved throughout. However, the final design also relies on a trust-built-in mechanism: senior travellers need to trust their travel buddies from their online profiles, prior to meeting them offline. Further research is needed to assess whether trust between seniors and regular travellers remains when they are not involved in the design process and if other factors play a role (e.g. digital confidence in older users).
- Empowering processes support an empowering solution: as 40 senior participants were empowered to be co-creators and all stakeholders involved contributed as 'problem experts', a sense of agency and ownership over the final outcome appeared to grow throughout the process. By building reciprocal empathy, it was possible to thoroughly understand potential barriers to a healthy lifestyle, identify a design opportunity and create a 'win win' solution. This is in line with Manzini's (2010) insights on the role of the participatory designer in projects for social change. In practice, her role is to 'trigger interests of multiple stakeholders, align their motivations and empower their capabilities' (Manzini & Rizzo, 2011). As a result, it can be argued that YouGoIGo is an embodiment of multiple stakeholders' perspective and it empowers them by giving them responsibility. Senior travellers, regular travellers, mediator organisations (e.g. Zuidzorg), partnering enterprises might have different motivations to join YouGoIGo and they can gain different benefits from it. However, by design, they have to assume key responsibilities, in order to achieve those benefits.
- Strategic and sustainable implementation of the service: YouGoIGo's proof of concept has been validated in a limited simulation, in terms of number of participants and iterations. Nevertheless, it was sufficient to highlight the need for further research to address liability and policy concerns, should the service exist at scale, once implemented in the Netherlands. A 9292 account manager and the director of ZuidZorg Extra have been consulted regarding the matter. They suggested collaborating on a strategic implementation roadmap starting with more extensive pilot studies to test and overcome the current bottle-necks of the service. This highlights the need for a collaborative culture, across industries and disciplines: in the case of YouGoIGo, designers, developers, behavioural experts, carers, policy makers as well as seniors and regular commuters, would need to come together to affect systemic change.

In light of the challenges set by ageing population, we argue that more focus should be put on empowering solutions to support one's sense of agency and efficacy, to maintain a healthy and active lifestyle. Such solutions should be integrated in a societal infrastructure that distributes their risks and benefits among different stakeholders.

Acknowledgment

The work presented in this paper was made possible in part by funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 690425. The authors thank all ZuidZorg participants, carers, Summa College students and the Zuidzorg director for their invaluable contribution. Special thanks to all students and PhD researchers at Studio Silver (TU/e Industrial Design) for their feedback and help in developing the concept.

Research Perspectives IN THE ERA OF Transformations

Integrating Business and Design through Experiential Learning

WINDAHL Charlotta

The University of Auckland, New Zealand
c.windahl@auckland.ac.nz
doi: 10.33114/adim.2019.c07.120

This case study highlights how design merged with business studies addresses some of the key issues facing management teaching and learning. It outlines a pedagogical design framework, capturing both content and process through balancing analytical and creative thinking. The students interpret and use theory throughout various stages of a design challenge; through presentations and written submissions, students turn knowledge into reflection and action. The case study highlights how the developed framework engages the students in continuous learning cycles that are supported by an iterative assessment structure and catalysed by curiosity, creativity and courage.

Keywords: Design thinking, experiential learning, business studies

Experiential learning foundations

Drawing on 17 years of tertiary teaching experience and seven years of experimental course delivery - exploring new tools and visualisation techniques – this case study outlines how the use of experiential learning (Kolb, 1984) and design principles, tools and activities (Dunne & Martin, 2006) played a crucial part in redesigning a 3rd year undergraduate course (50-70 students) at a traditional Business School; as such, it provides insights into how design principles integrated with more traditional theoretical content may assist in addressing some of the key issues facing management teaching and learning, for example, emphasizing inquiry based learning and guided discovery (c.f. Starkey & Tempest, 2009). The pedagogical framework supports the students' learning journey; more specifically, it:

- Captures both content and process
- Catalyses curiosity, creativity and courage (traditionally not emphasised in Business Schools)
- Engages students in a positive team-work experience
- Creates a mutually meaningful interaction between academia and industry

Theory-in-use and reflective action: an iterative learning cycle

The foundations of the pedagogical framework is based on the experiential learning cycle (Kolb, 1984), where content is linked to practice through experience and reflection; learning is an iterative process and it is important to conceptualise/ abstract reflections in order to take action (i.e. learn) in future scenarios and hence provide new (learning) experiences (Figure 1). Thus, as illustrated in Figure 2, three key activities support the learning cycle: theory-in-use, reflective action, and iteration. This case study will further explore how these key principles were addressed when merging service marketing theory with design practice.

Figure 1 The experiential learning cycle

Theory-in-use	Balancing the Concrete Experience with Abstract Conceptualisation *Perception continuum 'How we think about things'*
Reflective action	Balancing Reflection with Active Experimentation *Process continuum 'How we do things'*
Iteration	Re-experimenting and reinterpreting

Figure 2 The experiential learning cycle with three key activities

Engaging students in a positive and real-life (teamwork) learning experience

Drawing on the experiential learning foundations, the course approaches (a) learning as a process which is continuously recurring (i.e. the experiential learning cycle), (b) learning having direction – experiences are related to our goals and needs and (c) learning styles as individual – different people emphasise different parts of the learning cycle (active, reflective, concrete, abstract). Thus, through knowledge about an efficient learning process, we can address our individual shortcomings (once we know about them) and become better learners. With regard to teamwork, different learning styles complement one another in an efficient team. This deeper understanding of the learning cycle and their own learning styles assist the students in understanding the rational for the team formation when they are placed in teams based on their different learning styles; it also lay the foundations for deeper understanding of one another, i.e. different people solve and approach problems in different ways. Furthermore, the teams are supported through a team kick-off process in which they thoroughly work through parts of the team formation process before even getting introduced to the task ahead. In addition, in iterative and structured peer assessments, the members provide feedback to one another continuously throughout the course. Finally, the teamwork activities has been moved into the classroom; students are responsible for bringing their individual, outside-class activities and contribute to the team discussion during class. In line with Beckman and Barry (2007), different learning styles shine through at different phases of the design process: the teams experience that different people (i.e. with different learning styles) contribute more (or less) during the various design phases, and that a diverse team is necessary to complement the team's learning experience.

Understanding service marketing and management through design principles

With emphasis on design principles, the course challenges conventional approaches to teaching service marketing and management. It bridges and balances theory and process. A so called 'service perspective on marketing' provides the theoretical underpinnings and emphasises a relational and value-based approach. Design, with emphasis on the human experience, provides tools and activities, and a way of thinking and doing useful for marketers (and others) facing challenges linked to the increasing importance of creating and maintaining relationships with customers and future users. Explicitly, the course addresses service design and innovation for the future; implicitly, and in focus in this case study, it addresses the learning experience.

The building blocks of the course

The course consists of 12 weekly four-hour workshops divided into five blocks (refer to Figure 3). The first block introduces service marketing and design practice, and kicks-off the team formation process. The last block concludes the course and provides an opportunity for the students to discuss organisational challenges and opportunities as well as reflect upon their own personal design journey. The three mid-blocks are the core and heart of the course; through addressing a real-life industry design challenge, the students are challenged to discover and comprehend the service experience, ideate and create the service innovation, and finally experiment with, and deliver, the service concept. Each block contains both content and process/practice dimensions. In the content parts of the course, the students read relevant literature and summarise, discuss and reflect upon key insights and how they can use these learnings in the design challenge and/or future careers. In the process parts of the course, the students get to address (through individual and team work) the (service) design challenge. Iteratively the teams go through the three stages of discovery, ideation and experimentation, and emerge towards the end of the course with a concept prototype of a solution to their team's identified problem.

Week	Workshops	BLOCKS
1	Service Marketing & Team Kick-off (1)	SERVICE MARKETING & DESIGN PRACTICE
2	Design Thinking & Team Kick-off (2)	
3	'Theory'	DISCOVER & COMPREHEND
4	'Practice'	
5	Insights Presentations & Feedback	
6	'Theory'	IDEATE & CREATE
7	'Practice'	
8	Idea(s) Presentations & Feedback	
9	'Theory'	EXPERIMENT & DELIVER
10	'Practice'	
11	Concept Presentations & Feedback	
12	Course Review & Summary	REFLECT & EVALUATE

Figure 3: Overview of the course

Discover and comprehend the service experience

The Discover & Comprehend phase starts with the customer and the concept of desirability. It is important to understand that what the customer/user might think that they want may not be what they actually need. In this initial phase, the students gather knowledge and information in order to comprehend the background to

the presented problem area as well as discover new things about it. Individually, they do observations and empathy interviews, and possibly some secondary research. As a team, they discuss and analyse the initial findings, start identifying patterns and analysing overarching problem areas, pain points and opportunities, group them into themes and create so called insights and point of view statements. Finally, through the first presentations, the teams will receive guidance and feedback. In this phase, a big 'aha-moment' for the students is usually when they realise that they, as a team, have to identify the problem, rather than solve a problem having been handed to them.

Ideate and create the service innovation

In the Ideate & Create phase, the key is to make the insights actionable and frame opportunities. This often includes an element of going back to the Discover & Comprehend phase in order to ensure that the defined opportunity areas actually correspond to the identified customer need. In this phase, the students are in the mode of 'ideating' - narrowing and culling information: making your insights actionable and framing opportunities (i.e. translate insights about the reality of today into a set of opportunities for the future). The teams have to generate so called 'how might we…' statements, conduct a brainstorm session and generate a lot of ideas. Additionally, they will start creating: they need to select a promising idea(s), refine it and start describing it. Finally, the teams present idea(s) and their 'journey' and receive feedback and further guidance.

Experiment with, and deliver, the service concept

In the Experiment & Deliver phase, it becomes important to bring the ideas to life in order to learn more about how they can be refined. In this phase, the student teams turn ideas into service concepts. They experiment through prototyping in order to bring the concepts to life. In the end, they include discussions about service models, client interface, technological options, delivery system etc. They will also need to analyse what is technically and organisationally feasible and develop some type of understanding of whether the idea is financially viable. Finally, the teams present their concept and hand-in a so called journey document.

Design practice and its links to the experiential learning cycle

It is important to note that even though the course is presented in a linear format, the students work iteratively through the challenge. For example, after having received feedback on the initial idea(s) most teams need to revisit their insights. In fact, throughout the years of course development, it became clear that the design process itself addressed the students learning experience. More specifically, the course explores the practical activities and tools linked to design practice, as well as its epistemological and cognitive foundations. The process dimension includes using activities and tools such as observations, ethnography, early and fast prototyping, visualisation and interdisciplinary teams; it emphasises the importance of working iteratively, combining abstract and concrete activities as well as divergent and convergent approaches (Brown, 2008). The cognitive dimension provides a deeper understanding of how knowledge is created (Martin, 2009). Firms (and individuals) need to make sure they balance analytical and intuitive thinking to achieve both reliability and validity. Design practice emphasises the importance of using both abductive reasoning - the 'logic of what could be' (Peirce, 1994) - and reflective practice (Schon, 1983) in order to achieve this.

This is in line with Beckman and Barry (2007; drawing on Owen (1998) and Kolb (1984)) highlighting design as a learning practice, proposing that:

> *The design process has both analytic and synthetic elements, and […] it operates in both the theoretical and practical realms. […] Movement between [these] realms happens as participants in the process draw insights from what they have learned in the world of practice, convert them to abstract ideas or theories, and then translate those theories back into the realm of practice […] (Beckman & Barry, 2007, p. 27))*

Thus, one key element in the course design has been the development of an assessment and activity structure that supports the iterative journey the students go through. The implications of this will be discussed next.

Key learning dimensions: iterative assessments, design catalysts and critical reflection

The pedagogical framework addresses both the perception continuum and the process continuum in the learning cycle. More specifically, all the course activities inside and outside class as well as the assessments

support the key dimensions of theory-in-use, reflective action and iteration. Additionally, it is clear that the design process itself catalyses the students' journey towards a deeper learning experience.

An iterative assessment structure catalysing the learning experience

In the course, in addition to addressing a real-life industry challenge, the students read and use service theory. Throughout the course, they need to put this theory in use, i.e. they need to balance abstract content with the actual experience of using it. This approach goes beyond 'just' applying theory, rather the students need to interpret theory, make a decision on if and what to use and when. Additionally, through emphasising reflective action, the students then reflect on their experiences and get to action their learnings in the next iteration. The iterations are extremely important for fuelling the learning cycle. Supported by the assessment structure, the learning cycle is reiterated and reinforced or changed a number of times throughout the courses (as illustrated in figure 4).

	Assessments and Activities *developed to support the key concepts*		
	Individual	Teamwork	
Key concepts supporting the learning experience	Reflection & summaries of readings (including self and peer reviews)	Individual contributions to the team challenge	Team contributions to the team challenge
Theory-in-use	Interpret theory and identify key concepts to use in practice	Put key concepts into practice through interviews, observations, prototyping or examples	Combine individual knowledge bases and make sense of findings
Reflective action	Reflect on readings and activities, digest feedback and demonstrate learnings	Reflect on role within the team, digest team feedback	Reflect on complementary abilities within the team, provide feedback
Iteration	Written submissions 3 iterations	Three contributions (e.g. observations, interviews, secondary research, prototyping)	Three presentations and feedback sessions.

Figure 4 Overview of how the assessment structure supports the learning experience

Curiosity, creativity and courage: design catalysts supporting a deeper learning experience

Drawing on the years of working with student teams and design professionals in the course, it is clear that three interrelated design catalysts further enhance the learning experience towards a deeper learning experience: curiosity, creativity and courage (illustrated in figure 5). Seemingly, they transcend the three design phases, as such they can be associated with design attitudes (c.f. Michlewski, 2008). Curiosity catalyses empathy and deeper understanding of the users and, in this specific course, the service experience and its context. Creativity supports divergent thinking and disruption of cognitive and perceptual sets (Amabile, 1983).

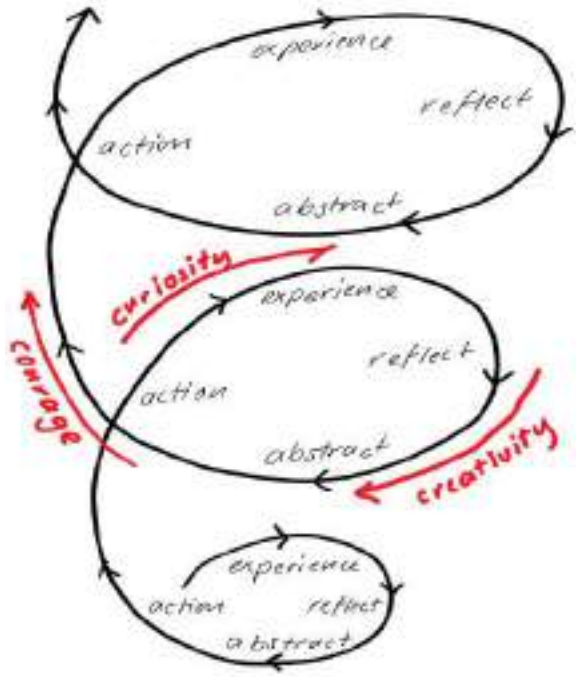

Figure 5 Curiosity, creativity and courage –catalysing the learning spiral

In the course, curiosity and creativity are highly interlinked. The curious teams gain higher empathy and a larger knowledge base, seemingly building stronger foundations for creativity. Courage mitigates cognitive bias with regard to assumptions present in curiosity and creativity-driven activities. The teams and individuals that are willing to test and learn and hence challenge their assumptions - try, fail, reflect, learn and try again - get a deeper learning experience. Drawing on a pragmatic approach to design practice (Dalsgaard, 2014; Steen, 2013; Windahl & Wetter-Edman, 2019), curiosity catalyses a situated and systemic understanding of the design challenge, creativity catalyses an interventionist and transformative approach, and courage catalyses the movement between the two, i.e. explorative inquiry.

Industry context – supporting the real-life learning experience

The relationship with industry goes far beyond so called guest lectures traditionally used in Business Schools. By involving professional individuals throughout the semester in a continuous interaction with the students, the course has created a mutually meaningful interaction between academia and industry. The so called design mentors (mentoring the students through the design process) and industry partner (providing the context for the design challenge) mentor between four to eight teams through three presentations, and give qualitative and quantitative feedback to each team after each presentation. Through these interactions, the students are exposed to a 'real-life' experience. This includes, not only a fuzzy process, but also ambiguity with regard to the feedback they receive and how to address it. Seemingly, the theoretical foundations of the course assist the students when questioning and challenging some of the external input they receive. In fact, this critical reflection is key to the students' growth: rather than 'ticking the boxes' for industry, they are allowed, encouraged and supported to question, challenge and rethink the challenge and its solution.

Work in progress – integrating business and design

Even though the course has been rather neatly described in this case study, many questions remain with regard to its survival and further development within a traditional Business School. A course like this pinpoints numerous challenges linked to the institutional inertia of a large university. Operational and immediate issues are linked to resourcing and space, as well as implementation of transformative assessment structures: How can we ensure appropriate resourcing for an interactive 50-70 students 'only' course (a small course in a Business School context)?; and, How can we support creative assessment structures with emphasis on formative as opposed to summative assessments? Strategic and structural issues are linked to capabilities and interdisciplinary collaboration: How can we encourage interdisciplinary involvement of both teachers and students? To me as an educator and researcher, it is clear that the use of design practice in business studies is breaking the existing and artificial academic boundaries and that the time has definitely come (c.f. Starkey & Tempest, 2009) to further explore the power of combining the two.

doi: 10.33114/adim.2019.c08.117

According to the World Economic Forum 2020, some of the most critical skills needed to thrive in the future economy will be the ability to collaborate in multidisciplinary teams, build diverse networks, and be human-centered problem solvers. However, many university students have limited exposure to interdisciplinary problem solving, and tend to build connections within their bubbles (socioeconomic level, college, the field of study). In this study, we'll review Innovate NYC (iNYC), an extracurricular program addressing these skills gaps. In three cohorts between 2016-18, 50 students from 12 New York City colleges, collaborated in multidisciplinary teams to solve real-world problems using innovation methods like HCD (Human Centred Design) and lean business strategies. The challenges were provided by partners like NYCEDC (NYC Economic Development Corporation) and other locally focused non-profits. However, did the program achieve what it set out to do and how might we apply the learning? In this study we aim to: 1. assess the strength and diversity of social connections between former iNYC participants, 2. identify any effect the program may have had on their career pathways, and 3. assess their continued use of innovation methods. To do this, we will examine the structure and delivery of the program, as well as review qualitative exit surveys and longitudinal survey results.

Context

In 2015, a workshop was held that brought together some of the biggest players in NYC higher education to discuss and seek to address some of the most pressing needs in the sector. Facilitated by the DO School, a Berlin based social enterprise, in coordination with the former Under Secretary of Education for the Obama Administration, Martha Kantor, the workshop's purpose was to not only identify shared challenges but to design a new program that might tackle them together.

Guided by a human centred design approach, Deans, Provosts, senior administrators and faculty from over ten New York universities, public and private, converged upon three key issues that all institutions were facing. These were, (1) the increasing cost of higher education leading to debilitating student debt for those who can least afford it, (2) the growing dropout rate among working class and immigrant families, and (3) the inability for institutions to adapt and design new programs quickly enough in order to adequately teach skills and mindsets for the new economy, leading to a 21st century skills gap. This skills gap issue was identified as most promising and suitable to explore further, and consensus was reached that it should be via a student facing extracurricular program that would provide real-world experience to students in interdisciplinary problem solving.

In 2016, the DO School launched Innovate NYC (iNYC) with funding support from Newman's Own Foundation and in collaboration with the following NYC higher education institutions: the New School, Columbia University, New York University (NYU), Pratt Institute, Fordham University, Cooper Union, Borough of Manhattan Community College (BMCC), Guttman Community College, Bronx Community College, and Macaulay Honors College. The program ran for three years, with up to 20 students recruited and selected each year from the partner universities, who would form a student design innovation studio that would respond to a city-based challenge set by a local non-profit organisation. Selection of student fellows was intentionally tailored to ensure diversity amongst the cohort, explicitly concerning their college, background, and level of experience with innovation, human-centered design (HCD) or interdisciplinary studios. Programs were designed and facilitated by experienced innovation and HCD facilitators.

The authors of this case study came together as representative stakeholders from two participating universities and the DO School, to assess the program's efficacy. Rhea Alexander is an Assist. Prof of Strategic Design and Management in Parsons School of Design at The New School. She is also Founder and Director of the Parsons Entrepreneurs Lab and served on the board of advisors for the Innovate NYC from 2015-2018. Her research focuses on how to integrate human centered design practices into impact entrepreneurship and innovation education. Shane Snipes is business faculty and Deputy Chair, Business Management Department at BMCC teaching and researching in the areas of entrepreneurship education and mindfulness. He also served on the board of advisors for Innovate NYC from 2017-18. Matt Stewart is an experienced strategy designer and innovation consultant. He's designed and facilitated human-centred innovation programs across the world, guiding diverse teams through the design process to tackle complex challenges. He managed and facilitated the Innovate NYC program in 2018.In this case study, we explore and assess the development, approach, learning and outcomes from our program with the aim of applying the insights to future programs, our practices and contribute both in academia and in applied innovation practice.

Narrative

Innovate NYC program operated annually in two parts, following a design innovation process. First, selected participants were invited to join for a mandatory two-day 'base camp' weekend in April. The purpose of this intensive workshop was to bring the team together and start to build trust and rapport. It involved a host of team-building exercises, with a specific focus on understanding different working and conflict styles, as well as identifying one's purpose and sharing that with new teammates. After a two month break, in the June summer holidays, a three-week studio took place where participants were guided through the various phases of a human centred design process, tackling a local problem.

To illustrate, in 2018, iNYC's local partner was non-profit organisation, Here to Here. They presented a challenge closely aligned to their organizational mission - to empower Bronx-based youth to reach 'family sustaining' careers. Students were asked to develop solutions that might help bridge the gap between education and employment in a borough that has a $20k a year lower average wage than the rest of the city.

After an initial 'challenge handover' to the 2018 cohort, industry experts and community members were invited to share different sides of the problem, and the students were taught to map the ecosystems and stakeholders, condensing key learnings to prepare for fieldwork. Regularly breaking up into new groups, the students then conducted simple ethnographic research methods, including interviews with youth and observing different environments across the neighborhood. Interview findings were condensed into some critical insights in a synthesis phase which were shared to the partner for feedback along with some early stage solution ideas. Based on validated insights, an ideation phase commenced, and two concepts were developed. Guest mentors offered input in storytelling, branding, and engagement which helped the students refine their ideas into basic prototypes. The final results were shared with Here to Here at a pitching event and celebration.

The solution concepts for this project were:

1. A card set and game for engaging community members as mentors, based on the insight that while many youth would like a mentor, they lack the skills to be a good mentee
2. A fashion traineeship program for Bronx high school students, based on the insight that many youths care more about fashion than grades

The Innovate NYC schedule also included a social event where all participants from previous cohorts were invited to attend and mingle. Below, figure 1 demonstrates various aspects of the program with photos from the process.

Here to Here's feedback, from a 'client' partner perspective, demonstrate the value they took from the initiative. First, they gained a new perspective to help with strategy and improving their work - *the students highlighted genuine insights that H2H hadn't thought of, including: finding out via local interviews that few people in the neighbourhood had actually heard of H2H, and highlighting specific challenges and perspectives of the target group (Youth)*. Second, their staff had a chance to work with creative young people, to share directly about their work and be inspired by new energy and ideas.

Figure 1. Participants during the 2018 iNYC program. Credit: the authors.

Post-Program Survey

In late 2018, it was decided that the program would no longer be supported and funded by the DO School and Newman's Own Foundation. Concluding a three year lifespan which involved many stakeholders from all levels of 12 NYC colleges, 50 participants, three local challenge partners and an impressive list of experts and contributors.

In December 2018, the authors sent out a survey to all 50 participants of the program (2016, 2017 and 2018). The purpose of the survey was to accurately evaluate the program against its ability to be a catalyst for healthy and diverse social connections between participants, have a positive effect on their career pathways, and also their continued use of innovative methods.

The survey was created on Google Forms, and former participants were recruited via email. There was a 70% response rate to the survey - 35 out of a possible 50 - with an even spread across cohorts, 14 from 2016, 10 from 2017, and 11 from 2018.

Survey Results

Innovate NYC offered participants a unique immersive opportunity to work in interdisciplinary teams and directly apply human-centered design methods and mindsets in order to tackle a real city-based challenge. The data which the authors gathered through the survey can give some robust indicators as to the short term impact on participants post-program.

Did iNYC increase the size and diversity of the participants' social network?

The researchers estimate that Innovate NYC has been a catalyst for approximately seven new strong connections and over 90 weak connections between participants. Connections were diversely spread between students from different colleges.

Diverse networks are valuable for future career development (Shipilov et al., 2007), and improve one's ability to work in interdisciplinary, cross-cultural teams. Indeed in over a dozen cases, participants have already found these connections helpful when making career choices or in gaining business introductions (Figure 2).

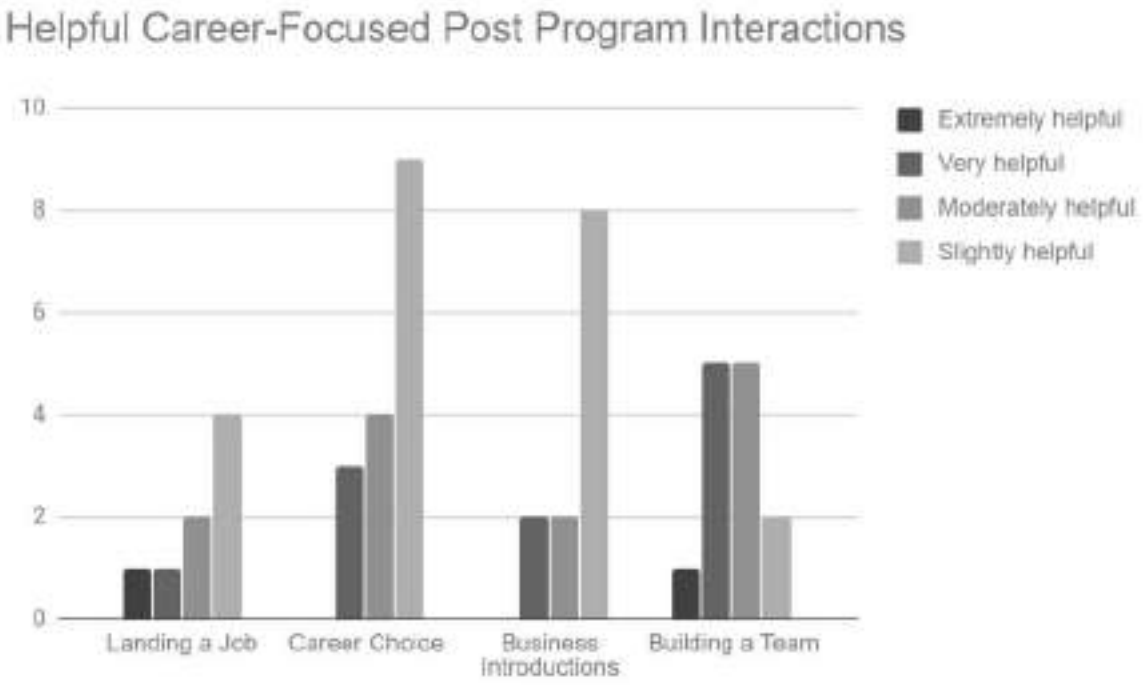

Figure 2. Participants who said that post program interactions were at least slightly helpful, taken from all cohorts (n=35).

"I met a wide variety of people and put a new perspective in my life."

- Innovate NYC Participant (taken from post-program survey)

How has iNYC affected participants career pathways and use of innovation methods?

On average, participating in the program made students more likely to want to work in an innovation related career with a mean response of 3.3 on a five point likert scale. Meanwhile 97% percent believed that they would use human-centered design in the future (Figure 3).

Many survey respondents said the program helped them validate ideas they had about careers in business and/or social innovation, allowing them to experience the design and consulting process first hand. Others noted that it was great for their CV and experience, in this way it validates such a program as a genuine competitor to internships, which offer similar value to students. Meanwhile at least nine of the thirty-five

respondents have graduated and are now working in a job that, based on the title, would likely involve business innovation.

In a time where being able to apply design methods helps bridge the skill and mindset gaps facing workers today, the authors found that Innovate NYC's 20th century approach of learning by doing , based on John Dewey's education theory (1938) and David Kolb's model of experiential learning (1984) combined with HCD (Cooley, 1989) and social entrepreneurship lean methods (Kickul & Tohmas, 2016), was an effective format for students to learn the approach first hand, learning from mistakes directly with a real societal problem and community partner need instead of studying the concepts.

"iNYC gave me important experience that will be relevant not only in my current position but in the plans I have for my career as a whole."

- Innovate NYC Participant (taken from post-program survey)

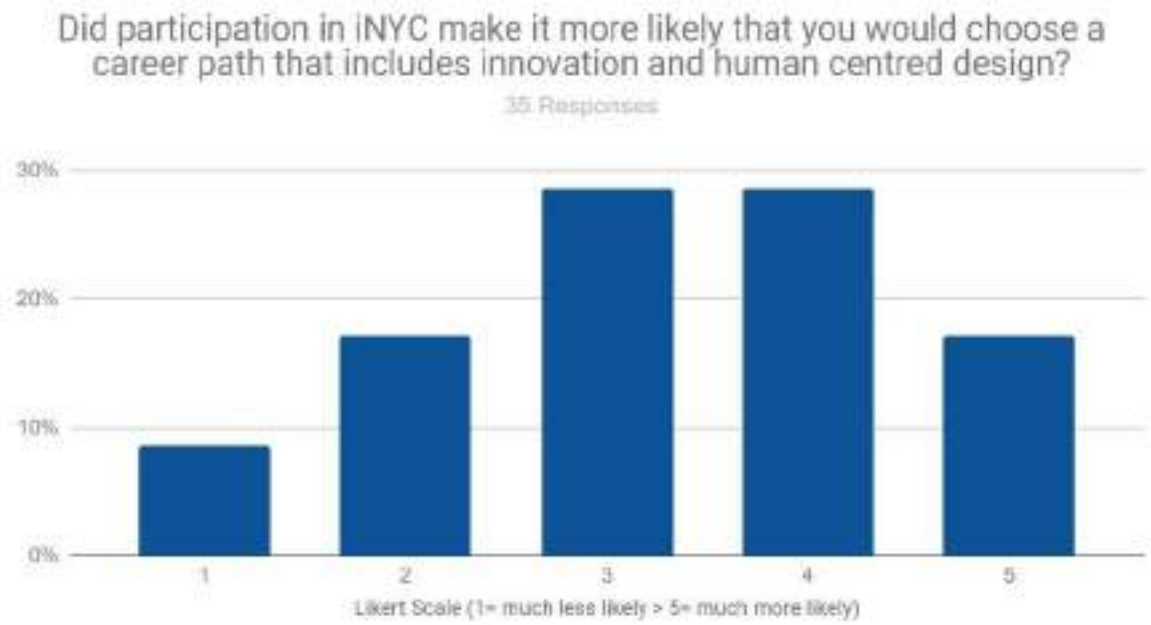

Figure 3. Participants who said that post program interactions were at least slightly helpful, taken from all cohorts (n=35).

Exposure to 21st Century skills, mindsets, and working in interdisciplinary teams

For many participants, Innovate NYC was their first time being exposed to design and innovation methods including user research, system analysis and mapping, ideation techniques, prototyping, and storytelling. They also learned transferable collaboration skills and tools such as conflict management amongst colleagues with different working styles, peer coaching, and client management, that can help them form and enrich future teams they work with.

Students from each cohort overwhelmingly agreed that after iNYC they are much more likely to want to work in diverse teams (Figure 4). They said it would inspire them to what to work in diverse teams, and that participants mainly saw value in offering them a new perspective.

21st-century jobs are affected by many factors including environmental sustainability, urbanization, increased inequity, political uncertainty, technological change, globalization, and demographic change (Bakhshi et al., 2017). Creative, design and engineering have bright outlooks according to Bakhshi. Championing design thinking and creative problem solving would allow students to remain employable throughout their lives. Higher order cognitive thinking like originality and active learning are also important. There is a need to negotiate the global context of work which will continue to expand (Dulebohn, 2017).

There is an eminent need to address the modern world of work skills gaps highlighted by the World Economic Forum (n.d.) and human resource firms (ManpowerGroup, n.d.). PayScale published in a 2016 Workforce-Skills Preparedness Report findings from responses of almost 64,000 hiring managers across a wide range of industries who were asked about the disconnect between the skills students have when they graduate from college and the skills companies need. In summary, 60% of managers said new graduates do not have the critical thinking and problem-solving skills necessary for the job, 46% said new graduates lack the necessary communication skills, and 36% reported new graduates have inadequate interpersonal and teamwork skills. Design and creativity around a specific community problem can help with many of these required career skills as students are forced to learn quickly about a specific problem, organize as a team, and execute on a creative process resulting in a solution for a specific client.

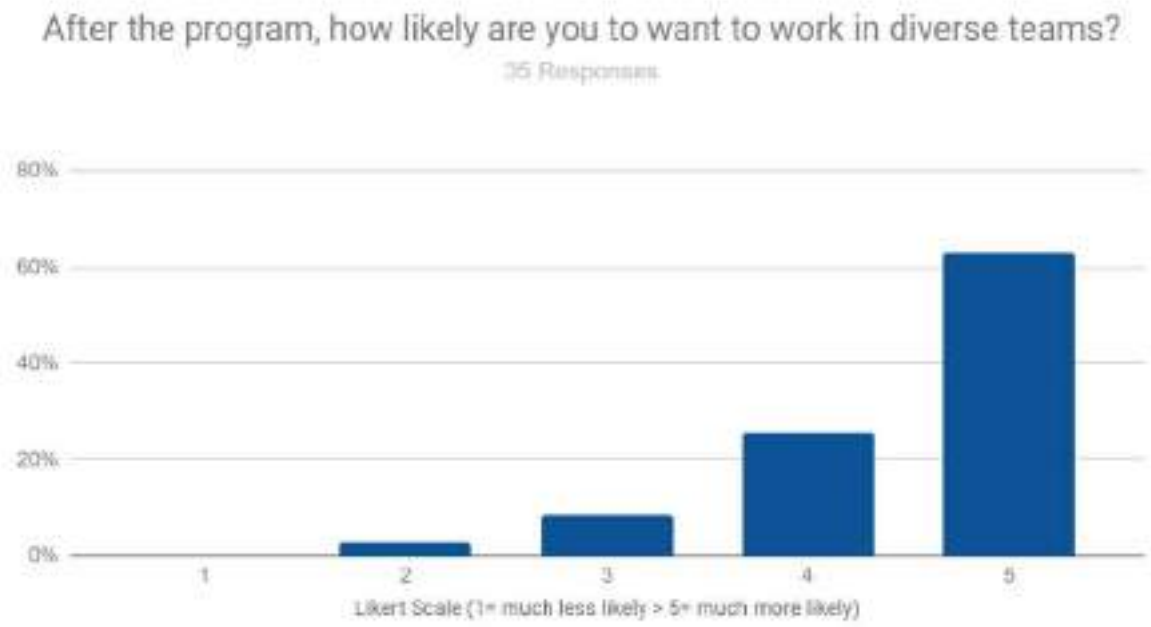

Figure 4: Participants on whether they were likely to want to work in diverse teams after taking part in iNYC (n=35).

"[Innovate NYC] gave me the confidence to find innovative solutions to problems on my own and develop a team"

- Innovate NYC Participant (taken from post-program survey)

Key Learnings

In this section, the authors share the key learnings that emerged throughout the research and discussions:

Coordination of iNYC took place in a VUCA environment, where change is the only constant.

With each passing iteration the researchers began to realize that with the rapid changes in the higher-education landscape most of the university representatives unintentionally changed each year, as did the DO School facilitators. These sit alongside the time and resource challenges of real life non-profit partner organisation and students juggling choices and other opportunities.This constantly shifting environment was analogous to what is happening in the economy across sectors, a more volatile, uncertain, complex and ambiguous (VUCA) atmosphere was developing (Alexander et al., 2016).

iNYC led to a small increase in the size and diversity of participant's social networks.

Clear limitations exist against the program's goals of catalysing diverse connections across fields and class divides, most prominent of which is the short nature of the engagement. Sociologists have identified three conditions that are considered crucial to the development of friendships: proximity; repeated, unplanned

interactions; and a setting that encourages people to confide in each other while letting their guard down (Williams, 2012). Innovate NYC includes all three elements; however, the authors (two representing university stakeholders and one from the DO School) believe that it would have been possible to increase the number of strong connections and levels of interaction post-program between cohort members if the program were to:

- Be longer in duration - to enable more time for the group to build strong bonds
- Involve more interaction outside of workshop hours - allowing more socially focused bonding that could take place by living together, cooking together and more.
- Included Follow-up engagements post-program - ensuring social contact is maintained, maximising opportunities to support each other in career endeavours.

iNYC provided students with a valuable hands-on taste of a career in design

The program was able to offer a short-term, hands-on glimpse into a career in innovation and HCD, carefully guided by expert facilitators. For non-design students, the program experience opened them up to the methods, and practices design innovators use, and they expressed these learnings were transferable to their chosen career paths. This was supported by research highlighting what non-designers bring to the design process (Morehen, Wrigley, & Wright, 2013). For those wanting to launch their career pathway in HCD, they require ongoing guidance and support far and above what iNYC could offer, both in time and input.

iNYC strongly demonstrated the benefits of working in diverse teams

Not only did feedback suggest that the diversity of participants was a clear highlight of the program but also that the students would be very likely to want to work in similar environments in the future (receiving a mean score of 4.5 on a five point likert scale).

The 2018 cohort included participants from nine countries and vastly different backgrounds, but despite their diversity each participant offered unique value and knowledge to the program. By way of example, a number of the local students offered direct experience and empathy to the challenge which no international could share, but the international students brought new perspectives and in some cases experience with the design process which helped guide solution and prototype development. This corroborates the benefits other researchers are finding with an international student perspective in the classroom (Beykont & Daiute, 2002).

Applications to the industry

Such a program could potentially offer opportunities for addressing mid-career skill gaps as cycles of economic and industry change become more frequent (Rosen & Jerdee, 1992). A tailored version of iNYC could offer someone looking to pivot their career a chance to gain exposure to new working styles and apply new methods while still offering a unique and valuable perspective to a challenge, based on their previous experience. It might also act as a format for different stakeholders in an industry to work together tackling a sector-wide problem while concurrently building connections across silos and giving those involved a fresh perspective and ability to support one another in a rapidly changing world.

Next steps

The data gathered about these three cohorts has the potential to become a longitudinal study. At the time of the survey, former participants were still in the early stage of their career, and hence identifying any actual long term impact from such a program will require time.

Conclusion

Innovate NYC was developed using innovation techniques and HCD as an extra-curricular program in response to a pressing shared challenge recognised by key stakeholders from the New York City higher education landscape. The program itself, which ran for three years, brought together a diverse spectrum of NYC college students and stakeholders, exposing many for the first time to design approaches and interdisciplinary teams, across universities and colleges and socio-economic divides to address some of the 21st century skills gap. It helped some students validate their career path, build hands-on project experience, and it exposed them to diverse new perspectives and networks which may play an increasingly valuable role as they advance in their careers.

Our evaluation of the program has touched on the difficulty of managing such a program in a VUCA world, the importance of quality time together in the building of lasting connections, the value of diverse teams in innovation and, hands-on 'learning by doing'. These lessons can be applied to any similar program that aims to bring together diverse stakeholders or teach human centred design skills.

APPENDIX : POST-PROGRAM SURVEY RESULTS

Qualitative Feedback:

Participants valued the diversity of people they met during the program, including fellow participants but also amongst experts and during the research phase. Specifically, they liked that it offered them a fresh perspective.

"I met a wide variety of people and put a new perspective in my life."

“The different types of people we interviewed and the people types of people I met from around the world.”

The program gave participants hands on project experience which enhanced their CVs but also helped some validate whether they wanted to pursue a career in innovation and design.

“It solidified my desire to work in the innovation/design field.”

“iNYC gave me important experience that will be relevant not only in my current position but in the plans I have for my career as a whole.”

It also gave participants a fresh perspective on interdisciplinarity and the value of diverse teams.

“I definitely enjoyed working as a team and will look for that in my career.”

“Gave me the confidence to find innovative solutions to problems on my own and develop a team”

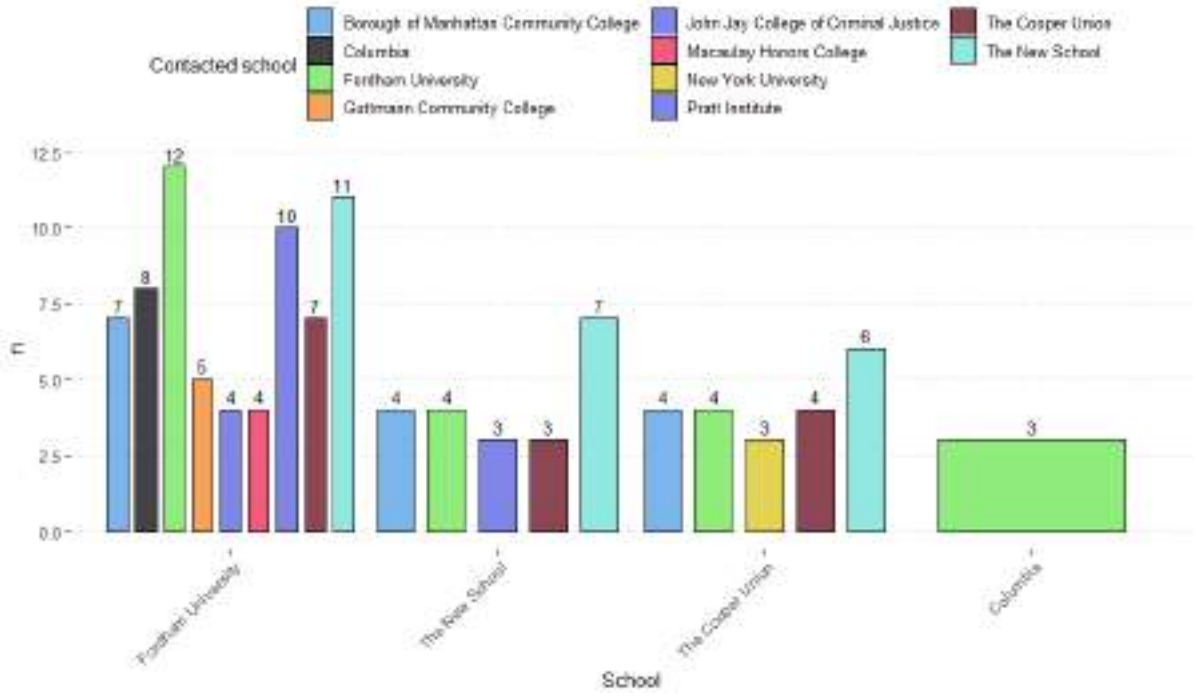
Quantitative Results:

With regards to whether the program could be a catalyst for lasting connections the results were mixed.

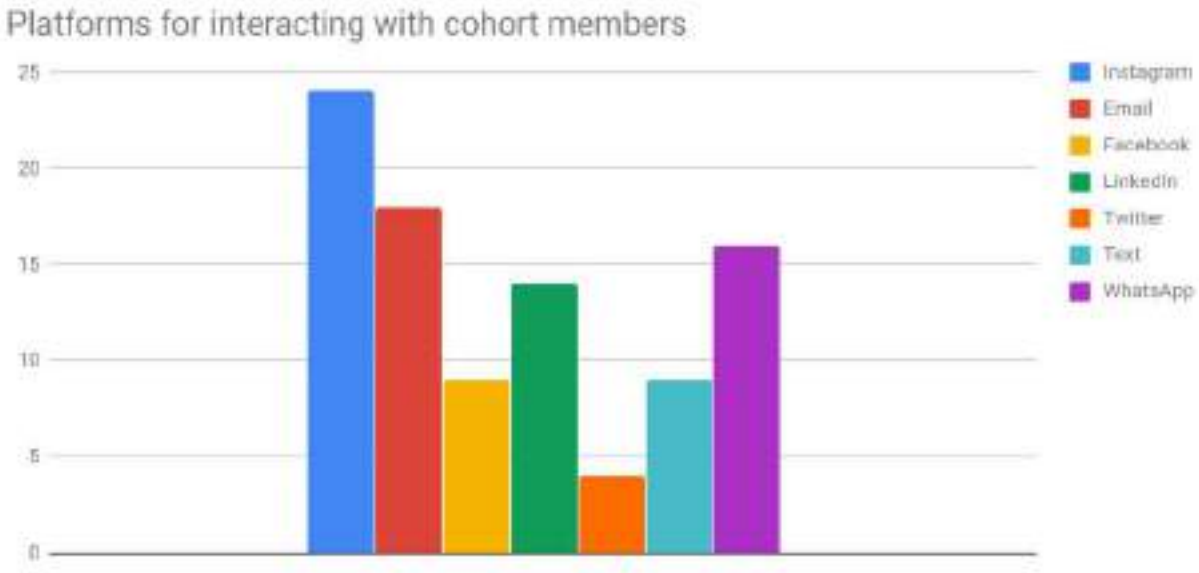
The researchers asked each participant to identify which members of their cohort they have had contact with following the program. They could choose between 'several times' 'monthly' or 'weekly'. Aggregating the responses, the authors inferred from the data that for every two cases (one case is if someone denoted that they'd been in contact with another at a certain interval) would serve as an approximation for one two-way relationship. The researchers defined a weak connection as one where two people have connected several times since the program, and a strong connection when contact is made weekly or monthly. From this, the researchers conclude that their remain 94 weak connections and 10 strong connections between cohort members.

It is known that in three of these cases, a friendship already existed before the program and thus it is likely iNYC only had a limited impact in strengthening their connection. Leaving 7 new strong connections made from the three cohorts.

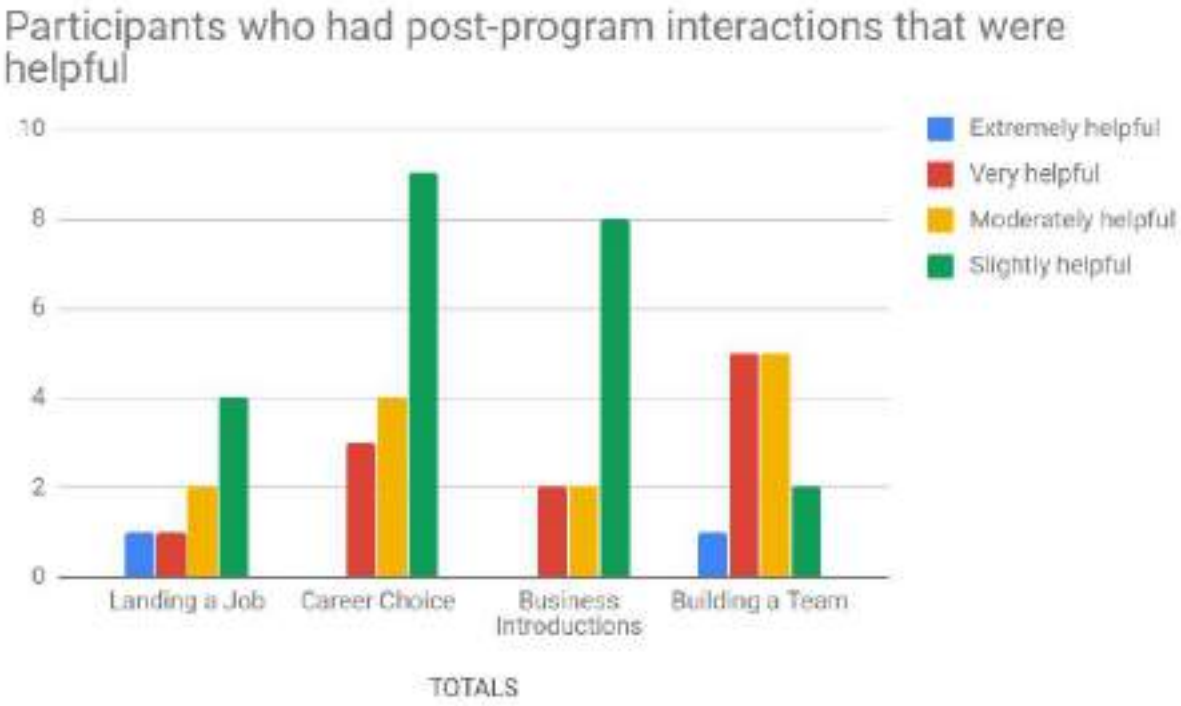
The following graph outlines connections made by students from different colleges, giving the authors an indicator as to the diversity of connections developed.



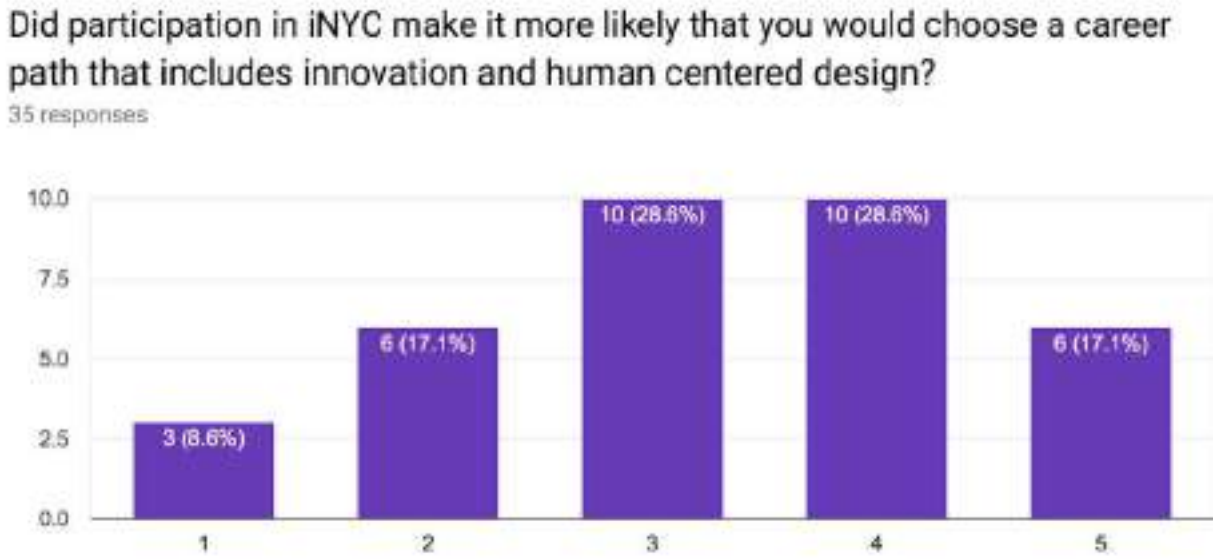
Participants connected with former participants across a range of digital media, however the most popular were Instagram, email and WhatsApp.



Asked whether any post-program interactions were helpful for their career, 16 said that they were at least slightly helpful in terms of career choices, and 12 found them at least slightly helpful for business introductions.



Participants felt that iNYC made them more likely to choose a career path that includes innovation and human centred design. They were asked to select a score using a five point likert scale, which resulted in a mean response of 3.3.



Over 80% of responding participants also believe it to be likely or very likely they will use business innovation, HCD or lean methods in their career. Less than 3% (or one participant) say it's not likely they will use HCD in their career.

In response to a question about propensity to want to work in diverse teams, respondents overwhelmingly agreed that after iNYC they are very likely to want to work in diverse teams, post-program - receiving a mean score of 4.5 (from a five point likert scale)

Research Perspectives IN THE ERA OF Transformations

Towards an interdisciplinary knowledge exchange model: Uniandes design school help to transform Avianca into a design driven company in the flight industry

DE FRANCISCO Santiago and MAZO Diego*

Universidad de Los Andes, Colombia

doi: 10.33114/adim.2019.c09.116

Universities and corporates, in Europe and the United States, have come to a win-win relationship to accomplish goals that serve research and industry. However, this is not a common situation in Latin America. Knowledge exchange and the co-creation of new projects by applying academic research to solve company problems does not happen naturally.
To bridge this gap, the Design School of Universidad de los Andes, together with Avianca, are exploring new formats to understand the knowledge transfer impact in an open innovation network aiming to create fluid channels between different stakeholders. The primary goal was to help Avianca to strengthen their innovation department by apply design methodologies. First, allowing design students to proposed novel solutions for the traveller experience. Then, engaging Avianca employees to learn the design process. These explorations gave the opportunity to the university to apply design research and academic findings in a professional and commercial environment.
After one year of collaboration and ten prototypes tested at the airport, we can say that Avianca's innovation mindset has evolved by implementing a user-centric perspective in the customer experience touch points, building prototypes and quickly iterate. Furthermore, this partnership helped Avianca's employees to experience a design environment in which they were actively interacting in the innovation process.

Keywords: collaboration, university, industry, design methodologies, innovation

From traditional development to Open innovation collaboration

More universities and corporations in Europe and the United States, have come to establish a win-win relationship to accomplish goals that serve research and industry in terms of innovation. Cases like Stanford or MIT that uses academic research to propose novel solutions to company problems, or TU Delft and DTU who use participatory methodologies to exchange of knowledge between professionals and practitioners are a common and valuable practice. However, this is not the case for the Latin American context, in which companies prefer external consultancy as their first option, underestimating the universities input.

That was the case of Avianca. In the Colombian context, Avianca is the market leader in flight services in Latin America with 27.000 employees and 97 years of experience in the industry. A couple of years ago, they were struggling in a severe crisis that ended with a new CEO, Hernán Rincón, former president of Microsoft Latam. The decision to appoint a tech leader was to promote the transformation of Avianca into a digital company that operates flight services.

To pursue this quest, the new CEO established drastic changes to the organization model. One of them was to open an innovation department. The primary objective of that was to build an open network of partners who could add cross-disciplinary knowledge to the company to develop cutting edge projects for the aviation industry. By these initiatives, Avianca's new vision aimed to foster a new organizational culture within the internal teams by promoting new ways of working through agile processes, rapid prototyping, and experimentation.

As a consequence of this initiative, the Design School of Universidad de los Andes was the first partner to explore new formats to understand the impact of knowledge transfer in an open innovation network aiming to create fluid channels between different stakeholders in order to build innovative service propositions (Gardien, Deckers & Christiaansen, 2014). The proposal consisted of a model called Pilot to scale, to define a medium-term vision for the collaboration. This model considers three steps to foster Avianca to become a design-driven organization: Seed, Grow and Spread (Figure 1).

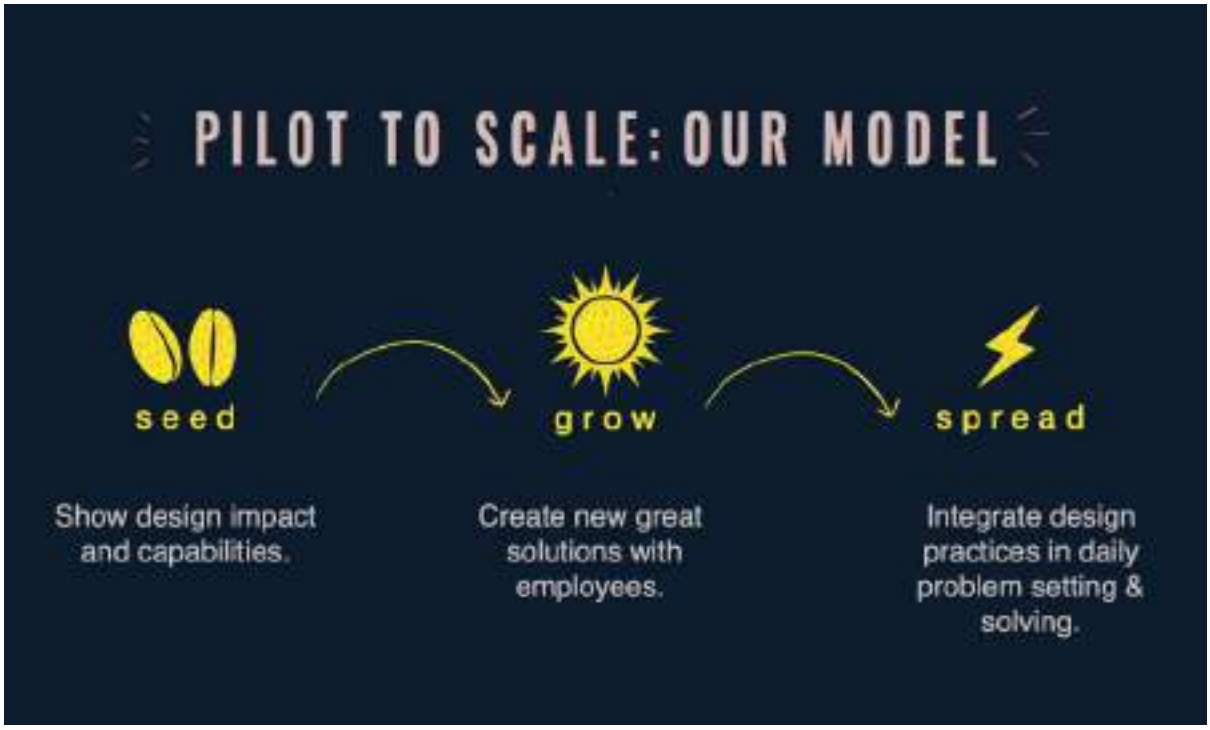

Figure 1 Pilot to scale model

Ready for take off

The first collaborative pilot proposed by the Design School was to use a Service Design course as a platform to explore eight user experience challenges proposed by Avianca. The course was offered in the bachelor program to last year students that were going to work with the assessment and guidance of two design professors, experts in service design (Figure 2).

Twenty-seven students enrolled for the course and were divided in eight groups, one group per challenge. Their task was to perform an extensive design research, visualize and generate new opportunities of interventions, and validate and implement those solutions (Beckman & Barry, 2007). They had to work together with the land and flight experience department of Avianca to enhance the customer's travel experience from top to bottom.

As proposed by Owen (1998) in any innovation process, the observation phase requires in-depth field research. In order to do that, the design teams needed access to some restricted areas to understand how the operational decisions were taken, how the front desk services were presented to customers, and how the overall perception of the experience was. The support, collaborations, and participation of Avianca employees were crucial for uncovering new opportunity areas in the front stage of the experience based on the research results.

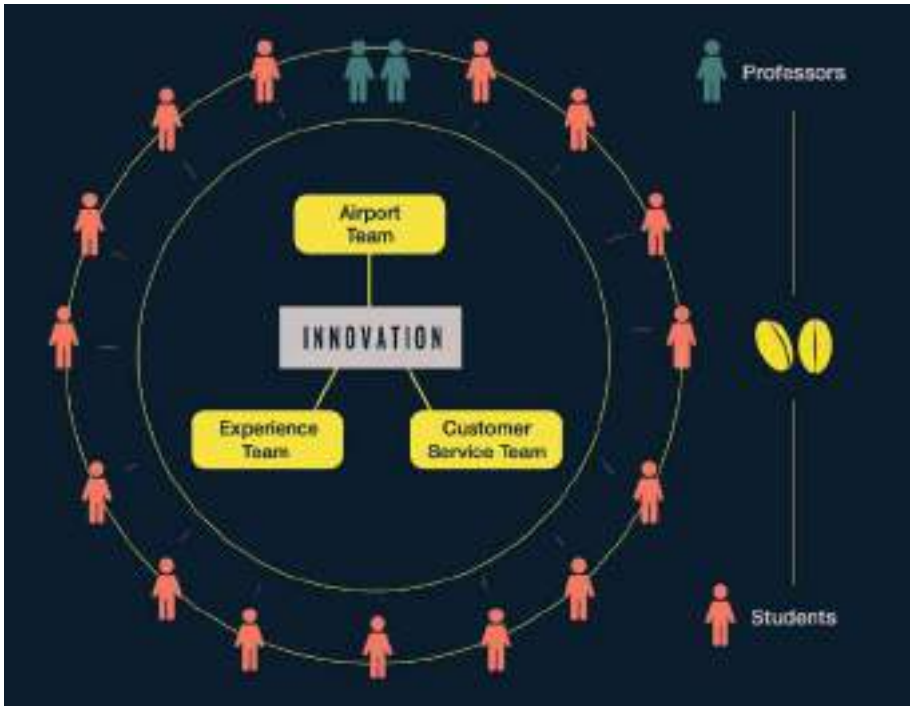

Figure 2 Seed phase. Bachelor design course

Those opportunities were translated into solutions and validated by prototyping them in the real context. Every team launched a minimum viable product at the airport considering the insights and user needs uncovered in the research phase (Table 1). For Avianca this was entirely new. In most cases, the launch of a new product or service waited until the process was completed and there was no window for validations or iterations.

Table 1 Solutions and concept descriptions of the MVP.

Name of the Challenge	Solution	Concept description
Improve the check in experience	CHILLOUT	CHILLOUT is based on Colombian families' habits of waiting for their relatives at the other side of the barrier while they are checking in. This moment of waiting was perceived as a waste of time and was emotionally painful. CHILLOUT takes the customer place in the check-in queue and allows the traveller to spend the previous moments before the flight with his family in a cosy space. Once CHILLOUT arrives at the front desk, the customer is called to continue with the check-in process.
Improve the experience in the waiting areas	Complaining was never easier	A testimony booth located at the waiting area where passengers could talk about any topic, situation or problem. There is an immediate response to make the visitor to feel confident. Moreover, Avianca will collect all complain to apply the suggestions to make improvements in the services.
Improve the experience in the VIP areas	VIP on the go	Partnerships between Avianca and companies located at the airport to let Diamond VIP passengers enjoy their benefits even when they do not enter the VIP area. They will have access to this service from Avianca's app.
Improve the boarding process	Colouring your day (Figure 3)	A boarding system that combines the current letter categorization with a colour code in the boarding pass. A lighting panel at the gate warns the passengers about their boarding moment. If the passenger

		boards in the wrong turn, the red light will represent it is an incorrect order.
Build a memorable experience during the flight	The perfect moment	The in-flight experience takes advantage of the aerial sightseeing and the amazing destinations passed by to use the window to connect the passenger with positive emotions providing a memorable experience.
Cope with 1-4 hours delay flights	The best host	A system to identify the interests and preferences of the passengers to deliver a more personalized and meaningful experience during a delayed flight. This system contains a direct channel of communication in the passenger's smartphone to be updated about flight information. The passenger can choose the type of compensation that she prefers from a variety of services (food, book, hairdressers, massage…)
Deliver a satisfactory flight connection experience	Carla, closer to you	An artificial intelligence system embedded in Avianca's app that helps passengers to get precise information through an augmented reality avatar who delivers a more personalized and familiar interaction.
Improve the luggage claiming process	Friendly luggage	It is a loyalty program with luggage based on values such as friendship, reciprocity, and support. The program provides luggage benefits to the users who apply best practices in the airport processes. The luggage would exit first at the destination, and it would be handled carefully in transportation.

Figure 3 Colour-coding boarding process MVP at the gate

These solutions were presented in a closing event to the Avianca staff team composed by two vice presidents, and several directors, including the director of El Dorado Airport in Bogotá. The design teams experienced how to showcase their work and how to respond to an audience of experts. Further implementations of these solutions are still in the project pipeline, but its development requires further internal ownership that was not in the scope of the objectives of the course.

Due to the success of this collaboration and the value output generated, Avianca's innovation team and their Vice president of experience decided to roll out a new course. However, and taking into account the idea to

give continuity to the projects, they required the course to have specific characteristics. First, the process should provide more engagement from the Avianca team, more like a partnership relation rather than a commercial relationship. Second, the application of the methodologies should develop a installed capacity that would increase the innovation culture to the inside of the company. Finally, to validate the impact of the new knowledge, the brief was aimed to tackle organizational challenges.

For the Design School, this meant that the new course was embedded in the second stage of the Pilot to scale model: Grow. This time, Avianca was more interested in acquiring design thinking skills, rather than receiving solutions for their problems. They wanted to be part of the process and allow the people from the different departments to experience the design research approach. For the second pilot, we proposed Avianca to enroll four of their employees in one of the master courses of the Design School. The master cohort for that year was multidisciplinary and had little experience with design research methodologies, so at certain point, all were even. The idea was to have the employees to be part of the team, share the feedback, experience the phases of the project and ideate solutions for the challenges presented by their departments (Figure 4).

As suggested by Avianca, the main goal of this second collaboration was to generate process of knowledge exchange, rather than providing solutions to identified problems. Nevertheless, the design teams, including the Avianca employees, would have to propose novel solutions for the challenges. In one hand Avianca's employees were engaged to learn the design process and apply it in practice; and on the other hand, master design students were able to face how design methodologies could be applied to systemic approaches. Moreover, undertaking these projects gave the opportunity to the Design School to apply academic research findings in a professional and commercial environment.

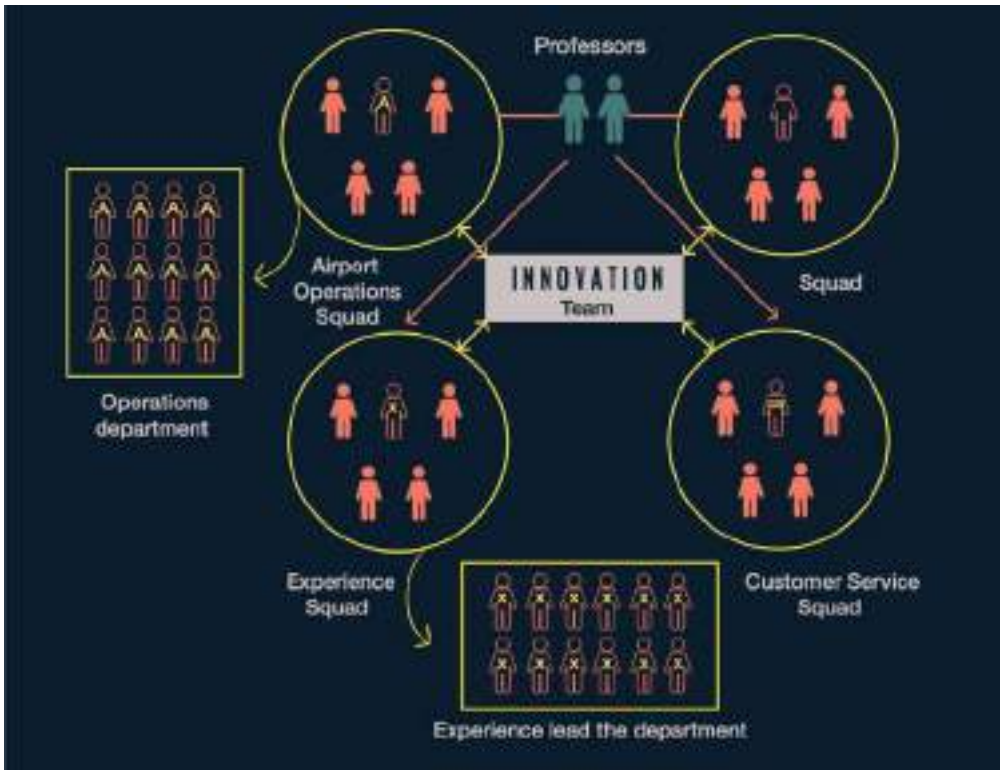

Figure 4 Grow phase. Master design course

Each Avianca employee was in charge of one of challenges selected for the course. Moreover, and as part of the design team, they had to perform certain design activities to move forward in the project. The design teams had to defined a research plan, deciding to use and apply different tools for data collecting, such as cultural probes (Gaver, Dunne & Pacenti, 1999), generative sessions (Sanders & Stappers, 2014) and participatory mappings (Buur & Matthews, 2008). After designing their collecting data tools (Table 2), the teams had to analyze the information that they gathered, in order to identify opportunities to intervene. Then, and as part of the course, we emphasize in the idea generation process (Figure 5). Usually for non-designers,

and sometimes for designers, that is the most frustrating phase. Finally, the teams had to validate their ideas in the real context.

Table 2 Solutions and concept descriptions of the MVP.

Challenge	*Concept description*	*Design tools used*
Opportune information: How can we transfer the operational information through all relevant areas in a convenient and clear way to be available in every passenger touch point?	AICS: An electronic message system customized for travellers that contains information related to the flights irregularities and allows the traveller to be updated in real time. The system will centralize all the information and will help travellers to know what to do in case of a delay. Irregularities backstage: A centralized multi directional communication channel visible for all the information chain that improves the decision-making of the personal in charge of the flight services.	Drawing activities in interviews. Actor-interaction maps. Value proposition canvas. Role-play. Jumping obstacles (creative session). Emotional metrics. Technological probes.
Assistance services: How can we improve the passenger experience while delivering the assistance services (food, hotel and transport) in a operational irregularity?	Mobile bookstore: Entertainment system for waiting rooms that provides the traveller with options to kill some time while waits for the irregularities to be solved. Additionally, it is present to show the traveller that Avianca cares Self management app: New menu for the Avianca app that allows the user to choose the best options related to his interests, pleasures and time availability once an irregularity or cancelation is presented.	Cultural probes. Generative sessions. Scenarios. Pain matrix. Personas. What if (ideation session). 10+10 (ideation session). Prototype. Paper prototype. Mockups
Cabin crew structure: How can we improve the current management and leadership model for the cabin crew?	CaroBot: A virtual assistant that provides useful information to the cabin crew about requirements, requests, and administrative processes. Support Troop: This support group's main activity is to visit the cabin crew, according to a schedule to give them support and answer questions that are not part of the standard procedures or require a more delicate handling.	Empathy maps. Ideal leader activity. Technological probes. Wizard of oz. Video scenario.
Effective communication: How can we improve the communication between Avianca and its cabin crew?	Moodbox: Set of cards to improve the communication between coordination and crewmembers to smooth things. There are two types of cards: practical tips and motivational reflections.	Technological probes. 5+5 (ideation session). What if (ideation session). Prototypes. Card sorting.

Figure 5. Master students and Avianca employees working together during the data collection phase.

The exercise was intended to be very practical, more than novel. We wanted to teach the course participants to learn by doing and experimenting. All the teams we exposed and force to create and implement their design tools and ideas. After each phase of the process, we came back to the key learning's and how the teams overcame the difficulties. It was important that every member of the team experienced how to contribute by applying their previous knowledge combined with the new methodologies that were presented. For the Avianca employees the course was an eye-opener to alternative approaches to complex problems. For the master students was a challenge to manage the client expectations with the developments of the project. In the end, this processes required new time and dedication, planting the seed implied to mingle with relevant actors inside the company. Again, and as the first course, the validation of the solutions gave insightful information to Avianca and hopefully a new perspective to manage future projects.

Crew prepared for landing

The results of theses collaboration gave us insights towards the way to collaborate with a corporation from the academic side. From doing user research in site to prototyping and validating ideas, the learning that both organizations got were important to keep projecting the future alliance. This alliance is building a solid ground for the open innovation network to be developed further with new partners who could add different types of value to the aviation industry and help Avianca to maintain its leading position.

One primary element was the collaboration between employees and students. Employees were able to provide the inside view of the business experience and enlighten the students to come up with fresh perspectives and build new and reachable services. Also, having the employees enrolled in the design course helped the methodologies and new perspectives to sink in the company's processes. Moreover, the role of Avianca's employees in the corporate hierarchy helped to reach the right people to move faster in the design process. However, the directors did not have the time outside the lectures to contribute and generate a fluent collaboration with the squad. Therefore, the selection of intermediate roles to lead the squad would have been more appropriate to ensure a more successful team dynamic.

Another key element of the collaboration was the hands on and multidimensional approach (Gardien, Deckers & Christiaansen, 2014). From qualitative research from the airport to the office building, as well as prototyping simple but ready to test solutions, helped Avianca to increase the speed of their innovation process. Normally, we think about design thinking in the front end of the experience. However, this project worked also in the back stage with internal processes of flight irregularities and crew management. Considering several dimensions at the same time helped Avianca to connect the processes with the passenger and crew experiences and envisioning new opportunities of improvement. In case that after testing the solutions Avianca decides to build these ideas, they have the ownership of the low fidelity prototypes. The students signed an agreement to assign the rights of commercial use to Avianca at the beginning of the course.

Our biggest failure during the project was the exclusion of important stakeholders to the open innovation network in the beginning. The owner of El Dorado´s airport in Bogotá, OPAIN, was an obstacle in the process of field research and prototyping in context due to internal regulations. To avoid these problems, it is our responsibility to convince key stakeholders about the value of this kind of projects and the benefits that the

airport could gain from them such higher customer satisfaction, better passenger flow, more efficient processes…

In conclusion, to recreate the success of this initiative, firstly, it is vital to have in place the willingness to experiment with new formats to share knowledge and learn from each other. Secondly, the commitment of every party to the collaboration is essential to reach common goals; for example academia should have a deep service understanding of the clients' highly regulated environment in both backstage and front stage, and the company should be willing to get their hands "dirty" for the low cost and fast iterative prototyping phase. Finally, as a collaboration that involves really young people, it is rather important to give them freedom to create fresh and innovative ideas, but also it is always a challenge to manage their fixation with technological solutions and let them understand the different layers required to design an efficient and memorable service experience.

"We need an internet connection" – Early exploration of physical/digital spaces for digital transformation

RESMINI Andrea* and LINDENFALK Bertil

Jönköping University, Sweden
* andrea.resmini@ju.se
doi: 10.33114/adim.2019.c10.133

The case details the application of a systemic, actor-centered design approach to a strategic process of digital transformation in support of industry/research collaboration in one of the administrative regions of southern Sweden. Project mainstays include regional development of "digital leadership", the creation of a digital/physical competence center, and a larger plan to connect these mainstays to an already established, extremely successful computing- and entertainment-centered yearly event in the main city in the region. Structured around the initial problem space identification and formalization aspects, the case specifically discusses the competence center, what it should be and what activities it should facilitate. It describes the process followed and the results obtained in the divergent stages of the project by means of the early engagement of different stakeholder groups through workshop activities. Preliminary conclusions are drawn in respect to what challenges currently hinder big-scale processes for the design of complex digital/physical environments and the experiences they enable; the relative solidity of adaptive or transformative approaches versus blended space approaches for digital/physical environments; the role and relative weight of "digital" in the organizational context of digital transformation processes.

Keywords: Digital transformation, systemic design, multi-actor approach, blended space

Introduction

The case resides within a large-scale project addressing the digital transformation of small-medium enterprises (SMEs) within the Jönköping region in southern Sweden, and it details one of its main subprojects, the creation of a "digital competence center" (DKC, Digitalt Kompetenscentrum). The project emerged from the notion that competence related to digitization that the local university and an established and extremely successful computing and entertainment yearly event attract should remain in the region and help it, culturally and economically, in its digital transformation journey.

The project, running 2018-2020, is funded with EU funds by the Swedish Agency for Economic and Regional Growth, and sees the collaboration of Jönköping University, through its International Business School and its School of Engineering, and of the regional business incubator, Science Park. Coordinated by a steering group comprising staff from all three organizations, the project is formally compartmentalized along organizational lines in terms of outcomes or subprojects: the Business School is in charge of the creation of "digital leadership" expertise; the School of Engineering of the creation of the DKC; and the Science Park of the more diffusive initiatives for connecting these to the planned growth of the annual computing event in the city.

The authors were not involved in either the writing of the proposal, of the project charter, or the initial planning of the activities for the initial exploration and formalization of the DKC. They were called in roughly four months into the project by the steering group to, upon suggestion from one of the members, to help design and implement the DKC, as they had established competence in the creation of similar physical spaces and in digitalization, and were readily available in-house resources.

Digital transformation

The European Commission defines digital transformation as "a fusion of advanced technologies and the integration of physical and digital systems, the predominance of innovative business models and new processes, and the creation of smart products and services", and states that digital transformation "is characterised by a fusion of advanced technologies and the integration of physical and digital systems, the predominance of innovative business models and new processes, and the creation of smart products and services." (European Commission, nd). According to the Commission, the digital transformation of traditional sectors of the industry "presents enormous growth potential for Europe", but currently "EU businesses are not taking full advantage of (...) the collaborative economy" because of disparities across sectors, "between high-tech and more traditional areas", between countries, between regions within the same country, and between large companies and SMEs (European Commission, nd).

While the global indices for "skills and innovation" in Swedish SMEs are above the EU average (Klingspor & Fortkamp, 2010), the push towards "digital transformation" requires novel competences and a change management mindset that these companies do not currently possess or know how to acquire. For this reason, and because of their number and relevance in the socio-economic fabric of the region, the project primarily targets SMEs and family-owned businesses and addresses their transformation processes at both the strategic and the operative levels. Strategic, through the initiatives connected to the "digital leadership" and "event" subprojects; operative, through the DKC subproject. The project charter also secondarily addresses "other actors that are influenced by the digital transformation of SMEs. The education sector, students, entrepreneurs, and other social actors".

The case

The case details the early stages, post project start, of the DKC subproject in the fall / winter of 2018-2019. It provides an overview of how various negotiations around the design process were managed within the context of a large-scale project where public / private co-production is a key element. It describes the friction between proposal-level goals (create a competence center) and operation-level goals that necessarily include exploration before any formalization can happen. It describes how the authors framed the problem and the early engagement of different actor groups in workshop activities directed at shaping the competence center: what it should be and why, what activities it should facilitate and for whom. It documents the results of the workshops, and the decisional processes connected to advancing the project.

Theory and methods

The design process was operatively approached as a co-design activity involving multiple groups of actors (SMEs, researchers, public bodies), and conceptually as a systemic design activity for social change (Stroh, 2005) to be enacted through a digital / physical space (or series of spaces). Organizationally, it was structured via a management-level decision group, not invested with day-to-day operations, a steering group, and the operative DKC group (fig. 2).

The authors introduced the UK Design Council's Double Diamond model (fig. 1) to frame the design and implementation process in all communications within the DKC group and with the steering group, and explicitly anchored the initial activities to the Discover and Define phases in the first diamond, those often referred to in the practice as "do the right thing" (the second diamond being "do the thing right"). The model allowed for easier alignment of the activities and better communication within the groups.

The Discover and Define phases were then specifically implemented as a set of exploratory workshops with attendees from the primary actor group alternated with reflection and discussion meetings with members of the DKC and steering groups. Communication with the decision group was left to the project manager.

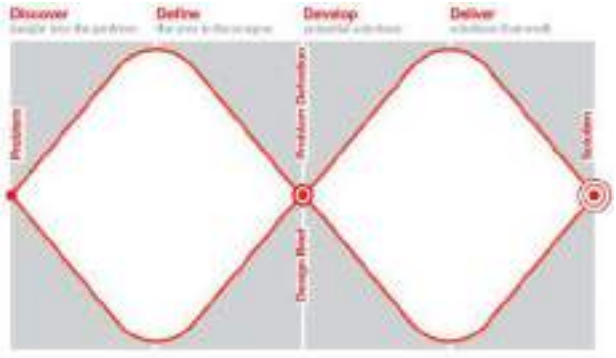

Figure 1 The Double Diamond model, UK Design Council (2005)

Before the workshops, the authors aligned with ongoing conversations and informally captured through one-on-one meetings and mail exchanges the steering group's own views of what the space ought to be. In these meetings the DKC was manifested to the authors as being primarily a "showroom", an exhibit space for "innovative digital products". Together with the requirements provided in the project charter, these views became the foundation of the prescriptive view of the DKC used to inform the October workshop.

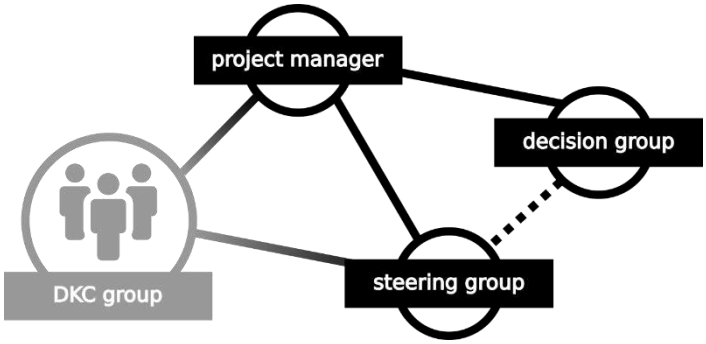

Figure 2 Organizational view of the DKC subproject

As the DKC was described in the charter as a digital / physical environment, the authors resorted to Horan's "digital places" (Horan, 2000) and Benyon's concept of "blended space" (Benyon, 2014) to frame the problem space conceptually.

Horan maintains that digital places are "new leverage points for creating new experiences and relationships that will profoundly redefine our experience of physical space" (p. 23). They "vary in scale and character but share space in both the physical and electronic world". Digital places are not finite artifacts, "stable end-states", but "dynamic settings that evolve over time" and as such are constantly emerging as "a continuum of technological integration". At one end of this continuum, Horan places "unplugged" designs, spaces that manifest little or no digitality. Midway, "adaptive" designs that "modestly incorporate electronic features in physical space". At the other end we have "transformative" designs: spaces where digital and physical commingle and where digital "influences the layout, program, and infrastructure of the place" (p. 9).

Benyon similarly defines a blended space as a space "where a physical space is deliberately integrated in a close-knit way with a digital space" (p. 79) and whose structure and properties emerge from its specific combination of physical and digital. While Horan's continuum explicitly looks at the artifact (the space being considered), the concept of blended spaces is structured around human embodiment and human activity: blended spaces are designed with the purpose of creating first and foremost a novel user experience. They instantiate a different sense of "being present" and lead to new ways of interacting.

The digital competence center

The project charter clearly established that the DKC should be an actual physical environment. The various initial project documents and meeting minutes describe it as a space company representatives travel to in

order to participate in unspecified activities connected to collaboration, dissemination, and networking facilitated by technology.

The overall funding structure, what it allocated for building work, and the requirement that the DKC be maintained and further developed by one of the university subsidiaries after the project has run its course, introduced the primary operative constraints. These pragmatically meant that the DKC be located inside an existing building and repurposed spaces, as opposed to a newly-built construction, and that while no punctual architectural specifications nor a location were determined in the project charter, a position on campus or its proximity was immediately established as highly desirable, for reasons of economic and logistic convenience.

The choice to adapt pre-existing spaces made the physical environment of the DKC a difficult starting point for a design based on actual needs and wants as opposed to organizational satisficing based on availability: consequently, conversations with the DKC and steering groups in preparation for the workshops centered on the concept of what “activities” and “experiences” the DKC should support, rather than what “spaces” it should contain.

In terms of the author’s theoretical framework, the project proposal, funding and setup phases clearly envisioned the DKC as an example of Horan’s “adaptive space”, where an already existing space is augmented with discreet digital interventions: teleconferencing tools, screens, computers. In the course of the initiation stage, before the authors were called in, the DKC started to be described as a transformative space, and attention focused on “activities”. During the workshop stage, coinciding with the authors’ engagement with the project and with the divergent phase of the project, the DKC was cast as a blended space to account for the feedback received and the challenges introduced by external and internal actors. Treating the DKC as an element in a larger, region-wide digital / physical ecosystem allowed the authors to resort to methods and tools they previously applied to the design of the studio spaces for Jönköping University and to the analysis of ambient assisted living solutions (Lindenfalk & Resmini, 2019).

The workshops

Figure 3 Project introduction at the October workshop

The October workshop was held in a separate conference facility on university grounds (fig. 3) in Jönköping. Planned by the authors and facilitated together with two members of the steering group, it registered the presence of 19 attendees from both SMEs and larger private and public organizations operating in the region.

The workshop was conceived as a 2-hour series of hands-on, group activities following a general introduction to the project, to the DKC, and to the goals for the day: explore what activities and what goals the center should support. Attendees were provided a detailed brief. In accordance with the Double Diamond model, the authors identified group exercises focusing on divergent thinking and modified them when necessary to suit the task (Gray et al, 2010). Ideas were to be elicited explicitly and in a way that allowed further subsequent reflection. Informal feedback from attendees was collected after wrap-up.

One of the most immediate concrete results of the workshop was a shift in language, as attendees found the "showroom" concept limiting, and used it sparingly and non-exclusively. This resulted also in a broader focus, with the DKC being diversely characterized as a connecting space, a learning space, and a meeting place.

Workshop attendees identified the DKC with a "space" or "series of spaces" aimed at solving specific problems in these areas, networking, learning, meeting, by providing concrete solutions. Words such as "implement", "survey", "measure", "metric" were used frequently in connection to expected outcomes. A point was made that the DKC should be a "riktningsvisare", a signpost for digital transformation and development in the region, to help local companies "make the journey" to and beyond digital.

Figure 4 The "writestorming" activity at the October workshop

Notes and deliverables were collected at the end of the workshop, analyzed, and informally discussed between the authors. They were then shared with the DKC group and framed in the context of the prescriptive view obtained before. The initial plan for what activities the DKC should support, for whom, and what kind of spaces these implied, emerged from this review (Table 1). A prioritized list of goals and steps to follow was agreed upon and then submitted in report form to the project manager and the steering group, together with a walk-through and recap of the workshop itself that included photos and samples of the deliverables created by attendees.

Table 1 Synthetic view of the characteristics associated with the three main roles of the DKC from the October workshop

Connecting space	Learning space	Meeting place
both a physical space and a digital space		
a place for business	a place where failings lead to successes	a place where to sit and have coffee
a space for showcasing innovative local solutions	a place where to learn unconventional things that open the way	a place where to book meeting or seminar rooms and hosts events
a place that addresses how to work with competition between players	a visible space, locally and globally	
a place where help can be found and ideas shared		
an up-to-date, digital layer that extends the DKC's physical reach		

Communication-wise, the workshop illustrated the digital gap portrayed by the EU Commission in detail. While very clearly discussing and describing a continuous blended space of a/synchronous presence, attendees phrased the DKC in terms of "we need an internet connection" or "I want to see a robot".
Attendees also clearly signaled the importance of directly engaging secondary actor groups, students, instructors, entrepreneurs through the DKC. Nonetheless, it was decided to prioritize the creation of a space that facilitates industry / research collaboration and dissemination, strongly focused on SMEs, to respect the project charter goals. The authors supported the decision as obeying systemic design principles. Focused

intervention on strategically chosen elements within a system, rather than a scattered approach, has proven to be more effective in enacting systemic change (Stroh, 2015).
Based on these outcomes, the authors prepared a preliminary list of desired characteristics that was used as the base input for the subsequent December workshop.

Table 2 Digital competence center: physical and digital elements and characteristics from the October workshop

DKC physical space	DKC digital space
manned space, with expert staff and expert workshop facilitators / leaders	physical presence in the competence center should be "one-click" streamable
reception area	physical presence in the competence center should be "one-click" recordable
flexible exhibit space	curated web presence
cafe corner	curated social media presence
specialized spaces for meetings, workshops, seminars, and teleconferences	interactive display of cutting-edge digital products and services online and offline
restrooms	

The December workshop was held on the grounds of Campus Värnamo, in Värnamo, Jönköping county. The location was chosen to increase the outreach in the region, and attention was paid to enrolling smaller companies from the area. Both authors facilitated the workshop, which ran activities specifically chosen to build on the results of the October one: attendees were given Table 1 and Table 2 as a starting point and asked to identify challenges and opportunities those activities and spaces suggested.

Figure 5 Introducing the December workshop in Campus Värnamo

Attendees primarily saw the DKC as a direct embodiment of abstract practices, a container, with no precise distinction between its physical and digital spaces, with “information” available “inside”: as a stand-in or avatar for a regional network one can “call on” if necessary to easily pull together resources, receive help with a problem, or acquire the necessary operative and strategic expertise to possibly solve it. Physically visiting the competence center was described as an unnecessary hurdle by many.
The October and December workshops were both filmed in their entirety using a two-cameras setup, with the permission of attendees. All deliverables, notes, posters, sketches, were retained by the authors.

Key learnings and preliminary conclusions

Adaptive and transformative spaces v blended spaces

Preliminary key learnings from this phase of the DKC subproject include how adaptive or transformative space approaches do not provide solid foundations for the design and implementation of digital/physical environments such as the competence center. A blended space approach provides a better fit, but with it

comes the need to consider actor-centered processes as the originator of the ecosystem itself (Resmini & Lacerda, 2016). This is currently a problem because of how the decisional process for large-scale project flows, exacerbated by the fact that the inclusive systemic process it implies is part of what digital transformation sets out to enable in the first place.

Role and relative weight of digital

People's experience of day-to-day processes, from education to travel to healthcare, happens across locations, environments, devices, and freely spans the digital and the physical (Resmini & Lacerda, 2016). Transformation is also a process, and a necessarily pervasive one, but decision makers in the setup stages of the project clearly drew a separation between physical and digital assets and outcomes. This separation impacted the way the project was budgeted and this in turn severely constrains transitioning to a blended space approach.

Figure 6 Group activity during the December workshop

Such an idea of digital is marketing-driven and fundamentally static and descriptive: a unidirectional tool to document and report in-project organizational progress, or a mere technological aid such as teleconferencing. This also led to the conceptualization problem codified by the DKC as a "showroom": a largely static if inspirational display of "what's been done".
As trivial as this might seem, the consequences are vast. Budget cannot be re-accommodated to support digital as a dynamic conversational environment that helps shape the culture of the space. Even the DKC web presence has been framed as an execution problem and not as a community building opportunity that needs steering, resources, continuous nurturing, and appropriate governance.

Execution v design disconnect

These issues can be ascribed to a disconnect between the binding constraints introduced at the proposal stages and the reality of a large-scale transformation process. In the case of this project, the disconnect appears to be rooted in a business-centered scaffolding that eschews the socio-technical and systemic complexities of co-creation and of turning ideas into actual structures and artifacts. The EU SPIN document mentioned earlier unwittingly illustrates this approach: "Innovation (...) needs (...) a visionary that has the idea; an entrepreneur that organises to put the idea into practice; a salesman to commercialise the idea; a financer to finance the product development; customers that demand new and innovative solutions" (Klingspor & Fortkamp, 2010). This is a huge misunderstanding of how such processes work. From idea to implementation it is simply "execution": a "vision" needs to be "put into practice" by an entrepreneur, financed, and commercialized, leaving little to no space for any design activities and human-centered reassessments.
Additionally, the use of traditional bottom-up co-creation processes can result pragmatically problematic. Both the steering group and the DKC group insisted on an inclusive, bottom-up co-design process built on a multi-actor perspective. This was partially sidestepped by companies whose decision makers mainly brought themselves into the process and personally attended the two workshops with the aim of bringing management seniority to the conversation. Especially in December, many attendees were "koncernchef", high-level managers with a strategic view, rather than an operative view, of the problem space. This not only

led to some last-minute retooling of the activities, but it conceptually turned a bottom-up conversation (DKC-side) into a top-down conversation (SME-side) (fig. 7).

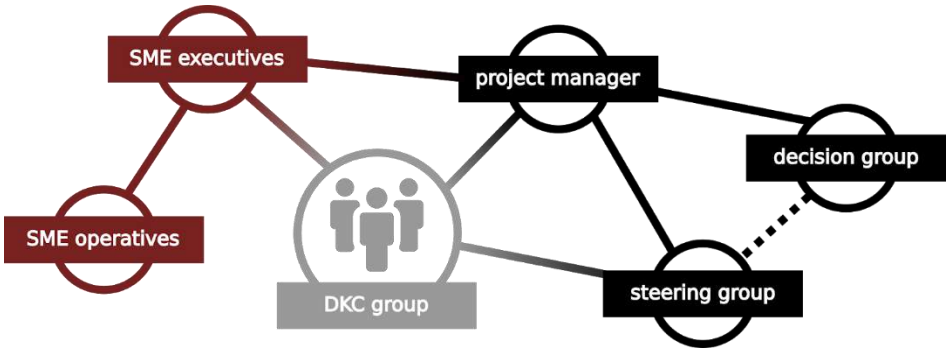

Figure 7 Organizational view shows SME executives introducing an additional top-down loop in the process

This appears to be yet another loop reintroducing the same problem the authors experienced first-hand in the framing of the DKC itself, with the initial top-down process initiating the project assuming pure "execution" and remaining completely unaware of and disconnected from the complexity and uncertainties of design for large-scale socio-technical change.

A design contribution to the entrepreneurial experience

ROLDAN ACEVEDO Juan David* and TELALBASIC Ida

Loughborough University, United Kingdom
* juandroldana@gmail.com
doi: 10.33114/adim.2019.c11.115

In recent history, different design approaches have been entering fields like management and strategy to improve product development and service delivery. Specifically, entrepreneurship has adopted a user-centric mindset in methodologies like the business canvas model and the value proposition canvas which increases the awareness of the users' needs when developing solutions. What happens when a service design approach is used to understand the entrepreneurs' experience through the creation of their startups? Recent literature suggests that entrepreneurial activity and success is conditioned by their local entrepreneurship ecosystem. This study investigates the Entrepreneurship Ecosystem of Medellín, Colombia - an ecosystem in constant growth but that lacks qualitative analysis. The sample consists of 12 entrepreneurs in early-stage phase. The data was gathered with two design research methods: Cultural Probes and Semi-structured interviews. The analysis of the information collected facilitated the development of 4 insights about the entrepreneurs and an experience map to visualise and interpret their journey to create a startup. The results of this study reflected the implications of the ecosystem, the explanation of the users' perceptions and awareness and propose a set of ideas to the local government to improve the experience of undertaking a startup in Medellín.

Keywords: Entrepreneurship ecosystem, Service design, Entrepreneurship, Startup, Design methods

User centred Design in Entrepreneurship

In recent years, there has been an increasing diversification of user centred design approaches, due to the exploration of experiences, products and services as a whole system. This trend could be seen in fields like management and strategy (Martin, 2009); retail, financial services, hospitality and human resources (Reason, Lovlie & Flu, 2016); health management (Lin, Hughes, Katica, Dining-Zuber & Plsek, 2011), social innovation (Anderson, Ostrom, Corus, Fisk, Gallan, Giraldo, Mende, Mulder, Rayburn, Rosenbaum, Shirahada & Williams, 2013) and manufacturing processes (Lighting, 2017). Specifically, entrepreneurship has adopted a user-centric mindset in the development of methodologies like the Business model generation (Osterwalder, Pigneur, Smith & Movement, 2010) and the Value proposition design (Osterwalder, Pigneur, Smith, Bernarda & Papadakos, 2014), which increases the awareness of the users' needs when creating solutions as the core of a business model.

The aforementioned methodologies have flourished as assistance for entrepreneurs in the planning, ideation and implementation of business ideas, in order to create and capture value (Trimi and Berbegal-Mirabent, 2012). This case study undertakes a different perspective and aims to explore the consequences of using a user centric approach to understand the entrepreneurs' experience through the creation of their startups.

Between the different streams of user centric methodologies, this study uses service design as stated for its capacity and methods to investigate and understand people's experiences, interactions and practices as main sources of inspiration for designing better services. (Meroni and Sangiorgi, 2011).

Complemented by Stickdorn, Hormess, Lawrence & Schneider, (2017) perspective about service design, first as a mindset, to help us to determine how to respond to situations; second, as a process, to find an elegant and innovative design driven solution and third, as a toolset, that should be used after understanding the mindset and process.

As some writers (Klaar, 2015; Penin, 2018; Stickdorn et al., 2018) suggest, service design is a holistic approach, which understands that users (or customers) are not only influenced by the core offering but by all the layers around the experience of buying/using, and therefore deliver a suitable solution. Due to this, the exploration of the broader context of entrepreneurship should be taken into consideration.

The systemic support for entrepreneurship

Particularly in the field of entrepreneurship, Fuerlinger, Fandl & Funke (2015) argue that start-ups' survival is conditioned by not just the business itself, but the (Entrepreneurship) Ecosystem. According to Isenberg (2010), the Entrepreneurship ecosystems (EE) are a set of conditions that foster entrepreneurial activity, which involves culture, policies, support, human capital, an open-minded market and that are limited to a metropolitan area.

In order to identify the conditions of EE, The Aspen Institute (2013) reviewed 9 different diagnostic tools for EE, mapping them by the level of complexity (number of indicators) and the geographical analysis (local or national) (See: Image1). This study selected Isenberg's (2010) Six Domains to understand the ecosystem where entrepreneurship moves in cities, for its analysis capabilities based on different aspects on a local and a national level with the same importance. This allowed to acquire contextual data for the analysis of the entrepreneurial support as a system.

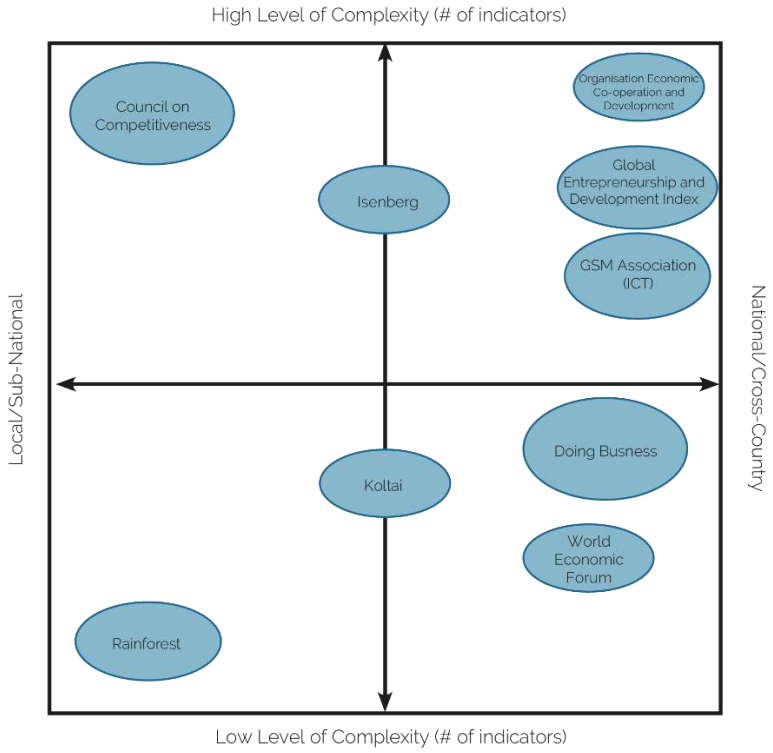

Figure 1: Diagnostic tools. Adapted from The Aspen Institute (2013)

The Entrepreneurial activity in the context

According to the Global Entrepreneurship Monitor (2017), Latin-American Countries has been increasing their entrepreneurial activity and their participation in early-stage entrepreneurship is even higher than in bigger economies. In a regional scale, Colombia is ranked fourth for ease of doing business in Latin-America (Doingbusiness.org, 2017); at a local scale, Medellín is the second largest Colombian city and it concentrates the second industrial centre in Colombia.

The EE of Medellín has been developing across 20 years of cooperation and work (Universidad Nacional de Colombia, 2016), led by the local government, but expanded by the industry. Figure 2, shows the interconnection of the most visible actors around the domains.

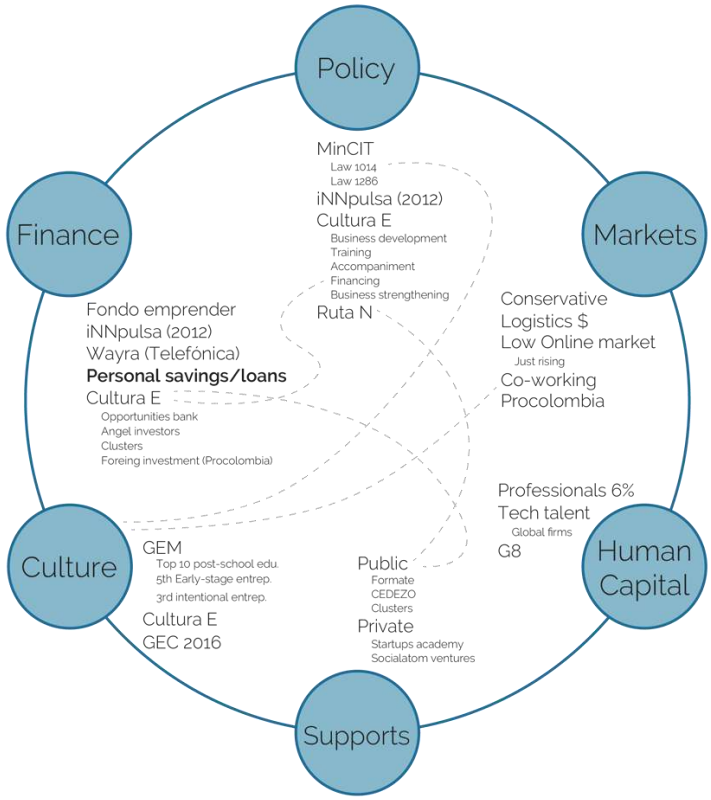

Figure 2: Medellín's domains of entrepreneurship.

From the entrepreneurs' (users) perspective, the ecosystem is compounded by a set of activities, programs or institutions that can support their venture and entrepreneurial development. These activities and programmes are services for entrepreneurs, which could be construed as touchpoints of an entrepreneurial support service (the entrepreneurship ecosystem itself). Figure 3, presents Medellín's inventory of programmes and activities of the EE of Medellín.

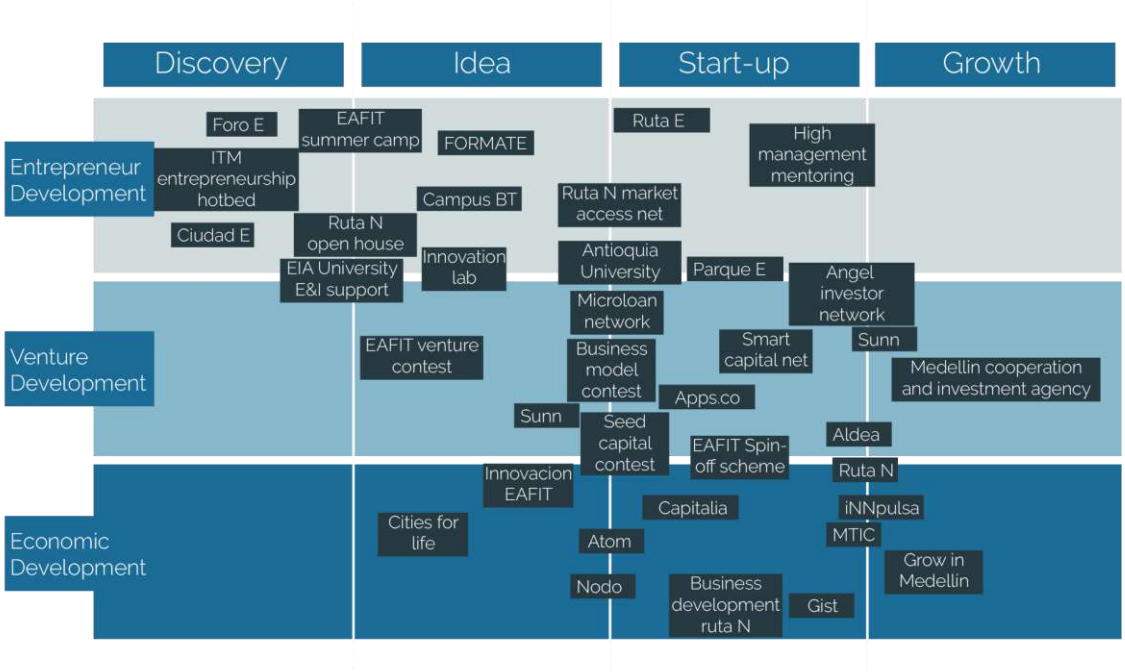

Image 3: EE of Medellín's Inventory. Adapted from Jaramillo, 2018.

Analysing the conditions of the ecosystem through the Isenberg's domains can be perceived that Medellín has a complex system loaded with actors, programmes and activities, but also that it has the characteristics that fosters its entrepreneurial activity. Although this approach explores in deep different characteristics, it leaves on a side the experiences, emotions and personal goals that entrepreneurs have. Based on Lederman, Messina, Pienknagura, & Rigolini (2014), the entrepreneurs are the actors that add value to the EE, therefore they need to be understood.

The research

The research used a sample of 12 entrepreneurs located in Medellín, with a start-up on early-stage development phase, which includes two types of individuals: Nascent entrepreneurs and New business owners (Global Entrepreneurship Monitor, 2017).

The first tool used for data collection is Cultural probes, defined by Gaver, Boucher, Pennington, & Walker (2004), as collections of evocative tasks meant to elicit inspirational responses from people, and also consider as a tool that produces unbiased data collected by participants themselves (Stickdorn et al., 2018). Its appliance consists of the filling of a booklet with a set of activities that participants solved by themselves. Specifically, the activities were designed to inquire about the entrepreneurs' emotions in relation with important events; to investigate, when and how they feel comfortable or challenged; to explore, how they have interacted with the entrepreneurship ecosystem; and how the entrepreneurial experience can be better (from their perspective). Figure 4, presents the booklet sent to the participants. It worth to mention that participants are native in Spanish which is the reason for the language in the booklet.

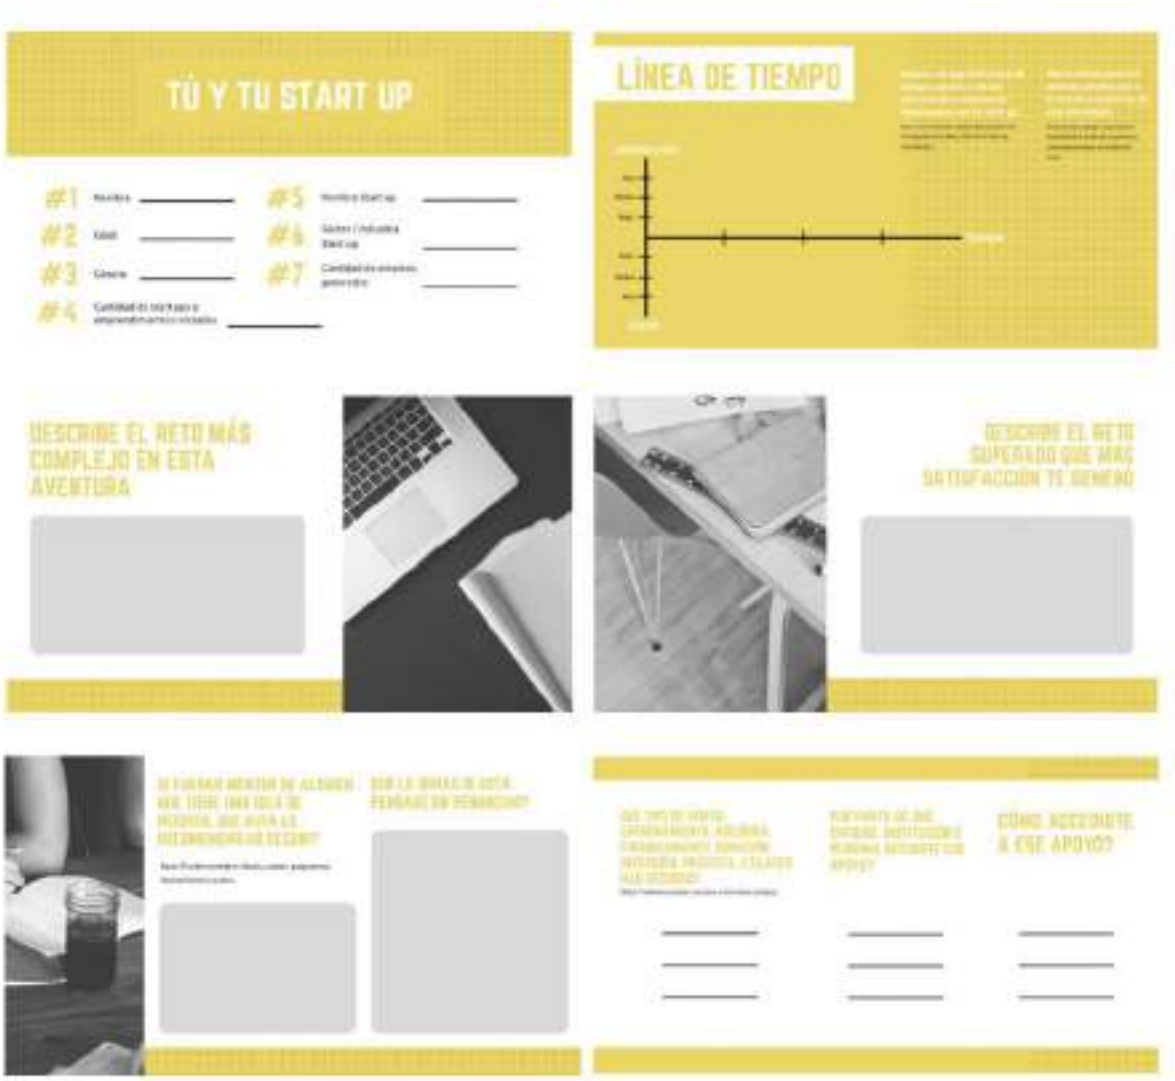

Figure 4: Booklet.

The probes generated a range of diverse messages, storytelling and descriptions that provide an understanding of how entrepreneurs feel and act around the EE, even if they are unaware of what the ecosystem is. For this reason, an initial scan of the responses was undertaken with the objective of identifying keywords in the answers, looking for patterns within opinions and the actions taken by the participants through their own experience. As described by Gaver et al. (2004), participants interpret questions and activities in different forms, and that was reflected in their answers. This required critical analysis of the data to clarify the meaning of the answer given based on the profile of the participants.

The initial keywords scan spotted similarities in perceptions, definitions and attitudes, but it further allowed the division of the participant entrepreneurs into two categories: entrepreneurs who have had access to some of the programmes offered by the entrepreneurship ecosystem, and entrepreneurs who have not had access to any programmes offered by the entrepreneurship ecosystem.

For both cases, the first scan identified missing information in the results. Therefore, a set of follow up questions was developed to be asked in an online semi-structured interview tool, to use with the participants. Yin, (2018) define semi-structured interviews them as a flexible tool that adapts to the situational context with a set of open-ended questions where a conversation guided by the interviewer develop the studied theme. The emerging inquiries allows the understanding of the entrepreneurs' awareness, particularly on what (other) programmes they knew existed to support entrepreneurs or ventures in the city; how they knew about those programmes; and why they did not access them.

Key Results and interpretation

Based on the answers in the probes in relation to the entrepreneurs' experience and complemented by the online semi-structured interviews, the data was separate as follows:

- Satisfactory events
- Stressful events
- Complex challenges
- Overcoming challenges
- Support and resources
- Mentoring advice
- Knowledge about programmes
- Programmes' communication
- And reasons to avoid participation

The key findings reveal valuable data about entrepreneurs in Medellín, their experiences, values and perceptions. The amount of data and its relevance requires deep analysis to interpret it properly. The following mindmap shown in Figure 5, presents a summarised viewpoint from the probes and interviews, and facilitated the definition of insights following Dalton's (2016) suggestion. The context sets a place, one activity and one condition that the entrepreneurs have in common; the dilemma is divided into two categories perceived by the entrepreneurs, and analysed by the researcher after transcribing the data; each item from the dilemma is related to a why, which would present possible reasons that produces the gaps in the ecosystem operation; the motivations are divided in motivations to be an entrepreneur and motivations to not interact with the ecosystem, the last motivation may not be related to all the entrepreneurs but aims to suggest what they think based on their comments; and ideal, presents optimal conditions for the different entrepreneurs when interacting with the ecosystem.

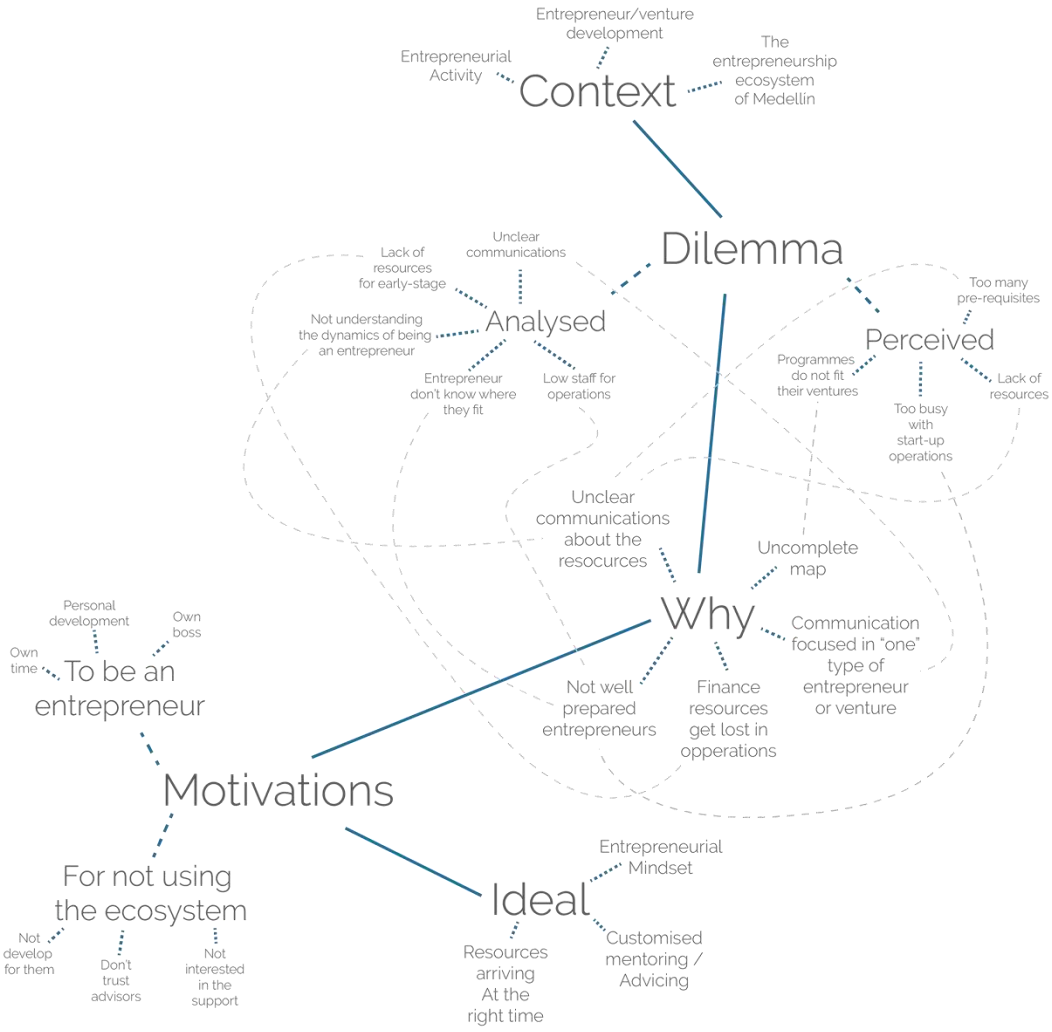

Figure 5: Mindmap.

After identifying the five characteristics around the theme, Dalton (2016) also recommends to state the insights by three sentences: the first one to describe a situation for a user's behaviour; second, to define the dilemma; and third, to describe an ideal situation. As a result, the following insights were developed:

> *"I decided to start my own business in Medellín because I will be working for something I feel passionate about. I've seen institutions that offer courses or contest for start-ups but I don't know which type of help they provide or where to look for it. If there was a source that briefly described the opportunities, I would give it a chance."*
>
> *"I have been working for a year on my start-up and I am really busy trying to do everything, I am feeling tired and I don't have time to look for courses or advice, I don't even know what they can provide me. If someone had told me about the challenges and difficulties of setting a start-up, I would have thought more about it"*
>
> *"I have my own business with a partner. We know Medellín supports entrepreneurs through advertisements and marketing, but that is just for technology-based ventures. I would like to see successful entrepreneurs outside of the technology fields."*
>
> *"I had participated in contest and courses for entrepreneurs before, all of them are the same, they are too general: business model canvas; but nothing on growth strategies, finance or staff management. I wish I could find offered valuable mentorship in specifics areas by people with real experience and not by junior advisors."*

The insights created aim to represent a variety of entrepreneurs' voices about their journey in venture development in Medellín, collecting different thoughts and opinions. Emulating diverse entrepreneurs, the first one was an entrepreneur that had chosen not to interact with the ecosystem; the second is an entrepreneur without any type of training in entrepreneurship, that started empirically and had experienced a difficult path; the third voice represents entrepreneurs that had encountered different sources and types of support but was meant for a different type of entrepreneur, which made them lose interest; and the last one is an entrepreneur that does not trust the ecosystem, someone that has experienced it and is tired of the redundant offers.

The entrepreneurs' experience in the EE of Medellín

One of the service design characteristics is the facilitation to visualise an experience through graphic maps that allows revealing different issues within the service. This research uses a method presented by Kalbach (2016), the experience map, which targets the observation of human behaviour and how the organisation fits in the user's aim.

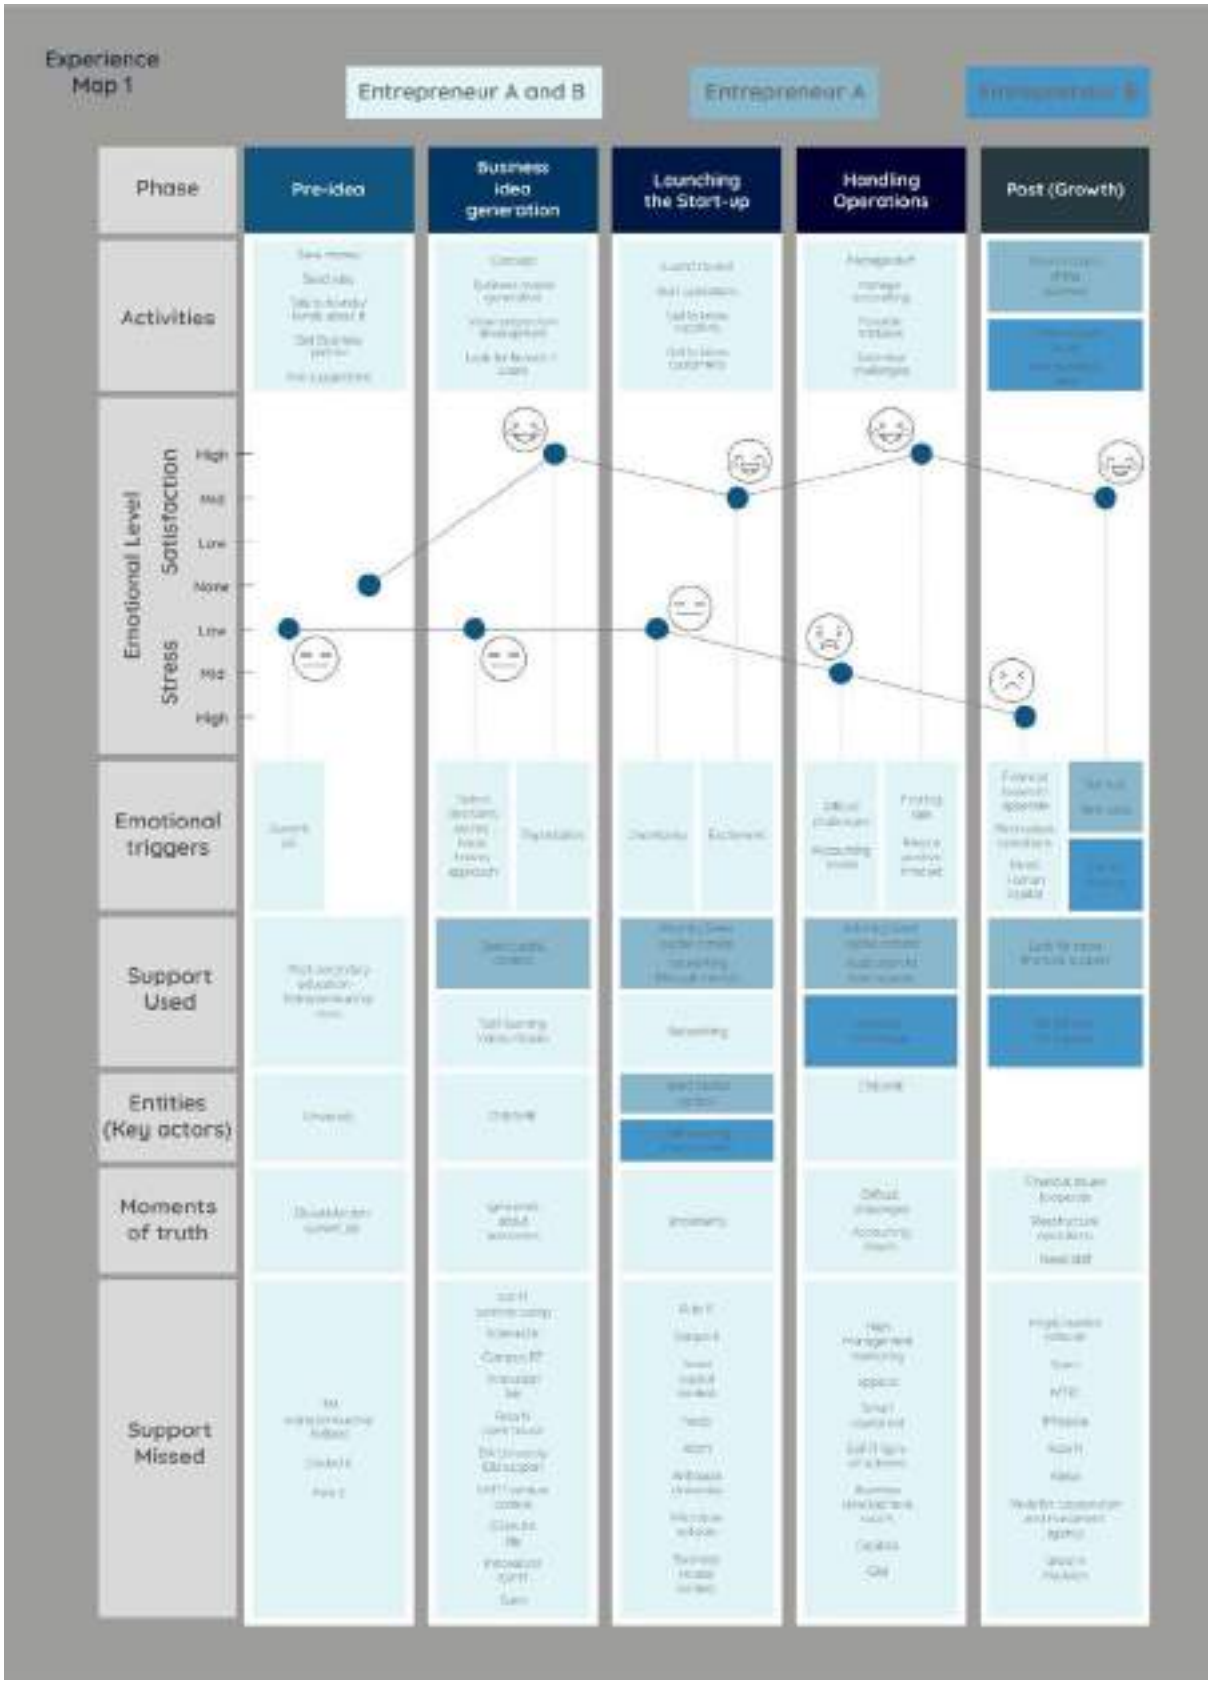

Figure 6: Experience map "As-Is".

Figure 6, shows an experience map chronologically divided into phases: Pre-Idea, Business idea generation, Launching the start-up, Handling operations, and (Post) Growth. Each phase is described by a set of

characteristics divided into two sections. The first section includes: the activities, what entrepreneurs develop and focus their efforts on in that time-set; their satisfaction and stress level at each moment; followed by the triggers of those feelings and their corresponding level. The second section contains: the support, which is subdivided into two types of entrepreneurs. Character one, represents an entrepreneur who chose to interact with the entrepreneurship ecosystem in order to receive support for each of the phases; Character two, illustrates an entrepreneur who had chosen not to interact with the ecosystem by choice or acknowledge anything about it; following the support is the entities section, institutions or organisations that provided the support mentioned in the previous characteristic; support missed, mentions programmes that could be used by the entrepreneurs but did not; and the final characteristic is the Moments of truth, the characteristic of the reflexive statement realised by the entrepreneur in that phase, which may affect its future interactions. It needs to be highlighted that this map may not represent the whole spectrum of entrepreneurs in the city but aims to simulate how some of the entrepreneurs' experience interact with the EE.

What else can Service Design offer to entrepreneurship?

By visualising Figure 6 and the identified insights from the entrepreneurs' experience, the needs of the users and the limits or conditions of service providers are clear. An idea generation stage can be used now to propose how to improve the service experience. Starting with a divergent step, where all the possible solutions to the ecosystem issues are explored; followed by the clustering and filtering of ideas based on cost, current facilities available of the ecosystem and easiness of development; to finish with a convergent step, by the selection and adaptation of the best options for the context.

This process results in a set of ideas implemented in Figure 10, an Experience Map "To be", that represents an ideal experience for an entrepreneur.

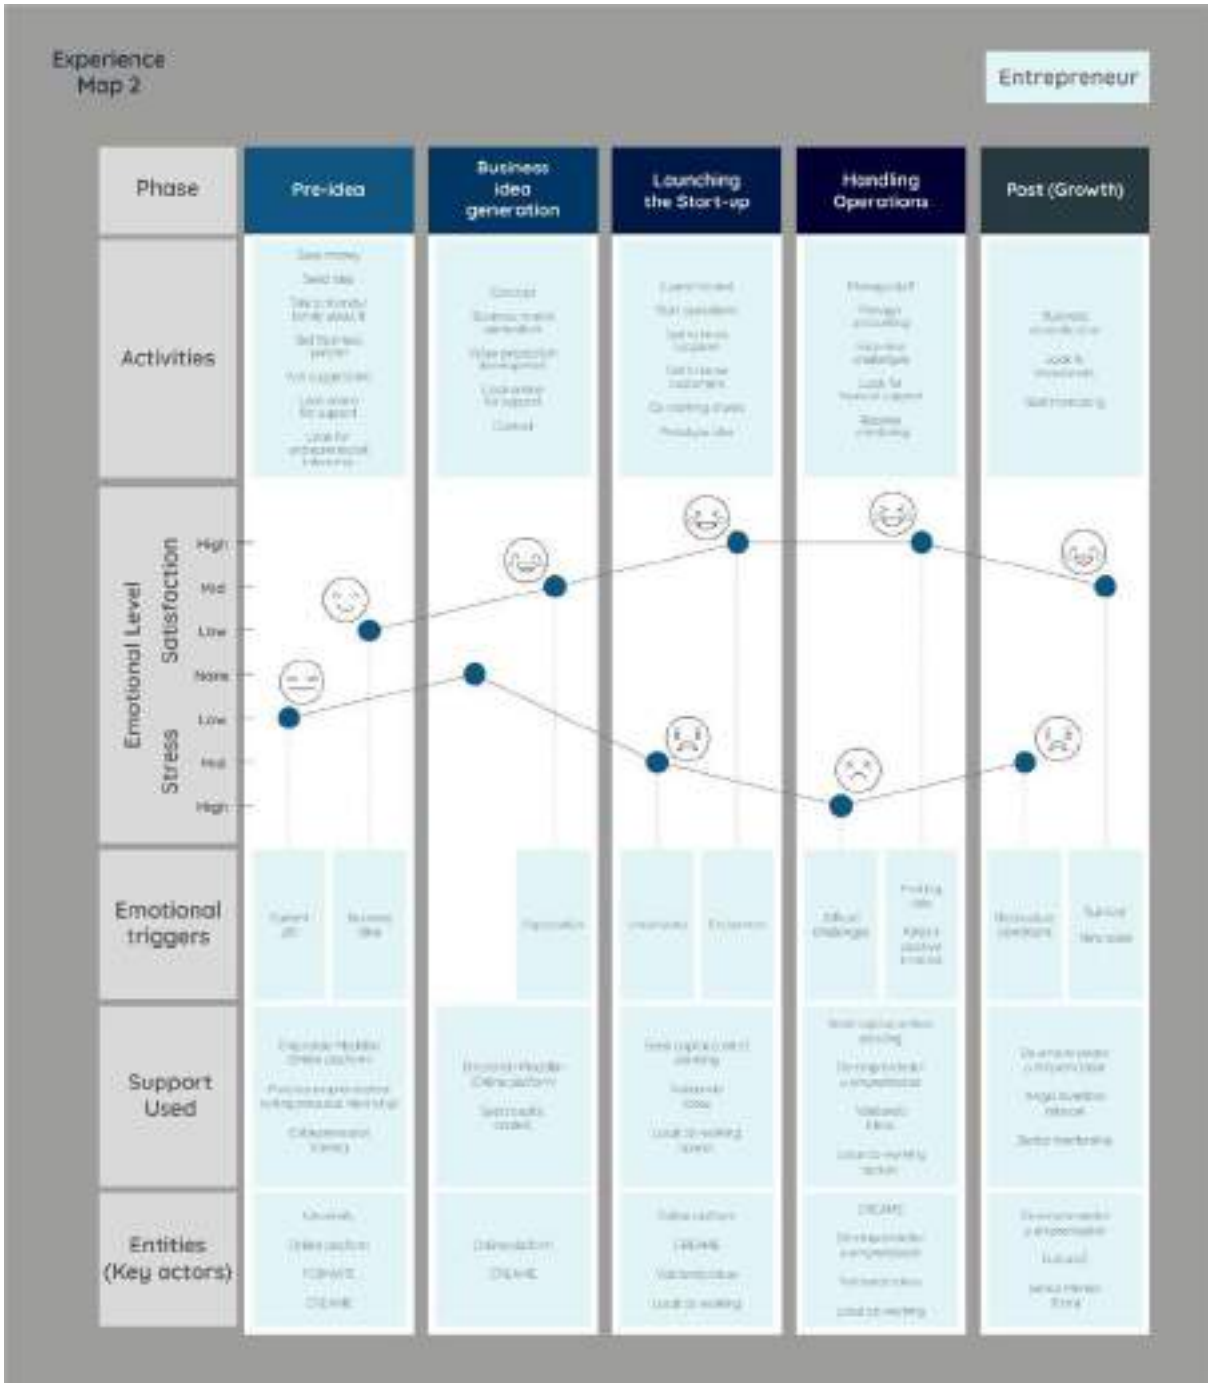

Figure 7: Experience map "To-be".

The previous map presents some similarities with Figure 6 (The Experience Map "As-Is"), in its composition. It is divided into the same five phases; as well as the activities entrepreneurs realise, the levels of stress and satisfaction with their triggers. The difference lies in the support received, this experience map represents one journey, not two as Experience Map "As is", and the legend that highlight the new programmes. The ideas implemented in this map, aim to make suggestions that can be useful in Medellín and are described in the following paragraphs.

The first Service/Idea proposed is an online platform named Emprende Medellín (Medellín Undertakes), where through an easy interaction, entrepreneurs will find programmes available in the city according to the development stage. This is a database that includes a basic description of the programme, the provider and the deadline to apply. Also, the type of development for each stage will be described to guide the entrepreneurs in their self-identification.

The internships programme Práctica emprendedora is the second idea, which will allow university students to have internships in start-ups and live the entrepreneur experience in order to understand the commitment this requires, this programme can be implemented as a tax reduction for start-ups that receive potential entrepreneurs.

The third proposal, are local co-working spaces. This initiative needs to be supported by the local government to allow the usage and synchronisation of public spaces available to the community as libraries, to generate a network compound by entrepreneurs encouraging the inter-disciplinary work which facilitates venture development and problem-solving.

The fourth idea is Validando ideas, a program that facilitates entrepreneurs to meet users and test their product or service, as mentioned before, Colombians are no early-adopters and that limits entrepreneurial products and services, this programme can be undertaken by Cultura E (the lead local initiative for entrepreneurship).

The last idea applied on the map, De emprendedor a emprendedor (From entrepreneurs to entrepreneurs), aims to use entrepreneurs that gained previous support from the ecosystem, to share one-on-one with new entrepreneurs the knowledge they earned through their initial experience, this programme is proposed to share successful experiences and motivational support that influence the entrepreneurial culture of the city.

What has been the service design contribution?

This study has used service design in two perspectives, as a mindset and as a toolkit (Stickdorm et al., 2018). In this case, it has helped to analyse the context, understanding it as a complex system (Sangiorgi and Prendiville, 2017). It also had been used for its research tools that represent a medium to acquire the information gathered from the entrepreneurs. Which helps to realise not just their awareness but the qualities and characteristics of the challenges the entrepreneurs face, but also their behaviours and values. Combining it through a holistic view and realising organisations' structure and resources, to be able to make suggestions (Junginger and Sangiorgi, 2009). Additionally, it has facilitated the discovery of hidden information and the visualisation of those in order to stimulate the idea generation for the issues previously found.

Furthermore, it has allowed us to raise the question about the effectiveness of the implementation of programmes to foster entrepreneurship in the city. It challenges the different design approaches to keep the exploration in new fields different than retail and services for massive consumption.

Suggestions and future research directions

Literature in entrepreneurial activity, entrepreneurship ecosystems and design approaches need to be explored in depth to strengthen the framework of information in particular for Medellín as the context, as well as the secondary sources to verify and track the number of programmes developed along with their impact.

From the methodological perspective, a larger and more distributed sample will increase the opportunities and approaches taken based on the different needs of the entrepreneurs, depending on their venture development stage and the local government's needs within the projections for the ecosystem and possible impacts. Using service design thinking, this issue can be undertaken by the tool personas to fulfil this categorisation and its understanding of users (entrepreneurs of Medellín), including an experience map for each entrepreneur profile if the differences in communication (strategy) and entrepreneurial needs require it.

Likewise, in the methodological approach, the tool 'Cultural probes' provided a large amount of data about the experience of being an entrepreneur (in Medellín), and also developed a reflective process in some of the participants who revealed that in the complementary interviews. Although the tool provides partial information in some cases as Gaver et al. (2004) explained because of the engagement of the participant variate, it produced a high value for the research and this study highlights its potential to use for other qualitative research studies.

The prototype stage needs to be considered in order to test the ideas proposed. This is a key stage for service design in order to iterate the ideas by test and improving them.

Another possible approach for future research identified in this study is the multiple case study within efficiency-driven economies. As highlighted by the Global Entrepreneurship Monitor (2017), particularly in Latin-America and Africa, they present similarities and are highly active in early-stage entrepreneurship. This

quantitative current approach needs to explore and confirm from the qualitative perspective in order to reveal new knowledge and patterns hidden in the experiences of the entrepreneurs.

Business as Unusual: Creative industries, international trade and Brexit

DUNN Nick; WHITHAM Roger and PATHA CM*

Lancaster University, United Kingdom
* corresponding author e-mail: c.patha1@lancaster.ac.uk
doi: 10.33114/adim.2019.c12.183

UK government statistics maintain that only 18 per cent of creative industries firms engage in international trade. The UK's *Industrial Strategy: Creative Industries Sector Deal* aims to increase UK creative industry exports by 50% within 5 years, arguing there is a "great deal of untapped potential in the sector." It also identifies small company size as a barrier to creative industry exports. Our research, however, challenges these assumptions. At least one creative industries hub is already deeply entwined in global trade. In Liverpool's creative and digital hub Baltic Creative, 69 per cent of tenants export. Furthermore, these exporters are highly dependent on their overseas income. Over one-third of exporters earn more than 50 per cent of their annual income from exports. Our research also finds that small company size was not a deterrent to international trade. Rather company owners report concerns about access to global markets after Brexit, which had already resulted in significant financial losses for some. Our study reveals that even the smallest micro-enterprises are exporting not by way of strained or concerted efforts, but simply because they are operating in an open, digital, global environment where international trade is integral to their business.

Keywords: Creative industries, design policy, international trade, Brexit, creative hubs

Introduction

Creative industries are growing at nearly twice the rate of the rest of the UK economy (Department for Business, Energy & Industrial Strategy, 28 November 2018). In 2015, they accounted for 6 per cent of UK jobs and an impressive 9.4 per cent of total services exports from the UK (Department for Business, Energy & Industrial Strategy, 26 July 2017).

Nevertheless, policy-makers are concerned that the creative industries are not sufficiently engaged in global markets. The government*'s* 2018 *Creative Industries Sector Deal* aims to increase exports by 50 per cent before 2023 because the sector still offers a lot of "untapped potential" with many businesses not yet exporting at all (Department for Business, Energy & Industrial Strategy, 2018). The Department for Digital, Culture, Media & Sport (DCMS) maintains that only 18 per cent of creative industries firms are engaged in international trade (DCMS, 14 February 2018).

Creative firms are seen as having industry-specific barriers to international trade, in particular small company size (Department for Business, Energy & Industrial Strategy, 2018). The average creative company size is 3.3 full-time employees (FTE) and 34 per cent of creative sector workers are self-employed, which is more than double the UK average (Bazalgette, 2017). The *Creative Industries Sector Deal* states that micro-companies lack the "absorptive capacity" to undertake extra export duties such as identifying and assimilating useful information and using it to commercial ends (Department for Business, Energy & Industrial Strategy, 2018).

Our case study calls many of those assertions into question. In at least one creative industry hub – at Baltic Creative in Liverpool – even small one-man-bands are already deeply engaged in the global economy. Creative industry firms in this cluster are exporting at much higher rates and with more economic impact than official figures suggest. Small company size does not appear affect their ability to export. Are small, local creative industries more global than we think?

International Trade at Baltic Creative, Liverpool

Baltic Creative in Liverpool provides commercial space specifically designed for creative and digital industries, housing almost 100 SMEs (small and medium sized enterprises) and dozens of freelancers. In the UK, the creative industries comprise advertising, architecture, arts, crafts, design, film and TV, IT and software, museums, music and publishing – including both goods and services in these fields (Department for Business, Energy & Industrial Strategy, 2018).

In May 2018, we asked freelancers and company owners all based out of Baltic Creative to complete an online questionnaire about their international reach. This "International Trade Survey" consisted of 16 quantitative and qualitative questions. It was sent to 75 tenants, of which 59 responded. Each question in the online survey left room for a supplementary, open-ended reply. Many respondents used this space to clarify their responses. All of our statistics about company imports and exports are derived from this survey. In July 2018, we also conducted almost a dozen semi-structured, personal interviews.

In addition, we cross-referenced the 2018 International Trade Survey with data from Baltic Creative's 2018 Business Owners Output Survey. Here, each year Baltic Creative's tenants are asked to provide key figures including questions on annual turnover, annual growth and expected growth. In 2018, 71 company owners responded to this survey. We used this data to arrive at figures such as median company size, annual turnover, and per-employee GVA of both exporters and non-exporters. Combing responses from both surveys, we have data from 89 SMEs or freelancers.

Since the sample size of 89 is relatively small, we have used the median rather than the average when discussing the results. A very small number of firms at Baltic Creative have turnovers well in excess of £1m and employ over 50 workers, which would significantly distort the average of a small sample. By using the mean we have arrived a more accurate snapshot of the "average" firm based at Baltic Creative.

Although "international trade" should normally refer to both imports and exports, we will use the term synonymously with "exports" for two reasons. First of all, the documents that we are interrogating – the *Industrial Strategy* and the *Creative Industries Sector Deal* – almost exclusively refer to international trade in the form of exports. *The Industrial Strategy* mentions imports only once and the *Creative Industries Sector Deal* never mentions imports. Secondly, of our 59 respondents, only one firm imported a small amount without exporting. In all other cases, tenants who engaged in importing also exported. Conversely some exporters did not import. Further details will be discussed in our results, below.

Results

SMEs and freelancers based at Baltic Creative are highly engaged in international trade, with 69 per cent of tenants exporting. Of the 31 per cent who do not trade internationally, one-third would like to start exporting in the near future (Figure 1).

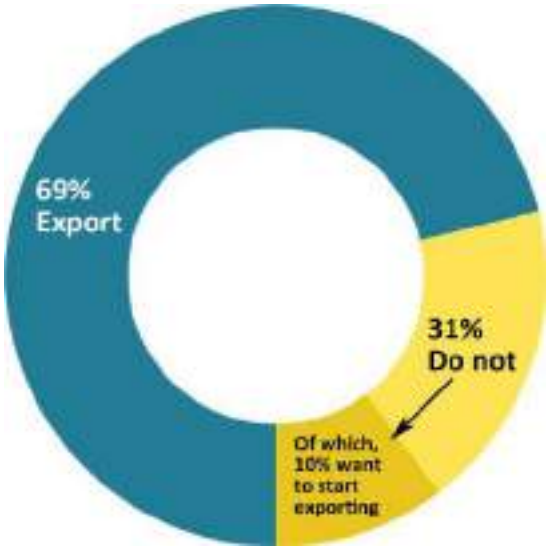

Figure 1 Proportion of Baltic Creative tenants that export

Isolating the exporting firms from the whole of Baltic Creative, henceforth "exporters," we find that most are trading in services with 70 per cent trading only in services, another 15 per cent trading in goods and services, and the final 15 per cent trading in goods only. Exporters reported that their primary concern around trade was Brexit. Europe is their main trade partner with 90 percent of companies exporting to the EU; 63 percent exporting to North America; and 51 percent trading with Asia.

Baltic Creative's exporters make a significant share of their income from overseas: 35 per cent of firms make over 50 per cent of their total income abroad, 37 per cent make between 10 and 50 per cent of their total income abroad, and 29 per cent make between one and 10 per cent of their total income abroad (Figure 2).

Figure 2 Baltic Creative's exporters rely heavily on their international income

Exporting is only half of the story. Exporters also import goods and services from abroad. While 21 per cent spent no money abroad, 38 per cent spent up to 10 per cent of their total expenditure abroad, 22 per cent spent between 10 and 25 per cent abroad, and the final 19 per cent spent over 25 per cent of their expenditure abroad. These last two groups of importers were hit by Sterling's sharp devaluation after the Brexit referendum in 2016. One business owner revealed that, because of sudden exchange rate fluctuations, his company lost £13,000 on the day of Brexit and more since then because of on-going international commitments.

Both exporters and non-exporters perceived the same major barriers to international trade: finding clients, access to knowledge and skills related to international trade, language and cultural issues. Interestingly, one would expect seasoned exporters to be less anxious, but instead exporters are more worried about customs procedures, delivery, tariffs and duties than non-exporters (Figure 3).

Figure 3 Perceived international trade barriers

Brexit then is a substantial concern for exporters at Baltic Creative because, at the time of writing, it is unclear whether tariffs and duties will be applied to goods and services entering the EU. Of all the companies we surveyed and interviewed, only two had managed to profit from Brexit. One business owner told us, “So far, Brexit has been good to us because the pound has weakened to the dollar and 65 per cent of our income is in US dollars. We've consciously spent more aggressively to acquire more US customers while the pound is weaker.” The rest of the companies were either apprehensive about the effect of Brexit on their future business or had already faced significant losses since the June 2016 Brexit referendum.

Although 85 per cent of the surveyed companies trade in services and therefore do not face the prospect of direct taxes on goods, company owners (and European clients) still worry what the new trading environment will mean for permits, insurance and other compliance standards. As one photographer said, “I need a work visa for any shoots I do in the United States. I can’t just enter on a tourist visa. My insurance would be void if I didn't get a work visa for the U.S. In Europe, I can just get up and go. I worry how Brexit will affect my work in Europe.” His turnover is highly dependent on exports with 30 percent of his income coming from international work, of which 85 per cent is in Europe. Another SME owner admitted, “We are retrenching all international business and making teams redundant to increase productivity. Because of Brexit, we've lost 7 major contracts in the last 12 months, a risk we cannot afford to make again.”

With 95 per cent of creative industry firms employing fewer than ten people (Frontier Economics, 2016), the *Creative Industries Sector Deal* identifies company size as a particular challenge to exports. Again, we have not found this to be true in our case study. Baltic Creative houses a selection of freelancers, micro-companies with under 10 employees, a few companies employing between 10 and 50 people, and only one firm employing more than 50 people. The mean company size of all tenants at Baltic Creative in 2018 was 2.5 full-time employees (FTE), with exporters slightly higher at 3.2 FTE. This is in line with, but slightly below, the national UK Creative company average size of 3.3 FTE (Bazalgette, 2017).

Discussion

The 2018 *Creative Industries Sector Deal*[1] contends that the micro-enterprises lack the "absorptive" capacity to increase exports. It does not, however, look deeply enough at the digital economy, which has – in less than two decades – dramatically reduced trade barriers for both large and small creative industries firms. According to the Centre for Economics and Business Research (Cebr), "We live in an era where the methods we currently use to trace trade flows are losing their relevance and ability to depict an accurate picture of trading realities," (Cebr, Creative Industries Council & Creative Industries Federation, 2018).

For an increasing number of creative industries firms, international business is not extra business: it's just business. One micro-enterprise owner told us, "We never set out to export. It's just the nature of the Internet to unlock that kind of potential without thinking you're starting a global business." This business creates YouTube content and over 75 per cent of its income is earned through overseas viewers and the associated advertising sales. The owner started the YouTube channel as a side project and now the firm employs 4 staff and 15 freelancers.

Another business owner told us, "In 2005…Google came up with this thing called Adsense. Overnight [my website] went from just [sitting on] the Internet somewhere to making more money than I made working full-time in the NHS." Using a website as their marketing tool, their company sold home-study DVDs. In 2013, they switched from selling DVDs to selling courses purely online, which only increased their international sales. The company currently makes 70 per cent of its annual income from exports and spends between 25 to 50 percent of its expenditure abroad. In 10 short years, the Internet transformed this micro-entrepreneur's career and business. The owner concluded, "If you are an online business and you are selling digital products, I think it's fairly standard that you are more of an exporter than…a domestic company because the cost of delivery is not there and the cost of fulfilment doesn't exist."

It's not only creative service providers that benefit from this borderless, digital global trading environment. Goods also have witnessed dramatic reductions in barriers to trade. "When we launch a product, we press release it [around the world]" another micro-enterprise owner told us. "As a result, it gets picked up by press and blogs in the US, UK and Europe. Our products are about film, music or literature…popular culture…that's why our customer base is so international." This micro-enterprise employs 4 full-time employees and earns between 50 and 75 per cent of income is from foreign sales.

The *Creative Industries Sector Deal* asserts that its priority for the creative sector is scaling-up: "helping the SMEs and entrepreneurs that overwhelmingly make up the sector to grow, in order to raise productivity," (Department for Business, Energy & Industrial Strategy, 2018). Interestingly, the two following examples of increased productivity resulted – not from scaling-up – but rather from clustering micro-enterprises into one shared location. One Baltic Creative company owner and exporter told us, "I recently hired a Google ads expert. I looked all over the Web to find somebody and there's plenty of companies or agencies that will do it…but in the end, I found a Google ads expert at Base Camp [a co-working space within Baltic Creative]. He is a real specialist and he sits next door. When you're in this online business everything is done by e-mail and it is a refreshing change to speak to somebody and express what you need in person instead of doing it backwards and forwards through e-mail…The first thing I do now is look to Base Camp." The company owner employs only 3 other people and earns between 50 and 75 per cent of its total income from exports. Rather than hiring a full-time employee to do the job, this micro-enterprise hired a neighbouring freelancer to increase exports. A second micro-enterprise owner told us, "We co-habit [our office] with another company, and they asked, "Why don't you claim for R&D tax credits? We do." The micro-enterprise owner had been unaware of the UK's Research & Development Tax Credit scheme. His unplanned, serendipitous conversation ended up saving his

[1]This includes the reports they reference: Peter Bazalgette's 2017 *Independent Review of the Creative Industries* and Frontier Economics' 2016 *Absorptive Capacity: Boosting Productivity in the Creative Industries*.

company thousands of pounds, which were then reinvested into the firm. Serendipity is an important benefit of clustering and it's countless opportunities for face-to-face contact (Storper and Venables, 2004).

No interviewees saw a direct positive impact of clustering on their exports, but the benefits of clustering at Baltic Creative may be increasing their productivity, which would result in expanding their ability to export (Marrewijk). Clustering micro-enterprises may be a more economically viable and efficient way of helping SMEs "scale-up" – by expanding the network and knowledge base – without actually having to increase employee numbers.

Besides, scaling up does not always have advantages. At least one company owner cited worries about increased risks with scaling-up. Hiring more full-time staff required certainty of increased turnover. In an era of instability marked by Brexit, this micro-enterprise owner was unwilling presently to take that risk and preferred to hire freelancers on a case-by-case basis. Some economists point to clustering flops such as business parks where many similar firms share larger premises, but no interaction between tenants results (Wadha, 2011). This may be true, but clustering micro-SMEs and freelancers may produce different results from clustering larger companies. Businesses employing more than 10 people may indeed not require the serendipity and peer support that clusters offer because, as they grow, they hire specialised staff members and develop their own internal logic. But micro-enterprises and freelancers may benefit from the spill-over effects, networking and peer support that clusters such as Baltic Creative offer. Creative industries firms in 2007 were 15 per cent larger than in 2014 (Bazalgette, 2017) demonstrating a clear trend towards decreasing company size. Trying to force the industry in a direction that it is not naturally heading may be counter-productive. Instead, supporting creative clusters may be a more effective policy for increasing the productivity and exports of micro-SMEs and freelancers in the creative industries.

Our research is based on a small, geographically isolated sample of companies and cannot claim to represent a broader snapshot of creative industries in the UK. Indeed, economics research has found that the differences between individual firms are so astoundingly large, so-called "firm heterogeneity," that they call into question the viability of generalising from case studies (Marrewijk, 2017). We are indeed undertaking further research in four more creative industries hubs in England's North West to see if the trends extend to other digital and creative hubs. Moreover, we will revisit Baltic Creative in 2019 and 2020 to assess the impact of Brexit on tenants' international trade.

Key Insights

Our research suggests that official statistics may be understating the true value of exports to the creative industries. More refined and accurate data gives policy-makers better tools for designing effective strategies and efficiently allocating public funds.

The government's 2018 *Creative Industries Sector Deal* focuses efforts on helping creative industries firms to scale-up in order to increase exports. Our findings, however, show that small size is not hindering the exports of micro-companies based at Baltic Creative. Furthermore, these small companies are already highly dependent on their exports for total annual income.

Our findings are important because undervaluing current exports underestimates the possible negative effects of a significant break with the UK's hitherto successful international trading environment. If creative businesses are as financially reliant on exports as this study suggests, shocks such as a no-deal Brexit – or even the uncertainty caused by prolonged Brexit negotiations – are potentially far more wide-ranging on this set of businesses. A key factor in their export success has been the global, open, digital economy where international trade is integral to their business. The policy focus, then, should rather be on maintaining seamless – or at least consistent – access to global markets.

Should this prove to not be possible, gearing policy efforts towards providing affordable, not-for-profit creative industry hubs – and in underserved locations – may be a wiser allocation of public funds. Our preliminary research suggests that many creative industry firms do not want to scale-up, preferring to stay small and agile. Locating in a creative hub where they can temporarily employ the talent they need on a project-by-project basis, and possibly taking advantage of knowledge spill-over within the hub, may provide small creative firms safe harbour while they navigate the vagaries of Brexit.

Research Perspectives IN THE ERA OF Transformations

Design innovation practices in a global supply chain: a Fung Group case study

DRAGICEVIC Nikolina*[a]; KELLY Richard [b] and CHEW Eng[c]

Whereas the contribution of design thinking has already been appreciated both in academic literature and practice in the West, there have been little serious and comprehensive studies focusing on Hong Kong and China. This case study paper, therefore, reports about the design innovation practice in Fung Group, a Hong Kong-based company whose core businesses operate across the global supply chain for consumer goods including sourcing, logistics, distribution and retailing. The analysis (1) identifies and describes design practices that the company initiated to support service innovation (including new products, processes and business models) (2) identifies challenges in adopting and institutionalising such practices. The results show that the company supports both externally and internally oriented design practices – and loosens the boundary between the two – through the activities in the Fung Academy and a new innovation hub, Explorium, with a particular focus on utilising digital technologies. Specifically, the study demonstrates how the company empowers and involves a variety of stakeholders (individuals, groups, and organisations) in value co-creating practices involving absorptive, collaborative, and adaptive practices that aim to challenge or disrupt current practices. The study uncovers that some of the major challenges in such aspirations lie in the adaptation of design thinking organising logic and mindset to specifics of the Chinese socio-cultural context.

Keywords: innovation, supply chain, design thinking, digital technologies

Introduction

Over the recent decades, within business and management communities, design thinking (DT) became a portal for the whole design area to contribute to innovation, especially well-suited for complex, "wicked" challenges facing contemporary service organisations (Buchanan, 1992; Gustafsson et al., 2016). Fung Group,[1] a Hong Kong-based multinational group with subsidiaries in trading, logistics, distribution and retailing, and a renown pioneering Asian innovator, has been on a similar path for several years now; Victor Fung, the chairman, has decided to rebuild a culture of innovation by adopting DT and hired an experienced designer from IDEO to be the innovation catalyst who would lead the change.

[1] It was founded in 1906 in southern China by Fung Yiu-Hing, an entrepreneur, and Li To-Ming, a merchant; today it is chaired by Victor Fung, Fung Yiu-Hing`s grandchild.

Whereas a number of researchers have outlined cases for design-based innovation (e.g. Leavy, 2010), relatively few studies (e.g. Ge and Maisch, 2016) have provided empirical insight into what kind of design practices companies in non-Western contexts adopt and what are the specific challenges in these contexts. This study attempts to shed some light on this issue. Hong Kong is a particularly interesting context to study since its development is driven by the service economy, with service sector dominating its gross domestic product (in 2016, 92.7 per cent of its GDP, of which trading and logistics equal 21.7 per cent, according to www.gov.hk). Looking ahead, the 2018-19 Hong Kong government budget plan assigned additional $6,4 billion to supporting innovation and technology, focusing on the first phase of the Hong Kong-Shenzhen Innovation and Technology Park. Moreover, Hong Kong serves as a bridge between the influences of Confucius China and the West, especially considering its legacy of British rule. As it will be shown below, this unique position creates conditions that posit some challenges to adopting and implementing design practices.

This study has an exploratory character; its purpose was to grasp the personal views, experiences and understanding (Kvale, 1996) of the practitioners involved in design practices in support of service innovation in the Fung Group. We have combined the interview data with document analysis and our own observations. The two-hour long interview with the innovation catalyst Richard, and a one and a half hour long group interview with Richard and two design-thinking practitioners and innovation specialists working within the innovation team—Peter and Mara[2]—were open and had little structure. They focused on certain themes, such as the key design practices which support service innovation (including products, processes, and business models), structural enablement, project examples, and the challenges encountered. Since the questions were aimed at drawing on personal experiences, and sometimes lead to narrative-like responses, this research could also, at least partially, be qualified as experience-centred narrative research (Bold, 2012).[3]

Fung Group: network orchestrator in the era of digitalisation

Fung Group is known for being a disrupter in the supply chain business, particularly with its innovative approach to knowledge management, such as taking and deconstructing orders, its problem-solving capability, and getting factories to learn from each other. To compete in a flat world, rather than relying on a bundle of assets, IPs and capabilities that would enable the company to compete in a closed market, the focus of the Fung Group became to integrate and connect to resources and competencies in the network through the so-called "network orchestration" competency (Fung et al., 2007).

In today`s digital and networked economy, Fung Group strives to create new business models, where fewer resources are used, which create entrepreneurship and growth in markets, create better products that last longer and enable people to live better. The present three-year plan (2017-2019) states: "Our goal is to create the supply chain of the future to help our customers navigate the digital economy and to improve the lives of one billion people in the supply chain." "That's our challenge," says Richard, and "there are not that many other companies around which can be a platform for doing something like that." The plan further emphasizes the role of digitalization in supporting network orchestration, which involves the development of the "digital platform that includes all [our] ecosystem partners and enables them to benefit from the convening power of a network that reaches over US$2 trillion of retail sales."

Due to the importance that is put on the role of digitalisation, across the whole Fung Group, experiments are conducted with different forms of technology, including AI. The future of supply chain, however, all the interviewees agree, will be much more open source, more networked and it will not rely solely on technology. It is more about enabling people in the business, whether it means going through short processes or finding ways to spot opportunities. The current roles will be disrupted as well, says Richard: "So the supply chain may be run by two kids in a garage, versus by a large multinational."

While reflecting on the question what the future of supply chain that Fung Group envisions is, Peter says that "it is less about what it is and more about how we prepare ourselves through the journey, it's about adapting yourself to any new situation." He stresses: "If we think that we have to define what the future supply chain is and that we're going to invent it, we have already lost because that's not going to happen."

[2] These are not their real names.

[3] The particular characteristic of this case study – and perhaps its limitation – is that it is largely based on the personal observations and views of the interviewees – non Chinese people - involved in the Fung Group work, which sets it up as an observational case study with inherent potential biases.

Striving for ambidexterity

Structural enablement of innovation

The innovation model that Fung Group is attempting to build is relatable to the concept of an ambidextrous organization, with capabilities of both exploring and exploiting, and hosting multiple structures, with different cultures and practices (Tushman and O'Reilly III, 1996). That is to say, apart from its core business, it boasts a portfolio of innovation, day-to-day incremental changes, and some disruptivity. The distribution of these depends on where the company is in its business cycle, however, if the core business makes up 80% of what the company does, it can be assumed that they are not doing enough and there is a threat that someone will disrupt them. The trap that the company wants to avoid, which often happens with large organizations, is to transition from being small, and wanting to grow, to being large and wanting to optimize, protect, and control, i.e., to fall into the trap of an exploitative culture. Furthermore, organizations expect data to generate new revenue models, but they are not generating any data in the first place because "they are not doing a digital thing. People in Excel, folders, all the day," says Richard. Business needs to become leaner and fitter, he argues: "If we had $100, we would need to put $20 on the crazy new ideas, and $80 on digitally transitioning the organization. There's a process around this new stuff, creating new value and in new ways, true innovation. And, 80% of the block and tackle change, change, change."

Figure 1 Three structural units within Fung Group

Within the Fung Group organizational structure, there are three interconnected units which, interdependently, aim to create ambidexterity—business unit(s) (BU), Fung Academy, and Explorium, a new innovation hub. Structurally, Explorium is incubated within the innovation team of the Academy and the talent that it leverages largely comes from the Academy. That is, the Explorium team (which consists of eight people) is a small subset of the innovation team, which is a small subset of the Academy (consisting of 40 people).

Explorium Hong Kong started with the same branded name as the "original" Explorium Shanghai[4] in May 2018, as a part of the headquarters, in the context of "less space and less startups, less all that stuff happening," explains Peter, and currently has a setup of a fuzzy front-end–a stage where value proposition and business model canvas are being iteratively defined.

The dominant roles of the Academy and Explorium are to be the explorative part of the organizational ambidexterity, which performs design practices, while the BUs are mostly responsible for the exploitative part, which performs routine work. However, innovation occurs when the institutionalized, routine practices in a BU change, as we will demonstrate in the following paragraphs.

[4] Explorium has been around as an innovation hub for three years; it started in Shanghai, where it has gone through three different phases. In the first, experimentation phase, it was focused at trying new retail formats and inviting customers and businesses to test how they might work. The second phase revolved around developing an experience centre where the Group wanted to closely examine what the business of the Group is, so that people can engage in it and understand it better. The third, current phase is about engaging the startup ecosystem in Shanghai, the community of providers exploring new technologies and new ways of doing things, testing new technologies and business models.

Operationalization of ambidexterity through design practices

The examples we will provide in the following sections show how Fung Academy and Explorium, through various design practices, identify the needs of the BUs, influence and transform the BUs to take a risk in exploratory (including digital) innovations and change routinised, institutionalised practices.

The Academy is ahead of BUs in the sense that it enables by building the core capability of business–it develops and provides talent (i.e. creates entrepreneurial learners or DT-based institutional entrepreneurs), whereas the BUs builds on the "wave" of these entrepreneurs and more or less incrementally changes some of its routine practices (its inherently exploitative nature). Located within, but at the same time on the edge of Fung Academy as an autonomous, small unit, Explorium has more freedom to experiment and open to new opportunities in the ecosystem. Through its flexible structure and decentralised decision making, it acts as a connecting point via DT-based innovation via conveying needs, providing direction and connecting relevant stakeholders – internal and external, such as startups, enterprises, universities, and AI labs. In this sense, Explorium acts as a sort of gatekeeper which enables open innovation (Hafkesbrink & Schroll, 2010).

Within this model (see *Figure 2*), the business provides the challenges and the assets; Fung Academy and Explorium provide know-how processes and talent. Getting business put their skin in the game, with specifying some barriers, is an important factor in the model. Richard explains: "The question is if it's going to take us $10 to go do a new thing, maybe business can put in $5, and we put in $5. Or, you put in $2. Or, maybe, your $2 is your two people for three weeks, full time, and then, if the business doesn't use the work, the innovation team has to pay back the money that was invested."

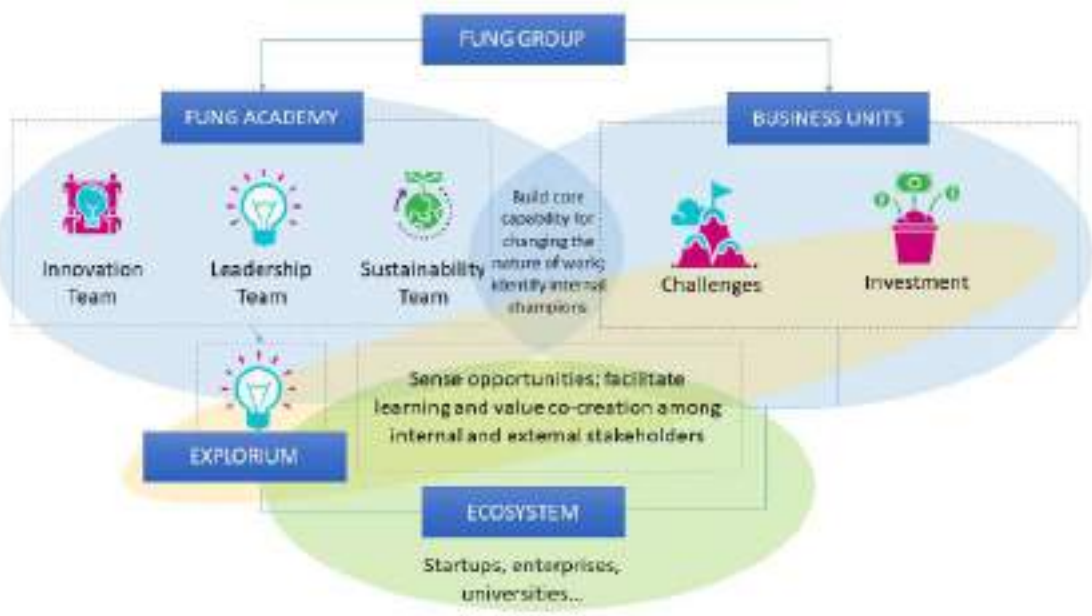

Figure 2 Operationalization of design-based innovation and ambidexterity

We further propose the trilogy of interrelated design practices which might be called absorptive, collaborative, and adaptive practices to depict the explorative work in the synergy of different units (cf. Lusch et al., 2007) (see Table 1). Then, we describe some examples of the practices within Fung Academy and Explorium.

Table 1: Roles and actors within various units in explorative part of organizational ambidexterity in Fung Group

Relevant unit	*Main actor*	*Role*
Business unit	Internal champion	*Collaborative practices*–co-creates with external champions (e.g. from startups); *adaptive practices*– implements a change of current practices to carry out the project and

		implement new solutions, support changes locally via internal champions.
Fung Academy	Innovation, leadership and sustainability team; innovation catalyst	*Collaborative practices*–empowers and enables employees by means of three pillars: innovation, leadership and sustainability; identifies and develops the champions/DT-based institutional entrepreneurs; *adaptive practices*–builds the core capability according to new knowledge and needs, implements the change in behaviour within the BU
Explorium	Part of innovation team; innovation catalyst	*Absorptive practices*–identifies the "below the iceberg" hidden needs of BUs and customers; senses opportunities in the environment (technology, partners, ideas in form of startups…); *collaborative practices*–creates opportunities for mutual learning and collaboration among relevant internal and external actors through workshops, showcases, hackathons etc.; facilitates value co-creation via DT practices that pilot new services, business models, etc.; e.g. via the Idea to scale DT practice
Startups, enterprises, universities, AI labs	External champion	*Absorptive practices*-provides new ideas; *collaborative practices*–collaborates with BUs and addresses their needs

The role of Fung Academy - building creative confidence and nurturing DT-based institutional entrepreneurs

Fung Group`s assumption is that in a network-orchestrated world, the network that learns fastest wins. In an asset-light business model, instead of capital, the assets are people. With its three pillars – leadership, innovation, sustainability–the Fung Academy poses questions such as: "What does it mean to be a leader in a global world? How to make Asian leaders feel really global?"

"It becomes less about doing innovation work and more about redesigning people's jobs to enable them to get the work done and act as innovators. It is about pushing new behaviours into business", says Mara. Ultimately, it is about building autonomy into the process and building people`s creative confidence, which DT can greatly contribute to (Kelley & Kelley, 2013). As the business grew, the Fung group hired T-shaped, IDEO like people, everyone from data analysts to graphic designers, who would support this mission. Along with this journey, Richard stresses, they gathered more and more people, and slowly, over time "you are building this army of, an army of, these sort of, communities of passion."

"Unless you lead through those people, they're just serving the system versus they're making the system," says Richard. And this is hard to do if the "base is low, if people are all sitting in cubes, doing stamp work, and answering phones. That's not the kind of work we need to do in the future", he notes.

Figure 3 Empowerment through Fung Academy

Over the years, after hundreds of individuals going through the programmes, workshops, internal competitions, and lots of conversations about DT, people started to realize that they could come to the Academy, and through different ways of thinking, they could come out with different things. For example, the Academy partially launched one leadership programme in collaboration with MIT and Stanford University. One unique quality of the company is that it has grown its business by acquiring small businesses, the majority of which were owner-operators, entrepreneurs. Today, these people are entrepreneurs within the company, "'little John Waynes', people who would, metaphorically speaking say: 'I'm, like, sheriff of my town, and I am the P&L owner,"–"very entrepreneurial," says Richard (cf. Fung et al., 2007). And there are thousands of P&L owners only in one part of the business. However, most of them have never attended university, because they have been building their business from a very early age. Having been presented with an opportunity to enrol in MIT leadership programmes, they came in tears because they went through this, Richard recalls, as if they were saying: "Oh, you think I'm good enough, so that you're going to send me to Boston for two weeks, to MIT?" These people are very engaged and still adopt some of the frameworks they have learned. And then, there are those high-flyers who started to embrace self-learning, they call them "entrepreneurial learners", people who are now constantly curious, learning all the time.

The role of Explorium – connecting between the needs of BUs and knowledge in the network

The primary role of Explorium is to be the *connector* between the needs of different BUs (the challenges that they are going through, as well as the challenges of their customers) and the knowledge residing in the network in order to enable growth through collaboration. Peter explains that the question becomes "How do we bring in and have access to a community of innovators, other corporates around Hong Kong to help us handle the challenges as they get thrown at us, and if they`re really good at that, then they can be part of the future of supply chain?"

The hypothesis is that if Explorium can persuade other people from the outside, such as startups, enterprises, universities, to work with them, they can show the people inside the BUs that it is feasible for them to try the same things. "So it can be as simple as say 'okay well you have that pain point, we know 10 Chabot companies over here, that's what we're doing we're building community, let's bring you guys together and facilitate you working together", says Peter. In a large organisation, in particular, the problem can be a lack of coordination of communication among the BUs, which might lead to not knowing what the units are doing; the role of Explorium is to connect these through DT practices.

Among internal (within the BUs) and external collaborators (within the community), the critical issue becomes finding the ones "that are highly engaging, the ones that are returning back, the ones who are constantly in the loop of what we want to do", these are the ones "on their way to become champions", explains Mara. A lot of their work, she says, is then revolving around how to convene some less comfortable ideas, benefits of it, and convince them that the team will provide support to their efforts to bring about projects locally. It is about instilling in these champions autonomy and a sense of ownership of the change.

Figure 4 "Idea to scale" framework

To find and bring together potential internal (BUs) and external collaborators, the team organises and participates in various community events (e.g. the TechCrunch event in Shenzhen), organises showcases with startups and runs experiments—from running workshops (both internally and in other companies) to hackathons. Explorium particularly aims at collaborating with startups. It is assumed that the Group needs new ideas to grow. And since ideas nowadays often come in the form of startups, the goal becomes to utilize this potential through collaboration.

"Idea to scale" is one of the key design thinking practices in Explorium which addresses this problem, which follows a collaboration framework that facilitates business experimentation and learning through piloting new products, processes and business models in collaboration with external partners. It comprises a series of sub-practices which starts from the human and business "below the iceberg" needs identification and analysis, which the team helps to identify in conversations and interactions with relevant stakeholders through interviews, design thinking workshops and other activities (see *Figure 4* for the different phases of the framework and *Figure 5* for different roles).

Figure 5 Different roles within the "Idea to Scale"

Cultural aspects of adopting design practices

Projects example: Changing company culture through experimentation

The conversations within the Fung Group revolve how they can begin to redesign how the core business actually operates, how to start to redesign the nature of the work by changing underlying values, norms, and assumptions, components of organizational culture according to Schein (2010). At Fung Group, design thinking (DT) is viewed both as a philosophy (mindset) and a set of practices. It is a frame of reference for the world and it is seen as powerful because it is pulling lean, customer experience and similar topics into the "overarching thing". However, there is an implicit notion that there is not much sense in "banging" about using the DT. The point is not to talk about it, but to do it, argue the interviewees and, then communicate the value of its output. The existing DT frameworks are seen as helpful in terms of how they codify simple steps, but it is not as important which one is used. Giving people a terminology, however, can have an effect that lighthouse projects have. DT is in GE and in IBM and other big companies, which enables people to say "Yeah, we're adopting design thinking." "Oh, we're part of cool kids!" says Richard. Thus, what really matters is what gives people confidence that they can do something different.

In their research into the link between design thinking and organizational culture, Elsbach & Stigliani (2018) have discovered that there is a recursive relationship between the use of design thinking tools and the development of cultural values, norms, and assumptions. Such a reciprocal relationship is also evidenced by the example of the early rapid 3D printing retail experiment, the project which brought some awareness to the organisation that "There's this team of people who can take a crazy idea, go and make it happen." That is, early attempts at changing organisational practices started in the company with experimentation and prototyping.

Picture 6. 3D printing experiment for Toys "R" Us

In 2013, Victor Fung, chairman of the Group, wanted Richard and his team to start with 3D printing and soon an opportunity to do something meaningful arose in 2013 when a gigantic yellow inflatable duck was about to dock in Victoria Harbour, a floating sculpture designed by the Dutch artist Florentijn Hofman. The team created awareness in the organization that there is an event which brings "crazy bunch in town" and that they can do something about it, that they can respond by creating new product and experience before the duck leaves the harbour in four weeks.

They reacted quickly, they assembled a small team that created (prototyped and iterated) customized 3D-printed toys in a super-fast way and brought a toy duck to retailer Toys "R" Us. They. This project did not only show the people in the organization what is possible, but also enabled them to do three more 3D printing projects, and started the conversations around questions such as "What does digital manufacturing mean?" "What is AI?" "What do robotics and automation do?" "What does mass customization do?" In other words, the project has served as a catalyst for numerous other projects that would have never happened without that first project. Projects like these are often called lighthouse projects because their aim is to enable people in the

organization to point to it and say “We can be innovative! Oh, we can do that!”, and in that way build innovation confidence and trust in the organization.
Over time, the use of DT tools helped to build more customer and user-centric focused culture, more open to experimentation and adoption of new ideas. Overall, the group’s capability for innovation and change has increased, according to the observation of interviewees. Following this experiment, DT tools, such as rapid prototyping (from digital MVPs to role-playing to discovering service prototypes), started to become an integral part of the company culture. More recently, the operating groups have established “voice of the customer” KPIs (which had not been in place before). Richard and his team are as well refocusing back on “brainstorming” and on developing tools around re-framing and H(ow)M(ight)W(e).

Picture 2 AI-powered smart checkout machines (Image Fung Retailing Group)

One recent important project (which created a new value) came out of “Idea to scale” practice is the partnership between retailing giant JD’s AI lab and the Fung Retailing Group to create AI-driven retail system with embedded AI-image recognition technology to enable checkout processing across Circle-K stores. The aim of the project is to develop a new retail format for China and Asia that would utilise AI-based technology innovations and integrated platforms. The project is continuing the path of building the culture of experimentation and user-centricity, with a specific aim to allow consumers to try out Hong Kong’s first check-out experience based on AI-recognition and provide their feedback.

Challenges in adopting design practices

Cultural factors

Some challenges stem from social and cultural factors such as having permission and saving face, related to Confucian culture. On a practical level, however, simple things can be done, as going local in adopting DT. People should not be forced to run a brainstorm in English if they are more comfortable to do it in Mandarin. As well, instead of making a competition of writing post-its, a better approach would be to write ten post-its, put them up on the board and talk about them. It is necessary to understand, that the natural Western way of “I wanna share everything I’ve got about myself, it’s just not an Asian thing," Richard stresses. However, bodystorming and prototyping are on the other hand easy to do here. Chinese people like a notion of play, which explains why karaoke is so popular here. He explains: "you get people to play a different role" and people will be like, “Oki, we`ll play that.”

Further on, the particular non-disruptive notion of how things are done in Hong Kong, according to interviewees, influences how the problems should be approached. For example, trying to get people to start from a lean experiment about something completely disruptive would result in the answer "What's that got to do with our business?". In contrast, starting from a different place, like “Here’s where we are. We've got ten choices. How do you prototype those?" would make them feel "Oh, we can do that!" Essentially, it is about how to find different ways of doing things that are actually the same.

In the Asian culture the disruption of balance, yin and yang of life, is not something which is often welcomed, says Richard. For this reason, Chinese innovations are often incremental and not disruptive. Richard explains, "That is why when you look at China, who is really disruptive?" Their natural inclination, he explains, is to take on a task, work on it and let the solution develop over time: "If you write in Chinese, right, you get little square blocks, and you do hours of characters. And, over time, your style comes out. But, it's emulating after 20,000 times doing the same thing. And, so, the natural idea of doing something completely new is hard. (…) “it is difficult to innovate here in an "IDEO kind of way" because people think that that's not their business.

Organizational structure and mindset

The hardest thing for most people is figuring out what the value is in various design practices in support of the innovation and how to make money out of them, because “What is the value created, it's not so visible and we need to make that invisible to come to the surface,” says Richard. One of the keys is not so much to talk about innovation but always about growth. "And, that's the point, right?", says Richard, "both design thinking and innovation are just useless words. You talk about growth and changing the value, and that’s all you do.”

People are as well incentivised based on the year targets and not on how portfolio growth might look for the next ten years, which is what innovation is essentially about. The interviewees point out that employees are sometimes caught up in traditional, industrial logic-based thinking or too focused on a daily business and immediate concerns. Often BU “adhere very strongly to ‘this is how we do this,’”; especially in Hong Kong, says Peter, and training that muscle to be more flexible is the goal of his team. “Which brings those champions back in into the room, how to build on those champions that we know will be more open to ideas like this than the ones who won't,” he says.

One other challenge is to work with “different customers, vendors, teams, cultures, time zones, which requires navigating through all these”; “what makes our job more exciting (…) is to constantly be with people, understand their pain points, apply the DT, and then see how we can customize for each customer,” says Mara.

Discussion and learnings

To be competitive, service organisations such as Fung Group need to be able to create (radical) knowledge continuously (cf. Ahmed and Wang, 2003); in this case, with the aim of satisfying the needs of their business units, customers and partners. The present three-year plan (2017-2019) emphasizes the Fung Group efforts in embedding an institutionalized mechanism for the reinvention of their business as a way to “anticipate changes and have a system of governance and management that facilitates this.” The establishment of Explorium and practices facilitated both by Explorium and Fung Academy can be seen as such mechanisms, with internal and external stakeholders becoming resource integrators in value co-creation.

Whereas the role of Fung Academy is internally driven–its main focus is to build the core capability of the BUs, to support learning and to empower the employees, Explorium is on the edge of the organisation, “where the skin is the thinnest”, with the role of sensing the opportunities in the environment and tackling the hidden, “under the iceberg” problems of the organisation (absorptive practices) through collaboration with partners within the ecosystem and pilots (e.g. through the “Idea to Scale” practice) (collaborative practices). In the feedback loop, the learning facilitated by Explorium is fed back to the Fung Academy and business units (adaptive practices).

The critical role is played by the actors who are likely to act as champions when they need to implement the changes that break with institutionalized practices. Champions can help to implement the changes locally, in specific business units (internal champions) and in the community (external champions). These champions might be seen as institutional entrepreneurs, i.e. individuals on whom the company might rely to initiate and carry out the necessary changes (cf. Battilana, 2006). The company encourages a culture of autonomy–

continuous learning, taking risks and experimenting particularly with the help of these champions and entrepreneurial learners.

The design practices within Explorium and Fung Academy act as an integral part of the larger value ecosystem. Through absorptive, collaborative and adaptive practices, knowledge is continuously co-created with all the participating actors in the network and fed back into the sub-systems such as business units, and at the same time to the partners in the community within the ecosystem. For example, the knowledge and capabilities that start-ups gain through collaboration with the company can help in solving a BU's (and its customers') specific problems, but can also support its own growth and, in the long term, affect other stakeholders. In this sense, design practices are boundaryless (ecosystemic) and interdependent with the wider social and cultural contexts.

By looking into the identified practices and experiences in this paper, and recognizing the complex relationship between design practices on the one hand and the social and cultural structure within the organisation and the broader ecosystem, on the other hand, managers can find some inspiration for managing change. Since change involves breaking with the current institutionalised practices, managers are invited to recognise that it is necessary that the social structures or institutions support change. For example, incentivising the champions (institutional entrepreneurs) who support change locally and develop the value of "intrinsic 'I want to help the world, I want to help my partners' versus extrinsic 'I`m going to win a competition'", notes Richard.

Causing a Stir: Co-creating a Crowd-voted Grants Platform for Creative Entrepreneurs

POTOCNJAK-OXMAN Camilo* and WARD Vincent

Ninpo Design Pty Ltd, Australia
* corresponding author e-mail: devilhanzo@ninpodesign.com
doi: 10.33114/adim.2019.c14.122

Stir was a crowd-voted grants platform aimed at supporting creative youth in the early stages of an entrepreneurial journey. Developed through an in-depth, collaborative design process, between 2015 and 2018 it received close to two hundred projects and distributed over fifty grants to emerging creatives and became one of the most impactful programs aimed at increasing entrepreneurial activity in Canberra, Australia. The following case study will provide an overview of the methodology and process used by the design team in conceiving and developing this platform, highlighting how the community's interests and competencies were embedded in the project itself. The case provides insights for people leading collaborative design processes, with specific emphasis on some of the characteristics on programs targeting creative youth.

Keywords: Co-creation, Collaborative Design, Community Building, Creative Entrepreneurship

Introduction

In late 2014, the Canberra Innovation Network was founded as a partnership between local government, academic institutions and the private sector, with the purpose of supporting entrepreneurial activity in the Australian Capital Territory. Their leadership soon realised that both youth groups and the creative industries had not been accounted for in their original plan. Using an in-depth co-creation process, facilitated by a team of design professionals, an initiative aimed at supporting the development of entrepreneurial intentions and behaviours among young creatives was born.

The initiative, named Stir, established a crowd-voted grants platform that ran between 2015 and 2018, received close to 200 project applications, delivered over fifty micro-grants, contributed to entrepreneurial competencies among young creatives, and built a community of over twelve thousand people.

This case study highlights the value of co-creation as a methodology that enables the simultaneous development of product, user engagement and word-of-mouth marketing. Additionally, it highlighted the shortcomings of pure design teams and the difficulties of attracting young creatives to the entrepreneurial ecosystem.

The case study will provide practical insights and guidelines for people leading co-creation processes, while surfacing some of the limitations present in a design-led team when building programs aimed at supporting entrepreneurial activity.

Part 1: The Context and the Opportunity

In November, 2014, the government of the Australian Capital Territory, in collaboration with local universities, research institutions, and the private sector, founded the Canberra Innovation Network (Canberra Innovation

Network, 2018). With the motto “Connect. Promote. Accelerate.” (Canberra Innovation Network, 2014), this new institution (CBRIN) aimed to provide cross-sector support for entrepreneurial activity in the region. It was in early November, shortly before the official launch of the initiative that the founding CEO recognised that the CBRIN lacked a way to engage youth and the creatives industries with the entrepreneurial ecosystem.

To address this, she contacted an interdisciplinary design team who had a track record of designing entrepreneurship education programs. The team was led by an industrial designer with experience in the development of student communities, interdisciplinary learning, game design and innovation education programs; a mathematician with experience in higher education, innovation research and small business management; and an undergraduate graphic design and marketing student with strong ties to local youth leaders and the creative community.

Her goal was to identify how entrepreneurship could be made attractive to a younger demographic. The initial brief was to design and deliver a one-day “hackathon”, where young people would attend, describe what they wanted from CBRIN, and have their ideas compete for some form of material reward.

To gauge interest, the team quickly drew upon their personal networks in the intended audience. After engaging with different youth groups, it became clear that success would require the project not be perceived as a “token gesture” or “photo opportunity”. Although a reward could provide extrinsic motivation for young creatives, the risk was that they would not feel represented or desire to connect with entrepreneurship in the longer term. It also became apparent that, through an in-depth co-design process, CBRIN had the opportunity to develop something novel and meaningful to young creatives, even if this would require a longer timeframe and better resourcing.

This was a daunting proposition for an organisation predominantly led by the public and academic sectors. The design team, interested in seeing what would come from said co-creation process, decided to show their commitment by halving their fees. This led to a mutual leap of faith and approval of the co-design approach for what was then known as the “Youth Innovation Initiative”.

This marked the beginning of a four-year project aimed at determining a way to engage youth and people from the creative industries with the entrepreneurship ecosystem. The following section will provide an overview of the design of the project, how it was implemented and some of the impacts it had throughout its lifespan.

Part 2: The Narrative

Tackling the question of how to involve young creatives in the entrepreneurial ecosystem was a complex issue, in particular due to the fact that “youth” is in itself a poorly defined concept, representing a broad demographic with diverse needs and interests that could be better understood as a mindset than an age bracket. This situation suggested that the best approach to addressing this question would be through a co-creation process (Prahalad & Ramaswamy, 2004).

The co-creation process used was comprised of three stages. The first stage focused on establishing relationships with local youth leaders. The second stage focused on engaging these youth leaders in a workshop aimed at discovering their needs and how these could be served. The final stage drew on the outcomes of previous two to collaboratively develop a solution.

Stage 1: The Secret Brand

The first stage of the process required engaging representatives of local youth communities. The challenge here was that these communities were diverse, exclusive, and often reticent to participate in programs run by “the establishment”. As one person eloquently put it “A government Youth Innovation Initiative is about as attractive as a poster that encourages me to get tested for a sexually transmitted illness”.

To overcome this, the team took steps to develop a community that could help to execute the project. This process began by attending a CBRIN event and capturing a photo that evidenced the lack of young creatives present within the organisation’s decision-making structures. The second part of building a community was developing a “secret brand”. This concept was inspired by William Gibson’s (2010) novel “Zero History”. Given that a key aspect of the community would be its focus on developing a tangible solution, the brand should emphasise practice, work, innovation and unexplored perspectives. The team arrived at the concept of “shift”, defined in the Oxford Dictionaries (Shift, n.d.) as:

Shift (n)
1. "A slight change in position, direction, or tendency"
2. "Each of two or more recurring periods in which different groups of workers do the same jobs in relay"

Figure 1: Logo for the secret brand.

The secret brand became "SHIFT ONE". The team designed a simple logo (see figure 1) and began building the community for the co-design process. Starting with their own networks, the team showed the aforementioned photo to representatives of the project's target audience, accompanying it with the following statement:

> *The local government is about to decide how to support young people's participation in entrepreneurship. These are the people making the decision. Want to have a say? Join the SHIFT ONE Crew.*

The team connected with approximately twenty people who were influential among specific youth or creative communities. They ranged between the ages of eighteen and thirty-five, with the majority in their early twenties. They were invited to a workshop on a Saturday, 22nd of November, 2014. To build upon the intrigue established by the secret brand, the email included a Google maps geo pin and a street view image with the message "entrance is behind the white van". This due to there being a vehicle parked directly in front of the doors to the venue.

Stage 2: The Co-creation Workshop

To make the most of the diverse group that had been recruited, the team designed a co-creation workshop that could help gain a better understanding of what they needed from a program aimed at encouraging them to engage with entrepreneurship. The process of designing the workshop began with a set of clear objectives from which the team designed a series of gamified activities that provided the structure for the workshop. These activities aimed to be playful and fun, allowing people to feel confident expressing what they really needed in a trusting and comfortable environment. The objectives and diagrams used to describe these activities can be seen in figure 2.

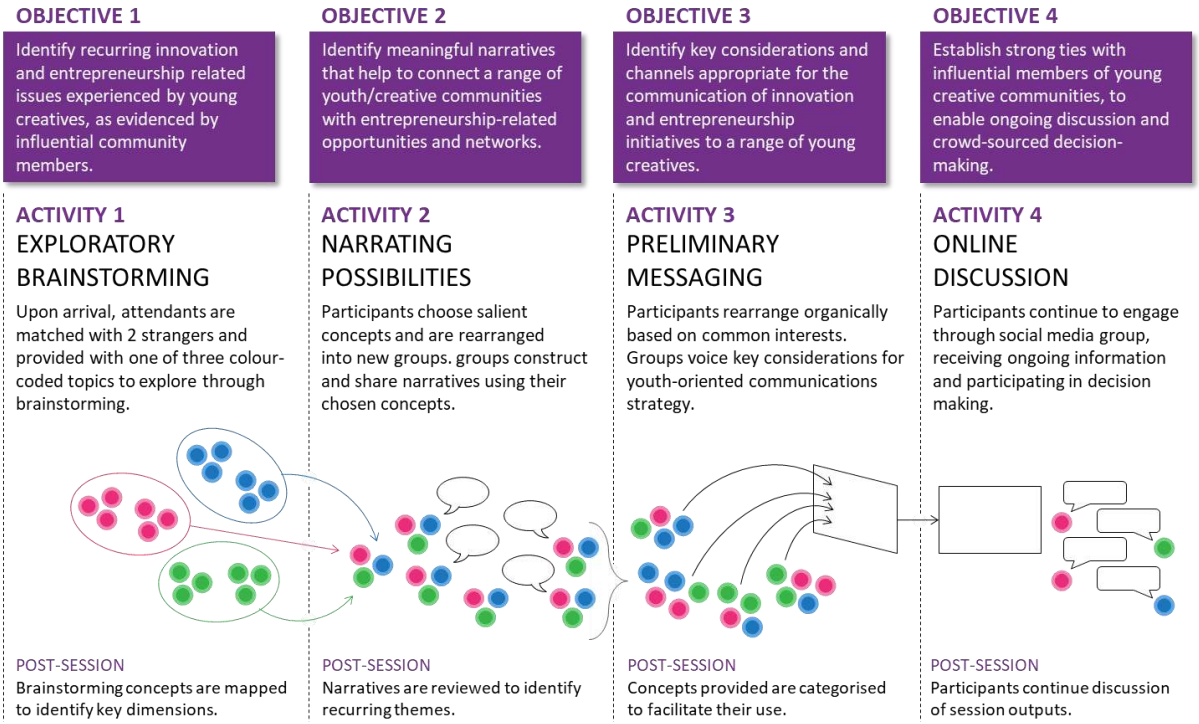

Figure 2: Objectives and activities for a co-creation workshop

Once the day arrived, they set up the room in the early morning and got ready to begin. There was an aura of nervousness amongst the team due to the short promotion cycle and the early, Saturday morning start, but when the time came, twenty-three people arrived. Attendees included people who had their own independent record labels, film-makers, event organisers, designers, game developers, photographers and visual artists. It also included café managers, appliance technicians, bicycle repair people and educators (see figure 3).

Figure 3: A gathering of diverse young creatives

As attendees were a diverse crowd, it was important that everyone, no matter their background, gender, age or experience, have their contributions received as equally important by others. For this purpose, the team introduced all participants and stated "*Now that we know who we all are, we can leave our egos at the door and focus on the needs of the thousand people we each represent*". At this point, the workshop began. It was divided into four activities which are briefly described below.

Activity 1 – Exploratory Brainstorming

People formed groups of three with others that they had not met before. Each group received one of three colour-coded questions (see figure 4) The questions were aimed at eliciting concepts related to what participants thought would be necessary for an entrepreneurship program looking to benefit them.

How would you like to see CBR described in the future?

Which opportunities would help young and creative people?

Which networks are required for young and creative people to flourish?

Figure 4: Questions to elicit concept generation.

Data generated through this exercise was analysed to detect key themes. These themes became the two axes of a conceptual map. Snippets of the resultant maps are provided in figures 5 through 7.

Figure 5: "How would you like to see CBR described in the future?"

Figure 6: "Which opportunities would help young and creative people?"

Figure 7: "Which networks are required for young and creative people to flourish?"

Activity 2 – Narrative Possibilities

Participants were asked to choose the concepts that seemed the most meaningful to them, forming a new group with people who had been given the two other questions. Their task was to draw on their previous discussion, constructing a narrative of how what they were envisioning could be made a reality. Three key narratives emerged from this activity – "Easy Start"; "Staged Learning"; and "Seasonal Innovation". These are described in figure 8.

THEME 1:

EASY START

A desire for Canberra to become the most favourable context for start-up activity in the country.

Opportunity to develop an easier start-up process, in terms of support structures and lowered regulatory burdens.

In addition, the hope was raised for a financial structure that provides support to low-cost ideas through "micro-grants".

THEME 2:

STAGED LEARNING

Recognise the unique educational needs of creative youth and their relative business knowledge and experience.

Emphasis was placed on the need for training to be delivered through a staged approach.

This extends to providing knowledge and experience of entrepreneurship as a viable career choice.

THEME 3:

SEASONAL INNOVATION

Incorporating natural themes into innovation. Participants expressed interest for creative-focused innovation festivals, exhibitions, and conferences occurring cyclically throughout the year.

Planning innovation activities in alignment with the city's distinct seasons, which recognising that innovation projects have a birth, or Spring, but also experience Winter, or closure.

Figure 8: Narratives to engage young creatives with entrepreneurship.

Activity 3 – Preliminary Messaging

The following activity was a group conversation aimed at determining how to best communicate these narratives to the members of the many communities represented in the room. The goal for this activity was to ensure that support of entrepreneurship among young creatives be perceived as relevant, desirable and accessible. There were four broad aspects discussed – "Considerations" or desirable outcomes; "Content" that messaging should include; "Tone" or nature of the relationship with the audience; and "Channels" or the means used to deliver the message (see figure 9).

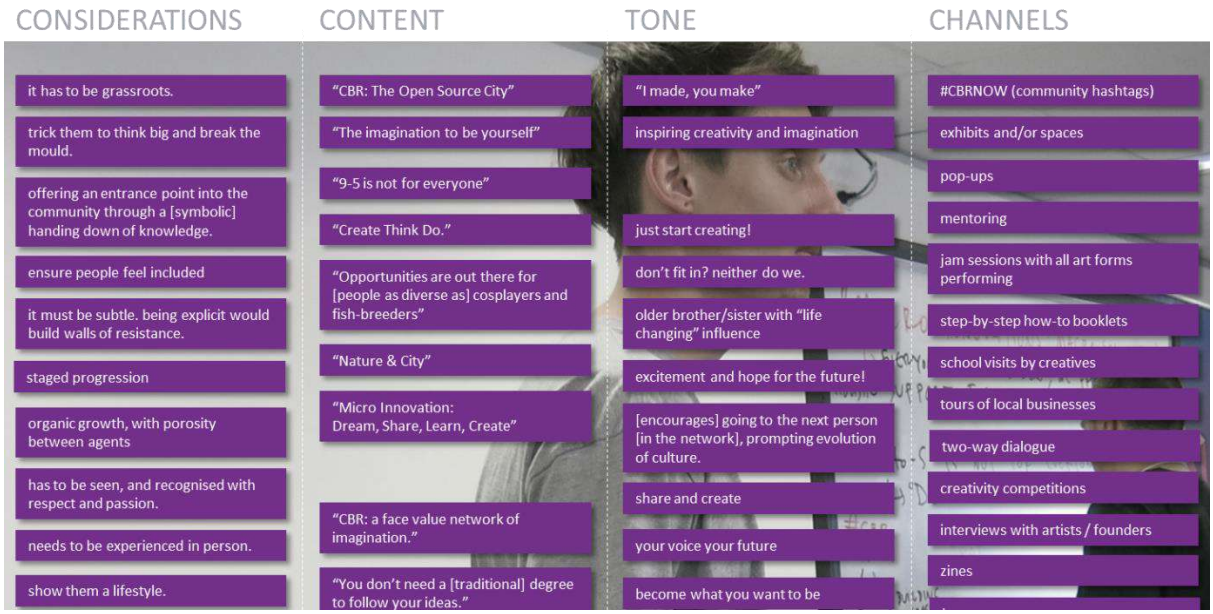

Figure 9: Narratives to engage young creatives with entrepreneurship.

Activity 4 – Online Community

The final activity set out to establish a way to continue the discussion after the workshop was over. This was not just to keep people informed, but also to present findings and involve them in development of the potential solution. The channel chosen for this purpose was a secret Facebook group. Community members were given the ability to nominate potential members. Once a nomination received a certain number of "likes", the person would be invited to join the "SHIFT ONE Crew".

Stage 3: Co-Designing a Solution

After transcribing hundreds of post-it notes, organising the data, and uploaded the results to the SHIFT ONE group, several interesting insights emerged. The most important were:

1. Young creatives are often very entrepreneurial. They do not, however, identify as such, and do not feel catered for by existing support initiatives provided by government or academia;
2. More than monetary support, many were interested in empowerment and personal development through education. They also wanted mentoring and business coaching for their projects; and
3. There was less interest in a "mass market" than there was in being part of one or more emerging "micro-collectives". Each of these represents a unique community with specific interests, which provides the validation and sense of purpose to the individual's work.

To begin developing a solution, the design team invited the SHIFT ONE Crew to participate in defining how these needs could be addressed. Proposed ideas were put up for a vote by members of the community. One member of the group asked:

> *"What if people could upload an idea, and if it gets a number of votes, then they get some money to make it happen?"*

This resonated with the design team lead, as it reminded them of "LEGO CUUSOO" (CUUSOO, 2014), now known as "LEGO Ideas" (LEGO, 2019), which they had encountered while in Japan in mid-2014. It led to an interesting series of questions, including: What does an incubator for young creatives look like? Does it have to look like every other incubator? Can it be something completely different? Could it be completely online?

These questions led to the following concept:

> *"An online incubator that could guide the young and creative through stages of learning, developing an entrepreneurial mindset and helping*

them to structure and present a business concept.

Projects submitted would be evaluated and voted upon by the public, incentivising a positive attitude towards sales and encouraging the project creator to obtain feedback from their target audience.

At the end of a season, projects with the strongest crowd response would receive a microgrant to help with their execution. After the season, grant recipients could share their stories and motivate the next generation of project creators.

This concept was presented to the CEO of CBRIN, receiving support and resources for execution. The concept was presented to the SHIFT ONE community, who were invited to participate in development of an "Online Micro-Grants Incubator for Creative Youth". The design team reserved some of the budget to remunerate those that chose to remain involved in the form of "consulting fees". Four project teams were formed, working interdependently on specific aspects of the solution. The project lasted seven weeks. Below are brief descriptions of each team and some of their key findings.

[Ed] Education Team: "Make it easy to understand"

This team included people with skills and experience in education. They worked on translating concepts from the Business Model Canvas (Osterwalder & Pigneur, 2010), with the goal of making the framework accessible to people non-business backgrounds.

[Ev] – Events Team: "Make a splash at existing events"

This team counted with the participation of people with experience managing venues and events. The key takeaway from this team was to leverage existing events in the city. This led to a presence at Art, Not Apart (Art, Not Apart, 2019), exposure to thousands and a social media following of over 750 people in one day.

[Ux] – User Experience Team: "Make a clear story that people can follow"

This team brought together people from the worlds of code, design, information systems and game development. Although their role seemed technical, the team included a film-maker who focused their efforts on establishing a clear narrative for the different user groups - project creators; voters, sponsors, etc.

[Br] – Branding Team: "Why don't we call it Stir?"

This team drew people from design and marketing backgrounds and was the last to meet. This ensured that they included the insights from the other teams. The name emerged as a perfect description of what the platform was looking to achieve: To mix things ups, to awaken people from slumber, and to create a murmur among the crowd.

The findings from these teams set the requirements for what would become the Stir platform. Although it evolved over time, figure 10 describes the platform's core functions at the peak of its lifecycle.

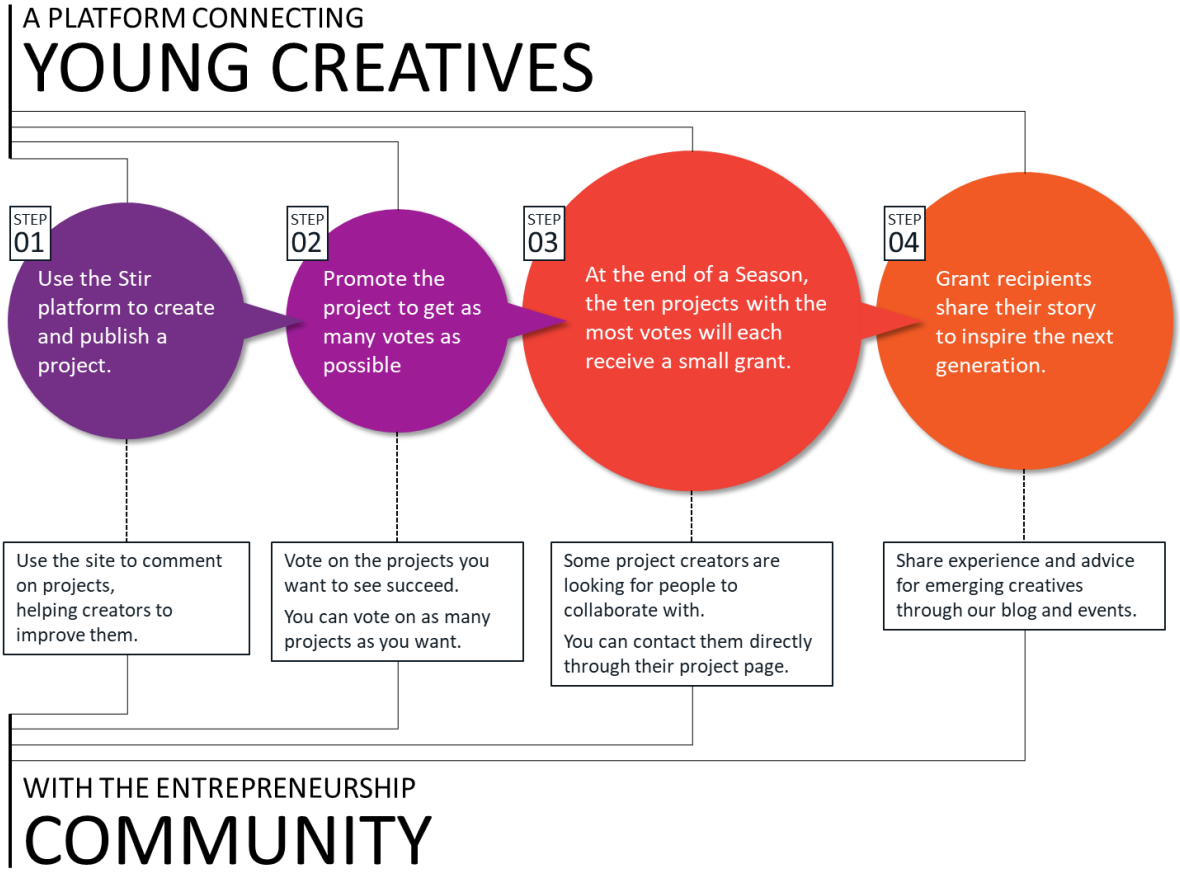

Figure 10: Overview of the Stir process at the beginning of Season 3.

Between launching on the 26th of March, 2015, and the close of Season 4 in early June, 2018, Stir ran 6 grant seasons. These included four major seasons and 2 shorter summer seasons. Seasons lasted approximately 50 days. During this time, over 13000 people registered to the platform, uploading close to 200 projects and submitting 12629 votes that determined who would receive a micro-grant. 57 individual grants were delivered, totalling AUD51000. The platform was visited 82747 times, with over 250000 pageviews. These numbers, although not large by global standards, were significant when taken in the context of the 403000 people that live in Canberra, Australia (Population Australia, 2019).

Although now defunct, Stir represented a shift in the scope of what was achievable by entrepreneurship programs in the Australian Capital Territory. Its reach was larger than the standard set by other local initiatives. Although it did not support high-tech, high-growth start-ups, it provided an avenue for underrepresented communities to feel their work was important and their passions were worth pursuing. Figure 11 includes some of the logos of the projects Stir supported. While many of the projects have since been discontinued, people who participated in its initiatives have now become embedded in the local ecosystem as founders, consultants, contractors, support service providers and community managers. It was a platform that, like its name, caused a stir.

Figure 11: Logos of some of the projects that Stir supported throughout the years.

Part 3: The Key Learnings

The process of engaging with the local community in the definition and development of the "crowd-voted grants platform" provided several key insights and lessons for a collaborative design process.

These lessons are specific to a context where the team was working towards establishing a common ground between two groups with very distinct values, goals and accountabilities. In this case a government agency and representatives from multiple creative youth communities, with the purpose of supporting increased participation of an underrepresented communities in a growing entrepreneurial ecosystem

There were many lessons derived throughout the project's four-year lifespan. Most of these were incremental and happened on a daily basis. It would be hard to capture all of these lessons in writing here, but it was possible to derive some themes that encompass these learnings. This section will outline some of those lessons and highlight some considerations for co-creation. It will also include personal observations and challenges derived from the experiences of the team executing the project.

Lesson 1. The Common Struggle

Engaging underrepresented communities in a collaborative design process requires an authentic understanding of their "common struggle", or the challenges they perceive themselves to have faced throughout their careers. In the case of creative youth, many expressed feelings of having been exploited by the business world, either through low wages, poor treatment or working for "exposure". For the Stir project, it was important not to trivialise these experiences. With a background in the creative industries, the team shared some of these experiences. This common ground between the team and the community that was emerging from the project led to strong ties and commitment between the two groups, which increased mutual respect, trust and willingness to contribute to the project. When deciding to undertake a collaborative design process, it seems that an important factor for success would be a genuine connection between the facilitating team and the target community. This will avoid tokenising the audience and could increase their sense of ownership as they see themselves reflected in the team that is supporting the process.

Lesson 2. Choose a Side, Start a Movement.

Without having experienced the aforementioned "common struggle", it was difficult for the parent organisation to understand the interests and concerns of the community of creative youth that were participating. Although they provided significant support and had a genuine desire to connect with the

creative youth community, they did not fully understand some of their challenges or aspirations. Some of this stemmed from a deep misalignment of values between the Canberra Innovation Network, a government entity set up in collaboration with academic institutions and private entrepreneurship support services – whose goals were associated with stimulating economic activity – and a community of creative youth, many of whom were interested in personal achievements such as exploration, expression, and recognition. To ensure the support provided was genuine, the team had to take a stand for the community on numerous occasions, articulating their interests and avoiding these becoming second to the institution. When undertaking a collaborative design process, it would seem that an important first step is to surface the values and principles of the community that is participating. It would be important to recognise which of these are non-negotiable and why, discussing these with both the community and any funding or supporting organisations early in the project. Establishing the central values of the community can help in ensuring that the parent organisation does not inadvertently make statements or take actions that could compromise the relationships that are being constructed.

Lesson 3. In Collaboration, Design can be the Mediator

Although the team strongly advocated for the interests of creative community to the parent organisation, it was equally important to advocate for the interests of the parent organisation. The team acted as facilitators and mediators between the two stakeholder groups, highlighting that the funding parties did not have an ulterior motive that played into the young creatives concerns about exploitation. For this purpose, the team also invited members of the parent organisation to participate in events and activities organised by the members of the creative community. The leadership of the organisation responded admirably, attending these activities with their families, enacting the support and earning the trust of those they were aiming to support. Eventually, this led to members of the community having the confidence to have their own conversations with the upper management of the Canberra Innovation Network. A key aspect of collaborative design processes would therefore be to not only involve the target audience, but also encourage the participation of “upstream stakeholders”. They should not just be seen as funding parties to be reported to, but where possible, involved as equals and get directly involved in developing the solution.

Lesson 4. Recognise the Value Inherent in your Target Audience

A surprising lesson learnt by the team and the parent organisation was that many young creatives had experience in many business functions, including accounting and sales, due to the self-reliance which is prevalent in their industries. A clear example of this were members of the community who were independent musicians. This observation made it clear that much of the messaging targeting these groups and encouraging them to get involved in business-related activities was inadvertently both condescending and not relevant to their stage of development and experience. Thinking of them as “at risk” will not benefit either party. The creatives did not just want to “start-up”, they wanted to grow, learn and develop the capabilities they already possessed. When developing a program for an underreported community, it would seem important that the offerings, language and messaging begin by recognising the existing achievements of the community they are intended for. In the case of young creatives, they will be entrepreneurial with or without the support of the existing ecosystem. Rather than framing support as a “handout”, it could be more effective to frame it as an invitation to collaborate and an exchange, where the target community is bringing their valuable existing knowledge and expertise to a context that will also benefit.

Lesson 5. Meritocratic Cultures may be Less Democratic

Distributing corporate funding to young creatives is difficult. They do not seem to be motivated by the funding itself, but rather what the funding enables them to achieve, and what obtaining said funding signals to their peers. Making it easily accessible through a democratic method such as “crowd-voting” does not make it more attractive. They seem to prefer the sense of accomplishment that comes from being selected for a grant. For this purpose, it may be beneficial to identify people whose opinions the community respects and invite them to be part of the decision-making process. Offering these individuals some form of “weighted votes” could have assisted in attracting the more meritocratic members of the creative community.

Lesson 6. Designers are Great Innovators, but may be Mediocre Administrators

The hardest lesson learnt by the design team was that they were uncapable of managing all of the functions required to achieve economic and institutional sustainability for the project. The collaborative design process itself was simple, and the team were comfortable with many aspects of an innovation process – identification of the opportunity; setting a vision; recruiting the community; generating excitement; developing the product; obtaining traction; and presenting clear value propositions to potential funding parties. However, it was not long before basic administrative duties became a burden. Accounting and other simple business activities were less familiar than dealing with uncertainty, leading to high levels of stress and animosity within the team. It would seem that increasing the chances for sustainability of the project would require a more diverse, multidisciplinary team that includes specialists in basic business functions. The challenge is in recognising one's own limits and ensuring that they can be overcome through collaboration with either the parent organisation or the community itself, as these two groups are the ones with the greatest potential to benefit from the longevity of the project.

We hope that these six themes can provide some guidance for people conducting similar collaborative design projects. Our greatest hope, however, is that people are inspired to contribute to increasing the number of creatives participating in the global entrepreneurship ecosystem. In a world of growing "gig economies", the arts will be needed to ensure that these gigs are humane.

Acknowledgments

The authors would like to thank Dr Sarah Pearson and Petr Adamek, leaders of the Canberra Innovation Network, for their unwavering support in seeing this project become a reality. They stood up to boards of directors for it to receive funding, and that is something that few people in their position do. They would also like to thank the Canberra Innovation Network team and the broader Canberra ecosystem for their enthusiasm and participation. Most of all, they would like to thank the SHIFT ONE Crew and all of the creatives who contributed to the platform, uploaded a project, and/or voted to support others. You inspire us.

System Design for People Dealing with the Liminal Space: Case Study: Family member that Take Care of Terminally Ill Family Member in Israel

SCHWARZ-LIS Ora* and PERSOV Elad

Bezalel Academy of Art and Design, Jerusalem, Israel
*oralis.design@gmail.com
doi: 10.33114/adim.2019.c15.206

A 23% increase in the number of family members that find themselves as care providers has been documented throughout the last decade. In 2017, more than 1.6 Million people in Israel (18%) are defined as 'caregivers' to family member.[1] In Israel, approximately 70% of yearly death cases are from terminal illness (Elizera, 2018).Accompanied is a family member who accompanies any terminal ill family member at some time during their illness.[2] This project examines a system-design solution for the helplessness and obstacles that the Accompanied experiences. This project combines qualitative methods and human-based design. Based on the findings, three prototypes were developed using a participative graphic experience map and the co-design of illustrated storyboards.[3] These prototypes were presented to senior caregivers in healthcare system and to a nursing manager of one of the biggest hospitals in Israel. This project found that the most efficient service for alleviating the Accompanied's helplessness is a Case Facilitator (CF) who has expert knowledge of the health bureaucratic system and Interpersonal skills. The CF will escort the Accompanied during all critical situations throughout the process. This system-design solution could also solve similar problems for any person who find themselves dealing with liminal bureaucratic spaces.

Keywords: Death, Service design, System design, Liminal space, Palliative care

[1] Israel Central Bureau of Statistics, 2016
[2] Accompanied was the chosen terminology to differentiate from 'care givers' which is the professional terminology of someone that get paid for doing this including changing diapers for example. The accompany family member usually choose the tasks they are able to do, sometimes changing diapers are not included in it and there is an addition professional care giver that get paid to do it.
[3] A storyboard is a series of simple illustrations that demonstrates an idea through visualization; if needed, some words are added.

Figure 1 Accompanied's feelings expressed visually

Introduction

The aim of this project is to make things easier for the Accompanied. In this project, I use Accompanied to refer to a family member who accompanies any terminal ill family member at some time during their illness.

My motivation is based on personal experience. During 2017, I accompanied two terminally ill, family members. Unfortunately, caretaking duties will reach us all. This research can apply to terminally ill individuals, elderly parents, or children with disabilities. In this project, I focused on families with a terminally ill family member. There is a lack of research on the influence of the imposed responsibility on the Accompanied.

We repress end of life issues. We are afraid of "the impossibility of further possibility" (Yalom, 2008, p. 59).[4] This is one of the reasons why there are no answers for end-of-life challenges. There was an art still life trend, *memento mori*,[5] the purpose of which was to remind us not to forget that one day, we are going to die. Knowing about death will help us deal with it when it arrives and will help us to live better lives.[6]

Caring for family members has several aspects. There are psychological aspects, including the fear of death, medical aspects include palliative care, and taking care of patients' pain and suffering when the "battle against illness is ended" (EE).[7] Along the many aspects of end of life process, families face ethical and legal limitations, together with social, spatial and cultural considerations. There are bureaucratic systems to be dealt with, which include duplicate services for the Accompanied in many organizations. Finally, we must consider what happens to the Accompanied and their support system after the death of a terminal ill family member.

This research utilized qualitative methods, including 20 interviews[8], three observations[9], two conferences, and self-documentation. The literature review included[10] 24 articles, 26 websites, 19 media resources, 23 blogs and journals, and four books.

One of the Accompanied duties is to ensure the quality of life of the terminally ill family member, despite their limited life expectancy. CF's purpose is to allow Accompany to do it. One of the CF's functions is being with Accompanied in the obscure liminal space where there is no clear responsible service provider. The liminal space is "when you are between …if you are not trained … how to live with ambiguity…" Richard Rohr (Barron, 2013). CF recognizes liminal space potential and with this knowledge, the CF will be able to provide the most accurate and holistic service that the Accompanied needs. The CF will help the Accompany "…tolerate the anxiety and develop the faith that things will take shape" (Barron, 2013).

[6] From Tibetans wisdom chapters
[7] See Informants layout Appendix B
[8] See Informants layout Appendix B
[9] See Observation layout Appendix C
[10] Right for July 2018

This potential solution could help the Accompanied during and after the accompany process. This solution has been tested and approved with Accompanied, end of life social workers, palliative care nurses, and hospital manager. Nevertheless, actual pilot program is still to be conducted.

The CF system design solution, may be found useful not only in this case of Accompanied terminal ill family member, but also in many scenarios in which people find themselves lost in liminal space, such as parents of disabled children, the unemployed, migrants, and children to elderly parents.

Literature Review

The purpose of palliative care is to maintain the quality of life and prevent suffering for terminally ill patients. Today's updated palliative care field is meant to maintain the quality of life and prevent suffering for all patients.

This project can be included under the third sustainable development health care goal of UNA 2015-2030 ((UNA) The Sustainable Development Goals 2015 – 2030, n.d.), to "ensure healthy lives and promote well-being for all at all ages." It could be also included under 2018 trends, such as "precision treatment " (PSFK Future of Health 2018 Webinar, 2017), to create the most accurate personal treatment to suit each patient's lifestyle.

The 2018 trends relate directly to the patient. They show the beginning of the understanding that patient treatment is complicated and requires additional involvement besides the medical professional team. The unprofessional caregiver, Accompanied, is missing from these trends. In Israel, "the patient is not hospitalized alone;" (LW) the family members tend to stay in the hospital during the hospitalization time.

This literature review contains academic articles, media resources such as TED and YouTube videos, documentaries, and family radio programs debating end of life issues. It also includes information from participation in two conferences—one about palliative care, and the other about end of life ethics issues.

This chapter will review the main issues that were found in the literature review. These are:

1. Making death a dignified end of life
2. Legislation
3. Palliative care
4. Place of death
5. Contact with the bureaucracy system
6. Multiple non-profit organizations
7. Family physician status
8. The joy of professional caregivers

1. Making death a dignified end of life

According Epicurus, suffering is the continuous fear of death (Yalom, 2008). Physicians are not trained to stop searching for healing options for their patient (Gawande, 2014). Hospitals are designed for diseases, not patients. In the video *What Really Matters at the End of Life* (What Really Matters at the End of Life | BJ Miller, 2015), BJ Miller proposes "to invite design thinking to this subject (end of life)," as there is a lack of attention to the design of palliative care medicine. Some physicians are not exposed to this field during their studies. BJ Miller is a palliative care physician who criticized hospital design and invite designers to redesign hospitals based on the thought of how they would like to die.

Palliative care nurses find that death is a process, like birth (What Hospice Nurses Know: Dying and Afterlife Questions and Answers with panel, 2014), and not an event. So, how might we turn death to a dignified end of life (LiLach, 2017)? How should we prepare for death, as eventually all of us are going to die, and there is no second chance to be prepared to die (Every one will die once so we have to get it right, the first time, dying at home - The Feed, 2016)? Based on the literature, palliative care nurses have the tools and abilities to turn death into a dignified end of life.

2. Legislation

The definition of terminally ill in this project was any patient that will die from their disease. For example, this project includes the Accompanied of patients with chronic diseases (Kol Zechut, n.d.), different stages of

cancer,[11] and ALS[12]. The definition of terminally ill is flexible and depends on medical development. During the 80s, HIV was defined as a terminal illness (al, Volume 14, 2002 - Issue 5, Pages 587-598) until the development of medical treatment.

During 2017-18, some laws were updated in Israel, including benefits for the Accompanied, but most of the Accompanied are not aware of laws existence (RL).

3. Palliative care

Palliative care, as one nurse said, is "specialized with the dying" (Nurses on Death and Dying, 2016). Professional palliative care accompanies the patient by guaranteeing their quality of life as much as possible until their death. Professional palliative care uses different tools, such as listening (Starkman, You do not have to hospitalize: the doctor who brought treatment to home, 2018), guiding family through the process of forgiveness, observing the patient without judgement (What Hospice Nurses Know: Dying and Afterlife Questions and Answers with panel, 2014), accompaniment rather than treatment, preventing patient loneliness, and servicing patient needs—"we just travel him" (Dying at home - The Feed, 2016). These tools can also be used by the Accompanied. The support volume of palliative care will be based on the patient's disease stage, including after patient death.

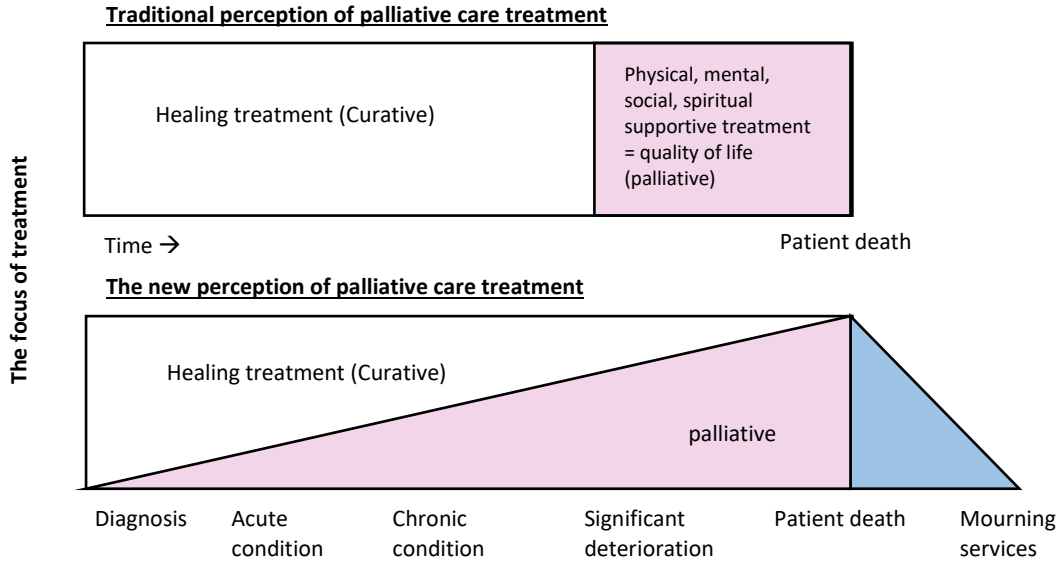

Figure 2 Traditional perception of palliative care treatment (top) versus new perception (bottom (Bentur, 2005))

[11] Only cancer stage four is defined as terminal.

4. Place of death

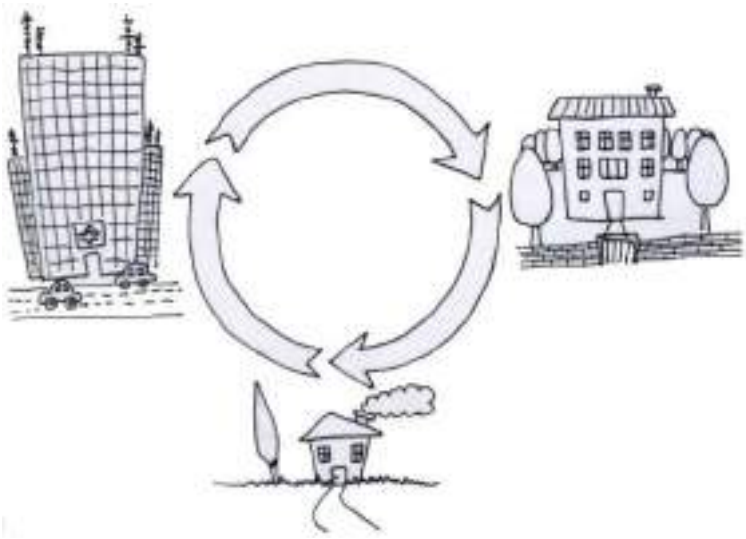

Figure 3 The place of death circle of changes: from home, to the hospital, to the hospice, back to home

In the past, the whole circle of life occurred at home. The exposure to death was extremely high (Molloy, 2015). Today, most people die at hospitals, although some choose otherwise.[13] When death is not easily visible, the exposure to it is low. This is one of the reasons that people are afraid of death.

5. Contact with the bureaucracy system

Caring for a terminally ill family member requires involving several authorities such as: healthcare, social systems, municipal services, religion, and medicine. There is a lot of paperwork required to coordinate between these functions. The services needed by the Accompanied are located in the liminal space created between the responsibilities of all authorities' services providers. There is no sole entity that has budget and staff to provide the holistic accurate need of the Accompanied. Instead of working effectively with the Accompanied, when the healthcare system and the authorities are most needed, they are adding difficulties.

Daniel Blake's (Loach, 2017) neighbor told him that the system will kill you. Does the system aim to kill patients more quickly, or is doing paperwork an escape option for the Accompanied?

6. Multiple non-profit organizations

Many organizations aim to support patients and their families, yet many organizations provide similar services.[14]

The Accompanied has various organizations that can help them. Duplicate organizations, however, can cause a waste of resources on both sides. One organization supplies multiple services that can be supplied by other organizations, instead of providing a unique service.[15] The Accompanied wastes precious time figuring out the differences between identical services supplied by different organizations.

7. Family physician status

Why should not the family physicians be their patients case manager? The family physicians will accompany the patient from the first news of terminal illness until the end. Family physicians are familiar with their patient's medical history. The family physician can connect different authorities and healthcare system

[13] For example, in Australia, 70% of patients choose to die at home (Dying at home - The Feed, 2016), while only 14% actually died at home; more than half of patient are dying in hospitals. In the USA (Gawande, 2014) only 27% of patients died at home, which is high, because most of these patients did not have time to reach the hospital.

[14] For example, one organization was established in 1990 to help cancer patients between the ages 0-25 and their families. Another organization was established in 2009 with exactly the same purpose.

[15] Multiple organizations→multiple services→resource waste→missing knowledge

information. “Incidents are not usually caused by a single decision or action… it is caused by dynamic interactions between people, tasks, technology and working conditions… management, policy, regulation…” (SystemsThinking - A New Direction in Healthcare Incident Investigation, 2017). Healthcare incidents are the third cause of death in world (Mozer, 2018). “In a perfect world, family physicians should manage patient cases and needs” (Levi, 2018). Family physicians connections will prevent incidents and help provide better service to the patient and the Accompanied (Reznik, 2017).

8. The joy of professional caregivers

Professionals palliative caregivers, although their professions expose them to death with great frequency, were found to be satisfied and happy people. “I think I am one of the happiest physicians in the world” (Nir, 2013); “we are all happy” (Steinmatz, 2016).This happiness was found to exist across the field; every professional caregiver I spoke with expressed their satisfaction despite the difficulties.

Research layout

This research used human-centered design management tools to find how the Accompanied can use their limited resources to improve the quality of their lives. The field research was based on qualitive tools such as interviews, observations, and seminars.

1. Informants

Professional informants were chosen for research. These included social workers, psychologists, physicians, and palliative care nurses. Nonprofessional informants included the Accompanied, volunteers in an organization that transfers information to elderly patients, researchers in this field, and company/application founders. Informants layout include 20 interviews.[16]

2. Observations

Three observations[17]of an up-to-date medical information center, a medical center oncological day care center, and a hospice were done. All observations included interviews.

3. Research Limitations

I could not interview the Accompanied mainly from ethical reasons. In addition, the Accompanied denied any connection to terminal illness. As long as the patients were alive, they maintained a hope that it was not terminal. Further research needs to be conducted to evaluate the proposed solution viability and integration with local systems.

4. Stakeholders

Hospitals, workplaces, health insurance and healthcare systems are the project’s central stakeholders.

5. Prototype

Mapping[18] and analysis of overall research findings suggested that the following five insights are the most critical for the Accompanied:

1. Diagnosis of terminal illness
2. Overwhelming information
3. Confronting bureaucracy
4. Release from hospital crisis
5. The kick (IR), 17 days on average (Nir, 2013), before death

[16] For Informants layout table see Appendix B
[17] See Observation layout Appendix C
[18] See Appendix D

At the last point, when the physicians announced there was nothing else they could do, they had the patient choose between hospital hospice and home hospice. Time limitations forced the Accompanied to use their resources efficiently.

Focusing on this point shows that many changes are required for patient home care. A two-room apartment was drawn and shown to the Accompanied. They[19] were asked to state which changes needed to be done to make the apartment suitable for home hospice. It was found that:

1. Home hospice is not available for all and required a special setting
2. Part of the information on how to prepare for home hospice was known retrospectively
3. The kick can be softened by advance preparations
4. Getting the sketch done by a professional made it possible for the Accompanied to prepare their home

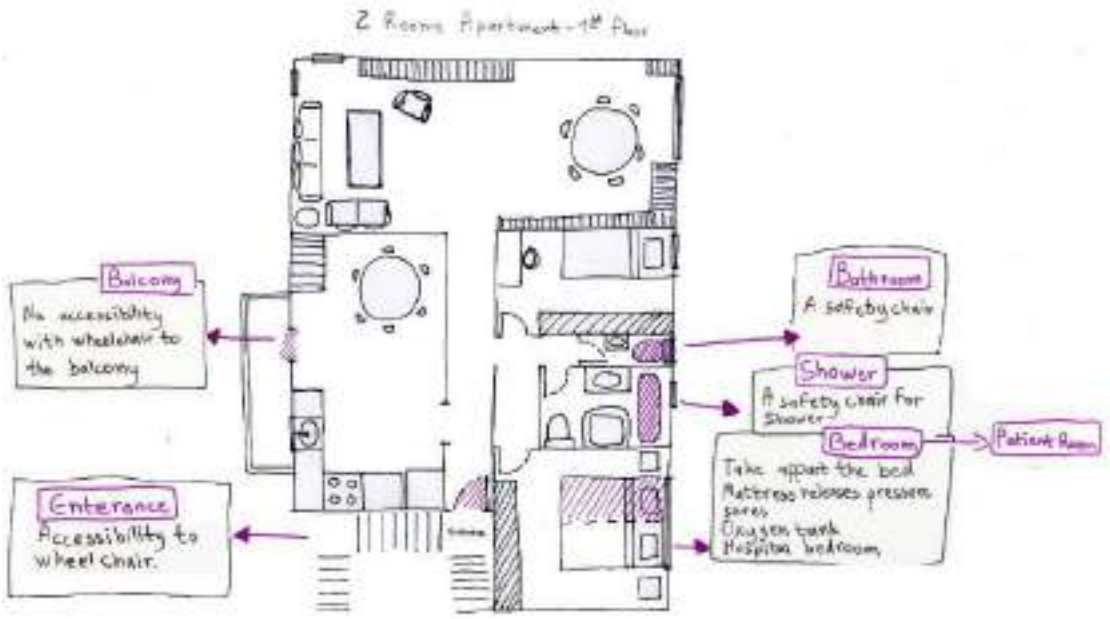

Figure 4 Prototype apartment sketch based on field research

[19] They already finished being Accompanied due to the research limitations mention above.

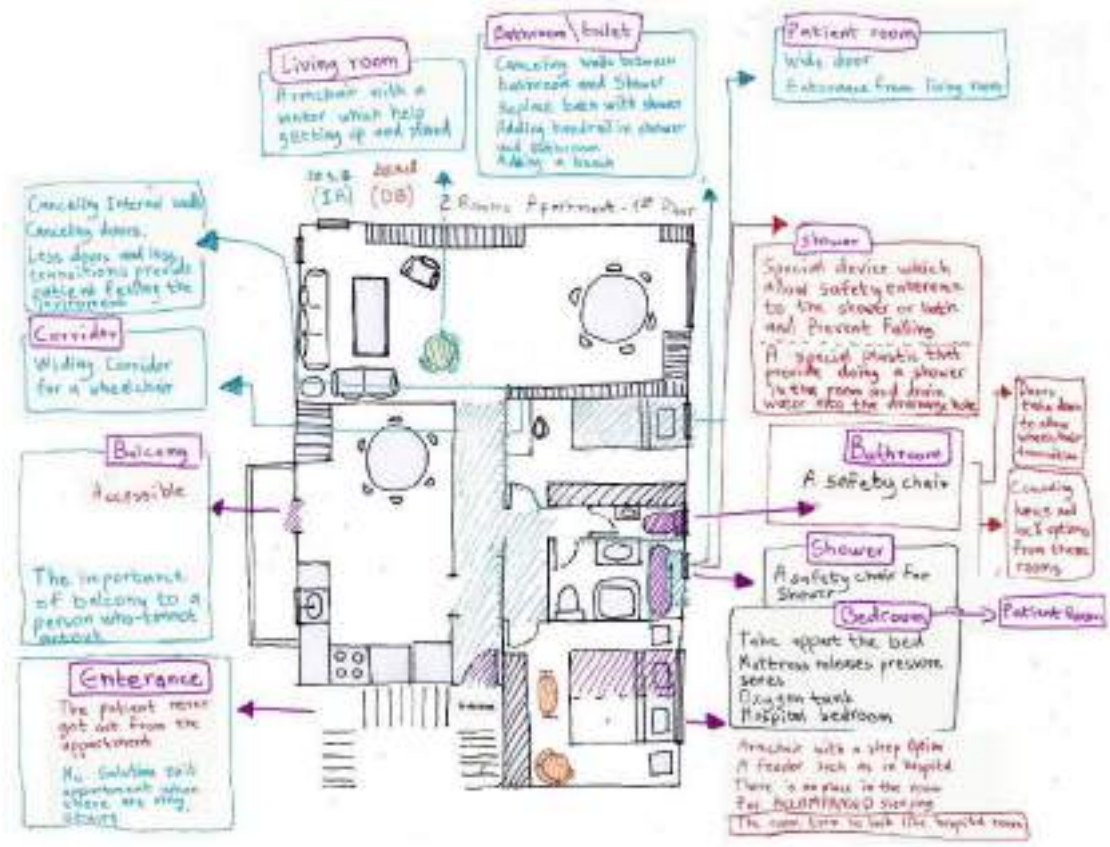

Figure 5 Prototype apartment sketch with Accompanied notes

Three different prototypes were made during this project. Two of them are detailed above.[20] The last prototype was multiple storyboards strips[21] which were presented to the informants. The methodology behind the storyboards is the visualization of informants in a familiar situation, which allowed them to freely express their thoughts, which created deep insights.

Five storyboard strips were presented to the informants. Each of them showed one critical pain point. These storyboards were presented based on a chronological experience map. They were presented to five informants in four interviews.

Selected Research Findings

1. Caregivers make up a quarter of the labor market in Israel (RL)

The term caregiver refers to any family member that takes care of the elderly, ill, or disabled. This project refers only to the Accompanied.

25% of employees are caregivers (RL). 60% of them hide the fact they are caregivers. 3.7% of them quit their job. “Based on USA data, caregiver employees cost $3,000 to the workplace because of absent work days, quitting their job, recruiting, and training new employees” (Saragusti, 2017). Most caregivers are around 45 years old, the peak of productivity (Saragusti, 2017). In the last decade, caregiver numbers rose by 23%.[22]

The Accompanied reported that they were occupied with patient care during work hours. “Being a caregiver is an additional career” (Saragusti, 2017). There are two ways to help the Accompanied:

1. Supply formal services, such a professional daily caregiver.
2. Supply services such as money or mental support.

[20] Experience map and apartment sketches
[21] See Appendix E
[22] Israel Central Bureau of Statistics

2. The Accompanied's status in the system

Being an Accompanied has emotional, health, economical, and social costs. It is not a role people choose. Most of the time, the Accompanied was given this role without any qualification or preparations.

There is no "one adjusted rule" for Accompanied (Reznitsky, 2015). Therefore, it is challenging to find one service that fits all Accompanied. "It is time to develop ethical rules to help the Accompanied to take their place in the medical decisions of their family patient. These rules should be adapted to state, community, and family values" (Reznitsky, 2015).

World trends recognize the special status of the Accompanied. In 1999, the UK declared a national strategy regarding the Accompanied (Brodsky, Reznitsky, & Citron, 2011). Role recognition opens an opportunity to provide holistic and accurate services. An example of how "a little service can support the Accompanied" (RL) is the Hertz pilot service.[23]

3. The liminal space between authorities add difficulties to the Accompanied

Hospital prescriptions do not contain enough medicine (IR); this is one of the issues with the system. There is no synchronization between different systems and authorities in the liminal space, such as hospitals and community healthcare systems (IR). The Accompanied spends a lot of their time filing papers and chasing signatures (OB). There is a danger that charlatans might use the system's weaknesses to gain unfair advantage or commit fraud.

4*. Family physician as a case manager*

The patient is surrounded by a professional team and the Accompanied. There is a need for holistically, effectively adjusted management. Family physicians are the most familiar with the patient and are able to minimize incidents during treatment. The system does not define the family physician as a case manager, but some family physicians act as case managers, despite not having the resources to do so (palliative seminar, 2017).

Due to the missing case manager function in the system, the Accompanied find themselves acting as case managers (ID). The Accompanied should not be case managers, since they do not have the required knowledge, experience, or understanding. The Accompanied should focus on accompanying their family member and not managing their case. The family physician should be the case manager. Israel Medical schools should include improved content about terminal patient care, including the Accompanied (DS).

5. Post mortem opportunities

After the death of the terminally ill, the Accompanied still need support (ID). Suddenly,[24] the Accompanied find themselves unoccupied. After death, they would use their free time to do good for future Accompanied. For example, developing an application with information for cancer patients (ID), providing information by volunteering (HB), and establishing organizations to supply caregivers' needs (RL).

These research findings supplied many opportunities. The challenge was to choose the best opportunity to fulfill most Accompanied's needs.

Project product

The case facilitator (CF) is a new professional. The CF will accompany the Accompanied from terminally ill diagnosis, through the liminal space between different authorities, up to and after death.

The CF will assist the Accompanied in using their limited resources in the most efficient way and will minimize the Accompanied's helplessness, especially when time is critical.

Goals

1. Maximize the accessibility of relevant information in the liminal space.

[23] Hertz drivers volunteer to transport disabled patients to their hospital treatment and back home. This service gives the Accompanied some breathing space.
[24] It will always be sudden, no matter how much you prepare for death

2. Minimize wasting time and money for the Accompanied and the system, especially when there is overlap because of duplicate organizations and services.

Mission

Israel healthcare system recognizes the importance of continuous treatment, but such treatment does not exist. There is a lack of hospital beds (RR), but it is forbidden to release patients from the hospital to home if their home is not adjusted for the patient's condition. The nurses are in a conflicting situation—if they release patients from the hospital, the hospital will save money, but they are not allowed release patients to non-suitable homes. It is not surprising when the current patient-nurse standardization is based on data from 22 years ago (RR).

Figure 6 Example of patient complexity (left to right): a man reaches to his 90th birthday; he may develop diabetes, walking issues, or/and damaged hearing, or/and be diagnosed with cancer

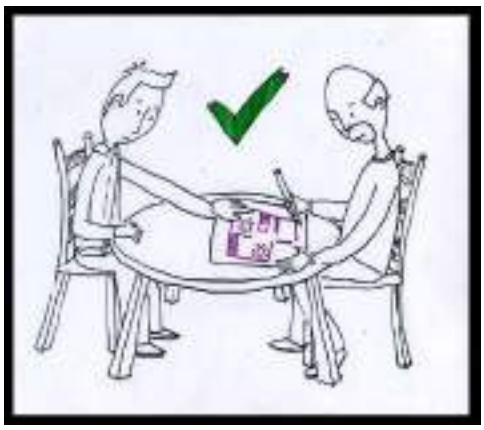
The solution

The Case Facilitator (CF) solution can help solve the complexity of Accompanied process.

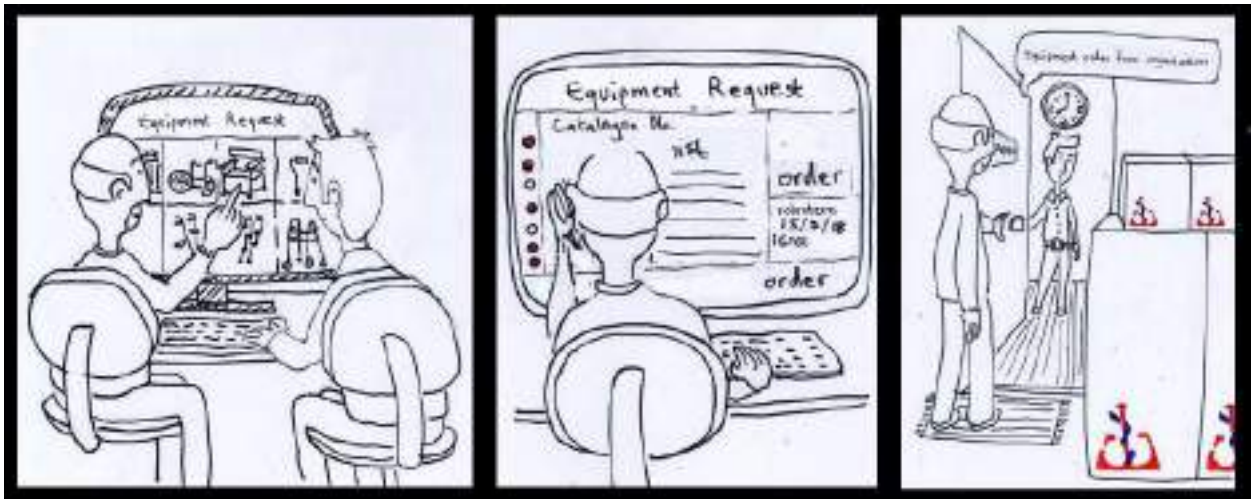
The CF is with the terminally ill patient family members from diagnosis. The solution will be presented by the following storyboard prototype. Let's join the CF, who is already familiar with terminally ill patient and family, during the 17 days (Nir, 2013) before patient death. The CF knows that this family could, with some arrangements, handle home hospice. The CF presents the two solutions, hospital hospice and home hospice, with their advantages and disadvantages.

As part of this presentation, the CF takes the family to visit a hospice and answers their questions.

In addition, the CF explains the home arrangements they need to make, based on CF familiarity with their home. The family chooses home hospice.



In coordination with the family, the CF orders equipment to make their apartment into a home hospice. The family receives the equipment order at home.



The CF checks the physician's prescription before releasing the patient. The CF is able to adapt the prescription with the physician and adjust the next 17 days. [25] This CF service prevents pharmacy visits by the Accompanied and lessens patient suffering. The CF collects the medicines.

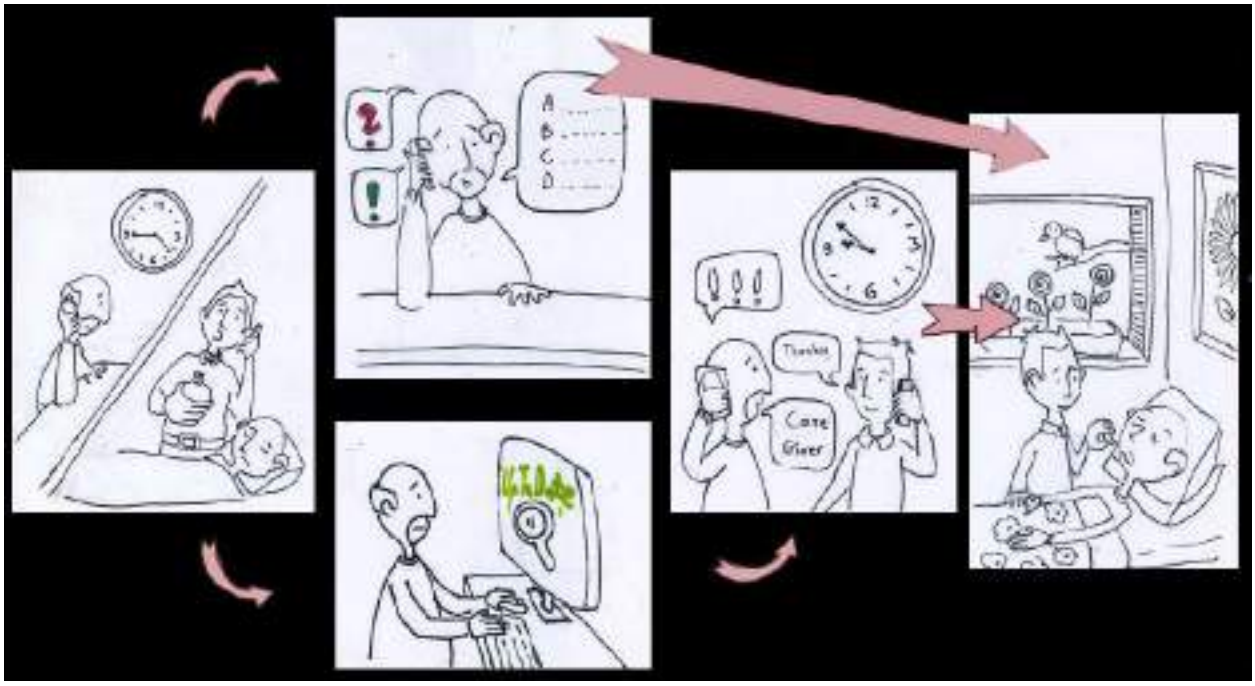
[25] 17 days on average (Nir, 2013), before death

The patient arrives at home. The CF guides the family in connecting the patient to their equipment. The CF leaves, reminding family that they are available for them around the clock.

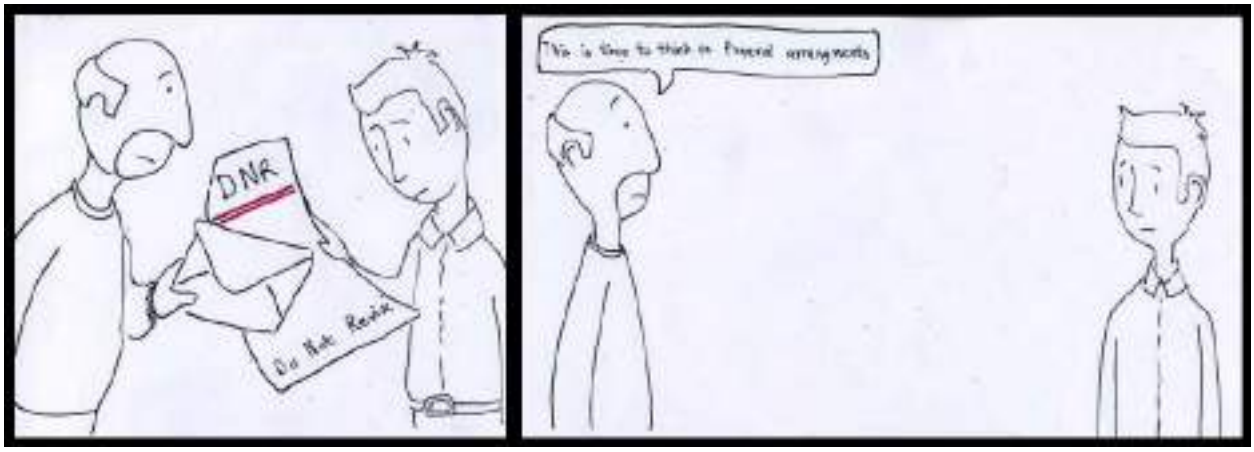
A few hours later, the Accompanied calls the CF about a medicine dosage issue. There are two optional scenarios at this point:

1. An experienced CF is able to guide Accompanied by asking the Accompanied a few questions.
2. The CF does not have the information, but knows how to get it and with whom to consult. The CF tells the family they will get back to them with information after consulting. The family is already familiar with such a scenario from the past, therefore they are not worried. After a few minutes, the CF calls the family with the answer. The CF uses this opportunity to remind family that the hospital hospice solution always exists if they regret choosing a home hospice.

This question and answer scenario occurs several times during these 17 days. If needed, the CF has backup from the CF center where they were trained.

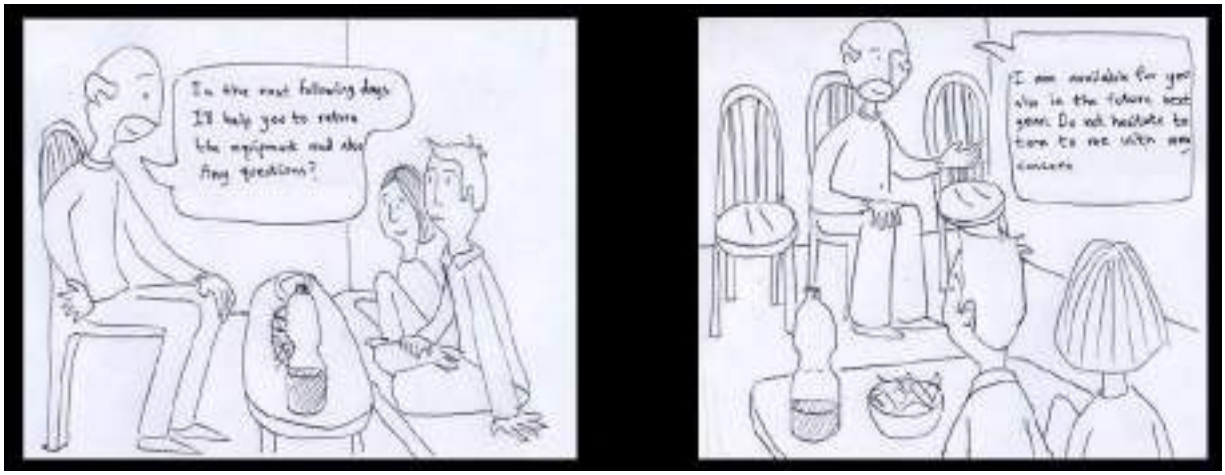


Based on the terminally ill patient's instructions, such as do not revive (DNR), the CF instructs the family on how to prepare for the day of death.



The day of death arrives. The family contacts the CF, informing them that the patient died.

The CF helps the family organize the funeral. Following the funeral, the CF visits the family, providing information about the following days, verifying that the family has what they need, and reminding them that, although the patient has died, they are available for them. As time goes by, the CF's accessibility decreases.



Product features

CF qualifications should be:

- Interpersonal skills
- Holistic view of the patient and family
- Knowledge and experience in systems and the liminal space authorities, such as healthcare, social systems, municipal authorities, religion, and medicine
- Ability to find missing information
- Life and health system professional experience
- Service consciousness

Following step

One of the CF solution's disadvantages is the additional factor in the liminal space, which already contains multiple authorities and functions. CF is a personal solution. Thus, it is not suitable for all. In fact, there are some advantages in dealing with liminal space (Barron, 2013) without CF. The aim is to experiment with the CF solution and to find a business model which answers the next questions:

- Will this service cost money or will it be free?
- Is it possible, based on current standardization in Israel, to supply this service?
- Which authority will be responsible for the CFs (budget and management)?
- Who will train CFs?

One of the biggest hospitals in the country, which has patients from different community healthcare systems and geographical areas—including patient from abroad—is willing to do a pilot.

If the CF solution is successful for the Accompanied, it could be scaled up to fit any person dealing with liminal space—for example, parents of disabled children, the unemployed, migrants, and children to elderly parents.

Summary

The number of Accompanied is on the rise. Literature and field research have found several pain points when dealing with liminal bureaucratic space –the space of transition, waiting, and not knowing (Barron, 2013). The authorities are missing the potential of providing Accompany needed services, although there are multiple national and local authorities, which would like to provide the in between needed service.
Accompany pain points include the diagnosis of a terminal illness, missing knowledge, and dealing with routine while accompanying a terminally ill family member up to, and after the patient has died. At these points, the Accompanied is helpless. Therefore, how can the Accompanied continue their routine without reaching a breaking point?

What will help the Accompanied? Will knowledge help? Or a specific person? Will the family physician as a case manager be the best solution, or other professionals?

The CF solution fulfills the project's goals. The CF will provide the Accompanied with the opportunity to maximize their limited resources. The CF solution was chosen because of the different levels of involvement potential throughout the entire process, rather than just the critical point 17 days before patient death (Nir, 2013). This is a holistic solution for all Accompanied pain points.

The CF solution was presented to the manager and nursing manager of the biggest hospital in Israel, and to a senior caregiver in the healthcare system. Research findings and the CF idea were approved by them. There is a similar solution for chronic diseases in the Ministry of Health work plan (Health, 2017; Health, Nursing administration 2017 work plan, 2017), yet it is not applied in the system.

The CF solution could help the Accompanied, who make up a quarter of the labor market,[26] by providing the needed "in-between" service that is most required at this time and moment by the Accompany. Authorities recognizing the Accompanied's liminal space experience, could use liminal space potential, for a better system service. The success of the CF in coordinating between systems and authorities, could be developed to other liminal space systems, which could solve many problems, for people who find themselves, dealing with the liminal space between many authorities.

Research Perspectives IN THE ERA OF Transformations

'Project Kapıdağ: Locality of Production': A Case of Research for Social Design in Complex Collaboration

ÖZ Gizem and ATEŞ AKDENİZ Aysun*

İstanbul Bilgi University, Turkey
* aysun.ates@bilgi.edu.tr
doi: 10.33114/adim.2019.c16.112

Social design is a much-discussed topic in the context of facilitating change towards social ends. Growing problems in the social and political realm can trigger social change. In the last few years, Kapıdağ, Turkey has been stuck between top-down mass industrialization and longstanding local production dynamics. "Project Kapıdağ: Locality of Production" was emerged from the struggles associated with local production in the region and was realized in collaboration with local organizations, local community and İstanbul Bilgi University Faculty of Architecture. The project aims to pinpoint the assets Kapıdağ for the collective wellbeing of the region and reveal the potential intervention opportunities in the region through mapping out the network of relations between production, materials, public and institutions. In this paper, the project will be examined as research for social design case in complex collaboration. Different proposals that were developed out of this undertaking will be exemplified to discuss issues on the responsive role of the designer in *'infrastructuring'* social design process. The paper further attempts to demonstrate how the research process can also function as an alignment tool between collaborators to attain objectives and open up possibilities for new collaborations and projects.

Keywords: Research for social design, infrastructuring, collaboration for social design, visual diary

Research for social design

Introduction

Social design is a process where design practices are led by social needs and carried out in collaboration with a variety of societal actors pursuing change for the improvement of social ends (Markussen, 2017; Manzini, 2014; Maze, 2014; Thorpe & Gamman, 2011). The problems caused by fast social and financial changes within an area can lead to an intervention space for social design (Manzini et. al, 2010).

Kapıdağ, where this project was carried out, is a peninsula extending into the southern Marmara region in Turkey (figure 1). Although it was a major tourist destination in Turkey in the 1950s, it has since lost its importance due to a variety of local management issues in time. In addition, because of the new industrial transformation around the region, the Erdek - Kapıdağ Peninsula has been dragged into social, cultural, economic and ecological changes. According to population data of the Turkish Statistical Institute (TUIK), it can be seen that the village population of Erdek has decreased since 1990 (TUIK, 2018). During recent years, companies have purchased many farmlands to establish factories in Erdek Gulf; as a result, several villagers have moved to urban areas in search of new ways of living (Öğdül et. al, 2018). Top-down political reforms of mass-industrialization threaten the socio-technical and ecological balance in the region, which, in turn, endanger local practices developed throughout the years.

One of the project coordinators is a native of Erdek and whose parents still live there; thus, she is a first-hand observer of the changes in Kapıdağ - Erdek. The initial idea of organizing such a workshop and employing the process of research for social design in Kapıdağ arises from this personal urge. The first contact with governmental authorities was made through local acquaintances. Erdek Municipality is also conscious of the situation and the demands of its residents; thus, they want to collaborate with volunteer associations and universities to create opportunities. The project coordinators used the opportunity to organize a workshop in the summer term, and the students participated in the project on a voluntary basis.

'Project Kapıdağ: Locality of Production' is a research study in the field of social design aiming to pinpoint the assets of Kapıdağ through engaging in a variety of social practices and things to open up resilient socio-technical and ecological possibilities that will enrich the region's self-sufficiency. It was realized between local stakeholders and Istanbul Bilgi University, Architecture Faculty members and students between August 14th and August 27th, 2017. Several collaborators were engaged in the process and brought their knowledge and resources to the study. Through ethnographic fieldwork, design students documented and analysed the assets of the region for further generation of ideas.

Figure 1: The geographical location of Kapıdağ Peninsula. Source: https://goo.gl/maps/CrnvRovaXEH2, 2017.

Infrastructuring Social Design and the Context of Kapıdağ

'Infrastructuring' (Hillgren et al., 2011) approaches social design as an ever-growing process focusing on developing the relationship between different stakeholders to facilitate new networks and resources that might give way to design opportunities. Unlike pre-defined paths, the flexible approach of infrastructuring allows fitting in complex situations and dealing with unexpected inputs as well as the mess inherent to a given social context (Björgvinsson, Ehn & Hillgren, 2012; Hillgren et al., 2011).

Therefore, in Project Kapıdağ, we contextualized the social design process as an open-ended, long-term relationship between different societal groups in the field in order to enrich and extend opportunities and discover assets which could be developed further. In each step of the project, new relations were built and existing ones were deepened. The knowledge and practices of collaborators informed the process to be able to discover existing *'assets'* (Manzini, 2014; Thorpe & Gamman, 2011). Social design reinterprets these assets in the light of the social and material context to lead up to social change (Binder, Brandt, Ehn & Halse, 2015; Manzini, 2014; Thorpe and Gamman, 2011).

Project Kapıdag aimed to detect the region's assets through a social design process taken as open-ended and was divided into different phases, thus building relations with different groups within the field. Kapıdağ is made up of a variety of societal groups with different cultures (though affected by the Convention Concerning the Exchange of Greek and Turkish Populations in 1923) and economic practices (from agriculture to mass industrial manufacturing). Today, the peninsula is inhabited by different ethnic groups—mainly by Turks, Pomaks and Cretans (figure 2). They share the same land while retaining their own rituals, habits and traditions. In time, these people of different backgrounds developed their own means of livelihood by making use of the natural resources of the region. This cultural diversity makes the region's ecosystem richer and more varied. To be able to explore homogeneities and heterogeneities in the field, the community was thus taken as a network of intertwined relationships between the social and the material, as well as between

humans and non-humans (Binder et al., 2015). Accordingly, research was designed towards discovering and mapping out these relations and making them available for further interventions.

Figure 2: Old photographs of Aunt Zeynep's mother and father when they first came to Erdek, Turkey, through the population exchange. Photograph: Participant students, 2017.

Research for Social Design in Complex Collaboration

Thorpe and Gamman (2011) define social design problems as *'wicked'* and note that they require a collaborative process where diverse actors play the role of co-creators to tackle with the complexity of the situation at hand. Because there is not one true answer that would make all human and non-human actors equally satisfied, a collaborative process is needed for all actors to be able to utilize their agency (Thorpe and Gamman, 2011). For example, we—as the coordinator of this project—played a role at the intersection of meeting the educational goals and expectations of local collaborators. We gained experience of conducting fieldwork to students, visualizing data from the field and turning them into ideas; we were also obliged to propose fruitful and applicable ideas in the region.

Although conflating education sensitivities with the needs of a project in a social realm with multiple collaborators outside the university can be tricky, collaboration between the university and the local government is also an important part of the social design process. Collaboration between design schools and local organizations is a fruitful platform for research, as well as for analysing and generating new ideas for social ends (Manzini, Zhong & Baek, 2010). Schools can be centres where new proposals are generated and tested through design research for a positive change. In the meantime, design students can also learn more about social problems, how to address these problems, and ways of developing the skills necessary for acting in sensitive situations (Margolin and Margolin, 2002).

Project Kapıdağ was realized in collaboration with a variety of stakeholders, each of whom brought a different set of ideas to the table. These included the local residents, local independent initiatives (Yesil Valiz Association for Responsible Tourism, Bandırma Mountain Club, Erdek Exchangeee Association), local governmental organizations (Erdek Municipality, Erdek Chamber of Commerce), İstanbul Bilgi University as an institution alongside project coordinators who also authored this paper, and 24 design students from different departments (industrial design, interior design and architecture).

Stages of the Project Kapıdağ: Locality of production

Pre-Project

The research proposal was presented to Erdek Municipality and Erdek Chamber of Commerce four months prior to the start of the project; initial arrangements for accommodation and transportation were then made. To establish the initial contacts with local bodies and people, project coordinators pre-visited the region, meeting and contacting more than 25 local people in the villages. Since the starting point of the project was the pinpointing of existing and potential local income sources within Kapıdağ, coordinators grouped these sources into five main routes after initial visits. These routes included: historical sites, villages, production

facilities, centre and shores, and bazaars. Besides thematic consistency, locational relevancy and convenience of transportation were also taken into consideration while deciding the routes and their contents.

In-Project

The research steps of Project Kapıdag were planned in the following order: understanding of the area with ethnographic methods; investigation of existing social and production practices; participating in local activities; and dividing the participants into smaller groups in order to reach personal stories for the purpose of deepening the knowledge obtained. Data was collected both via observing on-the-moment interactions between people, as well as by students participating in these interactions. Observation supported by interviews (Blomberg, Giacomi, Mosher & Swenton-Wall, 1993) was the main ethnographic method. The process was also supported through unstructured interviews, note-taking (both written and visual), written sources, videos, photographs and sketching (Barab et al., 2004).

The routes were discovered with design students; they had the first-hand experience and learnt about Kapıdağ's villages, sites, agricultural products, hand-made products, and different cultures and practices. Additional information was obtained on the locals' methods of generating income, the ecological potential of the area, the variety of flora and fauna, the different uses of plants, and the opportunities that the sea brings (i.e. fishing and sea tourism).

At the end of each day, design students were asked to keep 'visual diaries' (Blomberg, Burrelland & Guest, 2003) as a means of preparing self-reports in order to be able to handle intense data. They sorted out and categorized the photographs they took according to the practice they were referring to and supported those photographs with texts on what they had learned, accounts of villagers, questions that arose in the field, and their ideas. These diaries also functioned as media for discussion between design students in the process of idea generation (figure 3).

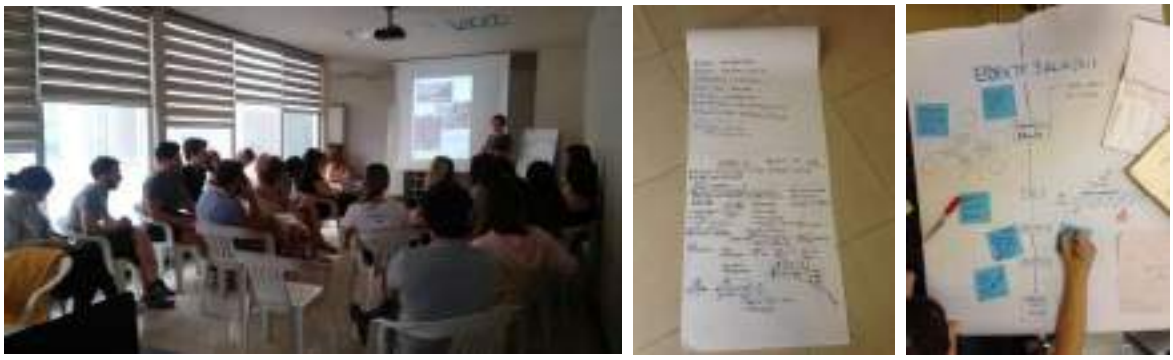

Figure 3: Scenes from a discussion session in the workroom that the Municipality provided. Photograph: Participant students, 2017

At the end of the first week, all participants came together, and a pool of visual diaries was formed. Each design student began to form both their area of interest as a potential for Kapıdağ as well as their potential for generating ideas. Next, seven groups of students were formed based on these interests. These seven groups approached Kapıdağ's assets from different perspectives and focused on the following: agricultural products; historical sites; cultural diversity; women's labour; architectural textures; fishery; and activity tourism. While some of the five initial routes were highly inspirational for students, some did not, in the end, trigger enough potential. For example, no ideas emerged from the production facilities route. In this route, participants visited large- and medium-scale production facilities, such as olive and olive oil production, dairy production, and a marble plantation. We believe that, because of these facilities' highly institutionalized nature and grand scale, students could not envision change within their capabilities. On the other hand, agricultural products, cultural diversity, women's labour, architectural textures groups were directly affected by what they encountered and observed during the village route. The diversity of cultural and agricultural production and social life in the villages is what students found unique and worth further elaboration.

After these seven groups were formed, the project obtained a more responsive structure. Each group had different needs to acquire deeper knowledge of their subjects. Being able to meet those needs required new collaborations, different paths and time tables. Then, design students as researchers also assumed the role of

facilitators (Thorpe and Gamman, 2011). How these roles were realized within the process will now be explained through a closer look at some of the projects.

- Cultural Values in Kapıdağ: The group that was interested in different cultures in Kapıdağ, namely Pomaks and Cretans, contacted Erdek Exchange Association and paid several visits to the area. After gaining trust, they were able to visit some of the exchange participants at home and at work (in offices and bazaars). In this way, they learned about their foods, herbs, alternative healing mixtures, and rituals (figure 4). Students visualized the information they gained and exhibited their drawings at an exhibition. In doing so, they obtained feedback from a wider audience and also interacted with people unaware of these traditions.

The knowledge that was sought was deeply situated in specific locations and groups of people. Thus, reaching even seemingly simple knowledge was challenging because it required strong networks and collaboration. For example, returning to a village for further investigation was a problem due to a lack of transportation facilities and walking paths. Thus, design students needed to get in touch with the people they met in the villages and bazaars so that they could be transported.

The projects of two groups, which focused on Ballıpınar Village, where transportation options were limited, provide insight into the challenges of the research process within situated knowledge. Many coastal villages in Kapıdağ have moved away from agriculture and chosen sea tourism as their main source of income. Ballıpınar, despite being a coastal town, is still a closed community, and their main source of income is agriculture, especially the purple onion (figure 5). The purple onion is very popular in the region and is known for its sweet and juicy taste, durability, healing power and purple colour (even women working in onion cultivation wear a purple skirt, as it does not permit onion stains). All families in the village in one way or another work in onion cultivation, women taking an active part in the production and preparation of onions for sale.

Figure 5: Purple onion, separate and weaved by their stem; Aunt Ayşe from Ballıpınar Village with her purple skirt. Illustration: Participant students, 2017.

- The lifecycle of the Purple Onion: One of the student groups documented and analysed the journey of the purple onion from soil to the dinner table. They tried to understand and visualize the steps of cultivation, how it was prepared for sale, and what the sales channels and actors involved were. They further proposed a labelling system by printing an onion on textile and showing its inner purple rings. Villagers can use this system to promote and sell their products in the bazaars.

- Ballıpınar Original Architecture: The architectural and rural structure of Ballıpınar is shaped especially in accordance with purple onion production. Every house has an awning (figure 6) made of wood and wicker. Women sit under these awnings, weave the onions by their stems and store them by hanging them from awnings. These awnings also function as social gathering points where women eat and drink together, while men prefer to gather in 'kahvehanes'. Ballıpınar Village is especially interesting for the nice combination of social and material values. Onion production affects social life, the architectural texture of the village, and even clothing. The group documented the architectural texture, streets and houses of the village and the social and material relations arising from onion production by examining the building techniques and materials used in the houses and awnings by section and detail drawings (Figure 7).

Figure 7: An original housing visualization from the village of Ballıpınar. Visualization: Burak Özçakıl - Burcu Berber - Büşra Hamzaoğlu, 2017.

Other projects include proposals on different activity themes and routes for tourists and locals; exploring the fish and fisheries culture in the region; women's handiwork by weaving, crocheting and knitting; and the pattern map for the Temple of Hadrian to assist visitors in understanding the excavation area and discover ancient historical stone structures.

End-project

At the end of Project Kapıdağ, a festival was organized with the cooperation of the municipalities and associations around Erdek and Kapıdağ. As a result of the two weeks of documentation and analysis, powerful visuals with clear visuality and clarity prepared by the students were exhibited together with activities organized in the district square (Figure 8). The fact that this exhibition was held at the festival dates increased the number of visitors to the district and led the project outputs to be reached by more people.

Design students stayed on and interacted with local people regarding the outcomes. Visual boards became tools for discussion and the exhibition turned into an open forum where people visited and shared their ideas about the place they lived in and gave feedback on the ideas for further development.

Figure 8: Exhibition in the Erdek town hall. Photograph: Participant students, 2017.

Key Learnings and Outcomes

Project Kapıdağ is situated as research for social design study that identifies the assets of the region to open up further ideas and possibilities aiming at social change in the region. The seven projects developed by the

students have as a significant strength the ability to make the future of the region more resilient. Not only these seven projects but also the interests of the students and collaborators, created a mutual understanding on social development for the region. These are fruitful initial outcomes for the project, as Project Kapıdağ was planned as the first step of a long-term social development study in the region. In addition, it can be said that an alignment of goals and objectives between different contexts and with different collaborators was achieved. Collaborators agreed to make the Kapıdağ Project a more complex social design engagement for generating ideas towards collective social change in the region.

The next step of the project was planned as a series of workshops for participatory idea generation with local people and collaborators to raise and strengthen awareness of the assets of Kapıdağ. The outputs of the Kapıdağ Project would provide a useful input for this second step. Meetings with the municipality and other organizations were carried out. However, due to political issues on the side of the municipality, these workshop sessions could not be accomplished. In spite of this, this project opened up new collaboration opportunities and future steps turned into new projects in new places. In the 2018 Fall academic term a design studio project was carried out in the city of Bursa (two hours away from Erdek) with a non-governmental organization which was met through Project Kapıdağ. Another design studio project is planned for the 2019 Fall term with the same organization in the town of İznik, an administrative district in Bursa.

As for educational purposes, the researcher-coordinators and participant students of this project gained experience in dealing with real project conditions in situ. Coordinators practiced developing a workshop between educational and governmental issues and sustaining communication between them. Students had experience conducting their own fieldwork, taking different roles within the project as researcher, designer and facilitator, and working and talking with people from different parts of the society. They enhanced their data collection and visualization skills and had a chance to interact with the people who played a significant role in the process. These teachings and gains were the main objectives of the project from the point of view of education.

Conclusion

'Project Kapıdağ: Locality of Production' was an attempt to *'draw things together'*, to contextualize and reframe existing practices and things in Kapıdağ to ensure regional development while protecting both the socio-technical and ecological environments. It aspires to highlight the local production assets in the area that have the potential to trigger change towards the collective well-being of different social groups. Material engagements of different communities were observed in their unique contexts. Looking at how these assets intertwined in the process of knowledge production allows us to handle the ethnographic field as a design space. This way, design can reconfigure relations between socio-material practices and contexts of use to attain social ends.

Besides being a research phase, Project Kapıdağ also functions as an alignment tool between collaborators. An agreement on the goals and objectives between collaborators is important for conducting a grounded project. It also enables discussion through practice where collaborators learn about each other's perspectives and ways of working through action. We believe this kind of an introduction through practice in a social design process will avoid any possible power imbalance and competition between organizational logic in further studies that will be longer and more complex. Also, mutual rapport among locals and design students was established. Many villages of Kapıdağ are closed communities; thus, building trust is especially important to be able to obtain knowledge, as this necessitates one-to-one observation and the participation of locals in daily life. Finally, Project Kapıdağ confirmed the researcher-coordinators' view of the region as a spot rich in cultural and ecological resources while offering diversity in practice and embracing change.

There were also difficulties and constraints encountered during the project. The duration of the project, which was realized through stakeholder in kind aid, was determined as two weeks, so the process was planned as a research phase and ended with the mapping of various possibilities. Although new processes are planned to explore design potentials through the findings, because of the timeout, negative impacts such as a decrease in the momentum, distance from the field, and the change of certain actors can be seen. At this point, as Thorpe and Gamman (2011) state, non-long-term commitments that do not involve the implementation process appear as a constraint to some of the projects proposed by students. Factors determining the duration of the project include the context of the project (summer internship) and limited financial support (again one of the cases listed by Thorpe and Gamman (2011)). Being aware of these constraints, the project coordinators designed the project objectives and questions at a certain level and maturity and set achievable targets. As a

result, the targets were achieved, a fruitful experience for the participants and a promising experience for the stakeholders were provided. This positive and progressive process has been seen as a step towards cooperation between stakeholders and has enabled long-term plans to be made.

As a positive result of the Kapıdağ Project's mediation tool function, other design studio projects are planned to be carried out in the nearby region amongst similar stakeholders, and it is hoped that the results of research for social design will be taken forward and become design ideas.

Research Perspectives IN THE ERA OF Transformations

Equity, Listening, and the Transference of Power in Design-Driven Healthcare Innovation

MANOS Matthew[ab]

[a] University of Southern California, USA
[b] verynice, USA
manosm@usc.edu
doi: 10.33114/adim.2019.c18.104

The American Heart Association has almost 100 years of experience uncovering barriers to better health across the United States. Looking to transition towards a more equitable approach to health, the AHA partnered with verynice, a design strategy consultancy, in 2017, to develop a design research toolkit that could understand the needs of rural communities, align scientific understanding with human-centered design, and build capacity for qualitative design research. In 2018, Professor Matthew Manos of the USC Iovine and Young Academy led a group of 19 graduate students on a Professional Practices Residential in Dallas, Texas. Along the way, students developed a series of strategic recommendations for the organization moving forward. In a second application of the toolkit, Professor Manos led 20 additional graduate students in a residential experience with the Children's Hospital of Los Angeles in 2019. By introducing the framework in the offerings of the Academy, we saw first-hand the power of the methodology in an educational environment as a tool for teaching students how to listen to community needs, and suspend their bias.

Keywords: Design Research, Design Education, Social Impact

The Challenge: Creating a Toolkit Centered Around "Listening"

According to the Center for Disease Control, the "factors that influence the socioeconomic position of individuals and groups within industrial societies also influence their health." (U.S. Department of Health and Human Services Centers for Disease Control and Prevention, 2013). Further, according to the American Journal of Preventive Medicine, over a period of 40 years, people living in urban environments have shown a significantly more rapid growth in life expectancy than their rural counterparts. Specifically, this gap is found to be attributed to higher rates of cardiovascular disease among other issues (Stephens, 2014). The American Heart Association (AHA) has almost 100 years of experience uncovering barriers to better health across the United States. As a national organization, the AHA has a unique challenge to represent all needs from all communities in order to fulfill a holistic mission to "be a relentless force for a world of longer, healthier lives." Some communities, especially those that are rural, can go unheard or can be inadequately addressed by solutions that don't match their circumstances. In recognition of the growing understanding of social determinants of health as well as the rural life expectancy gap, the American Heart Association needed to develop an approach that would allow them, and other mission-driven health organizations, to better understand the needs of all Americans.

Design Research and Human-Centered Design have a unique ability to serve as the connecting bridge between people and business. This is typically accomplished with an empathy-first mindset that believes impact within

a community, organization, or enterprise can come upon shifting from a top-down mindset to one that is bottom-up and "people first". When compared, the promise of design research, and the gap of understanding the needs of rural and vulnerable communities in the United States reveal a unique opportunity to apply the human-centered design process to the outreach and health equity initiatives of the American Heart Association. As a result, the AHA collaborated with my design strategy consultancy, verynice, in 2017, in order to develop a creative methodology that could build capacity for Design Research and "Listening" within and beyond the organization. The goal of this toolkit is threefold:

1. Understand the assets, needs, and circumstances of rural communities.

2. Align scientific understanding with a more human-centered perspective.

3. Build staff capacity in qualitative design research and rapid ethnographic methodologies.

In addition, it was important to both the client and the consultancy that the resulting methodology be made publicly available for any individual or organization tackling similar issues. While counterintuitive to open-source a new "trade secret" that would soon be developed, both the client and the consultancy understood the potential ripple effect of impact that could take place if the methodology were to be made openly accessible. Further, as both the lead Strategist for the development of this toolkit and an Assistant Professor and Assistant Dean at the University of Southern California, I saw a unique opportunity to take advantage of the toolkit's open access and apply it to the classroom environment. The primary goal of this application was to teach students actionable skills and approaches to suspending their bias while also learning to be collaborators *with* the end user as opposed to designers *for* the end user.

The Process

My working relationship with the AHA began in 2015. I have personally led projects with the organization related to business planning, strategic planning, and research & development. These projects include the revitalization of the organization's "Heart Walk" experience, and the redesign of the organization's strategic value proposition. When approached to create a new toolkit for the organization that would merge the principles of design with the incredible impact of the AHA, I was thrilled.

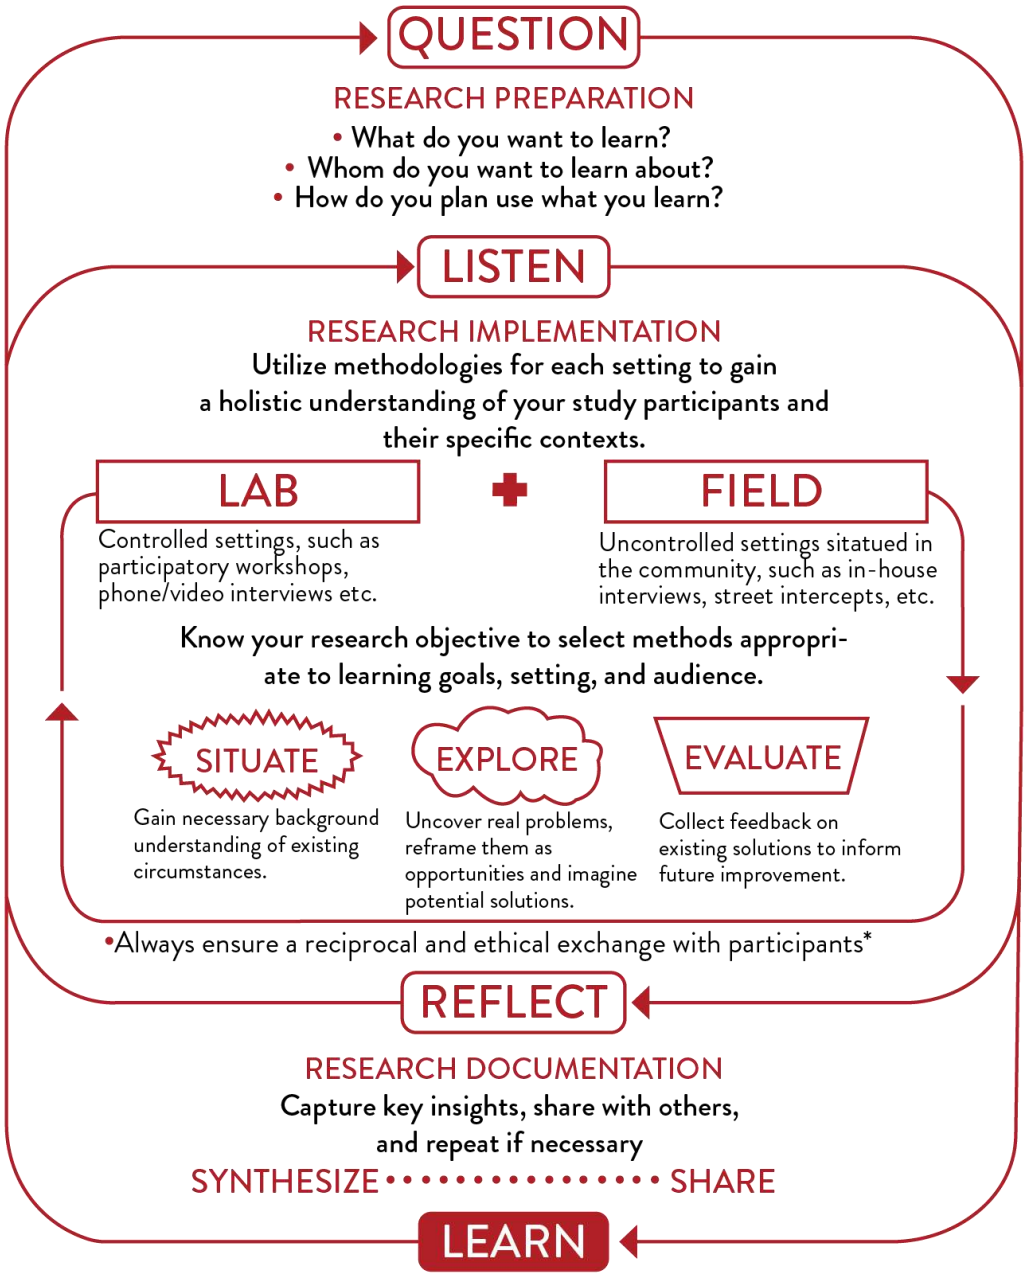
How might we develop a design research methodology to better understand the needs of rural communities? With the primary goal of the toolkit being to design research methods and build capacity within the organization for listening skills, we began the project by doing a deep-dive into exploring "listening". To begin, we identified a series of 7 experts to interview about the art of listening. These experts included practitioners in journalism, leadership coaching, education, and social work. The interviews were synthesized and provided to the organization in the form of a series of short films. In addition to the films, we produced and moderated a panel discussion and workshop at the AHA's Los Angeles office with additional experts in listening.

Following this initial research, the team at verynice developed a draft of the design research methodology to prototype with a rural community in Salinas, California in September, 2017. This participatory workshop was held at a local community center. Over the course of 2 hours, our facilitators led 14 participants through a series of activities. From the workshop, we made adjustments to the flow of activities as well as the instructions, and came to a finalized model and toolkit for the organization.

The Methodology

The methodology itself is comprised of 4 key phases including Question, Listen, Reflect, and Learn. This toolkit differs from the mainstream design process of "Empathize, Define, Ideate, Prototype, and Test" by filling a necessary gap in Design Thinking: the ability to transfer power. In Design Thinking, the end user or beneficiary is typically involved in the beginning stage (empathize), and the end phase (test). This creates a power dynamic in which the designer is the translator and author of the subject's own ideas and observations. In doing so, bias is naturally attached to the ideation and prototyping phases. Instead, with this toolkit, the user is involved throughout the entire process. In doing so, the the person who is empathizing does not become a hero, and the person who is being empathized with does not become silenced.

Figure 1 The toolkit includes the above diagram. The methodology itself is comprised of 4 key phases including Question,



Listen, Reflect, and Learn. In the Listen phase, the designer identifies both the setting of their research as well as the key research objective in order to proceed and select more specific activities. The full toolkit, videos, and additional documentation is available for anyone to freely access at https://ahaislistening.tumblr.com/ (Manos, 2017)

Question: Every great study starts with great questions. The first phase of the methodology consists of research preparation. In this phase, we reflect on what we want to learn, whom we plan to learn about, and how we plan to use what we learn.

Listen: The best way to learn about others is by listening to them. The trick is being able to hear what you need to learn for the purpose of the study. The second phase of our methodology uncovers answers to the research questions by implementing the research. The toolkit includes scenarios and

suggested research activities for 3 research objectives (situate, explore, evaluate), and 2 research settings (lab, field). While the lab setting is a controlled environment such as a participatory workshop or phone/video interview, the field setting is uncontrolled, with interviews and interventions taking place in the community itself. The objective to “situate” is most appropriate in a scenario in which the researcher aims to gain a necessary background of understanding within a community. The objective to “explore” leads to the uncovering of real problems, re-framed as opportunities. Finally, the objective to “evaluate” focuses on collecting feedback on previously developed solutions. The methodology recommends a blended approach as it pertains to setting, but a specific approach as it pertains to objective.

Reflect: The reflection phase is about making sense of what was heard. This is done by way of reporting out on findings to the larger research group and community, or through written synthesis.

Learn: In this phase, the researcher completes the research by putting newly gained understanding into action. The researcher thinks about the observations, interpretations, and implications, and what those mean for the greater goal and impact of the study.

Upon completion of the toolkit’s development, verynice hosted a training with the AHA in order to onboard all staff working in health equity and community impact. The training was recorded so as to allow those who could not attend to have equal access to the content. The organization continues to use the tool in rural and vulnerable communities in order to gain key insights for the ways in which they can best assist as a national organization.

Applying the Toolkit to the USC Iovine and Young Academy’s Professional Practices Residential Experiences

Shortly after the methodology was made available online for anyone to access and use freely, our toolkit was incorporated into a course at the Santa Monica College, a public, two-year, community college in Santa Monica, California, United States. The course focused on teaching students the design thinking approach and mindset. Santa Monica College students leveraged this toolkit to conduct field research for a group project focused on the issue of food deserts in Southern California.

After hearing of the success of the toolkit when applied to the Santa Monica College, I became intrigued to apply the toolkit as the centerpiece for a class of my own. At the USC Iovine and Young Academy, we have an online graduate program, the Masters of Science in Integrated Design, Business, and Technology (MSIDBT). While primarily online, the MSIDBT also includes a series of Professional Practices Residential (PPR) experiences, that bring students on-the-ground into an organization or enterprise to take on a challenge over the course of 5 intensive days. The purpose of the course is to give students the opportunity to work on a design research challenge with a real organization facing a real challenge. When asked to lead a PPR focused around healthcare, I immediately thought of the AHA as a perfect partner.

With 19 graduate students, we embarked on a journey to the AHA’s headquarters in Dallas Texas in order to leverage the toolkit in local communities to help the organization identify new partnerships and opportunities for impact. Students were provided the following prompt upon their arrival in Dallas, Texas:

> *For nearly 100 years, the American Heart Association has been fighting heart disease and stroke, striving to save and improve lives. With the unique mission "to be a relentless force for a world of longer, healthier lives", the American Heart Association has developed a range of approaches to driving innovation from an equity first perspective at a national and community level. In this Professional Practices Residential, graduate students in the Iovine and Young Academy are challenged to leverage Design Research methodologies in order to conduct field work in local Dallas communities. Inspired by their field work, students will enter two intensive hack-a-thon sessions in order to synthesize, ideate, and further develop a series of strategic recommendations for design-driven innovation opportunities that can inspire future work by the organization at the local level.*

In addition, students were assigned to work with a partner organization in one of 4 Dallas communities in order to minimize the time required to understand the nuances and environment. Finally, students were trained on various methodologies and activities from the Design Research toolkit that would be specifically

relevant in the context of the communities they were assigned. The experience resulted in tangible strategic advice for the organization's various non-profit partners including business model design for a local community garden, a concept for a community mural, and curriculum for an afterschool program.

Our next Professional Practices Residential experience was in partnership with the Children's Hospital of Los Angeles (CHLA). CHLA has a history that spans over 100 years, and offers 350+ pediatric programs and offerings to meet the needs of their patients. At the commencement of this residential, students were trained on the toolkit, and were provided the following vision statement:

> *OUR VISION is to enable our patients with diabetes and their families to lead healthy, thriving lives with minimal disruption and inconvenience. We want our program to be adaptable to a patient's developmental stage and life experiences.*

Guided by this vision, students engaged in a series of interviews, interventions, and observational studies in order to clarify their understanding of the current patient experience. Following this serie of ethnographic studies, students developed strategic recommendations and product design concepts for the hospital's innovation team to carry forward. This included a chatbot that would reduce emergency hotline calls, a mobile health clinic to reduce the pain of traffic for patients, and a gamified onboarding experience for new patients.

Next Steps and Initial Conclusions

Based on the success of the toolkit's application to the PPR with the AHA, the tool is in the process of being implemented into the core curriculum of each residential experience in the MSIDBT program as well as an undergraduate course on Design Consulting/Design Strategy. The university is currently planning to work with the AHA for another 2 PPR experiences in the Summer 2019 and Fall 2019 semesters to take the tool to Boston and Puerto Rico. The following are 3 key learnings from the engagements to-date.

What people say is often different than what people do.

Limiting the research process to phone interviews or surveys is limiting. By leveraging design-driven techniques such as drawing exercises, and by learning how to pay attention to body language, we drew more comprehensive research results that led to more impactful recommendations for the clients. For example, in a class we recently had students interview their grandparents about the process of using prescription pills. One student claimed their grandmother had no issue with the pill bottle itself, but after further observation, the student learned this was due to her "hack" in which she removed the caps of the pill bottles and replaced them with plastic wrap.

By having an on-the-ground partner/client, student work can be less disruptive.

It can be very disruptive to a community when a group of students enter without context and begin interviewing and speaking to as many people as they can. By developing on-the-ground partnerships with organizations that work in the space day-in and day-out, we were able to earn buy-in more quickly. Further, by incorporating the end user throughout the design process, we can more successfully design in an manner that is not filtered through our own biases and aspirations.

Shift focus in design for social impact.

In teaching design research practices in the classroom, there is a great opportunity to focus that work by assisting organizations such as the American Heart Association and the Children's Hospital of Los Angeles who do incredibly impactful work with significantly less resources than many other private sector enterprises. For example, in previous institutions that I taught in, we would create speculative client projects. Instead of the speculative approach, we are able to have the same rigor of project, but make it "real" by reaching out to the community in order to turn those speculative projects into challenges for our students to contribute to.

Design Thinking Mindset: Exploring the role of mindsets in building design consulting capability

SOBEL Leanne[a]*; SCHWEITZER Jochen[ac]; MALCOLM Bridget[a] and GROEGER Lars[cb]

[a] University of Technology Sydney, Australia
[b] Macquarie Business School, Macquarie University, Australia
[c] RWTH Aachen University, Germany
* corresponding author e-mail: leanne.sobel@uts.edu.au
doi: 10.33114/adim.2019.c19.154

This case study reflects on the role of design thinking mindsets in building design thinking capability within professional services consultancies. The nine design thinking mindset attributes developed by Schweitzer et. al (2016) formed the basis of five engagements with consultancies including workshops and semi-structured interviews. Data collection and observation by the authors identified key themes relating to the role of design thinking mindsets at an individual, team and organisational level, as well as the challenges and opportunities of embedding design thinking mindsets to build capability. The authors believe that capability development through the use of design thinking mindsets has the potential to support professional service consultancies to make more significant progress in embedding design thinking beyond the current focus on methods. Potential experiential learning frameworks and measurement tools are also identified.

Case study context

Design Thinking (DT) has gained popularity and awareness within private and public sectors in recent years for its ability to develop unique responses to complex problems and enable a human centred innovation agenda (Verganti 2009; Dorst 2015). Following this, many traditional professional services consultancies (including business, engineering and technology specialists) have moved to acquire, hire and develop their own internal design capabilities (Rousseau 2015). The objective is to both improve business operations and processes to become more client focused and to offer professional design expertise as a consulting service (Muratovski 2015).

In this case study we draw from our experience in practice-based design and innovation research, which includes working within professional services consultancies as designers/innovators and working within a university research environment studying and supporting organisations to develop design capabilities.

Working with consulting practitioners we observed their significant emerging need to better understand the role of what is described as DT mindsets alongside the often already well understood methods or tools of design. We find that while a focus on practising DT methods is widely used and has been effective at communicating the value and ways of working through design (Liedtka 2018), it is limited in achieving the full potential that DT can bring to both solving complex problems and the consulting services associated with it. Current efforts to build design capability are too often falling short of effectively changing the way people work to what Adams et.al call the “different way” (2011 pp.589) that DT seeks to provide. We believe that further understanding the role of DT mindsets and finding ways to enable practitioners to reflect and build upon on these will help professional services consultancies and other organisations make more significant advances in their capability development.

In this case study, we draw on recent research that began to establish a set of distinct DT mindsets (Schweitzer et.al. 2016), which has since been further refined and validated. We then report insights and discuss implications from engaging consulting and research professionals with DT mindsets.

The evolution of design thinking as a method and mindset

Design has a varied history through the many fields of architecture, product design and graphic design. While some fields such as product design initiated a focus on human usability, others saw design as an end process to improve the visual appeal and marketability of products (Brown & Katz, 2008; Dorst 2015). From the 1960s, the design professions began to advance in their development as a science and the opportunity to develop non-physical things including software and interactions (Szczepanska, 2017). Following this time, design began to attract broader recognition for its ability to create new ideas over a focus on aesthetics (Brown, 2008) and researchers and began studying the way designers think and work in order for other professionals to be able to learn from these creative approaches (Szczepanska, 2017). A new understanding of 'design thinking' was then identified, described in various ways from a cognitive style, a general theory and an organisational resource (Kimbell 2011) and promoted as a powerful approach to enable business innovation by early proponents (Buchanan, 1992; Brown & Katz, 2008; Martin 2009).

The iterative stages of a typical DT process include deep empathy with end-users, re-framing of the problem area, ideation, prototyping, and testing. While hundreds exist (VanPatter & Pastor 2016), notable examples include:

- Double diamond model - discover, define, develop, deliver (UK Design Council 2005)
- d.school design thinking process - empathise, define, ideate, prototype, test Plattner, (Hasso Plattner 2010).
- Liedtka's design thinking phases - What is?, What if? What wows? What works? (Liedtka & Ogilvie 2011)
- Frame creation - archaeology, paradox, context, field, themes, frames, futures, transformation, integration (Dorst 2015)

While such codified articulations of DT as a process and set of tools are helpful toward explaining the actions or 'steps', they do not yet explain how individuals or innovation teams enable these steps cognitively when interplaying between and throughout the design process. Other definitions of DT have articulated and explored the role of mindset in undertaking DT in practice, stating that DT is both a method and a mindset. As a mindset, DT refers to the underlying values, cognition and resulting behaviours that over time find their way into individual and organisational practice.

It has been argued that the notion of 'design as a state-of-mind' implies that true innovation is a company-wide phenomenon and should not be left to marginalized functions within a company (Venkatesh 2012). While individuals and whole organisations can adopt the processes and tools and learn new innovation practices over time, it is the mindset that ultimately helps achieve innovation objectives at a deeper and more sustainable level.

While DT is being adopted in other business contexts, definitions of design mindsets are largely drawn from design practitioner accounts without considering the placement of these into new organisational contexts that design is being practiced. These definitions also vary in characteristics and emphasis with few attempts to make a distinction between mindsets in the frame of cognition versus behaviour. Further, they have not been developed through broader research input, or tested for coherency and application into business let alone professional services consulting.

Defining Design Thinking Mindset

We refer to DT mindsets as an articulation of how individuals will possess or seek to improve in the way they think, feel and emote in their practice to support design thinking activities. In other words, a mindset is a characteristic mental attitude that determines how one will interpret and respond to situations. Boland and Collopy (2004) referred to design attitude as 'expectations and orientations, one brings to a design project' (pp 9), whereas, more broadly, Gollwitzer describes mindset as configurations of cognitive procedures; e.g., being open-minded (Gollwitzer 1990).

In the context of DT as a service, consultancies often focus on developing design thinking capability with an emphasis on teaching the 'process and methods', which omits consideration of the individual who is undertaking the training and the role they might have in achieving a desired innovation outcome. In sharing and discussing DT mindsets with consulting practitioners, we have discovered that they are important enablers in providing a deeper understanding about the different ways of working that are representative of design practice compared to more traditional business practice.

Exploring Nine Design Thinking Mindset Attributes

Throughout 2018, this research involved exposing large professional services consultancies, who had all made significant efforts to embed design capabilities within their business over the last 10 years, to the DT mindsets across five engagements. The mindsets we focussed on in this work were the nine attributes based on the work of Schweitzer et. al (2016), which are described below:

Table 1: Design Thinking mindset attributes, Schweitzer et. al, 2016.

	**Be curious**: The extent to which a person demonstrates curiosity and a desire to learn new ways of understanding the world.
	**Be collaborative:** The extent to which a person buys into working together toward a shared purpose and solution; is effective in the service of the team's purpose believing that no one person is responsible for the final outcome.
	**Reframe**: The extent to which a person challenges and re-frames assumptions associated with a given situation or problem, thinking differently to create new contexts and perspectives.
	**Embrace ambiguity**: The extent to which a person is comfortable with ambiguous and complex situations.
	**Embrace diversity**: The extent to which a person can work with and engage people with different cultural backgrounds, diverse experiences and diverse ways of thinking and working.
	**Make tangible**: The extent to which a person understands and activates all five human senses to make ideas tangible
	**Take action:** The extent to which a person has a preference to take action and get things done.
	**Be empathetic**: The extent to which a person experiences another individual's needs and context from their perspective. It is the ability to place yourself, your thinking and feeling in the view of another person.
	**Be optimistic:** The extent to which a person is hopeful and confident about achieving positive and favourable outcomes.

The format of these engagements included workshops in which DT mindset attributes were used as a reflective tool for capability development with groups of professional services design and innovation leaders

and in-depth interviews with design and innovation leaders within professional services consultancies to test and validate the conceptual clarity and relevance of the DT mindset attributes.

The workshops particularly focused on testing how individuals relate to the mindset attributes in their work, including how they understood them in their individual and group contexts. A specifically designed reflection and sharing activity helped participants to experience DT mindset attributes. This was designed in three parts.

1. **Attribute discussion and validation:** a group discussion to share the definition of the mindset attributes, discuss what these mindset attributes mean in the participant's organisational context and consider further dimensions of the attribute which may be relevant.
2. **Personal reflection:** an activity where participants were asked to reflect on their strengths and weaknesses in relation to each mindset attribute and consider how each mindset is relevant in the way they work as innovation leaders.
3. **Making differences visible:** in order to reflect on the mindset attributes as a group, three attributes were chosen and the participants were asked to self-organise along a line on the floor in order from where they felt the attribute was a particular strength to weakness. Participants then shard stories about where they placed themselves on the line.

Our findings are based on the analysis of workshop artefacts, interview findings and direct observations as well as our own collective reflection on experiences working in professional services consultancy contexts for more than 10 years.

Key learnings: DT mindsets in professional services consulting

> *"Design thinking is rarely a graceful leap from height to height; it tests our emotional constitution and challenges our collaborative skills, but it can reward perseverance with spectacular results" (Brown & Katz 2009, pp.65)*

We were surprised by how strongly the DT mindset research has resonated with managers working to build design capability within professional services consultancy. While these insights were defined through exposure of DT mindsets to consulting practitioners, the broad reflections on the challenges and opportunities of embedding DT mindsets may also provide useful and relevant for any organisational context where DT capability is being developed. The findings of our case study are presented as key learnings below.

Practitioner challenges adopting DT and the relevance of mindsets

As a result of exposure to the mindset attributes, practitioners of both workshops and in-depth interviews expressed a realisation about why DT had been challenging to adopt in their respective organisations. These insights also highlight the relevance of DT mindsets as a reflection and learning tool. The following are themes were observed:

- **Individual experiences:** Every individual is unique and therefore brings different thinking biases and strengths and weaknesses across different mindset attributes to the practice of design
- **Awareness of self:** In order to continually develop design expertise, individuals need to be self-aware and actively undertake reflection of their own practice. While consulting practitioners were familiar with reflecting on their behaviours and actions, the experience of reflecting on mindsets was a new and novel experience.
- **Diverse disciplines:** Professional service consultancies represent diverse skill sets and individuals who have been trained across different disciplines. These disciplines bring with them their own unique ways of thinking, seeing and emoting. The articulation of DT mindsets can more clearly communicate the internal changes that consulting practitioners need to embrace in order to increase their depth of design expertise.
- **Team to individual:** Often design thinking is discussed at a team level, with a focus on how methods can be integrated into a program of work. Less attention has been paid to individual cognitive transformations that occur when actively learning and practising design. While these insights support individual learning, they also transfer to improving team dynamics through highlighting different mindset strengths and weaknesses in a design team.

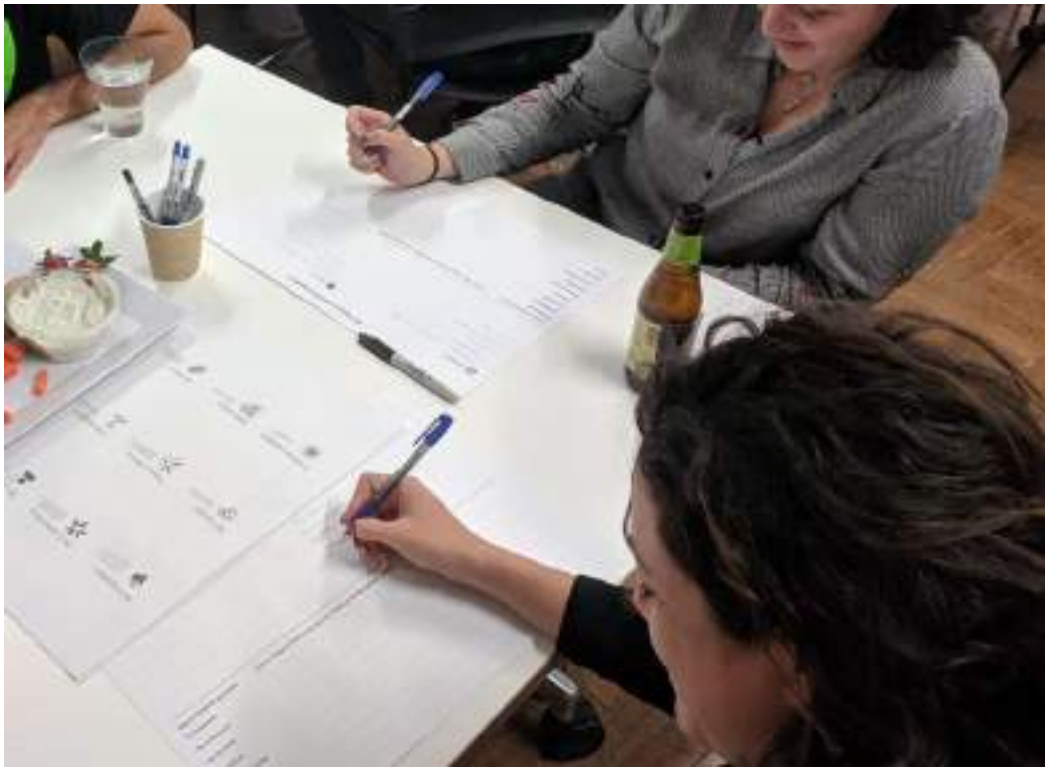

Figure 1: Workshop participants engaging in a personal reflection activity on the DT mindsets

Professional services consulting context and the adoption of DT mindsets

The professional services consulting model of selling highly defined and trusted methods and expertise does not align easily with the framing of DT projects and utilisation of mindsets. While design practitioners with high levels of expertise can consistently apply strong methods and approaches to new problems, there will always be uncertainty in the results. For example, results can involve broadening the problem frame, finding new ways to perceive the problem, or identifying new stakeholder challenges or opportunities that may not align with the client's original expectations and brief. While these reframes, and the methods and mindsets adopted to achieve these, are exactly what is so valuable about design, it becomes challenging when sold within a business model originally based on results, assurance and confidence (Rousseau 2015).

Likewise, traditional work pipeline management within professional services consulting does not always allow for the more explorative and adaptive nature of design processes which may require more flexibility than standard milestone and deliverable schedules. This characteristic of consultancy practice in turn results in the reliance of more reliable and 'known' methods in order to achieve project outcomes, essentially limiting out the opportunity for DT (Martin 2009). This highlights the need for consulting leaders to navigate these forces to ensure that projects are scoped and planned sufficiently and that DT can be effectively pursued. That DT mindsets are able to flourish in realising project outcomes and teams can be set up for success from the outset.

Encouraging DT behaviours and implications to organisational culture

When the professional services consultancies we engaged with began to understand the nature of design thinking mindsets, their perception of capability development shifted from considering individual skill development, to the development of team and organisational culture. This brought new interest in DT from managers in Human Resources and culture change roles to consider what cultural enablers can encourage design to flourish. This realisation highlights why DT is so difficult to fully adopt, as essentially it is proposing not only a change in how the individuals conduct themselves but how the system (organisational context) allows for that way of thinking and working to take place. As Martin (2009) states "Even as corporate leaders chase the vital elusive spark of creativity, their organisations' structures, processes, and norms extinguish it wherever it flares up. Their culture and routines privilege analysis over intuition and mastery over originality"

(p.7). This positions a new role for design researchers and practitioners to explore the implications of culture to support DT capability (Kimbell 2011, Michlewski 2015)

Building DT mindsets

Our experience running these engagements around DT mindsets highlighted key considerations for the approach to effectively build mindset capability. Firstly, it was clear that the group workshop engagements provided a richer source of reflection on DT mindsets than the individual interviews. This seems to be based on the benefit of participants hearing and discussing other perspectives in a group setting and considering how their own understanding and experience of a mindset related to their that of their team members. This raises the question of the nature of organisational learning and reflects claims by Stacey (2003) that learning is simultaneously individual and social and that learning cannot occur in isolation. There is the potential to investigate the nature of organisational learning further and to develop DT mindset training that draws on the latest knowledge about social and experiential knowledge.

The unique individual strengths and weaknesses across DT mindsets and the diverse disciplines being drawn to design practice also highlight the need to better understand and measure levels of DT mindset maturity on a cognitive and behavioural level (Howard et.al 2015). Various manifestation of DT maturity frameworks have been developed to aid how DT capability may developed (Kretzschmar 2003; Storvang, Jensen & Christensen 2014; Peppou, Thurgood & Bucolo 2016). Further, Gardien, & Gilsing (2013) provide a comprehensive articulation of how a custom maturity framework can assist in teasing out the unique contextual considerations to a given organisation. Custom DT maturity matrices that incorporate DT mindset considerations for consulting practices could provide useful tools in seeking to work through the complexities of individuals and team dynamics in capability building programs.

Case study limitations

This case study is limited to a small number of engagements and reliant upon informal data collection including reflections by the authors. We envisage undertaking further formal research studies to understand the role of DT mindsets within professional service consultancies and other organisations. Further studies would also benefit from stronger alignment with behavioural psychology and organisational culture studies, including using these theories to explore how a DT mindsets maturity tool may be developed (Kolko 2015).

Conclusion

Our exposure of the DT mindsets to professional services consultancy highlighted the relevance of mindsets to support organisation in their journey to embed DT capabilities and move beyond the limitations experienced when focussing primarily on embedding DT methods. The insights from this research also highlight opportunities to further develop experiential learning resources and measurement tools to support professional service consultancies in their efforts to build DT mindsets, as well as opportunities for broader changes in culture and support systems to foster an environment that consulting practitioners can think, feel and emote in more creative ways.

Case Study – Designing a business unit and creating the first ever responsive kitchen

CORA Tommaso*; FESTA Paolo and FAZIO Lucilla

Tipic, Italy
* tommaso@tipic.it
doi: 10.33114/adim.2019.c20.129

Introduction

Is it possible to transform stone into a technological and innovative device?

The meeting with one of the main stone transformers in Europe produced the intention of a disruptive operation that could affect the strategy of the whole company. A contagious singularity.

By intertwining LEAN methodologies and the human-centric approach of design thinking, we mapped the value creation in the company activating a dialogue with the workers and the management, listening to people, asking for ambitions, discovering problems and the potential of production.

This qualitative and quantitative analysis conducted with a multidisciplinary approach by designers, architects and marketing strategists allowed us to define a new method. We used it to design a platform that could let all the players express their potential to the maximum.

This is how the group's research laboratory was born, with the aim of promoting the relationship between humans and stone through product innovation. With this goal, we coordinated the new team, developing technologies that would allow creating a more direct relationship between man and surface, making the stone reactive. The result was the first responsive kitchen ever.

Context & problem / opportunity area

The worktops market is one of the main sectors of consumption for natural and synthetic stones with 133.24 million square meters sold in 2016 globally. A relevant part of this amount (7 parts on 8) goes to the kitchen and bathroom industry. The companies that produce and process stone slabs on an industrial scale are therefore closely connected to the world of furniture, its behavior, networks and production approach.
One of the leading European stone processors has hired us to design a demo product that could express the technical capabilities of the company, to launch a branding initiative for the Milan Furniture Fair (i Saloni).
The company wanted to enhance the value perception of its worktops and its range of surfaces for architecture & design.
The company's plan posed a risk. Launching a demo to the public in the same exhibit where its clients were unveiling their new products could present the company as a competitor to her partners.
For this reason, we proposed a re-briefing: instead of creating a demonstrative product (a kitchen) to show the technical potential of the company, we would research the know-how potential of the company to understand how to apply it and to build the best storytelling of it.
This reverse process aimed at mapping for the problem-solving practices implemented by the company during the years in a sort of “native” PDCA iterative approach (Plan–Do–Check–Act) as in the TQM’s continuous improvement of processes and products. Our ultimate goal was to make explicit the innovative behavior of the

firm and, subsequently, to apply it methodically on new subjects through a pilot-unit devoted to b-to-b special projects development. Something similar to the Value Stream Mapping in the Lean methodology.

This re-briefing allowed:

- to refine the focus of the initiative: to establish the firm as the best partner in its field, consolidating existing business relations and creating new ones.
- to initiate a company that considered innovation as a product's upgrade, to the concept of innovation as a contaminating internal agent inside the organization.

The Narrative

Empathy

To start the exploration phase, we activated a round of desk research and one-to-one interviews within the company. The first interviews led our group to define desk research that led to the second phase of more targeted interviews in order to dig into the VOC (voice of the customer both internal and external).

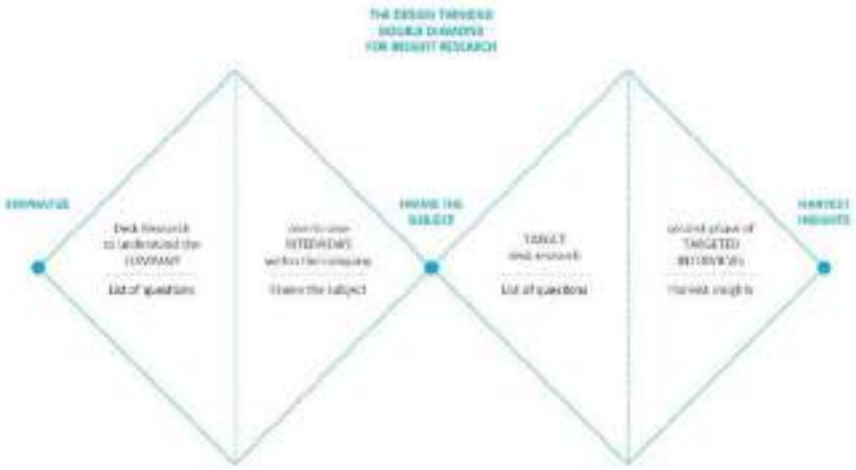

Figure 1: The Double Diamond of Insight Research. source: TIPIC 2019

We interviewed key people working in diverse positions inside (department heads, production supervisors, marketers, sales, board) and outside the company (suppliers, distributors/retailers, architects). In this way we managed to collect a wide information base on industrial production, customers, market, employees commitment and we analysed them looking for insights.

The survey team was made by a multidisciplinary group of professionals like strategic marketers, architects, industrial designers and mechanical engineers, in order to capture the diverse typology of relations and decision making inside the company and their strategic, economic, productive impact on the firm’s proposal to clients.

The project managing team included the marketing manager and the company's research and development manager in order to maintain a strong connection with the corporate structure.

The multidisciplinary composition of the group supported an open platform for debriefing and analysis based on mutual integration, essential for the understanding of such diversified data. In an extremely compressed time (only six weeks) we visited the corporate factories in Italy and Germany, mapped the company's distinctive capabilities, verified the reference markets, and the main trends.

The Definition

The research allowed us to identify the three main company know-how macro-areas:

- The production of synthetic stone (the culture of the material);

- The industrial processing of stone worktops (the company's core business);
- The inclusion of technologies (a relevant theme as worktops are the playground to many devices).

We crossed the insights from our investigation to the three know-how areas to identify potential innovations responding to the emerging insights from the empathy phase: “customizable integrated devices insanely easy to use” and “new durable materials with natural touch”. However, we were missing the tool that could stream the action without affecting the company's D.N.A. but bringing value to the all group through its work. Thus we outlined the guidelines for a "Group Product Research Laboratory", an independent business unit that could engage experimentation, operating dynamically and building bridges towards new directions . The new unit would have been devoted to prototyping new ideas, products and solutions based on the collaboration of the different group competencies and technologies. Its pillar are:

- Customer centricity;
- Strategic approach;
- Employee involvement;
- System and competencies integration;

Common principles with the fundamentals of TQM system used by companies engaged in organizational advancement through a commitment to customer requirements.

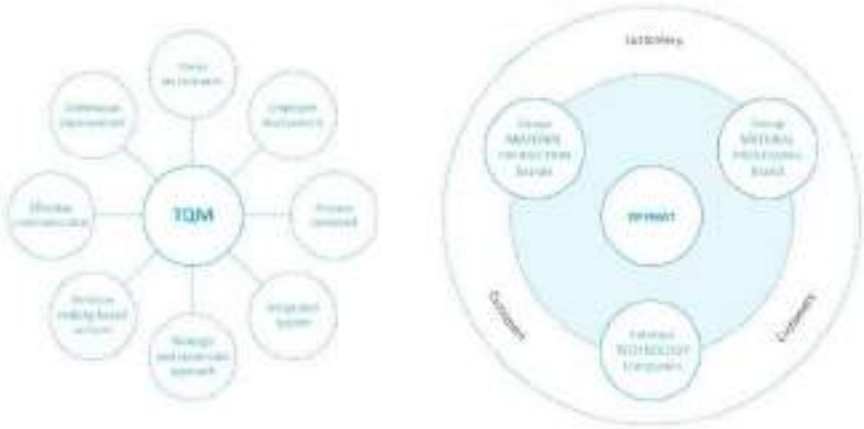

Figure 2: TQM pillars and the Offmat ecosystem. source: TIPIC 2019

Since the company identity is intimately connected to the stone processing and its products are sold as technical elements to design furniture brands, we defined a strategic framework based on quality, collaboration and mutual enhancement: the ingredient brand approach (like Intel, Gore-Tex, Vibram). This allowed us to create the necessary coherence filter to activate parallel experiments which could then be summarized in a common synthesis. We called the new unit "Offmat", from the union of "Officine" (Workshop) and "Materia" (Matter)

Impossible Stones

Starting from the synthetic stone production, we reversed the common design approach based on the Market Follower strategy in a Customer Centric Strategy. Instead of designing a new perfect imitation of the natural stone we activated the research team to identify a series of macro trends in design and architecture projects. We then selected a panel of blends proposal based on the different cultures and market areas and implemented it in the industrial process of engineered stone production prototyping samples in a series of iterations to optimize possible technical and qualitative issues. The final result was a collection of “impossible stones” proposed as tools for architects in the design process.

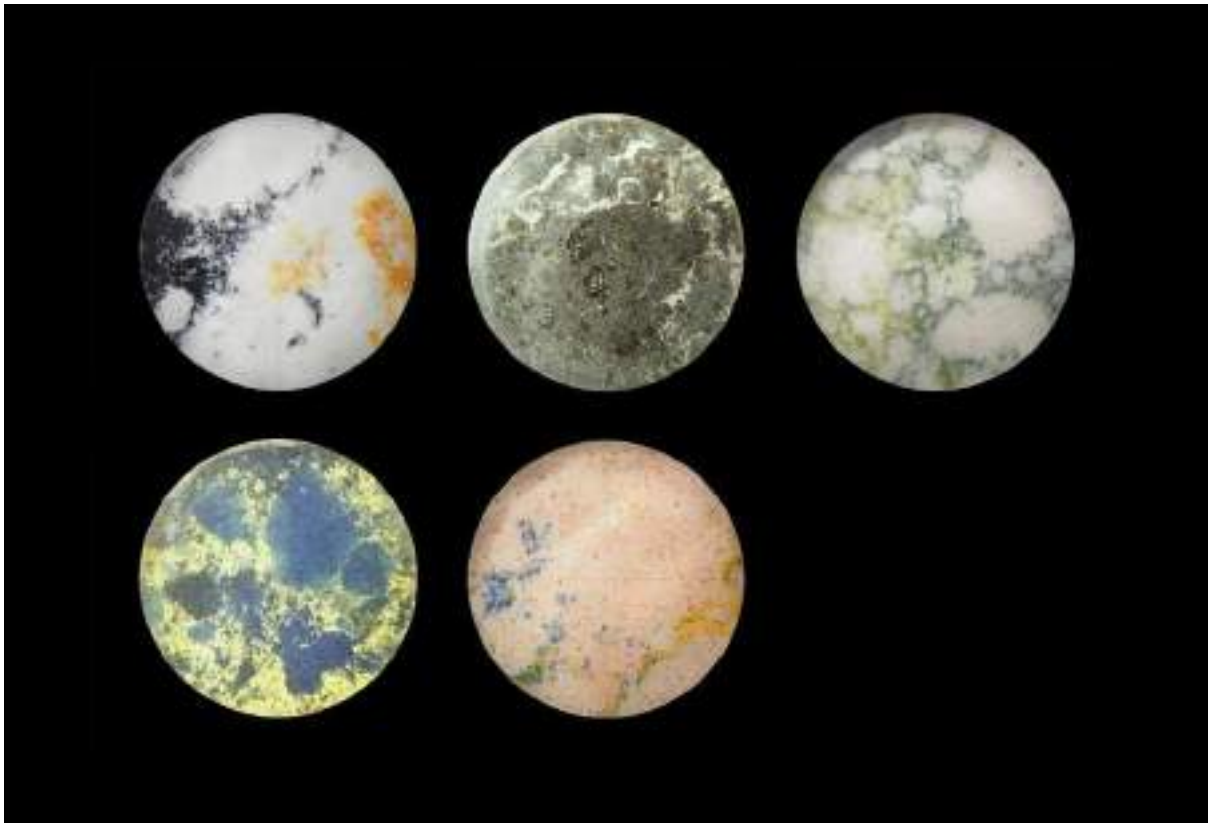

Figure 3: The Vulcans stones samples from the laboratory tests. source: TIPIC 2018

It was a small revolution in an industrial sector (the production of synthetic stone) where technology had always been used to produce better and better imitations of natural stone and not to create “new design tools” (a step forward from push to pull strategy).

The collection was named "Vulcans", inspired by the place where mother nature mixes matters.

This process, a sequence of customer centric research, ideation, prototyping and industrial implementation, results can be read as a contamination between the 6 sigma process (DMAIC) and the Design Thinking. It mixes the advantage of the Design Thinking emphatic approach and sprint execution with the 6 sigma scientific approach through analysis, prioritization and measurement for effectiveness.

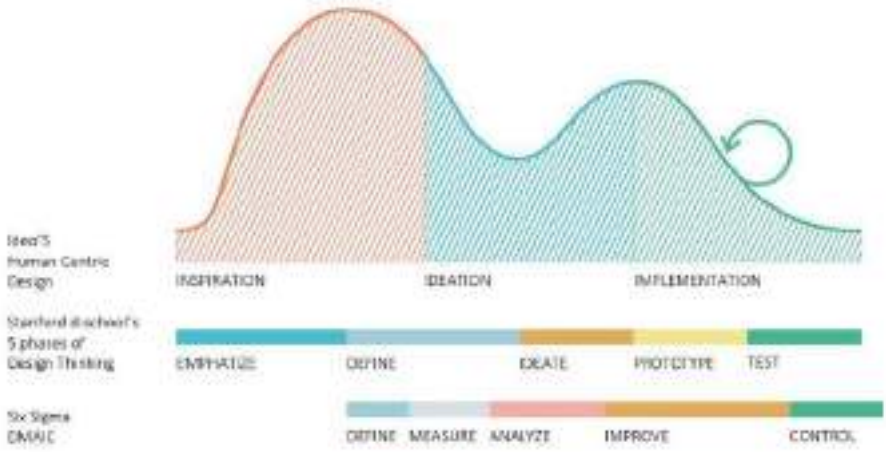

Figure 4: Comparison between the Ideo Human Centric Design Diagram, the D.School 5 phases of Design Thinking and the 6 Sigma DMAIC. source: TIPIC 2019

A new relationship with stone

The inclusion of technology is a recurring issue in the worktop processing industry. Every worktop, especially in the kitchen, must support diverse devices that manage washing, heating, cooling with different technologies (electricity, magnetic induction, gas, water) matching strong safety standards both on individual products and on their possible interaction. It is an overcrowded technical playground in which the stone worktop declines in relevance.

Thus we mapped the actions that take place in the kitchen like in the production line stations. We cleaned the area from the unnecessary and focused the attention on the essential user actions to design a simple and efficient process using Lean methodologies like Spaghetti Diagrams in production flow analysis.

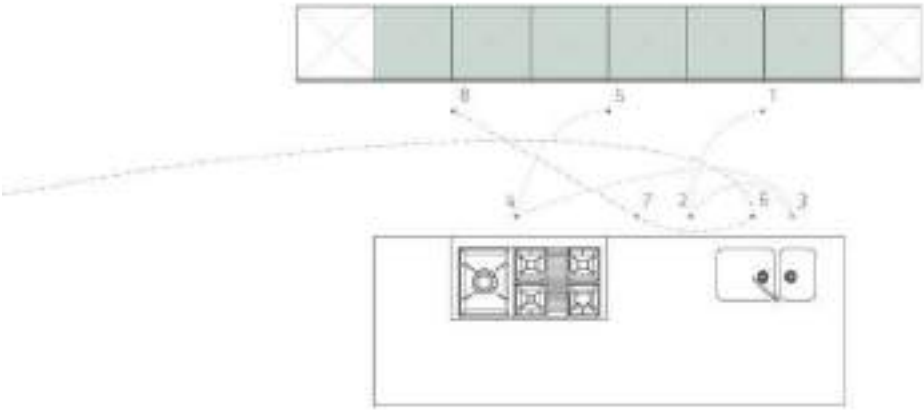

Figure 5: Mapping the user actions in the kitchen. Spaghetti Diagram as a design tool. source: TIPIC 2018

To enhance natural gestures in the kitchen we removed all unnecessary accessories creating a more direct relationship between the user and the worktop.

To go deeper, we tried to understand if it was possible to cook, wash, prepare on the stone without accessories. So we disassembled induction cooking systems, faucets, scales, loaders, drawers, to understand how they worked and we redesigned them as integrated elements on the same worktop, testing and testing evolutions of devices gradually customized (a practice known as “reverse engineering” in the lean methodology).

We focused primarily on the three main phases of food preparation:

- Stage one, the washing: thanks to I.O.T. sensor technology we coded the gestures that could control the flow of water and the opening of a hidden sink without touching any object when operating with hands in direct contact with food ingredients;
- Stage two, the fitting: we designed a new visual scale U.I. to integrate it into the worktop and make the stone itself capable of weighing for an effective preparation area;
- Stage three, the cooking: we studied many materials couplings in order to manage the thermal stress due to the cooking process to integrate an induction system in the stone worktop;

This is how the modular system of integrated solutions was conceived, a line of innovative accessories for the stone worktop: the “Offmat Solutions”.

Processing to the limit

Still today the company core business is the processing of stone worktops, with significant efficiency and quality. Furthermore, the company patented an invisible junction system that allowed to join slabs of stone without signs of evidence.

To express this know-how, we developed tense and angular geometric lines that would bring to the limit the firm stone processing capacity, creating a demo worktop that would remind a slab of natural stone of unprecedented dimensions. The plan was made using the new “impossible stones” (Vulcans) and integrated the responsive solutions that enhanced natural gestures, thus proposing a coherent synthesis of the whole innovation process. We called it "Tulér" as the old 19th-century tables from the Italian kitchen culture, used to make homemade egg pasta, equipped with marble top, integrated rolling pin, cutting boards and removable shelves.

Tulèr was the first ever responsive kitchen.

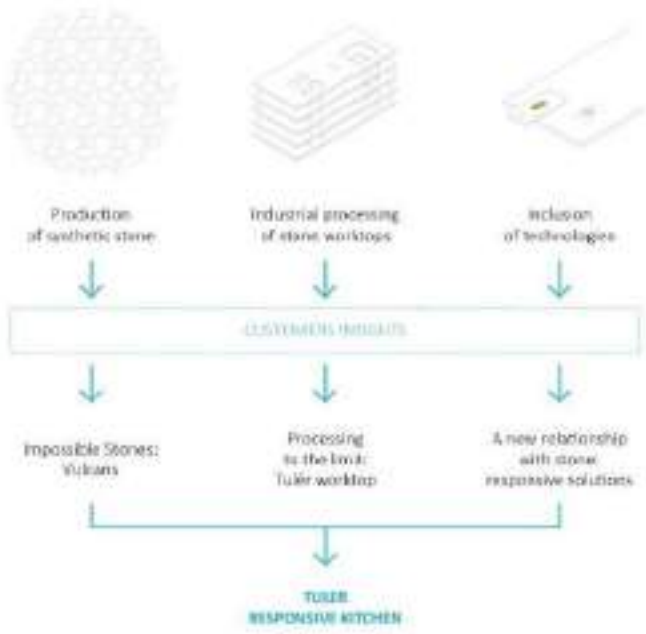

Figure 6: From Group Know-how macro areas mapping to Offmat initiatives : TIPIC 2019

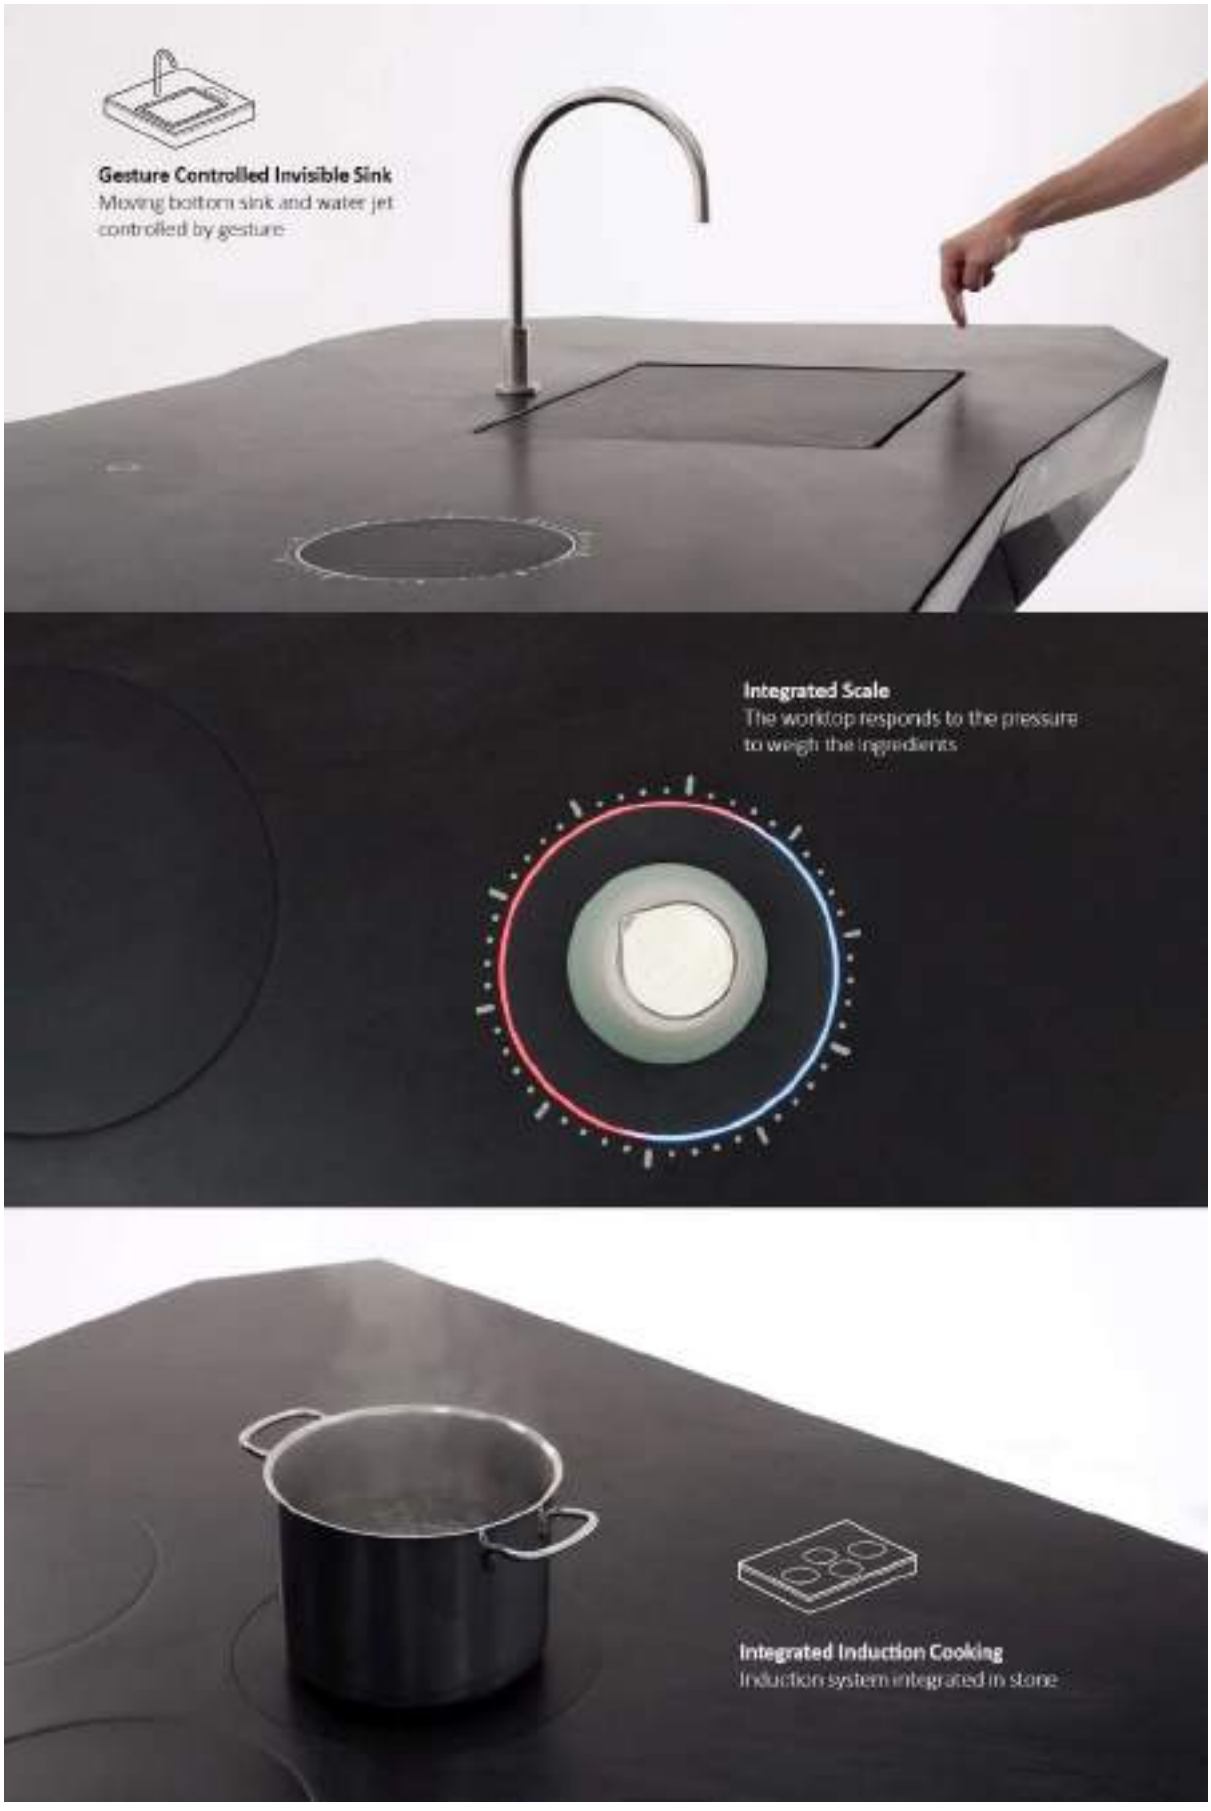

Figure 7: The responsive solutions that enhance natural gestures. source: TIPIC 2018

The key learnings

The “Offmat project” met excellent feedback, but it was especially a contagious singularity.

Not all the Offmat products have become standard products, but the company has recognized the value of the experimental process and the effectiveness of devoting pilot units to exploration and prototyping, to test ideas in a fast and effective process. The Firm has today launched a new reorganization of its company group of which Offmat has become a central element.

Other companies in the field have started to present experiments in the direction of simplification of gestures and functions and are now exploring a growing integration between technologies and materials. The human-centric culture is pervading the industry.

On the other hand, the empirical approach based on the reiteration with increasing awareness, usual in workshops and formalized in the "ideation-prototyping-test" cycle of Design Thinking, has allowed us to find precious and faster "insights", even in strategic research, and to implement them in the short term.

Working between strategy, marketing, product and frequenting the production line has allowed us to identify similar patterns in methods coming from different disciplines, such as the Lean / Six Sigma Methodology, the Design Thinking, the Design Sprint and the Mapping of distinctive capabilities in Strategic studies. They are discrete tools that merge along the line of the project, notably in the face of complex issues that require multiple validations.

In such circumstances, our working group horizontal structure proved to be fundamental to allow the needed flexibility in face of the “fluid” challenges that occurred.The Offmat team consisted of a mix of people internal and external to the company, with different levels of responsibility and different culture. This allowed

to proceed quickly without losing focus, maintaining traction, enhancing resolutory debates. It is an example of how the ability to interact accelerates knowledge and the transfer of knowledge with relevant effects on the company's growth and innovativeness.

We have called this modular approach "Thinkingram", from the matching of "Design thinking" with the "Tangram" game, where each piece represents a module of the process and the modules together, depending on their order, shape unlimited figures.

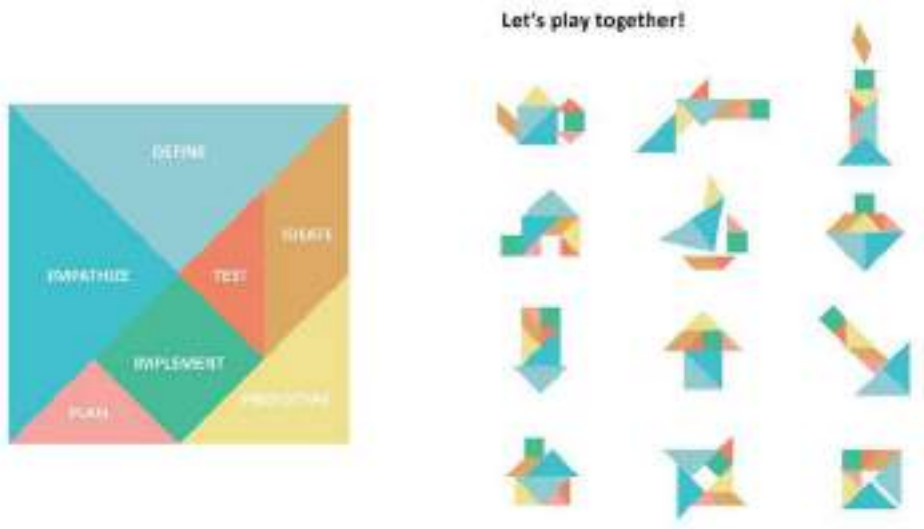

Figure 8: The Thinkingram Diagram. source: TIPIC 2018

In addiction to the 5 phases of Design Thinking theorized by Stanford d.school we have identified two specific moments that allow us to design a complete framework of the consulting activity from research to market.

These two phases are:

1. plan: “Plan” is when the team plans future events, allocates resources and tasks and involves possible external supports and contributors. “Plan” turns the target of “Define” in a series of actions.

1. implement: “Implement” scales the result of the "ideate-prototype-test" cycle, managing and monitoring the planned actions to integrate the product or the service in the company ecosystem or brings it to the market.

The 7 resulting phases (Empathize, Define, Plan, Ideate, Prototype, Test, Implement) let us describe and organize the complete process from the beginning of research to the marketing plan implementation in a unique storyline that integrates strategy, marketing and design.

The Thinkingram is our possible answer to the emerging need of integrating design thinking with strategy, marketing and efficiency methodologies in a common framework. The modularity of this approach emphasizes the single phases without losing the big-picture. It is a plus in complex projects in which multiple subjects are called to collaborate.

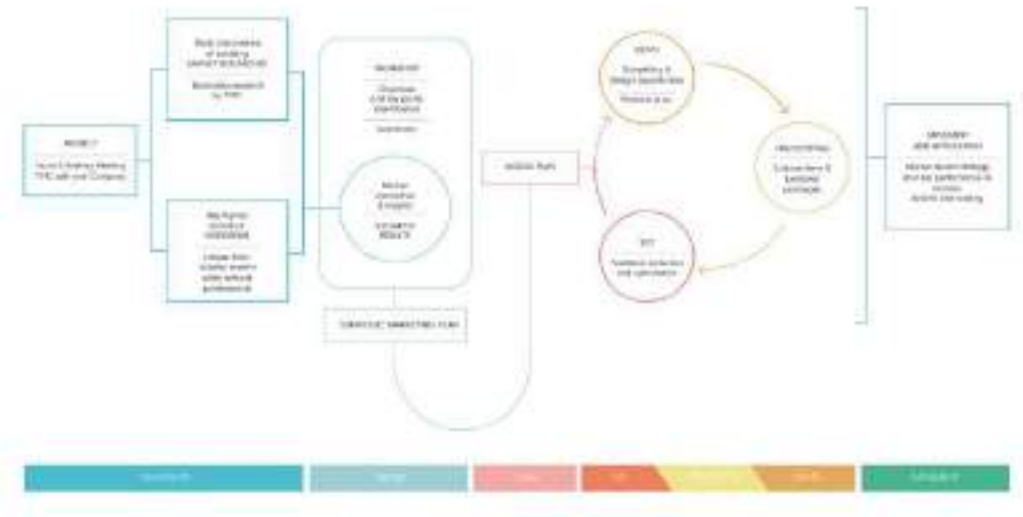

Figure 9: The Thinkingram’s phases Diagram. source: TIPIC 2018

After almost a century of several attempts to establish a coherent land registration system across the whole country, in 2017 the Portuguese government decided to try a new, digital native approach to the problem. Thus, a web-based platform was created, where property owners from 10 pilot municipalities could manually identify their lands' properties using a map based on satellite images. After the first month of submissions, it became clear that at the current daily rate, it would take years to achieve the goal of 100% rural property identification across just the 10 municipalities. Field research during the first month after launch enabled us to understand landowners' relationships with their land, map their struggles with the platform, and prototype ways to improve the whole service. Understanding that these improvements would still not be enough to get to the necessary daily rate, we designed, tested and validated an algorithm that allows us to identify a rural property shape and location without coordinates. Today, we are able to help both Government and landowners identify a rural property location with the click of a button.

Keywords: Service Design, Design Thinking, Rural land, Big Data

Context & problem

For the past century, several Portuguese governments have tried to implement nationwide rural property registry initiatives, not only focusing on gathering ownership information, but also rigorous property boundaries identification. Though several methods have been tried - some promoted by the government, other by local power - with varying degrees of success, as of today only half of the country (mainly south of Tejo river) is registered in an updated database of both rural ownership and property boundaries. The other half (which contains a much larger number of smaller, individual properties) has been stuck on a negative feedback loop, resulting in the degradation of the value of said properties, and also hampering the ability to sustainably manage these lands, either by owners or public institutions. This loop has been boosted by various reasons: an aging rural population, the loss of knowledge about where properties are and the fast declining of commercial exploration of these properties. All these factors result in large areas of unkempt vegetation and forest, which then leads to even less interest in these rural properties. Unfortunately, this unmanaged territories have also been the ones where environmental catastrophes, mainly fires, have been the most common.

So, it was not surprising when in June 2017, 53 thousand hectares of land in the Portuguese interior were destroyed by one of the biggest forest fires to ever occur in Portugal, also taking the lives of 64 people. This human and environmental catastrophe would then be followed by more destruction, just four months after, in October 2017, when hundreds of smaller fires consumed another 54 thousand hectares of land across the whole country, resulting in the death of 50 more people.

Though a new initiative for rural properties registration was already in the works, the June fires sped up the urgency of understanding who owned what and where. As one of the main constraints of previous initiatives had always been the high costs of acquiring GPS equipment and hiring (or training) technicians that could go on the field to gather hundreds of thousands of precise property coordinates, this time a digital native mindset inspired the writing of the decree-law behind the new initiative.
Hence, BUPi — Balcão Único do Prédio (roughly translates to Centralised Property Desk) — was born.
A web-based platform that would allow for rural landowners to register their properties and identify its boundaries using aerial/satellite photos. Because the main target of this tool would be a very aged population, the decree-law also included the setup of physical counters where technicians could help owners using the platform. These physical counters were positioned at each municipality's town hall and could be accessed by appointment only. Though web-based, during the first 8 months of the initiative, the platform could only be accessed through the physical counters and with the supervision of the technicians.
Because of its novel approach, BUPi was designed as a pilot program, to be tested in a small region of the country, before a wider launch. The June fires ended up being one of the decisive factors in the selection of the 10 municipalities that would become part of the year-long pilot. In order to rapidly implement the defined vision, an assembly of companies, with different types of skills and know-how, was hired. As a Strategic Design Consultancy, specialised in research, strategy and design outputs, we were invited to evaluate the service, both in the digital platform and the physical counters, and devise a communication strategy that would generate the necessary demand by the targeted local communities.

The narrative

To better tackle all of the challenges ahead we assembled a multidisciplinary team composed by a researcher, a digital strategist, a communication strategist, a service designer and a digital designer, working together throughout the duration of the whole project. Our very first challenge was a kind of *go-to-market* strategy before the research project even started. We only entered the project one month before the decree-law's starting date (November 2017), and during the first full month we focused on helping to create the conditions so that BUPi could work from day one. This work involved service design for the counter, reviewing/improving the existing web platform and creating the first communication pieces to be used. It is important to note that for the first six months of BUPi, the online platform could only be used by certified technicians, provided by each municipality.
Though this was not part of our core challenge, we embraced it and saw it as a way to set up the stage where we would be doing research. During this initial period, we were able to engage in web platform testing, use roleplaying to experiment with different counter concepts, establish productive connections with the most relevant local actors, and build several prototypes for communication mediums that, besides serving for the upcoming launch, would also allow us to understand what kind of messages resonate with people. This was also the time when it was decided that we would focus our research effort mainly in the municipality of Penela.
When the pilot was launched, we started a two-month-long field research phase during which we not only visited Penela, but actually lived there for several weeks. This was an intensive research and empathy phase, containing not just information gathering, but also reiteration and prototyping.
Besides doing research on every village of the municipality, talking with both private and public actors, interviewing all kinds of owners, observing how people interacted at the BUPi counter, even trying to buy a rural property, and using tools for property boundaries identification, we prototyped a lot: new kinds of counters, new ways of identifying a property (both digital and physical), several versions of communication pieces and even town hall meetings. All of this served not only the purpose of mapping the challenges and improvements to the physical and digital services, but also rapidly understanding what actually worked, in order to spread it across the other 9 municipalities.

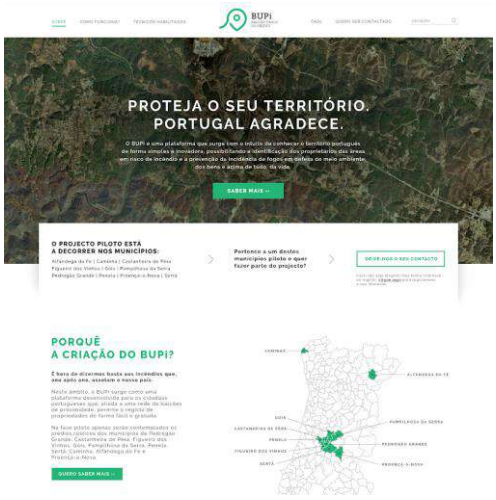

Figure 1: The first landing page we built

Figure 2: Our attempt to buy a rural property helped us understand how lands are priced and sold.

Figure 3: Besides using the digital platform, we also experimented identifying properties through the old fashioned way.

One example of this research approach is the prototype for a decentralized counter we created in Penela's weekly market. After understanding that some of the main bottlenecks of the project were the time each technician spent with each owner, each municipality having only one technician per counter, and the hard time property owners had searching for their properties on a 2D migital map, we decided to test a way that could allow each owner to get to the counter with as much applicable knowledge as possible about the whereabouts and boundaries of their properties. So, for 3 wednesdays in a row we set up a table at the center of the weekly market and using Google maps, a digital tool already used either by the target population or close relatives, we helped several people drafting the shape of their properties on top of Google satellite images. This whole experience allowed us to understand several things:

- The kind of questions a technician might use in order to help a property owner;
- Mapping of strategies for knowledge gathering before an owner goes to an official BUPi counter;
- The different media that owners use to record this type of information;
- The way this knowledge should be structured for easy reading by the technician;
- How a decentralized counter might streamline the whole process;
- The new role we would have to create for this kind of *help counter;*

Figure 4: We prototyped a new "help counter", outside the city hall, where owners could get support, gathering information before going to the main counter

Figure 5: Testing Google Street View as a way to streamline owners' identification of property location

Figure 6: One of the prototypes we built with the goal of raising awareness and collecting owners contact information at local restaurants and other gathering places

By the end of this intensive research phase we had identified 4 main issues present in the whole initiative:

1. Disorganized and complex communication between the different entities and with the target population, originated by a lack of understanding about the overall goals of the initiative, different interpretations of the law, lack of a coherent governance model and generalized misunderstandings about what the digital property boundaries identification was all about;
2. At the base of the creation of the decree-law and the first batch of communication were unrealistic scenarios that did not take into account different kinds of property owners and the different reasons why each different type of owner might be interested in this initiative;
3. Although the main goal of BUPi was to allow for a better management of rural and forest lands in the future, the registry of rural properties ownership was seen as the single most important thing in the user flow, reducing the identification of property boundaries and shape to either a hard in-between step, or an after thought that was dismissed by everyone;
4. All the work imperative to reach the initiative goal was dependant on the daily work schedule of each technician, a factor that would be very hard to scale.

To tackle these problems, we defined a strategy around three main principles:

1. Refocusing on property boundaries identification, not only communication-wise, but also in the way both the digital and physical flows were designed;
2. Decentralization of the counters, using public spaces and under-used public resources (e.g. computers, vans);
3. Highly targeted offline communication taking into account three different types of rural property ownership and the different and idiosyncratic communication spaces available.

Using these three principles we redesigned everything across the whole project and delivered a service design and communication report. Several key recommendations were implemented days or weeks after the report was presented.
But all of this was done inside the scope defined by the decree-law, which contemplated only one of the ways the overall goals — rural property registration and boundary identification — could be accomplished. So we went further and redefined not only the overall goals, but also the way to get there.
We understood that the end goal was not amassing property registries and pixel perfect boundary identification. The end goal was to increase existing knowledge about a massive area of rural properties and forest. This redefinition allowed us to show to the Portuguese Government that in order to better manage this huge area there was no need for thousands of owners to go to a BUPi counter or learn how to use the online platform, and identify exactly where their properties were. Attributing this responsibility to landowners could actually delay reaching the previous goal — to registry and map one hundred percent of rural lands in a year — by decades.
The passive approach adopted by the Portuguese Government, whose role besides creating the decree-law and building the offline and online tools was simply to wait for owners to seek the service, did not make sense in an age of satellite images, artificial intelligence and huge amounts of data. Thus, on top of everything we recommended, we also proposed a redefinition of the vision for the whole project, to use satellite images,

historical databases of ownership and every bit of publicly available georeferenced data, together with computer algorithms, in order to understand the amount of rural properties that exist in a given area, the most likely boundaries of these properties and who might be their owners.
This new approach opened the door to new opportunities in the long run. If successful, it would be possible to get a citizen to confirm if what was deduced was true, changing the incentives system for participation: you wouldn't have to put in the work, just check if everything you owned was deduced. It would also allow for more clear identification of the owners who had neglected their properties (increasing the risk for catastrophes). So, together with one of the other companies working on the project (specialized in big data) we started a two-months-long proof of concept, with a mini project.
During this period, we collected public information from both public and private institutions, tested different kinds of satellite imagery, cleaned and improved databases. In the end, using three different methods according to the data points available for a given property, we were able to show that it was possible to identify the probable location of any given property in the municipality of Penela, the municipality chosen for the proof of concept. This capability was then included in the platform, in which both technicians and property owners could now automatically get the probable location for a given rural property number, without any other input. The development of the property boundaries identification algorithm is as of today a work in progress, together with the further development of the overall concept behind this new vision, in order to scale its capabilities and usefulness.

Figure 7: First concept of the location and shape detection algorithm

When we presented the service design and communication report, together with the new vision for the project in January 2018, two months after the launch of BUPi, the average goal completion for the 10 municipalities was around 2%. By November 2018, the project was able to go above the 50% mark of overall goal completion — properties location and boundaries identified/checked by its rightful owners. BUPi became one of the fastest initiatives of its kind, and extended beyond the initial 1 year pilot program. As of today, a national roll-out is being discussed in the Portuguese parliament. The big data effort also allowed for an increase in the project scope. For the first time, georeferenced data that was *owned* by different institutions and seldomly shared is now centralized in a single platform which allows an unprecedented level of knowledge creation about the Portuguese territory. As a tool, this knowledge can only grow in capabilities, with the potential to go from a tool deployed for catastrophe prevention, to an active platform available to everyone who wants to reinvent how value is generated using areas that have been abandoned for several decades.

Key learnings

From all the things we learned during the research phase and the following months of implementation of the report recommendations and the new vision, we want to highlight four that we believe can be applied by anyone practicing Design Thinking:

1. Taking time to setup the real world conditions where we will apply Design Thinking is not a problem, but rather a strength even when we have to actually build the things we will end-up studying. We would even argue that this is at the core of prototyping and testing as principles of Design Thinking;

2. Applying the Design Thinking principles, beyond a linear process, is in itself a way to start solving the problem we are studying while doing the project. Everything we did during the research phase in Penela, even just talking with people at local coffee shops, helped this municipality being the one with the best average completion goal while we were there. No one can study a problem in a vacuum, Design Thinking can be used as an impactful change agent during this process.

3. Gradually presenting micro-results and strategically valuable knowledge generated in an immersive and empathy-focused Design Thinking approach allows for growing confidence within the project team and third-party entities, uplifting design to be the discipline that leads a strategic and innovation process across multiple dimensions (law-making, operational support, communication, service, digital platforms);

4. It is quite common for the challenge to be set around means goals and not end goals, which can limit how the strategy is developed. In any project, taking a step back and reaching a clear and defined overall end goal can open up or even change the scope of the challenges and solutions devised within the strategy.

Final thoughts

Before the program was launched (November 2017), there were 243.195 hectares of properties that needed to be georeferenced by its owners on 10 pilot municipalities. From November to the middle of January, the program had achieved the 2% mark of completion. This was around the time when we presented our research reports and the new, data intensive approach. Once the service design report recommendations started being applied we saw significant improvements in the number of properties georeferenced across all municipalities and the percentage of completion skyrocketed to 47.47%, until October. This percentage includes 82.860 properties identified, for a total of 35.601 hectares of rural land. On top of this, all the mobilisation generated 45.000 individual counter bookings that couldn't be fulfilled as of October: by the end of the project, demand exceeded supply.

Besides the expansion of the project, improvements of the algorithm and development of visual supports for mass media communication, we are already studying how the data collected can be used to empower entrepreneurs from all over the country to find new ways to enrich rural Portugal.

Research Perspectives IN THE ERA OF Transformations

Development of JIT patient-specific implants: design-led approach to healthcare and manufacturing transformation in an Australian context

SOBEL Leanne*; SKELLERN Katrina and PEREIRA Kat

University of Technology Sydney, Australia

doi: 10.33114/adim.2019.c22.157

Design thinking and human-centred design is often discussed and utilised by teams and organisations seeking to develop more optimal, effective or innovative solutions for better customer outcomes. In the healthcare sector the opportunity presented by the practice of human-centred design and design thinking in the pursuit of better patient outcomes is a natural alignment. However, healthcare challenges often involve complex problem sets, many stakeholders, large systems and actors that resist change. High-levels of investment and risk aversion results in the status quo of traditional technology-led processes and analytical decision-making dominating product and strategy development. In this case study we present the opportunities, challenges and benefits that including a design-led approach in developing complex healthcare technology can bring. Drawing on interviews with participants and reflections from the project team, we explore and articulate the key learning from using a design-led approach. In particular we discuss how design-led practices that place patients at the heart of technology development facilitated the project team in aligning key stakeholders, unearthing critical system considerations, and identifying product and sector-wide opportunities.

Context and Background

In 2017, the Australian Government funded a unique collaboration between a specialist orthopaedic and oncology hospital, University Technology Sydney and the Royal Melbourne Institute of Technology and a medical device manufacturer to produce bone tumour implants based on 'just-in-time' (JIT) principles[1] in a hospital environment. The determinants to deliver this manufacturing transformation research project were based on the hypotheses that a JIT patient-specific pathway would not only improve the speed and accuracy of surgery but also improve overall patient, hospital and health system outcomes.

This innovative, technology-led project aimed to combine specialised imaging techniques, the accuracy of robotic assisted surgery and 3D printing to deliver a personalised implant in time for the surgeon to remove the tumour and repair the patient's bone in one operation. Currently, the patient specific implant design, manufacture and delivery process can take between 8 – 12 weeks.

[1] Relating to a manufacturing system in which parts and materials are delivered when they are needed, rather than before and reduces the cost of storing parts and materials and reduces waste.

To achieve this, the project aimed to:

- Develop innovative manufacturing and health care pathways
- Reduce implant production timeframes,
- Reduce cost of implant manufacture,
- Deliver custom solutions to oncology patients
- Save lives of young and older Australians, and
- Improve limb salvage surgery.

Each member of the research team were tasked with discreet parcels of work relating to the overall manufacturing research brief. This case study documents how practitioner-based researchers from the Centre for Business and Social Innovation (CBSI) and the Design Innovation Research Centre (DIRC) from the University of Technology Sydney (UTS) facilitated a design-led innovation workshop to understand and explore the business considerations relating to this overall research project. Specifically, it examines the role of workshop design, facilitation and artefacts to achieve business model innovation and sector transformation – with considerations specific to additive manufacturing and delivering a just-in-time (JIT) patient-specific solution in an Australian context. The transdisciplinary research team was formed by members from both CSBI and DIRC at UTS and consisted of a strategic design practitioner, with a background in communication design and business management, a visual communication designer, and an industry transformation research fellow, with a background in business development, project management and stakeholder engagement.

The anticipation of introducing a new technology to the market can often transcend a true benefit assessment that such new technologies might bring to a value proposition and the end users. Thus, critically assessing the need for new technology at the pointy end of service delivery was required with a design-led frame and specific attention to the role of; patient-centred design, visual artefacts and workshop facilitation. A design-led approach is representative of the application of traditional design practices into non-traditional contexts – also known as design thinking and human-centred design (Brown & Katz, 2009; Martin, 2009; Kelley & Kelley, 2013; Dorst, 2015; Liedtka & Ogilvie, 2011).

The narrative

As part of the broader manufacturing research project, The UTS research team was tasked with undertaking research on the sarcoma stakeholder eco-system, to form an understanding of the business model considerations related to project delivery. The UTS team worked collaboratively to gather and synthesise qualitative stakeholder research across the broader medical device and health system including stakeholders from industry, government and hospitals (including: patients, surgeons, other health professionals, design and manufacturing, operations, governance, regulatory) . Extensive semi-structured interviews revealed the pain points of the current patient and stakeholder journey whilst also highlighting the gain points and opportunities the JIT project could address.

The UTS team adopted a design-led approach to developing workshop activities and facilitation plans in order to enable all project partners to fully explore and make use of the rich research findings. This approach was specifically adopted to help facilitate broad stakeholder engagement to comprehensively explore complexities and considerations relating to a project of this scope.

The team also drew upon service design methods (Stickdorn & Schneider, 2010) for mapping patient and stakeholder experiences and creating current and future state ‘Patient and Stakeholder Journey Maps.’ These journey maps were the culmination of a six-month qualitative research program, synthesised for the purpose of sharing insights from this with participants of the interviews as well as the broader project team.

Applying a design-led approach; reframing, synthesis and artefact development

Whilst CBSI team members conducted the qualitative research, the DIRC members brought a design-led innovation approach to reframe the potential of this project around the benefit for patients. This shifted the focus from a technological viewpoint only (Bijker, Hughes, Pinch & Douglas, 2012) to one that considered the patient as core (primary beneficiary) and surgeons (primary user) and broader system participants including healthcare providers, insurers and regulatory bodies (Figure 1).

DIRC’s design practitioner skills assisted in the ‘sense-making’ (Kolko, J. 2010) of the vast volume of data accumulated through the qualitative research phases (including 30 semi-structured stakeholder interviews).

The team was tasked with translating the data into visually digestible artefacts to share with stakeholders' representatives from across the system. These artefacts not only supported the relevancy of reframing the problem but pointed out the true opportunity that the innovative technology had for the system participants and what might need to be explored in realising this.

Both centres worked together to synthesise the research of the patient pathway and system, and discuss how best to organise this information in a way that would be:

1) Easy to understand
2) Visually stimulating and relative to current state
3) Consultative and participatory
4) Representative of future state scenarios
5) Developed to inform business model innovation

Figure 1 – Participants first worked together in small groups debating and validating elements of the current state while stepping through the journey of the patient and stakeholders.

Agenda as a design output and process

In the curation of the design-led workshop, the articulation of research insights and the outcomes of the workshop needed to provide input into the team's objective to build information and knowledge about what kind of business models may be most suitable for the realisation of this technology. Therefore, the agenda development was an important step in the process toward realisation of this. Agenda items were designed not only to inform stakeholders of research outcomes and strategic intent, but to also help shape possible business model innovations.

The process of developing the agenda (Figure 2) was time consuming and took over two months to finalise. It was a complicated process as there was an interplay between several moving parts:

Figure 2 – The agenda as a working document showing the interplay between all the moving parts of the workshop.

The workshop experience and facilitation

One element of the workshop's success hinged upon the facilitation of the workshop itself and the management of participant experience. The objective being to elicit all knowledge present in the room across key agenda activities. This process was important as it relied on each member of the UTS research team to perform specific roles as part of the facilitation process. These roles included:

- **Lead facilitator:** research project lead, and owner of key data inputs from research,
- **Second facilitator**: facilitating design-led activities, providing explanation of why activities would be conducted in certain ways, content knowledge, and
- **Support facilitation:** Working with teams, guiding participants on how to engage in design methods, documentation of workshop.

Figures 3, 4 and 5 illustrate key points in the workshop for participants to come together using the visual artefacts.

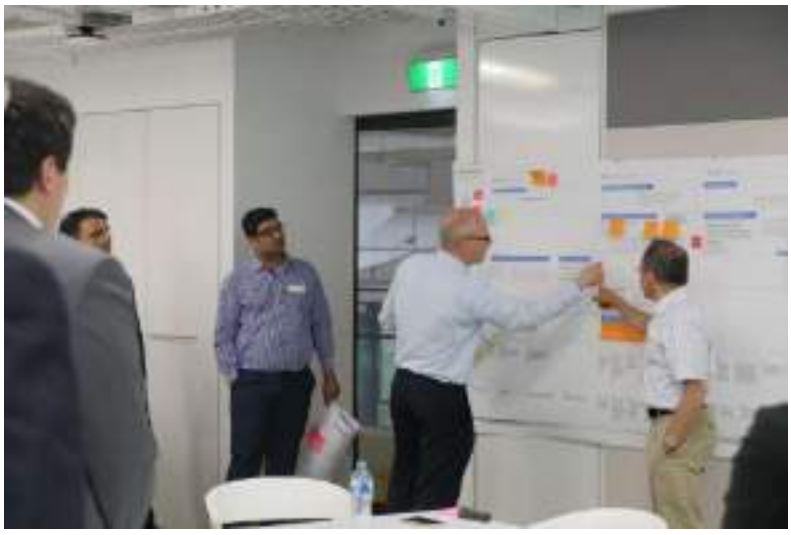

Figure 3 – The scale of the artefact allowed for physical interactions to take place simultaneously to the verbal discussion, also highlighting particular areas of the patient journey to emerging areas that could be changed or we deemed as important by participants.

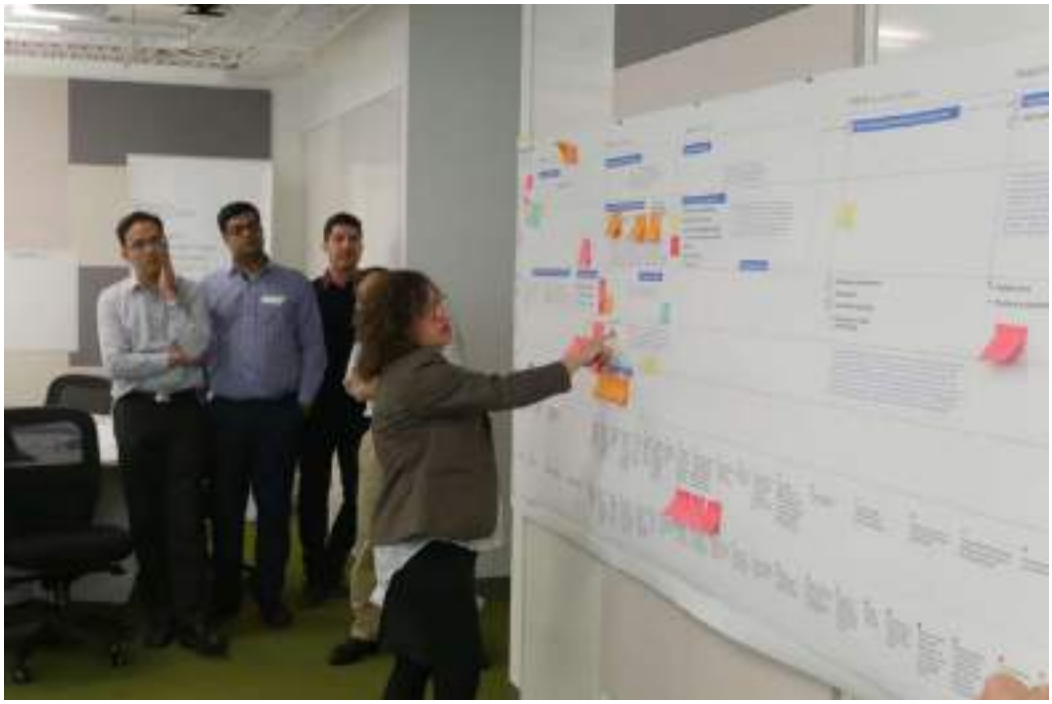

Figure 4 – A whole group discussion facilitated around the large format journey map artefact allowed for different perspectives and expertise to be heard and then visually collated, resulting in the discussion to progress to a validation of the current patient journey.

Figure 5 – Groups became more comfortable with the design process as the workshop progressed and embraced the physical space around the artefacts as their place for discussion around the patient journey.

Key Learnings

The problem framing and reframing (Dorst, 2015) generated an important pivot for this project refocusing the attention of the manufacturing research project members to patient and system needs. However, further supporting the value of this, the development of physical artefacts (including the Patient and Stakeholder Journey Maps) was critical to aid the communication of data insights and the patient process flows and

dynamics (Boland & Avital, 2015). The 'Patient and Stakeholder Journey Map' was key to achieving effective collaboration and input from diverse stakeholders of the project to inform the business model design. Further, it helped to build a consensus amongst stakeholders about the project direction and possible initiatives to consider. Ultimately this artefact was adopted by the project team as a 'working system tool' and guide for the project going forward.

Consideration was also given to understanding gaps and opportunities not only for the project team but the sector and medical device industry more broadly that could not be anticipated in advance. The outcomes of the workshop and project to date have generated a 'ripple effect' across key stakeholders in the journey including government regulators, health insurance agencies and supply chain. At a macro level the project has also generated new opportunities to provide enhanced patient pathway interventions related to this issue not otherwise understood – all of which derived from the main project scope.

On the surface, the delivery of *one* design-led workshop could have been perceived as a simple task, with benefit measured by the experienced of the event. However, as the research project team from UTS and broader manufacturing research group discovered, the workshop process and deliverables were critical in ensuring:

- a synthesised current and future state journey were achieved
- identification of pain and gain points to explore opportunities to address gaps in the journey
- initial ideas were developed for business model innovation options including 'scale' of market development and 'space' for physical location
- stakeholders validated and understood the existing research and next steps of the project
- the importance of the project to the patient and stakeholders across the system
- an articulation of the project system, what it set out to achieve and what it would need to consider to be able to share with others from outside the immediate project group in the form of artefacts

Contributing factors

The key components that contributed to a successful collaborative design-led process are identified as follows:

Table 1: Contributing factors

Synthesis of research findings	
Insight development	Synthesised stakeholder interviews through 5 - 7 iterations – what was the 'so what' of each insight and how to best summarise key points that would be effectively communicated.
Developed and reworked workshop agenda and artefacts	
Problem definition (reframing)	Validate the definition and need of JIT, and the problem that the team was aiming to solve. Thus emphasising the importance of the patient experience as a starting point for how we understand the problem and that success primarily hinges on good patient outcomes (rather than achieving the delivery of new innovative technology in itself).
Map system complexities	Identifying all of the key stakeholders and beginning to map dependencies within the system for technologies' success within the health care system.
Journey stages and stakeholder interactions	Working through key steps in the system that may significantly need to change through the realisation and support of technology and its users.

Critical journey moments	Articulation of the Patient-centred journey mapped to all system actor pain points and gain points and opportunities.
Future state pathways	Develop future state opportunities. Given the volume of content and limitation of time in the workshop, there was a need to identify some hypothetical futures and process options (which also arose from research undertaken by the team) for validation and exploration into the workshop.
Designing of things	The role that visual communication design played in developing a patient-centred journey artefact and associated content. The artefact has now become an instrumental device for the manufacturing research project team and medical device manufacturer ongoing and is continuing to evolve. Recognition that the agenda development was also a subject of design; considering how associated artefacts and experiences would align to achieve desired outcome for the workshop.
Business model inputs	
Space	Explore the options and needs of a physical space required to house the technology and the implications and considerations of this on service delivery to patients.
Scale	Explore options about how the technology application may be more broadly applied to other patient-specific solutions beyond osteosarcoma –
Prioritisation and validation by workshop attendees (project team):	
Concluding with purpose	Discussing critical factors for the project and what needs to happen next (which was curated by the UTS team, but the needs of project members also directed the prioritisation of these). Identify broader project needs (involving people and system) in order to realise project vision.
Teaming and collaboration	
Diversity of thought	Leveraging the diverse skills and experience that the joint UTS team brought to the project. Particularly for this project the mix of business, design, strategy and visual communication design (graphic design) expertise. Further to this, understanding each other's backgrounds, skills and being open to new ways of thinking through the project requirements was key to this successful partnership.
Facilitation interplay	The interplay between facilitators within the workshop. Sharing roles throughout, leaning on each other for support and the ability to adapt and change where required through the day, and sensing from participants when this would be needed and what it might involve.

To achieve these outcomes, the bulk of the work and thinking was completed in the preparation of the agenda, workshop design and development of visual artefacts. The collaboration of skills from the expertise of the design team joining forces with experts in business development practices, strategy-led approaches and innovation management, that led to the outcome. The key to this collaborative partnership was in the tensions that arose when meeting together to discuss approaches to the design of the workshop, types of activities and ways to communicate the artefact. These tensions can be further explained as traditional strategy-led frames with biases toward solutions (hypothesis) meeting exploratory design-led frames whereby future directions and opportunities were kept open (Martin, 2009).

Conclusion

Successful innovative products and services do not simply arise out of the realisation of a new technology in itself. Their success is dependent on integration across the whole ecosystem and the implications across a range of human and non-human actors within that system, and a collective fit within an organisational culture and business model. Further, key attributes and characteristics are not known until stakeholders within a system are aligned. All stakeholders need to be aware of the considerations and implications that introducing a new technology and process will have on the broader system and to be actively participating in designing and considering not only the technological solution, but also the social, economic, cultural and environmental implications of innovation (Brynjolfsson & McAfee, 2014). Therefore, we propose as this case study demonstrates that the fusion of both design-led practices to business strategy approaches is a powerful mix for complex system-wide innovation challenges, and that engagement of design practitioners be encouraged in an effort to create physical experiences and tangible artefacts in aid of such project efforts.

Designing and Developing Entrepreneurial Culture for a Small UK Based University

VALENTINE Louise

University of Dundee, Scotland, United Kingdom
l.valentine@dundee.ac.uk
doi: 10.33114/adim.2019.c23.145

An undeniable truth is the rise of status and responsibility assigned to Enterprise and Entrepreneurship within the UK Higher Education Institutions, as a means of crafting a more competitive economy. With a growing interest in this area from the Creative Industries, there is a need to articulate the entrepreneurship developments more often, and pinpoint where, how, and to what degree, design innovation management research is supporting this in a meaningful manner. It shares why the development of entrepreneurial culture has been purposefully designed and offers insight into how this has been achieved. This is to give a tangible example of design as a strategy for leadership. The case study is a reflection on practice; a contemplative dialogue on design innovation management research as agency for cultural change and development of a process of *becoming* an entrepreneurial university. It is an example of work undertaken to create an outward-facing, more networked entrepreneurial culture within a small UK based university, as well as leveraging adjacent cultural and economic resources as part of a more entrepreneurial ecosystem within the residing city and country. It discusses a grand-scale entrepreneurial activity within a traditionally rigid structure i.e. a University, as a means of sharing how design innovation management can be used to nudge cultural change over the medium term and beyond design's own discipline and culture. It captures the essence of concept development using a macro lens. In addition to deploying traditional methods, the work uses a dynamic participatory process, designed to grow iteratively and deliberatively working with people as collaborators throughout. The five key learnings shared are the importance of making entrepreneurship a strategic priority; employ design as a strategy for developing an entrepreneurial culture; uphold the act of being inclusive; value a strategically activist approach, and actively manage risk using design principles.

Keywords: Design, entrepreneurship, education, culture, knowledge exchange

Introduction: context and opportunity

In the UK's Creative Industries, a sustained interest in enterprise and entrepreneurship education stems from a need to strengthen the sector's business infrastructure; maximise its network (and its associated resilience), craft new engagements and heighten impact with other sectors. Additionally, its driven by a duty to innovate, with a concern to economically enhance and support its largely self-employed, freelancing practitioners, micro enterprises and small businesses (Department for Culture, Media and Sport, 2006; Clews, 2007; Dellot, 2014; Dellot and Wallace-Stephens, 2017). Lately, a further rise in status and responsibility for enterprise and entrepreneurship within UK Universities has occurred because, for example, of the EU's ambition to be the most competitive economy, the QAA's strategy for Enterprise and Entrepreneurship Education (2014, 2018) developed to capture impact while providing a roadmap for the future; the wider educational entrepreneurial

reports highlighting a pressing need for change in enterprise education and skills development (Universities Scotland, 2015; APPG, 2018) and the UK's Industrial Strategy (BEIS, 2018) that fuels an exigency to be the most innovative economy via grand opportunities with ambitious modernisation.

In 2013, the University of Dundee in Scotland were looking to solve a problem and ended up transforming their idea into a new design-led Centre of Entrepreneurship in support of new business start-ups and cultural nudging. What began as a traditional academic exercise to manage resources with greater efficacy and impact, organically grew into an orchestrated partnership strategy with dedicated commitment, resource and investment from likeminded individuals across the full breadth of the organisation and its network. Through a four-year process (2013-17), the University of Dundee drew on a design for business innovation model to fashion new relationships, mobilise fresh ideas, secure investment and further cultivate an appetite for change by design towards entrepreneurship education for all subject specialisms. This curated a new product and a new service, thereby presenting a unique hyper-local offering in a growing competitive marketplace.

Role and Expertise

With an established design research and knowledge exchange background with experience of delivering impactful entrepreneurial projects (notably the conception and development of V&A Dundee) I began working in this area as the Director of Knowledge Exchange and Enterprise, before becoming academic lead for entrepreneurship. My vision (and place within an emerging pan University team) was to build upon the momentum. It was to develop a culturally developing recognition of design as a strategy for social and cultural transformation with economic impact that was occurring in the University, across the City of Dundee and Scotland more widely: design-led entrepreneurship. This understanding of design is a relatively new characterisation in the eyes of the general public and outside of the discipline of design.

In itself, V&A Dundee, Museum of Design exemplifies design-led entrepreneurship in three ways: 1) attracting a world leading brand, namely V&A , to Dundee which is a city of <150,000 people, 2) its manifestation as an award winning, world leading piece of architecture designed by the renowned Kengo Kuma and, 3) as an entrepreneurial example of design innovation management in terms of the process by which it was conceived, developed and realised (2007-2018), and its subsequent developing impact on social and cultural transformation of a small city (which is ongoing). Together these acts and levels of entrepreneurship are facilitating cultural change in terms of growth and behaviours: scale of ambition – collective and individual, creative confidence, policies and politics, perception of self, external perception of the City and its Universities as a game-changing community.

Problem and Purpose

In this case study, a relation between design, education and entrepreneurship is highlighted. It is a topic and set of relationships that are not well-established academically. In UK higher education institutions, entrepreneurship is predominantly offered as an extra-curricular service or activity; it is a subject largely confined to business and management schools, and it is uncommon to have it applied to and proactively used for developing University strategy.

Entrepreneurship education is slowly growing within teaching and learning programmes with an increased interest that is fueled by the new Teaching Excellence Framework. In the academic business of Research, entrepreneurship is similarly propelled by the impact agenda and responsibilities of the Research Excellence Framework; research council funded projects which seek to ignite new possibilities while concurrently comprehending the benefits of multi-million pounds investments in innovation, research and development, beyond the traditional confines of University environments.

Characterised as 'the pursuit of opportunity beyond resources controlled' by Professor Howard Stevenson, (Eisenmann, 2013) entrepreneurship in higher education is often taught through management frameworks, theories and case studies which are frequently hierarchical in nature. In this case study, design-led entrepreneurship is the lens with which operation is led; a middle-out centrally connected model. Its focus is on collaboratively creating new interdisciplinary activities with a commitment to regular active experimentation and meaningful output. Entrepreneurship is embedded as a life skill as much as business start-up and business growth process. Design as a strategy for change with its thinking tools and processes coupled with entrepreneurship brings design-led entrepreneurship: a capacity that is within us all; a mindset

and skillset that can be taught (Aulet, 2013; Neck, Greene and Brush, 2014; Spinelli Jr and Adams Jr, 2016; Neilson and Stovang, 2015).

Design as a Socially Dynamic Principle for Driving Cultural Change

Phase 1: identifying, framing and defining the problem (September 2013 – October 2016)

Drawing on the work of the Creative Problem-Solving Group Inc., the LIMA Institute, John Maeda (2011), Liz Sanders (2013), Richard Buchanan (1995, 2001), Rachel Cooper (2011), Nesta UK, Neilson Norman Group, Design Council UK and the Hasso Plattner Institute's design thinking research, the character of a design for business innovation and design-led entrepreneurship is one of inclusivity; a curious questioning mindset; an approach driven by a concern for value and love of people; collaboration and the act of co-conception and co-creation; visual thinking and the capacity to visualise; an iterative and rhetorical cycle of looking, listening and questioning which takes the form of physical and virtual making, testing and learning from an idea. The design knowledge, mindset and methodology were implicitly and explicitly used to create a basic infrastructure and roadmap for developing a more entrepreneurial culture. In addition, the globally growing interest in design for social innovation and social impact (Manzini, 2015, 2016), along with increasing attention for design thinking, design sprints, and agile management as tools for change also came to bear directly (Figure 1).

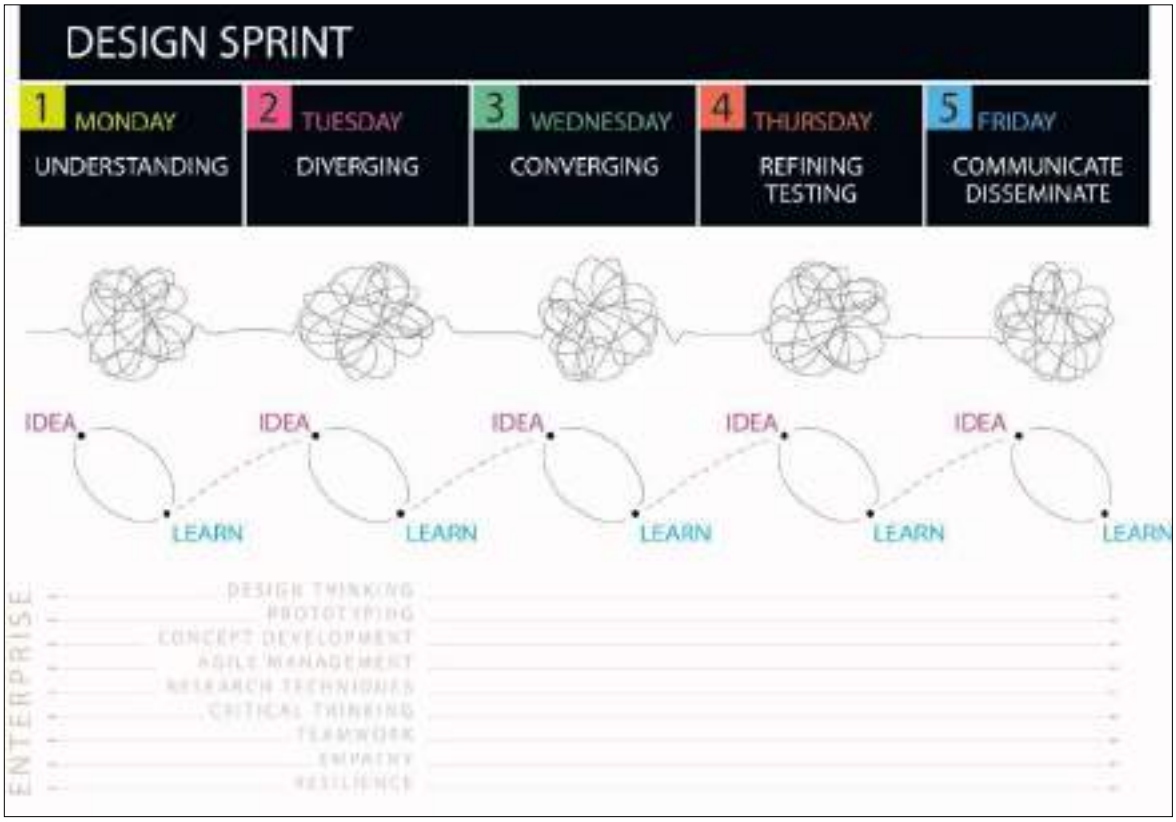

Figure 1 A visual summary (created and applied by the author in her work) of an example of a five-day design sprint developed through research and used to teach design enterprise as a socially dynamic process with an inherently entrepreneurial mindse. It employs design thinking for challenge led problems (such as breast cancer, mental health), and introduces the theories and practices of agile management, teamwork, prototyping, empathy, resilience, design process innovation techniques and design management research methods.

Drawing on design for business innovation management processes and design-led entrepreneurship experience, a series of activities were organised with an open-invitation to academic and central services staff (of all levels) across the organisation: three 'Pollinate' ideation workshops, three 'Show and Tell' seminars, three Creative Futures workshops, and four invited talks. The aim was to understand how we might raise

awareness of the increasing function of entrepreneurship in UK Higher Education across our institution and, ascertain where an appetite to engage and facilitate a change exists.

Upon this basis, an entrepreneurship strategy development workshop was held with a rich mix of (18) senior academic staff, central services managers (such as careers, academic skills, library, research, and innovation services), president of the student association, senior and executive management, specifically the Vice Principals of Teaching and Learning and, Research, Knowledge Exchange and Impact. It used the HEInnovate method and eight generic areas of entrepreneurship related to University business – entrepreneurial teaching and learning; knowledge transfer and collaboration; preparing and supporting entrepreneurs; organisational capacity - funding, people, and incentives; the internationalised institution; leadership and governance; and measuring impact – to provide a shared platform for the potential growth of entrepreneurship in our institution. Subsequently, two additional activities were orchestrated in support of extending the reach of people contributing to how entrepreneurship is shaped:

A shared experience; a visit to an established social enterprise with an accelerator programme, in a different city and not attached to a University. The objective was to gift people a physical experience of the design of a new dedicated facility for nurturing new business start-ups with a distinct brand and creative interior environment designed to a high specification. The point being that if we do not pay attention to our environment then people cannot act in ways that are consistent with their goals. If we do not learn from existing lessons, then progress cannot be made. With this metaphoric mirror, the design led activity was inviting everyone to practically ask: How are we going to create an environment that is consistent with our goal of becoming an entrepreneurial University?

An inaugral pan-University EE symposium (a precursor to the now established Entrepreneurship Week, an annual event) was held. Its entrepreneurial focus was the principles of design, social innovation, and social enterprise. 60 people from across the University and the wider City community, along with invited guests – business leaders, entrepreneurs, ambassadors, policy influencers - working at the coal face of entrepreneurship today, took part in this which included a second HEInnovate workshop. The method of symposium was employed as a community improvement method and a listening exercise in terms of the perceived pain points and potential solutions when it comes to developing entrepreneurial ambitions and culture. It was used as an interactive learning tool and an awareness raising exercise about the intention of becoming an entrepreneurial University. The point being that we must actively listen to and dynamically engage with many people with a diverse range of backgrounds and experiences, in order to get closer to a fuller appreciation of what is actually needed by the community that we seek to service: to hold the principle of listening intently as a priority throughout the entire creative process of change and to make transparent the idea of transformation from the earliest point.

Visualisation and visual representation to communicate the outcomes of the HEInnovate workshop was strategically used because it captures the imagination and demands that information be processed in a rhetorical manner. This is critically important when managing an idea in a state of flux, especially ideas and visions which are embryonic. The visuals are seen to capture a moment in time within a creative process rather than offer a definitive description of an end point. They are used as facilitators of further conversation; a means to maintain ‘flow’ with and between people (Figures 2 and 3).

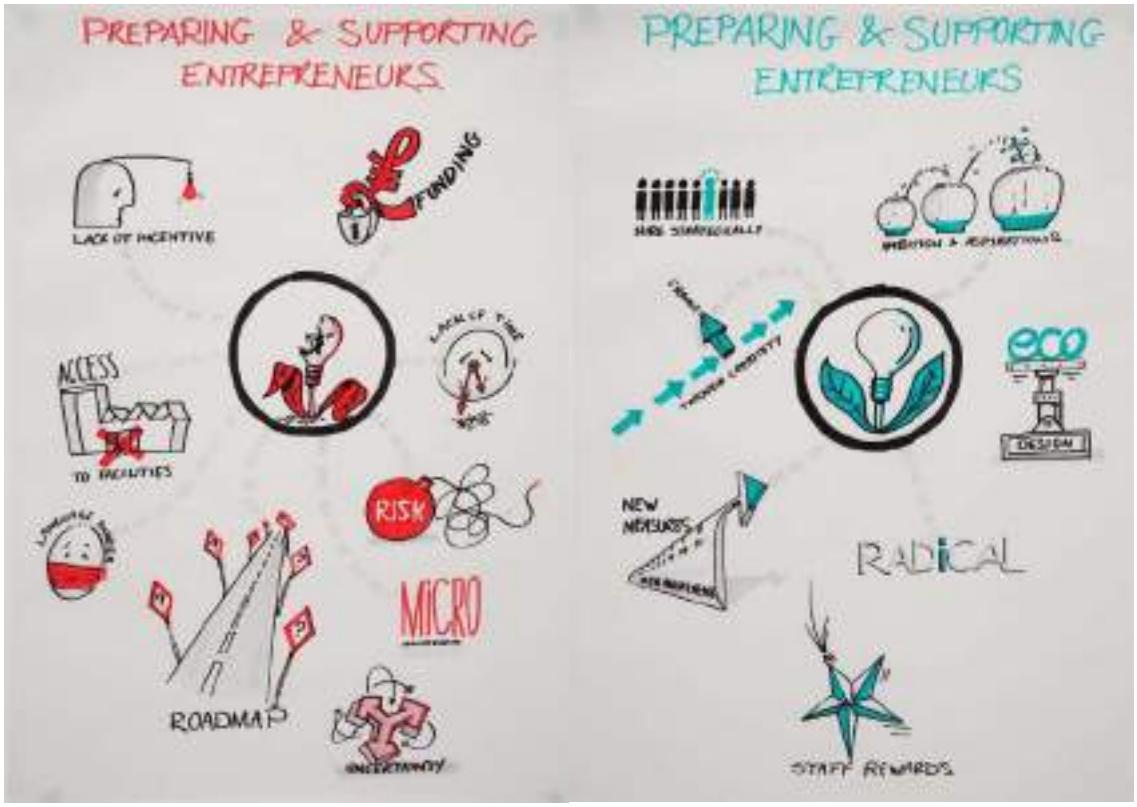

Figure 2 and 3: Upon completion of affinity mapping within the HEInnovate method, the results were visualised as a way of summarising the discussions and in figure 2 the visualisation of key pain points (which are denoted in red, on the left hand side) and the proposed key solutions in Figure 3 (denoted in green, on the right hand side) are associated with the strategic area 'Preparing and Supporting Entrepreneurs'.

'Becoming an Entrepreneurial University' was the identified mission emerging from this dynamic participatory process, designed to grow iteratively and deliberatively working throughout with people as collaborators. Eight specified solutions (to the eight strategic challenges) and an accompanying series of 36 priorities for facilitating and achieving these changes were arrived at (Table 1).

Table 1 Details the eight strategic areas with the solutions and 36 priorities identified for enabling change

Strategic Challenge Area	*Solution*	*Priority Activities*
Leadership and Governance	Metaphorically raise the anchor and permit the ship to explore; sail the seas to reach new shores	• Challenge the business culture • Encourage risk taking • Encourage people to get involved in EE leadership and governance • Provide coaching on EE • Talk less. Do more
Measuring Impact	Create alignment to the business strategy and group the impact measurement units; synchronise the energy between the different units.	• Broaden how we measure impact for EE • Better connect people and data to improve data management • Create a new framework for the very heavy load of DLHE
The Internationalised Institution	Metaphorically, 'the internationalised institution' is a jumbo jet in flight. The proposed answer is to expand its flight paths and airports with more trained pilots and more aircrafts.	• Create clear, strong links between the University's business plans and individual Schools • Embed more understanding of the international institution into the curriculum • Increase languages study offer

		• Develop more flexibility between research, teaching and learning • Sandwich. University, International, Business
Entrepreneurial Teaching and Learning	Metaphorically, the space rocket is on the launchpad waiting to lift off. Prepare a strategy with a team of 'astronauts' to enable a successful journey into the wider galaxy of opportunity.	• Include risk taking as a criterion in T&L assessment • Offer more practice • Include practical assessments • Offer choice • Promote mentoring and networking opportunities
Knowledge Transfer and Collaboration	When it comes to the subject of EE, people and communities are mute. Metaphorically, talking heads was the solution; to get people talking directly with each other about EE	• Value serious playtime • Engage in more collaboration and collaborative activities; • Join the dots; create a dynamic connected system • Create space(s) to think and act in this way • Unlock the doors; give Industry wider and greater access to University intelligence and facilities; make them feel welcome • Increase our global outlook
Organisational Capacity	There's no petrol in the tank. Fuel up; insert gas into the tank so we can travel.	• Nurture Entrepreneurs (and intrapreneurs) • Be more cross disciplinary in nature and outlook • Grow staff development opportunities • Create an entrepreneurial study radar to detect opportunities • Invest more in innovation
Preparing and Supporting Entrepreneurs	Care from the roots up. Feed the 'EE plant' for the continued sustenance of innovation and ideas.	• Hire strategically • Grow ambition and aspirations • Facilitate the change through creativity • Create new measures and new measurements • Be radical • Create staff rewards • Design ecosystem

These aforementioned activities ran parallel with the development of a new Entrepreneurship Strategy led by the Entrepreneur in Residence and a new EE University Working Group of which design was an integral voice. This included an initiative where each School within the University appointed an academic lead for the development of EE across their educational disciplines. The activities and decision-making processes culminated in a commitment to invest and provide a new purposefully designed Centre of Entrepreneurship.

Phase 2: Problem Solving with Impact (Oct 2016 – Sept 2017)

The creation of a dedicated centre of entrepreneurship ensued (opening to the public in September 2017). A flagship offering for staff, students and the local community to use for the development and growth of new business start-ups: a strategic partnership with Elevator UK whereby an innovative new, open access, public-facing, stand-alone facility was designed and developed to offer a suite of services, mentoring, and investment awards, in the pursuit of identified new goals. It organises 50+ events each calendar year: including Entrepreneurial Masterclasses, an Entrepreneurship Week, a Venture pitching competition (£27.5k fund annually with the School of Art & Design taking the position of most entrepreneurial School for the past three years), and large public lectures with leading entrepreneurs including Josh Littlejohn MBE, Mark Beaumont BEM and Mike Souter. It also boasts the first University strategic partnership with Entrepreneurial Scotland and is strategically building on Dundee's global reputation for design innovation and research (Duncan of Jordanstone College of Art and Design, UNESCO City of Design, V&A Dundee Museum of Design). The facility is one of the first entrepreneurial centres in the world to capitalise on a design-led approach in the way that start-up and

scale-up businesses are guided. It draws on this rich resource to apply 'design thinking' into the Entrepreneurial mind-set of the businesses within the centre along with specific design-led sessions delivered by V&A Dundee. Linking to this the university delivers a unique Design for Business MSc developed in parallel with V&A Dundee which has a close relationship with the Centre.

Key Learnings: Reflection on Practice

The case study is a contemplative dialogue on design innovation management research as agency for cultural change and development of a process of *becoming* an entrepreneurial university. It has not detailed the concurrent policy developments made or showcased all of the project work, partnership developments, advocacy, industry input, teaching initiatives and-or management meetings. The intention is not to diminish these procedures and junctions, rather to hold focus on the higher-level strategic use of design to fashion new strategic relationships to mobilise cultural change together in a middle-out centrally connected manner. To redirect attention from this would undermine the accomplishment of design for transformation within a University to secure investment and further cultivate an appetite for change towards entrepreneurship education for all subject specialisms.

The five key learnings to share are not rocket science but they are nonetheless imperative:

1. Make entrepreneurship a priority and place strategic importance on making time and resources available to find and network with new, likeminded people across three geographical levels - international, national, and local with a focus on entrepreneurship;
2. Employ design as a strategy for developing an entrepreneurial culture and when employing design and its middle-out centrally connected model, maintain respect for the hierarchy of current University structures; achieve executive buy-in to the use of design as a strategic tool from the outset with further sponsorship from academia, industry, external agencies and organisations to sustainably build on this;
3. Uphold the act of being inclusive *and* the design innovation management of fun, freedom, and friction to help achieve this;
4. Value a strategically activist approach to design innovation management to ensure the integral use of design as an agency of change from the outset;
5. Actively manage the risk taking involved when building a fresh collective of community champions for entrepreneurship through the principles of design

All five insights are risks needing to be managed with an entrepreneurial mindset, that of agility, resilience, gumption, and tenacity. The use of design innovation management as a framework is advocated to enable the sustained openness and the perpetual cycles of divergent and convergent thinking required. This is vital as it brings a mindset that views fear as a friend rather than a foe, which is necessary as getting it wrong – often and in small ways– is needed in order to get it right.

This was a large ambitious endeavor filled with complexities and politics, and in terms of capability building, the most challenging was the fact that the nature of design as a strategic process is (largely) antithetical to public facing hierarchical organisations, therefore learning to dance with this political tension becomes the job when seeking to advocate design as a strategic organisational and cultural development asset. Sustained investment in collaborative actions, innovative experiments, and activities by and through design were instrumental.

Design for social and cultural transformation is a long-term commitment to strategy and community. Drawing on V&A Dundee we know that from the point of conception to the point of delivery is a deeply intensive 10-year collaborative process. Going forward, the challenge for design as a tool for developing entrepreneurial culture is to measure the impact of applying the knowledge and practices of design for business innovation management to business, culture and society. It is to collaboratively engage in research to evidence the impact and value, thereby delineating what design is beyond the traditional and popular boundaries of products and services.

Co-designing Community Dental Services software

VALENTINE Lucille[a]* and WASSALL Rebecca[ab]

[a] Newcastle University, United Kingdom
[b] NHS England, United Kingdom
* lucille.valentine@ncl.ac.uk
doi: 10.33114/adim.2019.c24.147

A dentist working in Community Dental Services (CDS) in the Northumberland Healthcare Trust of the NHS wanted to develop open source software to use in their clinics since most of the systems that they currently use are paper-based. The question was, what should the software look like? Here, where teeth are the easy part, oral health services are provided for patients with very complex or special needs or disabilities including autism, dementia and phobias. All NHS Trusts deliver these services and four Trusts with varying software systems agreed to second staff for half a day a week for six months to take part in the discovery. Co-design workshops were facilitated by the care analyst every second week and in alternate weeks staff were given tasks to do at their Trust clinics; observing, timing, collecting forms and data. Each Trust has its own version of every piece of management form. At first people act as though their document flow represents the pathways that should be "automated". Software specification in the NHS is often done by people without special skills or experience but persistent co-design delivered an agreed patient care pathway as well as an extended narrative for future software development.

Keywords: Open Source Software, Healthcare, Special Care Dentistry, Co-design

Context and setting

Where it started

OpenOdonto CIC launched a project setting out to frame the functions, reach and purpose, or discovering the user needs, of new, open source software that will be used in Community Dental Services (CDS), the providers of special care dentistry in the NHS in England. Essential to the brief was the aim to make open source software using an Agile software development methodology.

OpenOdonto CIC, a clinician-led Community Interest Company (CIC) was established in 2015, by a senior dentist practising within Community Dental Services in the North East of England, with funding from NHS England Open Source programme via Apperta CIC. The lead dentist was frustrated at having to use paper systems for everything from referrals and appointments to patient care notes.

Community Dental Services

Community Dental Services (CDS) is the part of each NHS Trust which 'does' Special Care Dentistry, oral healthcare provision for patients with complex disabilities or medical conditions. Clinicians practicing in CDS work hard to ensure dental care is available, despite complex difficulties in communication and access.

Clinicians and admin staff will say that "the teeth are the easy part" and patients' additional needs are complex and widely varied in their complexity. Examples of treatment complexity core to CDS and which are

outside of the mouth includes providing domiciliary care for people unable to leave home, providing care under sedation or General anaesthetic theatres for people unable to accept care with local anaesthetic alone, the use of hoists to transfer patients from wheelchairs to dental chairs, modifying communication to maximise understanding for people with dementia or learning disabilities and using interpreters when languages are different, balancing risks and benefits for older people on multiple medications. . What is now clear is that for CDS, the ageing population will continue to place increasing pressure on these services (Lievesley & Wassall, 2015).

Why do it this way

While the earliest drive for this project was from clinicians demanding a better way in the clinics where paper-based systems are in use, it is also fuelled by the frustration that dental software *is* available and is in use at some Trusts in other parts of the NHS, but it is seen as not fit for purpose and is almost impossible to improve or change. This crystalized into the OpenOdonto discovery project: what does fit for purpose would look like for CDS?

Studies on the non-adoption of technically detailed automated procedures note a lack of consideration of usability issues i.e. the "world of people and human purposes" for how the records, forms and letters are used (Thyvalikakath et al., 2007). Where "truth" about a patient is often arrived at through careful repeated questioning and patients have complex truths and have difficulties communicating, heuristic technical systems for populating electronic health records (EHRs), or making decisions, easily become too rigid and then clinicians will deviate significantly from the programmed methods (Walji et al., 2013).

The project team at Newcastle University – care analyst and living lab specialist – was contracted because the usual means of extracting the user needs for software in the NHS has proven insufficient. Currently where NHS software is bought using a 'specify and procure' process, clinical practitioners do much of the specification though often without the language and the agency to negotiate with software suppliers. The national programme for IT in the NHS highlights the consequences of implementing software that is 'bought off the shelf'; it "imposed uniformly derided systems that few if any wanted, delivered late, and ran up costs never seen for an IT project planet- wide"(Maxwell et al., 2010). However, there is an 'alternative way', in which digital tools are viewed as part of the continuous improvement of services (Government Digital Service, 2017) and opensource is embraced.

The choice of software development methodology affects the project fundamentally. Agile methodology has as one of its core principles that it values "individuals and interactions over processes and tools" (Highsmith & Cockburn, 2001) and therefore suits participatory design. In addition, it features works in small cycles emphasizing incremental development and small design steps guided by frequent interactions with customers (Martin, 2003), (Goldman & Gabriel, 2005). Working towards open source code also as has benefits of easier collaborations and higher quality (Government Digital Service, 2017).

For the living lab process real users are taken out of their place of work, guided in conversation and supported to make things together. To promote discourse, and thereby allow for the development of confidence among participants who then participate in co-designing the software that they require, extensive use is made of boundary objects (Sapsed & Salter, 2004) and prototypes (McLoughlin IP, 2016). The facilitator was the author who has training in computer science, industry experience in software development, and many years as a business analyst before joining academia.

The narrative

The four Trusts

Implementing new software at a CDS clinics means that there will be systems change through technology that solves particular problems and so it is essential that the most important problems are solved, as defined by the people who are working with the current systems on a daily basis (Mumford, 2006), who feel the frustration and will potentially be the people who would be working with a new system. These are the people who must be able to recognise the design of the proposed new system as being something true and that it will support better work (clinical care in this case).

Stakeholders were, in this first instance people from Trusts who could reasonably travel to Newcastle University on a regular basis because co-design works best when the community works together in person and do so over many meetings.

In addition to the directors of OpenOdonto CIC the lead dentist recruited four northern Trusts who seconded staff members to the OpenOdonto project for half a day a week from September 2015 to March 2016. Those involved were dental clinicians, including nurses, and administrators and managers of the service.

Participants were active, current staff employed in the Community Dental Services (CDS) of the Trusts listed below who were seconded by their Trusts.

Trust 1	Northumbria Healthcare NHS Foundation Trust (Northumbria)
Trust 2	The Newcastle upon Tyne Hospitals NHS Foundation Trust
(NUTH) Trust 3	County Durham and Darlington NHS Foundation Trust (CDDFT)
Trust 4	Pennine Care NHS Foundation Trust (Pennine)

Each participant in our exploration had a particular experience as Trusts have unique geography, clinic type, and composition of patient cohort.

For example the patch for the Pennine Trust in Manchester is urban and densely populated though it is geographically smaller than the Northumberland Healthcare Trust which includes more rural areas and clinics are widely spread out. Dentists have to see patients in multiple clinic locations; some clinics are in hospitals, some are part of community health centres, for domiciliary appointments patients are seen at their own homes and some elderly patients are seen at care homes. One patch has a large number of adult patients with autism, one patch has a lot of children currently looked after within social care services.

Differences mean that there is a legacy of accumulated systems: of the forms, letters and the piecemeal acquisition of software, and expensive hardware such as radiography. This is set against the similarities in training of clinicians and the straightforward expectations of the patients, the regulatory requirements and the practises that build up around this.

Co-creation and co-design: In the Living Lab with the care analyst

Discourse and sense making was the process whereby space was allowed for co-designing and preserving ambiguity. On alternate weeks all participants gathered in Newcastle University Business School KITE research centre's Living Lab workshop, a flexible and enabling space with large tables, computers and wall display and screen, wraparound whiteboards, flipcharts – material to represent whatever things that arise.

When the author identified herself as a business analyst it was very quickly made clear this has a specific meaning within the NHS, often being linked to specific software companies and, as such, not really trusted and later, when the author had to be given a named role, this became the care analyst. The researchers who were part of the design process were the care analyst, care system architect, and living lab specialist.

Since the enquiry has its own purpose i.e. to generate guidelines for eventual software development, workshops were iterative and data was allowed to flow naturally under the direction of the care analyst. Participants were given tasks before each meeting and for the first meeting participants were asked to find and bring along every form or document in use within their Trust and talk us through the processes that these represent. This was shocking to the researchers and the first stark reminder that while each CDS delivers the same care to a similar patient population that each one had evolved to be, seemingly, mutually incompatibly different.

After each workshop the care analyst gave the participants "homework", these were direct observation tasks and paper chases and timed activities about patient care at their clinics.

The care analyst's "homework" was to be ready for the next workshop; to process the data and stories and quantitative data and forms to 'make sense of it', gain specialist input such as from other future potential users of the software or other participants from NHS Trusts. Representations were developed: these are care pathways or models or physical pictures of the care and responsibilities or the roles that interrelate in a clinic / Trust and beyond. These are further boundary objects and these are then presented at the following Living Lab meeting. The boundary object / the model / prototype / architecture is shared and commented on and fixed,

iterated, discarded; omissions are added and misunderstandings pointed out in ways that does not happen with straightforward questioning. Through it all each participant's collective knowledge is grown.

Discussions off the topic – "they have no idea how long this takes us"

A fair amount of time was spent on discussions that seemed peripheral to software. As an example, participants compared the management structures in their Trusts or procurement processes or the X-ray machines in use at their clinics. These and other unrelated discussions were moments of rest that did not add to the boundary objects but these times of stillness seemed to allow new information to arise, general insights almost like revelations. The most important of these – information that nobody thought was important or necessary – was the insight about undocumented care.

For weeks the discussions followed formal processes, explaining data capture, what the forms mean, and harmonising understanding between Trusts around processes. Once participants trusted the format enough to reveal deep frustration in connection with correcting patient data in referrals documents they burst out with "they have no idea how long this takes us". Only then could we start to tease out all instances of what we came to call 'undocumented care'. This work is almost routinely done at some points in the care pathway, work which is essential to good continuous care but which is not recognised, nor planned in, nor paid for.

Direct Observation: Setting: Clinics

The care analyst conducted field trips, visiting clinics in Trust 1, Trust 2 and Trust 3, to observe the practises and processes in clinics directly, to ask questions and see and hear how staff explain what they do and why they make choices. Visits were done when there were no patients present and all available staff were queried; clinicians, dentist and dental nurses and admin staff walked the researcher through the systems – be they letters, forms, software, and people – that manage patient referrals, appointments and interactions and the management reporting that is required to record and arrange payment for care.

The final pictures and the show and tell

Within the timeframe of the project, there was a level of saturation (Bowen, 2008) and agreement about the following

- the patient care pathways (figure 1), (figure 2)
- User personas (figure 3)
- Paper prototypes of the referral system (figure 4)
- the video prototype of the preferred patient experience (Wassall, 2016)
- the reference architecture (figure 5)

Show and tell events were held to engage more widely with NHS managers, commissioners and healthcare software (open source) professionals. We hoped to gain more data for the business processes but they also provided a proving ground for the robustness of the boundary objects for clear communication and confirmed that these other stakeholders recognise this reality.

Persona:
Referring Dental Team

Photo

Fictional name: Linda Jones

Job title/ major responsibilities: Associate dentist at Apple Road Dental Practice / Do clinical dentistry efficiently and in a way that is a practice builder

Demographics:

- 31 years old
- Lives with partner in flat
- No kids
- Has a Post Graduate Diploma in Conscious Sedation

Goals and tasks: She is focused, busy, task-oriented within a strong desire to 'make a difference' to her patients. One of her concerns is maintaining quality within the increasing pressure to maintain productivity even though she now sees lots more poorly older patients.

Spends her work time:

- Working chairside with a dental nurse doing oral health assessments, X-rays and Treatment Planning
- Working chairside with a dental nurse making crowns and partial dentures
- Supervising a dental nurse who records, collects and curates documentation necessary for every course of patient care.

Environment Busy 5 surgery dental practice. There are always lots of patients in the waiting room, the reception has one shared PC and the phone is always ringing.

In her surgery Linda's dental nurse uses the PC most of the time to manage patient appointments, record history & clinical findings & outcome of Treatment Planning discussions on behalf of the dentist. In the 1 minute between patients Linda 'checks and approves' each record. Linda squeezes making referrals into her dinner hour.

Quote "Can I talk you through your treatment options and then you can make the decision that is best for you?"

Figure 3 User: Persona for software development

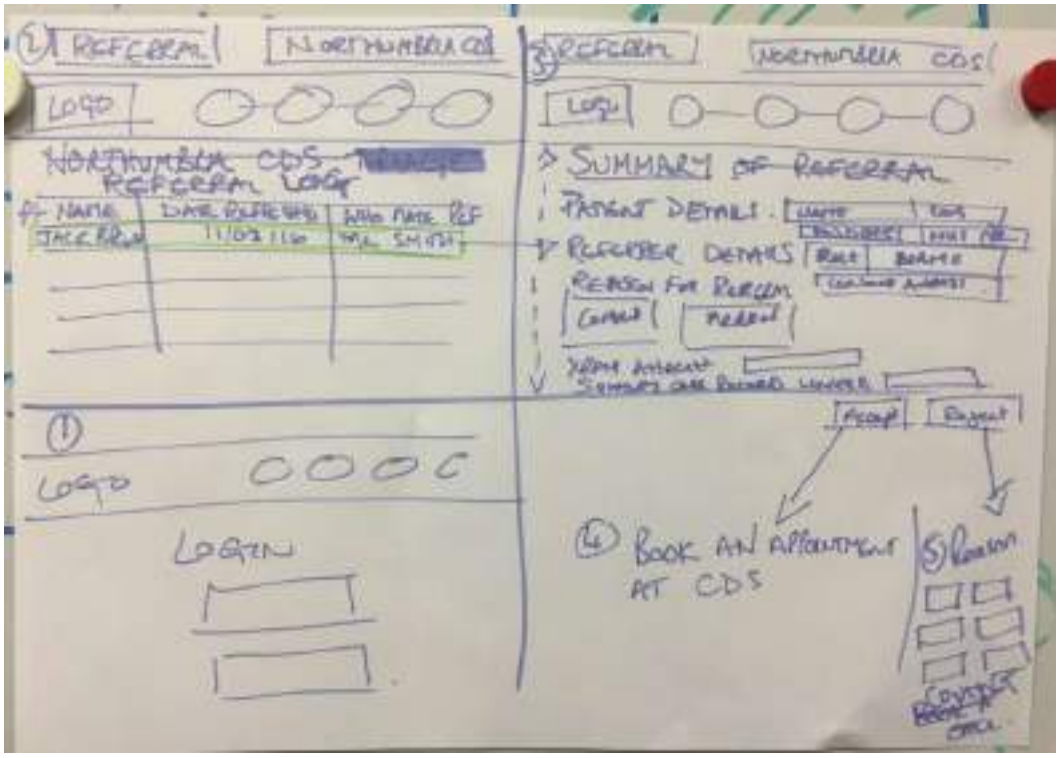

Figure 4 One of many versions of paper prototype - the referral system

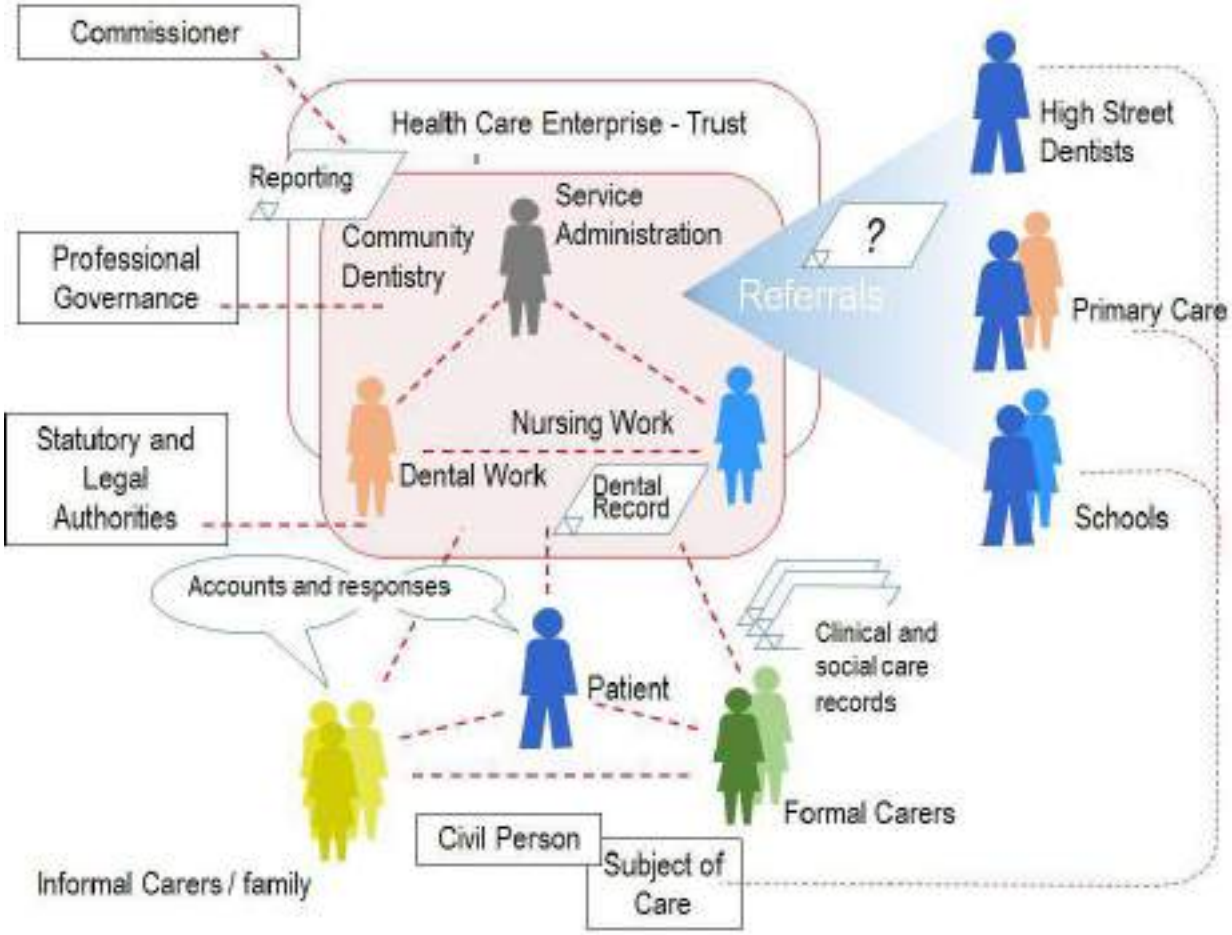

Figure 5 Care system reference architecture (Mike Martin)

Software that leaves room for care

In clinics where software is in use it is thought of as having value and people do not want to lose what they have, they like it when electronic patient data can be shared across the patch, when patients are more easily triaged, and appointments can be set up centrally. However the care analyst observed clinicians in practise and it is startling; their interactions with the software user interfaces were often a torture to watch.

In those clinical spaces insiders stop noticing the workarounds – the double data entry, pages long drop-down lists, transcriptions, data faking/placeholders that they later return to fix. But it was not a surprise to hear that it can take up to six months to be able to use the system properly. Since clinicians and admin staff at clinics prioritise patient care and "just get things done" their extra work becomes automatic enough so as to be almost invisible. Difficulties with software were hardly mentioned in the workshops, this is a testament to the adaptability and skill of all of the users.

In the meantime the extra work that this software adds takes up lunchtimes and extra time after hours. It also suggests that no software system should dictate what care should look like, software should support care and software should leave room for care.

The key learnings

Providing excellent care despite frustration

It was seen that when clinician time is taken up with administrative tasks that seem unnecessary or repetitive that not only will the clinician see fewer patients, they also feel deeply ill-used as they catch up with admin at their lunch breaks. When admin staff time is taken up by phoning and faxing around to complete forms and gather data, or fix data on the computer system after workarounds, all tasks that could have been collated more securely through digitally linked sources, there are more errors and fewer patients are processed and seen. Less time means that patients wait longer to be seen for acute dental care, the backlog on recall appointments is longer, and the CDS clinic "bills" for fewer units of dental activity (UDA's).

The sense-making tools of co-design

The co-design research provided the opportunity for sense making with the data allowing the emergence of the essential user needs for digital tools in community-based dental services. Mapping, personas, storyboarding and narratives allowed stakeholders to engage with data and create new user journeys based on their collective experiences, especially activities that take a lot of time, are necessary for safe care, but are not currently recognised, captured, or rewarded.

By producing prototypes, we make research findings more tangible – making it easier to imagine a better system and how those recommendations would affect the provision of services. Paper prototypes are so easily understood that administrators were developing proposed software interfaces.

A working prototype reduces the risk of misunderstanding and allows people to engage immediately with how such a tool is relevant to their own pressing needs in practical service delivery. When building digital tools for use by people in multiple roles and within different organisations we have found an iterative cycle of storytelling & prototyping allows divergent user needs to converge around the prototype. It also emphasises the stages of development that must be accomplished by actual clinical users.

A video prototype was made to demonstrate a preferred (ideal) patient journey which translated the vision of what the digital tools need to accomplish beyond the initial participants to the managers and commissioners and ultimately the software developers and funding agencies for that software.

Final software elements

It was agreed that every Trust Community Dental Service needs, at least

- a referral system including triage
- appointments management system
- a way to manage recall appointments
- manage patients' records
- patient communications

- chairside access to patient records
- chairside access to the payment system or FP17's
- flexibility in management reporting

Collaborative exploration means inclusive discovery

Extracting the software requirements by interviewing or observing people in a single Trust has often been done at these Trusts. However software user needs based on one Trust, no matter which one, would lead to a poor picture and software built on that poor picture would be less universal and less robust.

Working with participants from four Trusts with significantly different management and systems was long-winded. It is when participants contribute, listen and respond to one another, reflecting back and interrogating the stories over time, that they improve the quality of the narrative. That is when they start to talk about workarounds and accept that their superfluous activity has value and may be necessary for patient care.

Co-design was the tool that allowed delving into the stories of many clinicians over time, allowing for real constructive disagreement, significant empowerment of the participants, and the distillation of a believable common vision. This is more likely to support the development of software that leaves room for judgement and complexity and variability - and work in many Trusts.

Research Perspectives IN THE ERA OF Transformations

Applying design to gender equality programming

GADY Isabella[a]; KHWEISS Nancy[b]; DE LA PEÑA ESPÍN Sara[b] and TARANCÓN María[b]

[a] Parsons School of Design, USA
[b] Fund for Gender Equality (UN Women)
* isabella.gady.poeschl@gmail.com
doi: 10.33114/adim.2019.c25.153

This case study explores the application of design methods and tools in women's rights programming and feminist grant making - both areas that are, despite growing interest and evidence on potential benefits, still rather underexplored. In 2018, following its first independent evaluation and with the aim to increase its grantees' qualitative impact, the Fund for Gender Equality, a grant-making mechanism of the United Nations Entity for Gender Equality and Empowerment of Women, launched *Re-Think. Experiment.*, an initiative exploring the potential for design to serve as a tool for innovation of programs. Through providing training in key principles of the design process and a safe space for experimentation, nine women-led civil society organizations operating in eleven countries have been equipped with tools and methodologies tailored to their needs to address specific project challenges. This case study introduces context, process and initial results of the initiative and discusses whether hopes for design to serve as a tool to foster innovation were met. Furthermore, it offers a critical reflection on its limitations, the need for contextualizing tools, and growing opportunities by marrying design methods with other social innovation disciplines.

Context and Problem/Opportunity Area

Using design to innovate development

Over the past nine years, the UN Women's global grantmaking mechanism, the Fund for Gender Equality (FGE) has directly impacted the lives of over 580,000 women and girls from the most marginalized groups across 80 countries and reached millions through policies and public campaigns. Its strategy combines grantmaking to high-quality projects supporting women's economic and political empowerment and strengthening the capabilities of women's civil society organizations (WCSOs) through technical assistance and training. As per independent evaluations, its projects have demonstratively advanced gender equality (GE), especially affecting changes around social norms, the creation of women's collective structures and development of their skills on the local level.

However, following its evaluation and a self-reflection exercise, FGE realized that its projects were not tapping into the full potential of the organizations driving them, that much more could be achieved with the same or even fewer resources posing the following events: Are we grant-makers and project implementers working in the most efficient and effective ways? Are our projects designed to respond to the real needs of the furthest behind? What alternative approaches and tools can lead to more transformative results?

At the same time, there is a large pressure to deliver effective and large-scale impact in the UN's Sustainable Development era, where 17 Goals have been identified as global targets for progress on key issues including gender, climate, education, health, peace, energy, and more. Traditional project approaches to tackle these issues are often times, good-willed and well-intentioned but many of them are complex and multi-faceted yet

are approached from narrow or misguided perspectives due to lack of capacity, buy-in, and participation from citizens, duplication of efforts, and donor-driven agendas.

Searching for alternative ways to address these issues, leading innovators have increasingly turned to design for help. (Dorst, 2015). As a thought process and way of problem solving, through its tolls and methodologies, design offers unprecedented opportunities to spying new opportunities for innovation and for managing ideas and creativity. (Yee et. Al, 2017). These considerations were the starting point of the Fund's *Re-Think. Experiment.*, launched in 2018, where over a nine-month span, nine WCSOs, were introduced to and trained in key principles of the design process to address a specific project challenge using a beneficiary-centered design approach.

In applying design to gender programming, the team saw an opportunity "to do development differently" with the objective of creating positive and more lasting impact while at the same time, putting into practice much of what it had been advocating for - placing beneficiaries at the heart of the work, flexible and adaptive processes, addressing root causes using systems thinking, and co-creative approaches that allow for inclusive and participatory development. Furthermore, despite increasing interest in how human-centered design might be utilized in the programming of development projects, its frameworks and concepts are still largely unfamiliar. With the *Re-Think. Experiment.* initiative, the team, also meant to encourage WCSOs to explore, generate and test design as a tool for their own social innovation in a safe-to-fail environment.

Ultimately, as the Fund supports WCSOs that both reach end beneficiaries – especially the most marginalized communities – and have the capacity to influence at a national level, investing in their innovation capabilities was a powerful catalytic potential to help yield more positive changes towards GE.

The narrative

Complexities of designing in the social fields

As the Fund identified social innovation as a means to shift understanding and traditional project cycles, it had to change on two different levels—its own way of working as well as at the level of the grantee partners and their projects.

As a first step, the Fund connected with individuals within and external to the UN to gather knowledge and different perspectives on the topic and methodology. This resulted in a collaboration with two independent experts with previous experience in innovation work at the UN (United Nations Development Programme) and the academic world (Parsons School of Design).

The project laid out the purpose, objective, and methodology that initially structured it into six main phases of iterative character: 1) Identify a challenge, 2) Understand and Emphasize, 3) Redefine the challenge, 4) Ideation, 5) Prototyping, and 6) Testing. The process was designed with the intention of creating participants with a safe-to-fail environment that encourages participants to explore, generate and test design as a tool for social innovation through small grants of $15,000, individualized mentoring and coaching, a week-long workshop on social innovation.

The FGE invited 9 grantee partners based and working in 9 different countries to identify a specific challenge that was preventing them from achieving a desired result in their projects spanning from: “how might rural women from disadvantaged communities transition from small-scale producers to profitable entrepreneurs” to “how can we find creative solutions to keep women’s rights in the political agenda in a conflict setting”.

With the aim of unpacking these challenges - the design problem - and considering that it was the first time that most of the grantee partners were applying design methods to their programming, the Fund undertook an expanded phase of coaching on design methods and research at the beginning of the project. Having an extended focus on research at the start also aimed at deepening understanding and building empathy with the multitude of constituents involved in each context and allowed each organization to reflect how it was best positioned to respond and in what way. The provision of coaching and extended time and space for research and reflection was quite different than the usual practice that FGE provided to partners which placed the most attention on designing a results based framework for the project, the modus operandi for most UN projects.

Through virtual coaching sessions on design methods and research by the social innovation experts and FGE staff, grantee partners were encouraged to reflect their initial assumptions underpinning their current problem statements. This was considered critical as the challenges presented by our partners were of complex - or in Rittel’s words - wicked nature, that require engaging with unusual actors, exploring new points of view, trying innovative solutions. (Rittel, 1972)

In addition, considering that partners were located in nine countries on four different continents, it felt important to appreciate each context’s complexities. All research activities were, therefore, designed as a result of careful inquiry considering the reality of each context, resulting in different research activities for each organization. For example, while in conversation with grantee partners in the Philippines, observation was considered to be an apt method. Others, such as the Paraguayan partners, were encouraged to engage in in-depth interviews, mapping exercises, or - as in most cases - a combination of multiple methods. “The best aspect of this [research] exercise was to be able to have conversations [with beneficiaries] at such a personal and emotional level. It was a very special moment.” - Project Manager, Centro de Documentacion y Estudios, Paraguay.

While recognizing similar areas of experience and expertise, the team recognized the careful consideration of each organization’s context to be critical to the process. By recognizing the unique context and a strong focus on co-creation and capacity building, the team hoped to provide the condition that allowed partners to adapt broad and general design principles to their very specific contexts. Furthermore, "exporting" particular design practices - which might be seen as political as they often come value systems attached - might lead to unintended consequences and hinder pluralism in design practices.

These initial rounds of research resulted in great variety of artefacts such as journey maps, empathy maps, personas, social value canvas, or back-casting which partners were asked to bring to a week-long in-person convening in Istanbul in September 2018. However, the great variety of data that partners collected as part of their research inquiry also drew attention to need of data in the development context.

Large quantitative data sets and long-term studies provide helpful information and assessment on approaches and trends, however, they often lack regional specificities, e.g. disaggregated indicators at local level on women’s political / public role; economic situation, etc. and information about the underlying reality of people’s behaviors and experiences. In addition, typical research tends to narrow its focus towards specific solutions to well-defined problem. Design research, on the contrary, often results in a broader understanding of the problem domain and many alternative potential solutions. By putting an emphasis on integrating design research activities at the early stages of the project, the team ultimately aimed at addressing intrinsic human

needs that may not be easily generalized and develop the empathetic capability need to achieve results of meaningful impact. (Faste, Faste, 2012)

Several rounds of research, ultimately, concluded in the redefinition of the initial problem statements of all partners marking the beginning of our week-long design workshop, intended to create a space for learning and leadership, collaboration, ideation and prototyping of potential solutions.

Figure 2: Activity at the Istanbul innovation workshop organized by the Fund for Gender Equality in Istanbul with representatives of partner organizations from eight different countries. Source: UN Women's Fund for Gender Equality 2019

Beyond a one-off training opportunity, the workshop, by building leadership and creative capacities on design as a tool for social innovation, intended to have a long-lasting and sustainable impact on the work of participating partners: drawing from fields such as systems thinking, organizational sciences, design, and behavioral economics, once more, through several sessions we co-created beneficiaries' archetypes, stakeholder and ecosystem maps, blueprints before moving into ideation.

The broad diversity represented in the room - geographically, culturally, as well as in the form of expertise - was a crucial factor for this workshop - and its extended process leading up to it - to achieve the expected impact: by sharing their experiences and expertise amongst each other, participants allowed for the workshop to become a rich South-South co-creation space. "The positive energy, the friendly environment, and all the collaboration and joint brainstorming are helping me learn a lot and make linkages between ideas," reflected one participant.

The benefits of this cross-pollination of ideas emerged during ideation as proposed solutions were strongly informed by the approaches and experiences of other teams; and through prototyping, where grantee partners had the opportunity to build, present and receive feedback on their ideas. Once a prototype was selected by each organization, a mini-action plan was drafted for the testing phase. Further monitoring and mentoring sessions ensued.

One process, nine journeys

While the structured process was the same for all partners, their journeys through it, were clearly not. It was the first time that most were introduced to design as a programming methodology and this required continuous adaptation due to partners' contexts and capacities.

By highlighting some critical challenges, key insights and results, the team hopes to contribute to the body of knowledge on the co-creative design process in the development context. As an emerging area of increasing interest and the growing evidence on benefits of applying human-centered design, a high potential for improved outcomes remains untapped and through this process, the Fund and its partners hoped to learn and share its findings and lessons with peer actors.

The case of Athika

Grantee partner in the Philippines - Athika has worked for over 20 years with migrant domestic workers in Singapore and Hong Kong, helping them understand their rights, improve their savings habits, and encourage successful reintegration back to the Philippines when they decide to return.

Athika's model, consisted in a ladder training program on financial education and entrepreneurship, had reached over 5,400 domestic workers and allowed them to access savings, investment, capital and training – generating nearly $700,000 of investments.

Atikha's identified challenge was getting more migrant domestic workers to enroll in their training programme. Through observation and information interviews Atikha found that their beneficiaries, who often work six days a week living with their employers, have little interest, in spending their only day off in training - despite an expressed interest in accessing knowledge in this area. Another finding was that they had a strong longing for community and belonging as well as a belief that a higher religious power would ensure easing of "financial issues". At the same time, they also learned, that due to their often physically isolated living conditions, Facebook and WhatsApp were their main networks of connection and information.

Atikha decided to prototype the "Pinoy WISE iTV", a 30-minute weekly web-based show centered on savings, entrepreneurship, family issues, legal rights, etc. to their network. The idea came directly from beneficiaries themselves through interviews, intercepts, observational research and informal conversations, and they have tremendous ownership over it.

Figure 3: Estrella Mai Anonuevo, Atikha Executive Director, during one of the Pinoy WISE iTV programmes informing about investment opportunities for Filipino women migrant domestic workers. Source: Atikha Overseas Workers and Communities Initiative 2019

The case of Centro de Documentación y Estudios

Similarly, FGE partner Centro de Documentacion y Estudios (CDE) in Paraguay also works with women domestic workers, who are among the most marginalized in the country, often lack access to basic social services and do not have a minimum wage - the only sector to not have one in Paraguay.

CDE described their challenge as having limited beneficiary participation in their supported local associations which provide a space for workers to gather, talk about their issues, and organize for advocacy and action.

Through coaching, CDE went back to their constituents and found that they:

- have limited time to dedicate to activism
- are overburdened with work and family duties
- do not know these local associations exist or how to reach them
- have a sense of risk in engaging in advocacy actions
- prefer leisure activities involving their families and community

CDE came with ideas to the workshop in Istanbul but Atikha colleagues suggested what then became their solution: a weekly radio programme made by and for domestic workers to help them access information in a familiar and safe way – and in their own language (Guarani) - and connect with their peers in a playful and accessible form of activism. This initiative also enabled them to have voice and agency over their own rights and advocacy efforts.

The enthusiasm and devotion with which the domestic workers have taken on this project is beyond expectations and tremendously inspiring. By the end of the year, they had already conducted a pilot and developed additional content. They even engaged a popular artist who has created a musical cover theme for the radio show and developed their own branding.

Key Learnings

As of today, the evaluation of the *Re-Think. Experiment.* is still underway with grantee partners wrapping up their testing phase. Final reports will be encompassing a two-part report: a narrative report and exit interview. The narrative report will focus on the results of the activities as well as the overall assessment and reflections on challenges and learnings. The exit interview will place more attention on the process and its effect on the organization and individuals.

Below are a few of the preliminary learnings:

Time investment in project design makes a difference.

- For grantees, the time allocation for project design and start-up is extremely important and not enough emphasis was placed on this moment previously. Rather, this stage of grants management was often rushed to get projects quickly starting up rather than taking the time to research, understand, empathize, and pilot activities to help inform the larger full scale project.
- From a design perspective this learning seems equally crucial. The fruit of an extensive phase of introduction of participatory design principles and research may not always be immediately evident, but as this project suggests, significantly impacts the short- and long-term outcomes. While the extended focus on research allowed the team to co-create solutions informed by insights gained through research or as one of the grantee partners summarized: "We thought, we knew everything about the issue, but the interviews showed, there are things we had not understood" - Project Manager, Pastoral Women's Council, Tanzania.
- Some preliminary feedback from grantee partners, however, also allowed the team to assume that the investment on strengthening the innovation capabilities may have longer-term effects as they continue to apply their learnings in participatory design methods, systems thinking, and leadership to other programmes and projects.

Enabling environment and good timing are critical.

- The right conditions and right timing allowed for this initiative to be designed and implemented with support from UN Women management and staff. The Fund's status of limited funding, an uncertain future, a downsized yet motivated team, a trusting donor, ample time allocation, and autonomous space were some of the key factors that allowed this experiment to come to fruition.
- The atmosphere of trust and openness that this project aimed to generate is the result of many factors, including the professionalism and personalities of the external experts. But it was also the result of a process that started years before: FGE had organized two in person grantee gatherings, including one a few months earlier, where informal and formal interactions were fostered in a relaxed and inclusive setup. The Fund started presenting concepts and practices of co-creation, reflection, "thinking outside the box" and horizontal relationships months before the initiative started, which prepared grantees to take on Re-Think.Experiment - by the time it started, they were aware and interested in trying different approaches. The coaching sessions also placed a central focus in being grantee-driven and had a friendly, safe-space feel, which was essential for to engage participants and devote time and efforts in such an unusual experiment.

Design approaches feel right.

- The team was pleasantly surprised about how most organizations almost immediately committed to the ideas that were being proposed. While other elements - such as the gender programming expertise of the social innovation consultants - played a role in this, the reactions observed during coaching conversations and workshops revealed a gratifying sense that proposals were resonating with counterparts and fitted their own previous experiences and thoughts about their projects, while providing new "aha" moments, as expressed by several of them. It felt right. And this made it possible for a set of eight organizations from completely different backgrounds to not only understand but also to immediately jump into using user-centered approaches, to a point that exceeded expectations (e.g. starting to apply them to their regular organization process and to other projects).

Better in person.

- The fact that the team members were based at different locations led to its own challenges: an appropriate time for coaching calls was difficult as time differences spanned over twelve hours. Additionally, internet connectivity, and particularly lack thereof, often led to having to reconnect several times during a call or postponing altogether. In this sense, while the team considered the first phase of coaching and research of strategic importance and overall the calls were the most suitable tool for a global project, pre- and post survey evaluation ahead and after the workshop in Istanbul, give us reason to believe that the end results have benefited from the in-person training. Grantee partners not only had the opportunity to develop their own solutions but also were able to connect, collaborate and find inspiration in the work of others, which in some cases changed the direction of solution.

New partnerships.

Exploring these areas has also provided increased partnership opportunities for the Fund. Prior to this initiative, the FGE did not have technical partners with its traditional grantmaking programme. This experiment allowed the Fund to work with academia (Parsons School of Design), inter-agency mechanisms (UN Behavioral Insights team), sister UN agencies (UNDP Innovation) and strengthen internal UN Women connections. Finally, this experience has been the basis for the Fund to embark on a new design-driven pilot in partnership with two researchers from the Parsons School of Design to test new ways for UN Women to support women's organizations in a way that better responds to their needs to become more resilient and sustainable. This work is ongoing and will conclude in the Fall of 2019.

Figure 5: Participants at FGE workshop in Istanbul in September 2018 developing personas and a causal map. Source: UN Women's Fund for Gender Equality 2019

Challenges

As with any project, there were certainly challenges — some within the team's control and others not. For example, three partners based in the Arab States each faced contextual issues: the partner in Yemen was unable to travel to Istanbul nor implement the activities due to restrictions. In Algeria, a government agency restricted the partner to access its funds due to internal approval processes. And in Palestine, as noted previously, the partner was unable to implement its solution because of political sensitivities concerning project activities from national and international stakeholders.

Another challenge derived from the fact that the FGE team tried to assume a double role in this project - one as facilitator and another as participant. The team aimed to learn about social innovation processes in an experiential way; to help solve important challenges; and to help develop more peer-like dynamics with its grantee partners. As such, FGE worked on a challenge of their own to bring to the workshop, hoping to be able to learn from the sessions and apply design methods to find a possible solution to test. Unfortunately, the highly time-consuming nature of personalized facilitation both prior, during and after the workshop made it hard for FGE to find the time to work on its own challenge. A less ambitious challenge, higher team

commitment to this aspect of the experiment and a more structured process for the team could be elements to improve in future similar exercises.

However, the main challenge is sustainability: as the project ends, FGE will not be able to continue its support as grantee partners continue to iterate and implement their solutions; additionally, it will be difficult for the Fund to track and asses the ultimate impact and potential ripple effects of this intervention. While this was foreseen from the inception and grantees were given the flexibility to incorporate their solutions into their ongoing projects, including by deriving some of the available funds to them, the team hoped that by the end of the experiment they would have had the chance to iterate a few times their solutions; yet, time was limited.

Working on future projects of similar kind, therefore, the team hopes to provide its partners with more long-term support throughout implementation and build an initial research and testing phase.

Conclusions

While implementation and analysis of impact are still underway, this project has provided us with initial findings supporting evidence on potential benefits - such as tailored approaches centered around the needs of beneficiaries through initial investment in design research - resulting from applying design to gender equality programming. Furthermore, design in the context of participatory processes functions a social process as designers, donors and participants interact on an eye-to-eye level as well as external stakeholders questioning long-held power dynamics in the field of international development.

Applying a design process, therefore, allowed FGE staff to completely change its approach with its grantee partners and delve deeper into projects with greater effort placed on the learning process and how organizations internalize this; consequently, the FGE's own knowledge and awareness of different types of understanding, planning, implementation, and evaluation approaches of development programming grew significantly over the course of this project. Using co-creation and blueprint tools, the Fund was able to critically re-examine together with the grantees its own processes and systems, drawing lessons e.g. to simplify their reporting templates, improve communication with grantee partners and streamline financial reporting.

In the light of ever more complex and highly interconnected human development challenges design, therefore, seems to be a promising tool to shift from linear "problem-solution" models toward more comprehensive analyses of realities and iterative processes with room for failure and learning allowing us to accelerate progress towards the 2030 Development Agenda keeping women and girls furthest behind at the center.

In this case study, we present a project of Reflex Design Collective, an experimental social equity design consultancy based in Oakland, California. Since founding Reflex Design Collective four years ago, we have reimagined the role of "designers" to transform relationships structured by oppression. To illustrate this reimagination, we present a case study of our work as ecosystem-shifters. In 2017, we facilitated a co-design innovation summit where unhoused Oakland residents led collaborative efforts to alleviate the burdens of homelessness, with city staff and housed residents serving as allies instead of experts. Our approach to design facilitation differs from a typical design thinking process by pairing our clients with those on the front-lines of social inequity in a collaborative design process. Specifically, we elevate the importance of democratized design teams, contextualized design challenges, and ongoing reflection in a design process. We highlight successes of our design facilitation approach in the Oakland homelessness summit, including outcomes and areas for improvement. We then draw higher-level key learnings from our work that are translatable to designers and managers at large. We believe our approach to equity design will provide managers and designers an alternative mindset aimed to amplify the voices of marginalized groups and stakeholders.

Keywords: Social equity, homelessness, design, detoxify, liberation

Introduction

Reflex Design Collective is an equity design consultancy in Oakland, California. We help clients partner with beneficiaries in mutually empowering ways. Instead of a typical design thinking process led by a small team of "expert designers" who design for passive "users," we facilitate a co-creative design thinking process pairing clients with those on the front-lines of marginalization to build solutions that address social inequities. By positioning technical experts and experts with lived experience as peers, solutions emerge from transformed relationships between institutions and the communities they serve.

In this paper, we present a case study of our equity design approach. We discuss how we worked as design facilitators to detoxify the fraught relationship between unhoused residents in Oakland and the city government that represents these residents.

Theory of Change

Design is a flexible, transdiciplinary approach to create unique solutions in complex environments (DiRusso, 2016). Applications of design are not limited to financial market-driven topics; institutions have leveraged design towards various social issues, including international development (IDEO.org, n.d.), youth empowerment (YLabs, n.d.), global health (D-Rev, n.d.), and more.

In this latter class of applications, however, there are often fundamental flaws in the approach of designers working for "social good." Within "social innovation," it is generally the power of design tools themselves -- practices of empathy, creativity, prototyping -- that is celebrated as the change-making force (Brown and Wyatt, 2010). However, Timothy Mitchell (2002) and Tania Murray Li (2007) note that complex social ills, like poverty, have as much to do with social power dynamics as they do with technical problems that can be solved with technical expertise alone. The practice of presenting technical tools as the sole remedy for systemic ills -- which are fundamentally generated by differences in structural power -- limits the effectiveness of social design, at best. At worst, this mismatch of problem and approach contributes to the invisibilization of privilege and oppression, which serves to protect the inequitable status quo (Janzer and Weinstein, 2014; Booth, 2015).

In response to these critiques, there are movements of designers shifting their practices to align with holistic, power-aware frameworks for social change. The Design Justice Network, for example, has developed principles that interrogate the definition, role, and positionality of the "designer" in ways that challenge Western colonialist hegemonic knowledge and expertise, which delegitimizes the experience of those on the front-lines of oppression (Design Justice Network, n.d.; Costanza-Chock, 2018). These principles demand an intentional subversion of oppressive power dynamics, including centering the agency of structurally-disempowered communities, to facilitate a shift towards liberation (Design Justice Network, n.d).

Reflex Design Collective was founded in alignment with these perspectives. Our theory of change holds that designers have greater potential to affect the roots of complex social issues working from the role of the facilitator, rather than as the lead creative expert. Design facilitators bring stakeholders together to engage in collaborative design processes. As facilitators, we leverage design to transform power dynamics between marginalized communities and influential institutional partners (Staton et al., 2016).

adrienne maree brown (2017) offers a natural analogy to illustrate the impact facilitators can have as transformative, connective tissue. brown observes that community-building lessons can be gleaned from mycelium, a fungus that consumes toxins, converts them to nutrients, and connects organisms to create supportive networks. Like mycelium, facilitative designers may enter contentious spaces and use generative tools of creative problem-solving to transform toxic relationships into collaborative connections. If trust is formed between influential stakeholders and grassroots communities, the former group may benefit from added "nutrients" such as increased perspective, and the latter may gain access to social capital, credibility in influential circles, and tangible resources to support their work. Through facilitated design efforts, all parties move closer to equity and liberation through radical collaboration.

In the spirit of Paulo Freire's notion of praxis (2000), Reflex Design Collective's equity design approach connects theory and practice to sustain the work of radical design facilitation. We draw on our professional experiences in design and civic engagement and our lived perspectives as women, people of color, and queer people to develop tools and skills to foster radical collaboration. To structure subversive design engagements, our core practices include: building upon pre-existing work of grassroots innovators, prioritizing decision-making power of those closest to the problem, and framing design challenges around oppressive systems that generate social problems. We distill our adaptations of traditional design thinking to three spaces: democratization, contextualization, and reflection throughout the equity design process. The following case study demonstrates this approach.

Context and Opportunity Area

In Fall 2017, we launched an initiative with an Oakland City Councilmember to address the homelessness emergency within District 3. The San Francisco Bay Area is in a housing affordability crisis (UC Berkeley's Urban Displacement Project, 2019). Oakland has experienced dramatic increases in housing prices following the 2008 financial recession. Between 2012 and 2017, median rent increased 51.1% -- the second highest increase of any city nationwide (Weidner, 2018) -- to $2,950 per month. With a median household income of just $63,251 from 2013 to 2017, it is easy to see why many Oaklanders have experienced burdensome housing costs and outright displacement as a region-wide housing policy has not kept pace with the booming tech economy in the surrounding Bay Area.

Predictably, this housing crisis has played out similarly to historical trends of structural racism, disproportionately affecting communities of color. UC Berkeley's Urban Displacement Project (2019) found that a "30% tract-level increase in median rent (inflation-adjusted) was associated with a 28% decrease in low-

income households of color" while "there was no significant relationship between rent increases and losses of low-income White households."

Conservative estimates indicated a 39% rise in homelessness in Oakland from 2015 to 2017 (EveryoneHome et al., 2016; EveryoneHome, 2017). This phenomenon became increasingly visible on Oakland's streets in the form of makeshift shelters on sidewalks and in parks. These settlements, called "encampments" by city officials and "curbside communities" by local activists, have been a source of political and social tension (Figure 1). Unhoused residents of these communities have protested subhuman living conditions and forced removals without suitable housing alternatives, while housed neighbors, local business owners, and the city itself have raised concerns to public health and safety attributed to the presence of these settlements (Roth, 2017; Villalon, 2019). In lieu of alternatives, activists have advocated for curbside communities to be sanctioned and provided with sanitation services. The contentious situation persists today, despite a flurry of activism (Brinkley, 2017; Drummond, 2017), legal challenges (BondGraham, 2018; Veklerov, 2018), government action (AB-932, 2017; Katayama, 2017), and a United Nations report condemning Oakland for inadequately addressing human rights violations presented by the living conditions in curbside communities (United Nations Secretary-General, 2018).

Figure 1. A 2017 "curbside community" or "encampment" in Oakland. Source: Wikimedia Commons.

The District 3 Councilmember shared a vision with Reflex Design Collective to bring creative minds together for a "hackathon" design sprint to devise short-term solutions to suffering in curbside communities. "Hackathons" are typically gatherings of technologists who rapidly plan, build, and test solutions to a challenge over a matter of days. This conversation created an opportunity for us to share our alternative vision of equity design that centered the needs and agency of those most directly impacted by the problem: in this case, unhoused Oaklanders.

The Narrative

Instead of a "hackathon," Reflex Design Collective engaged in a five-month process to build relationships, learn about sociopolitical context, and host an innovation summit to develop creative solutions to the homelessness emergency impacting District 3. We sought to foster equitable partnerships between front-line leaders and influential stakeholders to create solutions to human rights violations in curbside communities.

Democratization

We began our work by partnering with community organizers and unhoused leaders. Our first attempt at forming these relationships involved hosting two meetings at City Hall, but this proved inappropriate and ineffective. Fortunately, through connections to a local Homeless Advocacy Working Group and with the guidance of two seasoned activists, Genevieve Wilson and Talya Husbands-Hankin, we were able to better build relationships by meeting unhoused people on their terms. This included months of 1-1 meetings with

community leaders and guided visits to curbside communities to connect with unhoused folks, provide support during forced removals, and learn about opportunities for allyship.

Instead of approaching front-line experts to simply learn from them, we presented our opportunity to participate in an innovation summit and asked how, or if, our resources could support their movement. We took a stand for grassroots power by holding ourselves accountable to their invitation and consent: if they were to have no interest, we would have abandoned the project. By honoring their agency, committing to transparency, and following through, we established trust via reciprocity rather than extraction.

Our grassroots partners were co-designers of the outreach and innovation summit planning process. Their perspectives provided an understanding of historical and political dynamics that we leveraged to facilitate a multi-stakeholder design engagement tailored to the needs of unhoused residents. Their input informed who we brought into our co-design process, how they should be included, how we framed the challenge, and how we co-developed solutions.

Contextualization

Although we were tasked by the Councilmember with hosting a design summit, our outreach and our partners indicated the need for the event to fill a different role to add value to unhoused folks, given their pressing day-to-day survival needs. At their direction, we leveraged our summit as a resource drive, which resulted in donations of over 160 mylar sleeping bags.

The City of Oakland and community organizers held highly contentious relationships: at open city meetings, city staff and organizers would occasionally engage in public shouting matches. Misunderstandings were commonplace, and controversial decisions were made by city officials that significantly harmed unhoused residents. For example, earlier in 2017, a self-governing village of unhoused folks living in tiny homes and receiving community-sourced services was evicted via bulldozer from an unused plot of public land due to enforcement of city regulations.

To foster collaboration between groups, we needed to design a space that was responsive to past harms and distrust, building a foundation for new relationships. This was accomplished using multiple tactics, including kicking off the weekend-long innovation summit with dinner at a church in District 3. Participants shared stories, discussed the pain and challenges of being unhoused, and learned about how folks survive on the streets. This set the foundation for more trusting interactions the next day when organizers, city staff, unhoused and housed residents, developers and nonprofit workers came together for an interactive co-design process.

Trauma-informed facilitation allowed harms to be addressed, and our acknowledgement of systemic violence created an affirming environment for unhoused leaders to vulnerably share their wisdom. With help from a community organizer who provided 1-1 emotional support, we created space for trauma and healing. These strategies proved essential for bringing people together across divisions and would not have been possible without our community partnerships and contextual understanding.

Reflection

We began our equity design process during the innovation summit by guiding participants to understand their positionality and how to foster authentic connections rather than status quo power dynamics. During a guided personal reflection exercise using the Paseo Protocol (School Reform Initiative, 2017), participants identified elements of their identity that either benefit from or are harmed by systems of oppression. They then unpacked in pairs how their identities could create barriers for connection with others, and what they might do to counteract this.

We leveraged systems thinking (Meadows, 2008) to allow participants to reflect on the connections between power, policy, and the material realities of homelessness. Therefore, participants identified leverage points for subversive and reflective, rather than superficial, intervention.

Co-Design

During the innovation summit, after participants reflected on their identities and the systemic nature of the problem, we guided them through a co-design process to collaboratively develop ideas to address challenges of homelessness.

We led a power mapping activity to acknowledge and subvert oppressive relational dynamics. Participants worked in teams to map out who has relative institutional power and who does not. They considered who is harmed and who benefits from the homelessness crisis. By visualizing these power dynamics, participants were able to identify who is exploited and has lived experience in the homelessness crisis. Equipped with this understanding, participants could identify who they needed to be designing with outside of the summit, and they created a plan to continue co-designing after the summit.

As participants began exploring generative possibilities for solutions, they engaged in a resource-sharing activity that surfaced the resources present in the room, whether they be social connections, specialized expertise, or physical assets. Equipped with this knowledge, participants tailored their solutions to leverage the resources they now had access to.

Outcomes

The summit resulted in nine proposals for the Councilmember, ranging from tactical solutions (e.g., Figure 2) to community building programs.

Figure 2. A participant in the innovation summit shares an idea for a schedule for folks in curbside communities to safely take showers. Source: Reflex Design Collective.

Each proposal was a comprehensive *vision* complete with physical prototypes, logistical details, roles for multiple stakeholders, and next steps for expansion. For example, one group created a program for local businesses to provide passports to up to four unhoused neighbors to use their restroom facilities, along with a sticker campaign publicizing those contributions on participating storefronts and elsewhere.

Beyond the solutions, participants reflected positively on the collaborative dynamics achieved within the room; following the summit, one unhoused participant partnered with the Senior Policy Director in District 3 for a number of months to co-develop supportive programming for unhoused residents.

The Key Learnings

This case study has several key learnings for the broader design community:

- We must look inwards to examine how we can shift our organization to embody the change we seek to bring to our clients' ecosystems;
- We must view institutions as embodiments of their values;
- We must work to address roots instead of symptoms of problems.

Look Inwards to Understand Transformative Change

How organizations operate is dependent on the values built into the organization, whether these operational tendencies are intended or unintended. In this case study, our ability to create equitable outcomes was dependent on our organization first functioning internally in an equitable manner.

While designing and presenting the summit, we leveraged our internal non-hierarchical structure to make logistical and organizational decisions, to collaborate on research and summit development, and to facilitate the summit. By implementing our organizational priorities of honest collaboration, leveraging capacities, and democratic decision-making, we developed psychologically-safe spaces for members of our team to contribute on concrete parts of the summit, instead of establishing rigid hierarchies that extinguish voices and recreate privileged experiences.

To Build Equity on the Ground, Shift Institutions from the Inside

We know that not all institutions share our values or vision. In pitching the "hackathon," the Councilmember emphasized a *tabula rasa* approach to developing housing solutions. Instead, we dove deeper to find out what had been done before and what tensions existed. This deep dive emphasized prior work of the unhoused community instead of brushing it aside.

For better or worse, institutions like city governments embody societal values that reveal themselves as implicit and explicit culture, policies, and financial decisions. Therefore, we focus our energies on understanding how we can shift internal values so institutions can develop community partnerships more equitably. Like mycelium, we infiltrate toxic networks and transform their internal workings, in turn transforming their external engagements.

Shifting institutions from the inside is a difficult, yet essential task towards building long-term change. When we enter a project, we must examine how clients may be embodying inequitable values that will prevent them from continuing to form equitable partnerships after the project ends. We are learning how to transform the different layers of an institution to explicitly embody anti-oppressive values, understanding that these explorations will be essential in understanding how our organization can create sustainable change.

Systemic versus Symptomatic Issues

We choose to address the underlying roots of problems instead of focusing on visible symptoms of these problems. When we started the project, the Councilmember intended to "hack homelessness," attempting to leverage the hackathon movement for innovative new ideas. As we conducted community outreach, two insights were revealed: (1) unhoused residents were offended and exhausted at interventionists bringing solutions without their voice, experience, or power; and (2) communities already had innovative solutions ready to implement in Oakland. Instead of hosting a design sprint, we developed a space that recognized stakeholders' dynamic complexities, healed existing tensions, and productively collaborated towards holistic solutions.

Conclusion

In this case study, we presented Reflex Design Collective's work with an Oakland City Councilmember, including the role we played as design facilitators, our successes and areas of improvement, and our key learnings.

We share our case study because we believe the design community can learn from how we have reimagined the role of designers.To design for social change and rectify oppressive systems, we must interrogate design practices to ensure we are not unintentionally deepening inequity. Instead of centering one's own creativity, we call for designers to create collaborative connections with people on the front-lines of oppression so that power, creativity, and equitable outcomes can be built and shared by many. In our Oakland innovation

summit, we functioned as facilitators rather than lead designers, allowing us to create space for collaborative innovation between unhoused folks and city officials.

We call for designers to critically examine design briefs they are given, and direct their efforts towards creating relationships and processes that center the agency of historically-underinvested folks with lived experience in oppression. We call for the design industry to apply critical thought into how design can contribute to grassroots movements, and identify what radical shifts must take place in design practice to avoid perpetuating oppression.

By shifting our collective understanding of what design is, we can begin to transform oppressive relationships, mindsets, policies, and systems. Our equity design approach of including space in the design process for democratization, contextualization, and reflection is one way to begin transforming these systemic and marginalizing systems.

Workshops

Workshops Introduction: A review

HANDS David; DONG Hua and PETERSON Fiona

Lancaster University, United Kingdom
Auckland University of Technology, New Zealand
Loughborough University, United Kingdom
doi: 10.33114/adim.2019.w08

ADIM 2019 witnessed a diverse and eclectic range of workshops that explored the many different facets of design, through both a strongly theoretical and practical means of enquiry. As such, these were testament to the emergent and dynamic nature of design within a highly globalised and transitional set of contexts.

Dave Wood workshop provided a series of mini workshop exercises that took a strongly constructionist approach to facilitate the participants understanding of how design can be improved through the application of semiosis theory. **Melanie Woods** and co workshop drew upon design thinking tools and methodologies to actively engage and work with communities across Europe who are currently monitoring soil in real time across a range of geographic and climatic areas. As such, its primary purpose was to test and reflect upon assets and materials that could enable other researchers and practitioners to better understand climate service innovation. Workshop led by **Bertil Lindenfalk** provided a unique conceptual lens of pace layers, and a system of temporal, spatial and socio-cultural indicators. A pace layer model was used to frame the outcomes and guide the participants through a series of individual activities. Pace layers postulated that different socio-technical superstructures move and change at different speeds. At the end of the session, participants created a pace layer visualization of processes, with the aim of having an organically built representation of what tasks, activities, opportunities and challenges reside in or across what layers when designing at scale. **Rael Glen Futerman** workshop aimed to critically investigate how innovative organisations build cross-functional teams around projects. As such, diverse perspectives drawn from personal world-views and organisational roles contribute to radical collaboration across traditional boundaries of work. Through this highly interactive session, participants tested rapid team activities in which they could align core values of the team and embed these within innovation learning cycles. **Joanna Boehnert** workshop explored the means to build capacity to respond more effectively to global environmental challenges by exploring the politics of design with discourse mapping. This workshop investigated some of these difficulties by focusing attention on the politics of design. It was set against the backdrop of an increasing awareness within the design research community of the many ways political and economic dynamics influence the potential for the design of sustainable transitions. Liv **Merete Nielsen** and co workshop found ADIM 2019 as an excellent means to use the workshop session to establish a Design Literacy International Network. For this purpose, it aimed to bring together a group of international scholars attending ADIM who are interested in exploring an emerging area of Design Literacy. With increased production and consumption rising at a rapid rate, they argued that it is increasingly imperative that citizens develop an understanding of how these products and services are produced and consumed. Workshop 468 led by Andrea Augsten and colleagues, critically interrogated the role of design and designer within the frame of designing organizations. Increasing numbers of designers are becoming involved in strategic projects in the context of organizational change, such as creating a more creative, design-driven work attitude, bringing a human perspective into existing processes and acknowledging employee's individual diversity. The workshops aimed to explore and answer the following questions - do designers feel prepared for that? Are they aware of the organizational design narratives of companies? **Felix Bendito** and **Pablo Bris** workshop was to show how a set of techniques from a DDI approach focused on service design projects and how to apply them in a disaster context to enhance current practices in shelter management. Their primary aim was to establish a direction for the ideation of a new meaning of post-disaster shelter through the unique

perspective of the participant through an ongoing value co-creation process. Workshop hosted by **Angele Beausoleil** was focused towards engaging design researchers, scholars and practitioners in exposing the epistemological challenges and opportunities associated with 'design thinking' in management and leadership contexts. The participants were carefully guided through a series of visual thinking and design techniques to develop concept maps and a visual thesaurus for 'design thinking' and design-related terminologies within the management discourse. Findings arising from the workshop reflected a multidisciplinary understanding of the subject for knowledge translation and possible future research initiatives.

doi: 10.33114/adim.2019.w01.476

Introduction

Droughts, floods and other climate-related hazards present critical challenges for communities across the world. Design is well-placed to respond to such wicked problems (Buchanan, 1992) however a user-led approach to the development of climate services is rare (Christel et al, 2017). Instead, scientists and governments rely on research and innovation between science and industry to develop climate services for early warning systems and decision-making. The design community is uniquely placed to contribute to such developments, particularly in proposing new perspectives where citizens are themselves potential users of such services and at the forefront of change-making practices.

Workshop purpose and aims

This workshop introduced delegates to the concept of Citizens' Observatories (COs), and, moreover, the GROW Observatory and its communities across Europe who are monitoring soil in real time across a range of geographic and climatic areas.

The purpose of the workshop was threefold:

1. To test and reflect on assets and materials currently in development for a CO Toolkit
2. To ideate services that enable other researchers and practitioners to better understand climate service innovation
3. To present climate scenarios and data from real communities facing critical environmental challenges.

Theoretical relationship

COs represent new developments in social innovation where citizens and communities are gathering environmental data on issues that matter to them and innovating with them (Schartinger et al, 2017). Many of these projects are driven by design thinking and methods that support action-oriented outcomes for communities to transform these matters of concern themselves (Woods et al, 2018). We propose large-scale climate services can be developed using design approaches, and in collaboration with citizens whose livelihoods and communities are affected by extreme events, such as forest fires, drought and flooding.

Workshop approach:

The workshop had three main phases:

1. An introduction to a) the workshop objectives and b) COs with a focus on soil moisture as a dataset for climate change adaptation, and an outline of related critical environmental issues e.g. drought, flooding, forest fires and heatwaves.

2. The group were presented with a toolkit comprising post-its, pens, an empathy timeline, and the ‘climate services’ deck of cards (figure 1) which included:

Personas: representing the roles as well as concerns and motivations of typical stakeholder groups

Places: information about a country, such as natural assets, climatic profile and main agricultural activities

Data: climate and environmental data relevant to the personas, place and scenario

Scenarios: emerging climate related critical issue

Figure 1 Climate Services Cards

In groups, each member selected a persona and data card, and collectively chose a country and scenario card. Participants were instructed to adopt their persona role and, using an empathy timeline (see Figure 2) respond to their emergency scenario. Groups discussed and recorded inputs and outputs of data from the perspective of their personas ‘needs’, using sensors, observations and other information required for decision-making and action. Subsequently, teams extended the timeline to consider the scenario in ‘pre and post emergency’ periods for prevention and recovery monitoring respectively.

Figure 2 Example Empathy Timeline

Groups ideated a climate service based on their scenario and data and shared the results. Using a 'dotocracy' of red and green dots, participants offered feedback on the method and resources used.

Results

The primary objective of the workshop was to test and evaluate the co-design method and tool, the workshop approach and activity is demonstrated by visual evidence of co-design and sharing in figures 3 and 4.

Figure 3 Group Sheets showing a critical environmental issue on the empathy timeline

Figure 4 Group Presenting their service to the room

The scenarios and service outcomes were judged as particularly successful and so we report on those in Table 1 which shows groups 1 to 3, with a brief description of their chosen scenario and service proposition. Feedback on the method and tool was gathered, attendees requested more information such as 'country' context, and details in the 'data' cards.

Table 1: *Results of the co-design session by group*

Group	*1*	*2*	*3*
Title	Rain Check Service	Agropoli 4.0	Ration My Water Tank
Climate Scenario	Flooding in a rural area of the Netherlands, 100 day rain non-stop and health outbreaks	Long term soil degradation in rural Greece with huge socio-economic impacts	Long term drought in Greece/Portugal
Service Proposition	An Observatory receiving and providing a wide range of information, from evacuation details to capturing excess for later use.	CO system to foster cooperation between stakeholders and a transition to a regenerative agricultural system.	Smart water tank that allows owner/user to monitor and ration litres available with peer to peer dimension.

Takeaways for the participants

There were two main types of takeaways for participants as part of the project:

Theoretical:

- The introduction to COs and the data driven business opportunity;
- Underlying value creation in relation to climate change regarding design innovation;

Methodological:

- A practical method and tool based on gamification and role play to support co-design of service innovation based on observatory data was tested, with high level outcomes.
- Groups valued succinct and background information that supported rapid understanding of the topic.
- A design process and resources can help groups of different stakeholders understand the premise, adopt roles, create scenarios, understand data flow and ideate a service in a constraint time.
- The purpose of the card set is to create dialogue, rather than to provide a highly accurate representation of a current or preferred reality.

Reflections

There were two main types of takeaways for participants as part of the project:

Quality of service propositions generated: The methodology allowed groups to generate high-level prototype services in a short session. One of the groups ideated a service for which GROW had already begun to develop the scientific basis within the project.

Trans-disciplinary approach: We validated and reinforced the CO approach through an integrated stakeholder response, and highlighted the contribution that designers offer to co-create climate services.

Potential for climate services: A sustainable observatory system can be a long-term powerful contributor to disaster management, prevention and monitoring recovery.

Empathy design (Gasparini, 2015) and design for emotion (Desmet and Hekkert, 2009): The persona cards and role play encouraged an empathetic response to stakeholders' concerns and motivations. The tool was also designed to generate engagement through emotion: rather than designing a service chronologically, starting with prevention, teams were placed in the scenario, a crisis situation, triggering an intense response to relate participants to a call to action more easily; teams then considered pre and post crisis event scenarios.

The introduction of the tool in the emergency phase of the timeline created a powerful narrative to which teams were able to respond in role.

Next steps: GROW will iterate the tool and workshop with a diverse audience including the categories of personas presented and with communities experiencing the scenarios in real life. This will be achieved through future sessions that 1) provide more time, 2) build on the stakeholders' expertise, and 3) acknowledge a deeper complexity likely when working with a community that is 'threatened', in order to generate deeper insights.

Acknowledgements

The authors would like to thank Jane Boyes for the design of the Co-Design Climate Services Cards and our participants in the workshop. This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 690199 (see www.growobservatory.org).

A Semiotic Rosetta Stone Workshop: Enhancing visual communication through design semiotics

WOOD Dave

Northumbria University, United Kingdom
d.a.wood@northumbria.ac.uk
doi: 10.33114/adim.2019.w02.464

Workshop purpose and primary aims

In this 90-minute design semiotics workshop, ADIM delegates will learn how the quality of user-participation can be enhanced by improving the visual communication within designed outputs. The workshop's aim is to provide a direct, hands–on experience, to explore how iconic, indexical and symbolic semiotic representation can improve design's message, concept or affordance. It will complement the conference sub-track 5.e Seeking signification in transformational times: design semiotics and the negotiation of meaning.

Theoretical relationship

Over 90-minutes through two exercises and a plenary, the workshop will explore how C.S. Peirce's pragmatic semiotic theory of Semiosis can be synthesised into design practice. The triadic nature of Semiosis focuses on the inter-relationship between the design concept, how this is visually represented, and how this representation affects how the intended meaning is finally interpreted. The workshop exercises take a Constructivist approach to facilitate participants' own revelation as to how design outputs can be improved through applying the triadic relationship of Semiosis.

Ethical Issues

As the proposed workshop will be an 'opt in' attendance for participating, an ethical informed consent agreement form will be issued before the workshop begins. Only the work of those participants who sign and consent to their workshop outputs will be used in any ongoing analysis or reflection in the report or future papers.

Workshop approach

The approach for the 90-minute workshop would follow this structure:

00:00 Welcome, workshop aims, semiotic audit (@ 20 mins)

- Welcome message
- Projection of a semiotic audit form and explanation:
    - Participants will have a paper copy of a semiotic audit form
    - They will complete first section before workshop begins
    - This captures the initial level of pre-existing understanding of semiotic theory
- Then an overview of rudimentary Semiosis and its triadic relationship between concept, its representation, and the role of interpretation in the context of designed artefacts.

00:20 Exercise 1: Symbolic representation in designing effective visual communication (@20 mins)

- Using print outs of existing design campaigns, products, etc. participants will discuss in small group the principle of the symbolic representation of the concept present in the design example.
- Using scissors/markers/etc. participants will indicate what they believe is the symbolic representation visually communicating the intended message in the design example.
- Participants will then be asked to connect the designed connotation to the basics of Peirce's semiotics using their own design terms.

00:40 Exercise 2: Indexical and Iconic representation in designing effective visual communication (@20 mins)

- Again*, using print outs of design campaigns, products, etc. participants will discuss in small group the principle of the indexical, and then the nested iconic representations of the object present in the design example.
  *each table will have several versions of the design examples so that multiple passes at analysis can be made by the designers
- Using scissors/markers/etc. participants will indicate what they believe is the indexical representation in the design, and then break the design down further into its iconic elements that help visually communicate the intended message or affordance.
- Participants will then be asked to connect these to the basics of Peirce's semiotics.

Figure 1: Example of plenary session with displayed worksheets

01:00 Plenary and Completion of semiotic audit (@30 mins)

- The results of exercise 1 & 2 can be displayed by group on a wall (see Figure 1), and feedback their assumptions which can then be discussed. Through this plenary phase participants can begin to understand how much of their tacit knowledge can be mapped to pragmatic semiotic theory, and how they can seek more theory to increase the effectiveness of their visual communication within designed artefacts.
- Participants will also complete the 2nd section of the designer semiotic audit form.
  - This captures their level of desire to understand more Peircean semiotic theory, and to ask how they would like that to happen.

01:30 Workshop Ends

Takeaways for the participants

The workshop participants will work together in small groups using handouts and an A3 worksheet. On this worksheet, they will annotate their emergent understanding of the inter-relationship between the design concept, how it is visually represented and interpreted. Then in the final plenary part of the workshop, the participants will discuss in their own words how they understand how the manipulation of iconic, indexical and symbolic representation affords different levels of meaning.

Strategy to capture content and results

The final plenary session is important to the Constructivist approach we take, as from a pragmatic position the participants' understanding emerges from the acts of engaging in the process of unlocking theory within existing design practice. Participants can opt into supplying their emails to be kept informed of the ongoing research.

Results and final reflections for consideration

The completed worksheets (or photographs of them), plus completed semiotic audits, will provide the workshop team with valuable sensory data to be further analysed as part of continuing Semiotic Rosetta Stone research. This ultimately is to define more designer-centric methods of disseminating Peircean theory into design practice.

Space requirements

A digital projector for our Mac laptop, in a room with flat tables and wall space for display will suffice.

Maximum number of participants

A maximum of 20 participants (5x groups of 4).

Big Design – Designing at Scale

LINDENFALK Bertil[a]; RESMINI Andrea[a]*; FENN Terence[b] and HOBBS Jason[c]

[a] Jönköping University, Sweden
[b] University of Johannesburg, South Africa
[c] Human Experience Design, South Africa
* andrea.resmini@ju.se
doi: 10.33114/adim.2019.w03.452

Introduction

Large-scale transformation projects have so far rather consistently embraced a dirigist, technicistic perspective. Their outcomes are on the other hand meant to be experienced by communities in a direct, engaged manner that is embodied, spatial and temporal. For processes meant to radically transform the lived experience of people, they have so far been strategically unconcerned with any human-centric view.

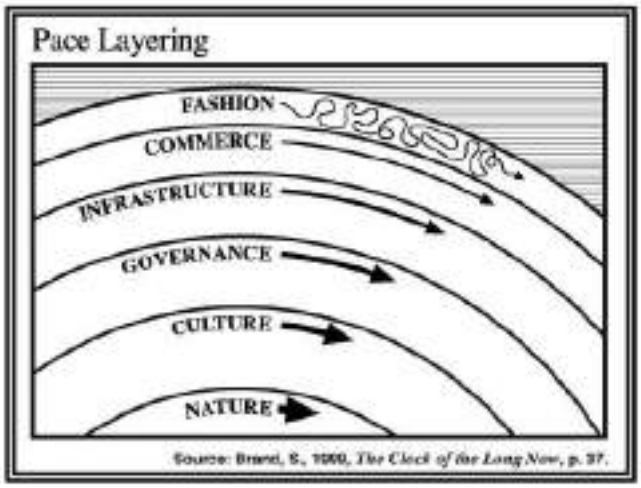
Workshop purpose and aims

The workshop intends to suggest a necessary shift in perspective through the conceptual lens of pace layers and a system of temporal, spatial, and socio-cultural indicators: place-making, power and plasticity, and proxemics, and discuss the role and responsibilities of design in the production of large-scale systemic change. Questions that will be addressed during the workshop include:

- When scaling up to regional level, does the design discourse belong? If so, when, where, how?
- What role and responsibilities for designers?
- Are designers comfortable with the level of abstraction these projects comport?
- Are current design processes useful or fit for the task?
- Is designing at scale designing for people?

Theoretical relationship

The pace layer model will be used to frame the outcomes of the workshop and guide the participants through the individual activities. Pace layers postulate that different socio-technical superstructures move and change at different speeds.



Participants will be asked to reflect on and formulate how the individual activities relate to the pace layer model. At the end of the session, groups will create a pace layer visualization for their processes, with the general aim of having an organically built representation of what tasks, activities, opportunity and challenges reside in or across what layers when designing at scale. Participants will be asked to consider that:

- in layers with high variability, adaptability should be maximized;
- in layers with low variability, structures should be stabilized;
- if changes happen too fast in a low-variability layer, their effects can become systemically detrimental as they negatively impact other layers.

These points will be recalled at wrap-up to foster reflection, frame the workshop, and further the conversation.

Activity 1: Placemaking

A dimension often overlooked in large-scale transformation projects is that addressed by placemaking. A core concept in city planning, placemaking centers on the necessity of designing environments that feel human and that speak to our sense of presence and belonging. While large-scale projects naturally work at the geographical scale, they seem to ignore the general need to meaningfully anchor infrastructure to human activities and the placemaking of the new digital/physical environments they create.

Activity 2: Power and plasticity

In cultural terms, power may be considered as control and the expression of biases in choices. Such control may be culturally explicit or tacit. Any call for large-scale transformation is a reflection on whether such efforts should alter or maintain the status quo. Human-centric approaches favor the individual and local bottom-up angle: strategic, policy-driven approaches favor the top-down, collective view. When designing at scale, as we abstract local needs upwards, can top-down structures provide enough plasticity to support cultural variance? What role does design play in avoiding technocratic approaches sidelining social and cultural needs?

Activity 3: Proxemics and public spaces

Proxemics is a cultural approach to understanding and representing how people experience space and spatial components and suggests a scalable framework that conceptualizes different interactions through methods of distance-setting. Using De Waal's three conceptual constructs for exploring proxemics at the level of the public space, the private, parochial and public domains, this activity will have groups figure out the how proxemics can contribute to make large-scale processes more human-centric.

Workshop approach

This is an activity-based workshop for 15-30 participants. After an initial welcome moment, the facilitators team up attendees in groups. These groups work on three distinct activities framed through large-scale design problems: the facilitators provide the practical and theoretical framing, a fictional hands-on case, supervision for the duration of the workshop, and finally coordinate the room for take-aways and reflections.

- 00:00 - 00:20 Welcome, introduction
- 20:00 - 35:00 Framing: Pace layers

- 35:00 - 75:00 Activity #1, #2, #3
- 75:00 - 90:00 Reflections, wrap-up

Takeaways for the participants

Participants will learn how to:

- define the role and responsibilities of design when designing at scale;
- recontextualize the role of technology in large scale transformative projects;
- systemically relate human-scale indicators to large-scale priorities.

Results and final reflections for consideration

The workshop provides attendees with a more mindful, human-scale approach aimed at re-centering large-scale transformation projects around the human elements. Final group reflections will center on how to:

- reduce the gap between the reality of large digital transformation projects and the current research framing and understanding of the problem space;
- challenge the current technicistic top-down approach, and disseminate a more rounded, humanistic way-of-doing that centers on socio-technical, spatio-temporal complexity;
- kickstart a process of aggregation of perspectives, cases, approaches, and results, and gauge current interest in post-conference dissemination and networking efforts.

Building Adaptable Teams for Co-configuration

FUTERMAN Rael Glen

University of Cape Town, South Africa
rael.futerman@uct.ac.za
doi: 10.33114/adim.2019.w04.451

Summary

In innovative organisations we are seeing an increase in cross-functional teams being built around projects. The diverse perspectives of collaborators draw from personal world-views and organisational roles, which contributes to radical collaboration across traditional boundaries of work.

This hands-on workshop aims at testing a rapid team alignment activity in which teams propose core values and align these to the innovation learning cycle, synthesising them into foundational work practices for each phase. These are then reframed as the teams' innovation narrative.

Workshop Purpose and Primary Aims

The purpose of this workshop is to test an activity aimed at contributing to the meaningful formation of new teams. Increasingly we are seeing teams form and reform throughout the product/service development lifecycle. These responsive teams are often cross-functional in nature, bringing together multiple perspectives into each phase of product/service design.

These purpose-driven teams often have to find alignment quite rapidly, so time is a constraint. Misalignment can lead to dysfunctional teams, resulting in longer product development, and innovation lifecycles. This in turn diminishes knowledge development of teams. Purpose-driven teams need to be rooted in a set of common values. The espoused values of the team should in turn be grounded & aligned to foundational work practices.

The primary aims of this workshop are to:

- Test an activity aimed at bringing new teams together rapidly
- Bring potential users of this activity into the design process
- Provide an interactive platform for participation and collaboration
- Generate insights around rapid-team alignment

Theoretical Relationship

Co-configuration, an emerging customer-centric mode of work, "involves building and sustaining a fully integrated system that can sense, respond, and adapt to the individual experience of the customer" (Victor & Boynton, 1998, p195). In practices of co-configuration there is a need to go beyond conventional teamwork or networking to the practice of 'knotworking' (Engeström, Y., Engeström, R., & Väläaho, 1999). Knotworking, the emerging interactional core of co-configuration, is where separate actors can quickly come together and "*tie a knot*" and work together and solve a problem or design a task in the most efficient way possible (Engeström, 2012).

Knotworking, Engeström (2008, 196) claims,"poses qualitatively new learning challenges to work communities." Critical to knotworking and the functioning of constantly changing participant configurations is rapid negotiation and improvisation (ibid).

The changing configurations of teams happen over time, specifically "the entire life trajectory of the product or service" (Engeström, Puonti, & Seppänen, 2003). The life trajectory of products/services is framed as expansive design thinking and aligned here with the iterative, innovation-learning process (Figure 1) (Beckman & Barry, 2007).

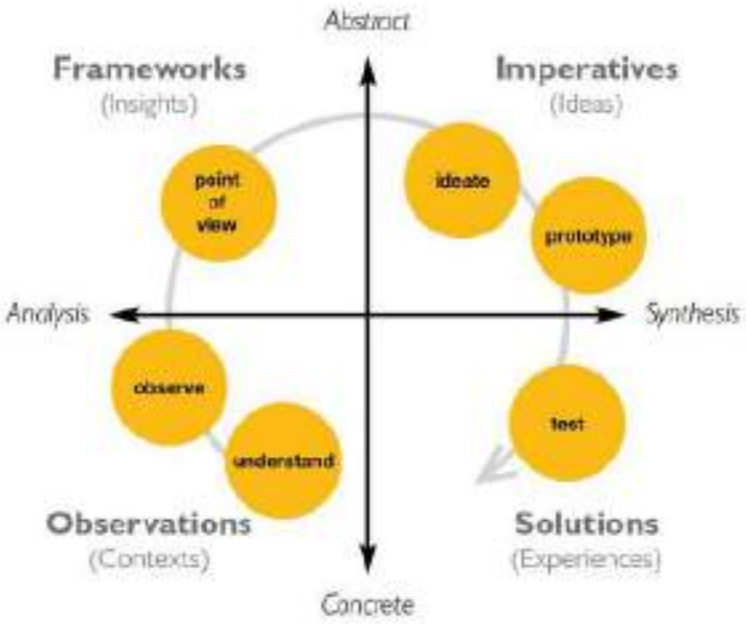


Figure 1: Innovation Learning Process. source: adapted from Beckman & Barry, 2007, p30

This diversity in collaborators and temporality of team configurations, based on objective/motive of the project at a specific time, can present challenges around cohesion, alignment and synchronicity.

Foundational work practices, that is, the enacted values of a team change with each iteration. These foundational work practices are rooted in the personal values of each individual and espoused as team values. With rapidly changing teams, the misalignment between espoused and enacted values can create tensions, which can hinder or derail a team's efforts.

Workshop Approach

This interactive, hands-on workshop will see participants form teams and develop foundational work practices for each phase of the innovation learning journey, that is, how they will embody and enact their team values dependent on where they are in the innovation cycle. This will be done through a guided, scaffolded approach moving from personal sharing personal values to collaboratively defining team practices.

This workshop embraces the activity-driven mind-set of design thinking and participants will each produce a personalised guide for future work, in the form of a lo-fi booklet.

After a brief introduction to the teams outlining how the workshop is structured, participants will co-create in teams of five, moving through the 6 stages presented in Figure 2. There will be intermittent instructions at each phase of the process.

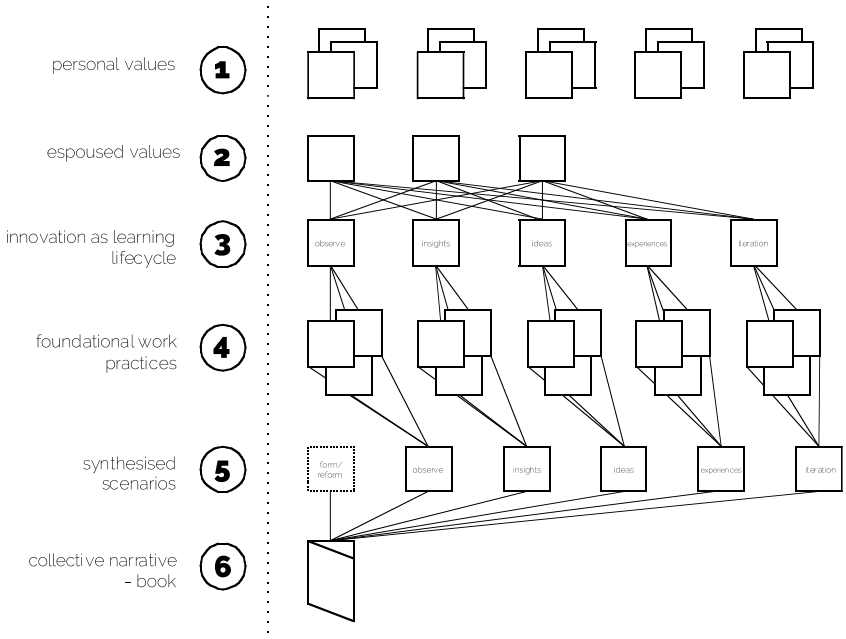

Figure 2: Workshop Phases. source: Authors Own

Takeaways for the Participant

Participants will each leave with a prototype of their team's co-created work guide in the form of a small booklet (stage 6 in Figure 2), which they will each produce.

After workshop findings have been synthesised, they will also be provided with the refined workshop outline and templates (via email) to carry out this activity within their organisations.

Results and final reflections for consideration

The results of the workshop will go toward refining the activity further.

Specific feedback I aim to capture is:

- What worked,
- What didn't work so well,
- New ideas/suggestions that emerge, &
- Questions that still need answering

Research Perspectives IN THE ERA OF Transformations

Discourse Mapping: Navigating the Politics of Sustainable Design

BOEHNERT Joanna

Loughborough University, United Kingdom
j.j.boehnert@lboro.ac.uk
doi: 10.33114/adim.2019.w05.471

Workshop Purpose and Aims

This workshop will create a space for discussion on environmental politics and its impact on design for sustainable transitions. It will help participants identify different sustainability discourses; create a space for reflection on how these discourses influence design practice; and consider the environmental and social implications of different discourses. The workshop will do this work by encouraging knowledge sharing, reflection and interpretative mapping in a participatory space where individuals will create their own discourse maps.

This work is informed by my research "Mapping Climate Communication" conducted at the Centre for Science and Technology Policy Research (CSTPR) in the Cooperative Institute for Environmental Sciences (CIRES), the University of Colorado, Boulder. With this research project I developed a discourse mapping method based on the discourse analysis method of political scientists and sustainability scholars. Using my own work as an example, I will facilitate a process that will enable participants to create new discourse maps reflecting their own ideas and agendas.

Theoretical Relationship

Discourses are shared ways of understanding the world. Political scientist John Dryzek's *Politics of the Earth* describes how discourses are ways of framing a problem that provide the basic terms for analysis and define what is understood as common sense and legitimate knowledge (2013, 9). Diverse values, vested interests, critical perspectives and insights are embedded within discourses. These both reflect and construct attitudes towards the natural world and create a foundation for design transitions for sustainability. Discourses frame problems. Framing is a means of navigating complexity and part of the problem-solving process in design (Dorst 2011, 528). Discourses can be understood as both diagnostic and prescriptive. Environmental discourses are a foundation for theories of change on issues of sustainability and prescriptive action.

The "Mapping Climate Communication" project identified five dominant climate discourses (these are plotted on a matrix in Figure 1). The following figure (figure 2) illustrates associated diagnostic/prescriptive concepts.

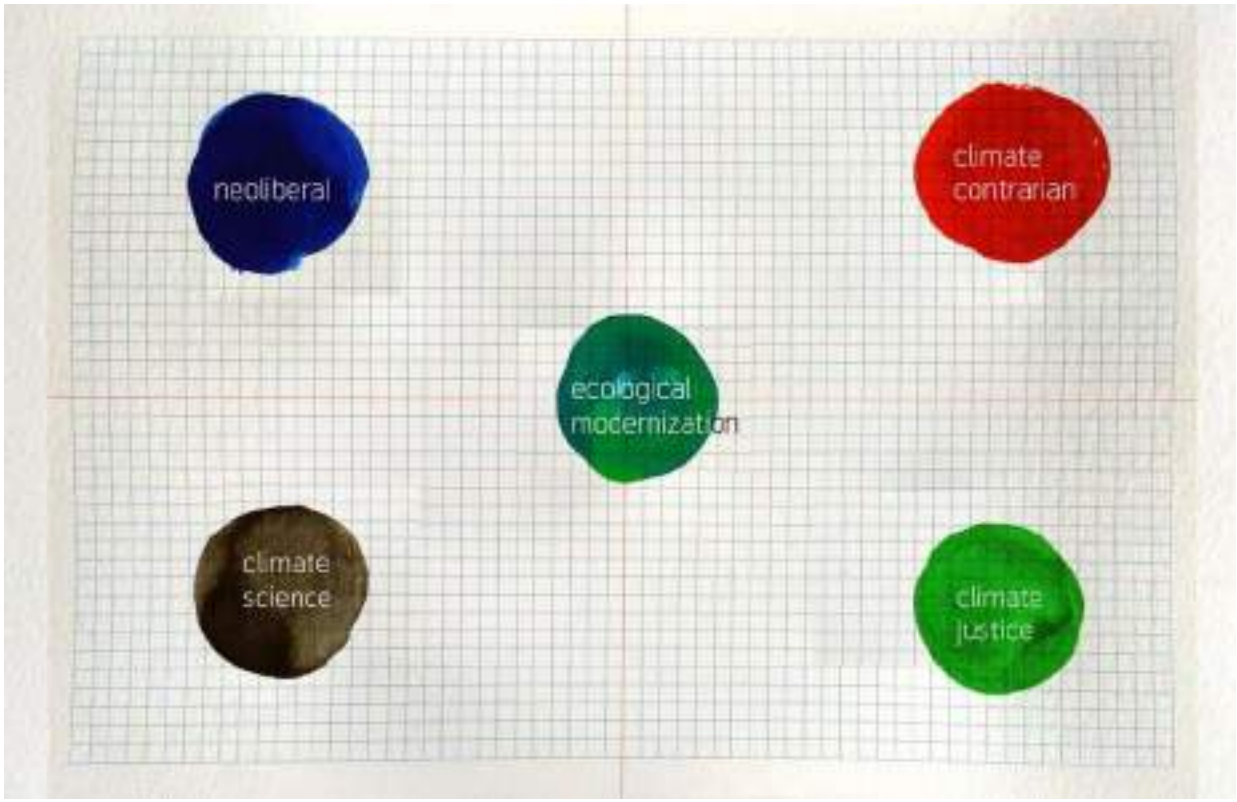

Figure 1: Five Climate Discourses. Boehnert, 2014.

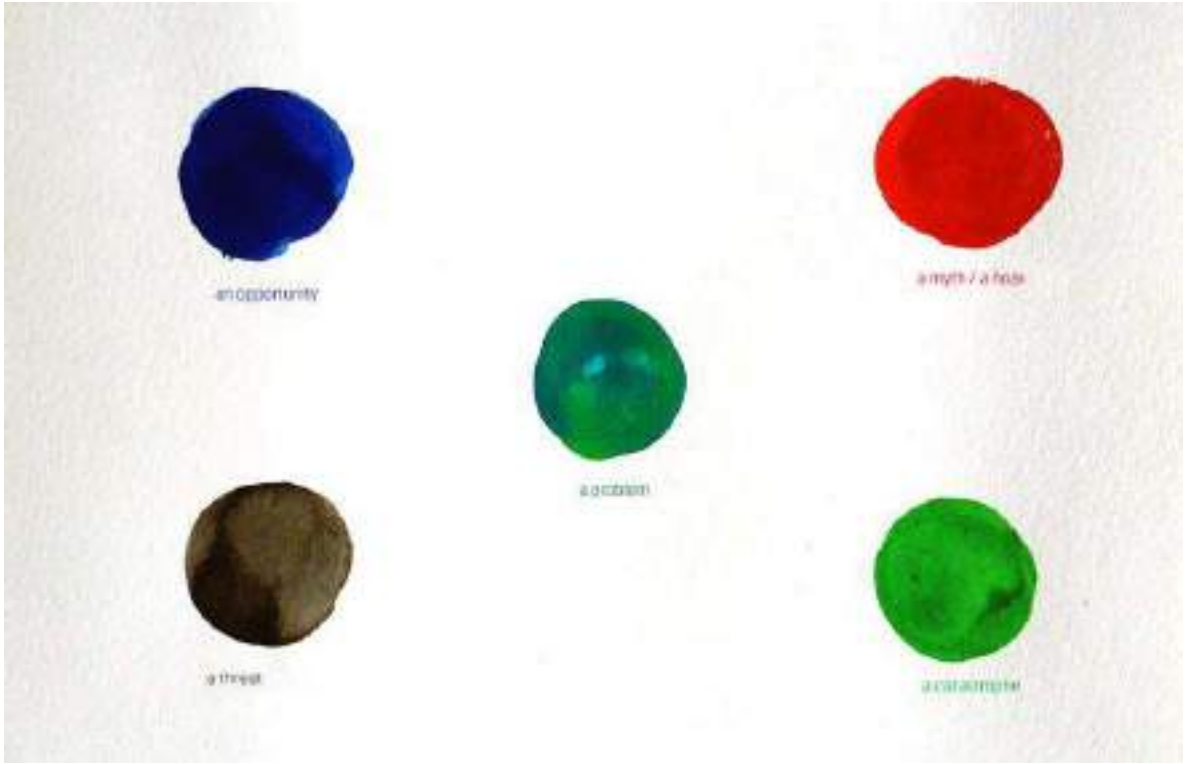

Figure 2: Five Climate Discourses – diagnostic/prescriptive concepts. Boehnert, 2014.

Summary of Five Climate Discourses

1. **Neoliberalism**. Within this discourse environmental considerations are subordinated to macroeconomic policy "imperatives". As a mode of governance, neoliberalism is characterized by privatisation, deregulation, financialisation and austerity (Peck 2010).
2. **Contrarian**. This discourse holds that environmental issues are not serious problems and/or if they do exist, they must not be prioritised over other concerns. The contrarian position seeks to continue unrestrained use of the Earth's fossil fuel reserves.
3. **Ecological Modernisation**. This discourse holds that environmental problems can be addressed within the current capitalist system and that low emissions and other benefits can be achieved with market mechanisms, clean energy and policy innovations.
4. **Physical Sciences**. This discourse relies heavily on the physical and material sciences. It looks to science as the way to address issues of sustainability with technocratic solutions. This discourse does not theorise either power or human motivation.
5. **Environmental Justice**. This discourse aims to create new forms of governance that support distributive and regenerative economies. It looks to support socio-political transitions to radically decentralize power, increase democracy and address injustices.

These discourses relate to the work of other environmental discourse theorists such as Dryzek (2013), Nisbet (2014) White, Rudy, and Wilber (2015) as illustrated in Figure 3. Within the "Mapping Climate Communication" project these discourses were used to categorise events in *The Climate Timeline* (figure 4) and 'actors', i.e. institutions, organisations and individuals, in the *Network of Actors* (figure 5). More recently, other environmental discourses have become prominent (including eco-fascism), and the maps presented here should be updated to reflect contemporary circumstances.

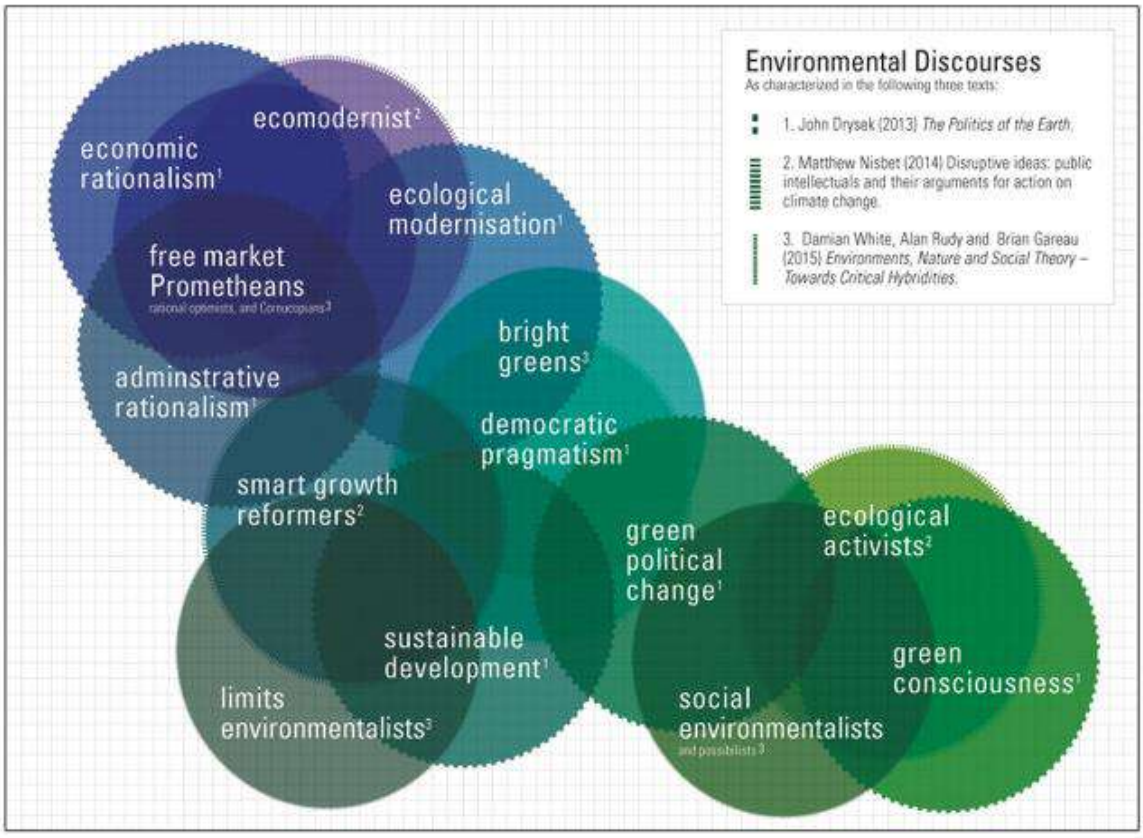

Figure 3: Discourses of different environmental theorists. Boehnert, 2014.

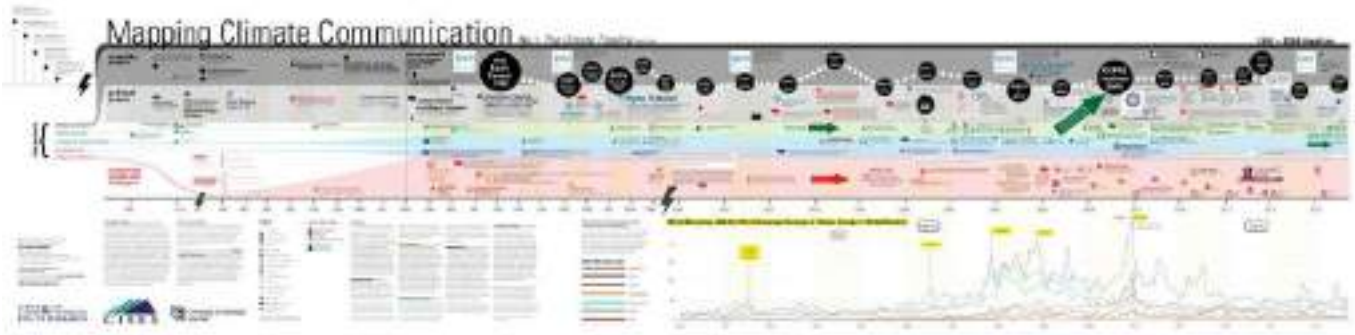

Figure 5: Mapping Climate Communication: No.1 The Climate Timeline. Boehnert, 2014.

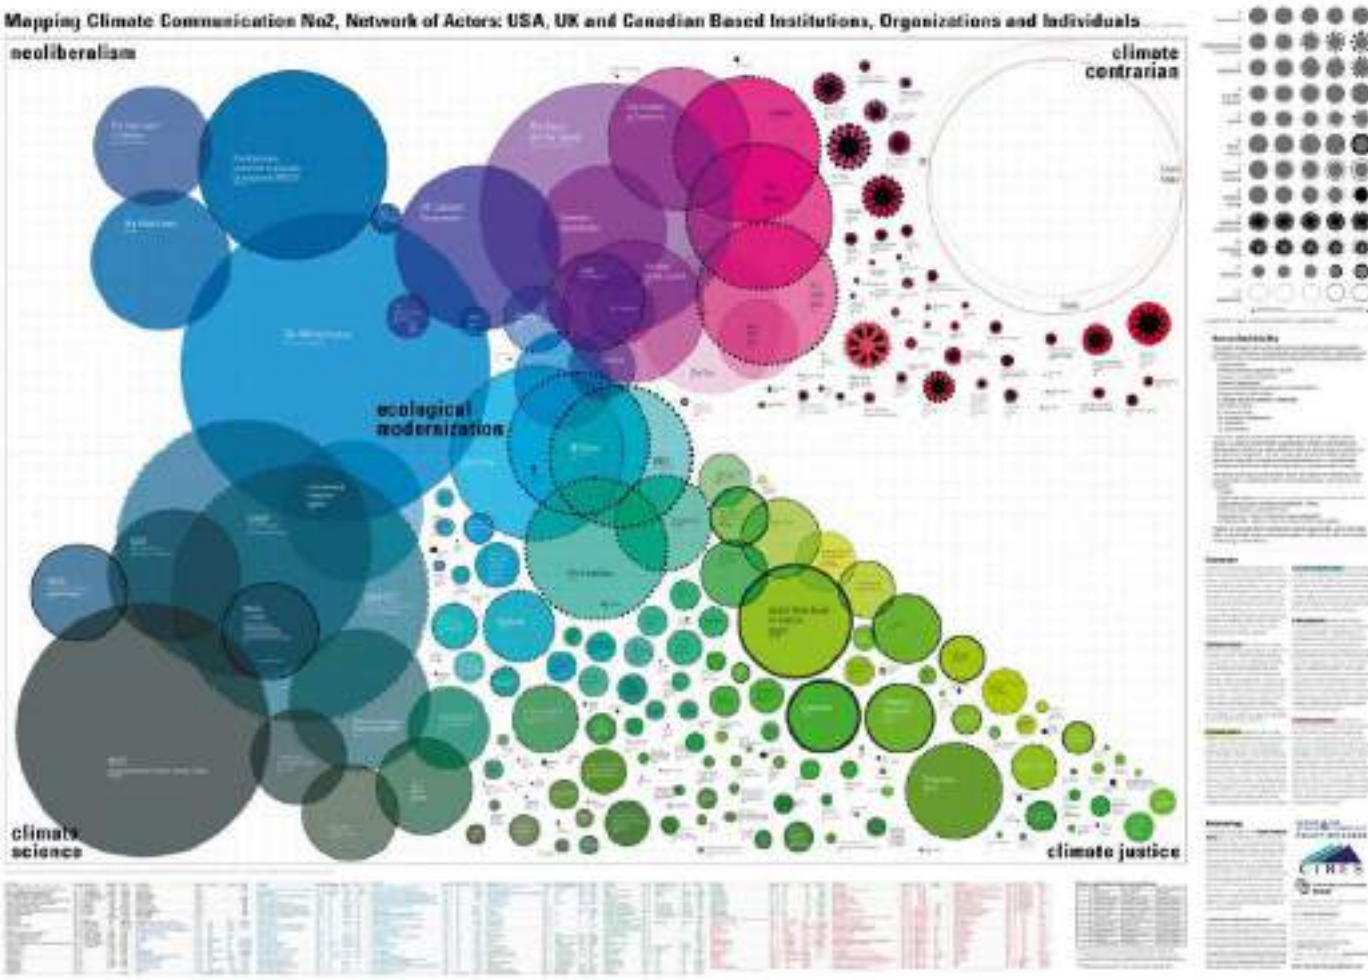

Figure 4: Mapping Climate Communication: No. 2 Network of Actors. Boehnert, 2014.

Workshop Approach

This project will offer participants a space to explore how environmental problems and sustainability agendas are understood. We will start with a theoretical presentation that will include my own discourse maps. I will then facilitate a group discussion on sustainability discourses in design industry. The group will identify dominant discourses and dynamics. I will lead a facilitated process to enable the formation of small groups based on alignments of theoretical positions (this process is central to the success of the workshop). Smaller groups will then have space to use mapping techniques to illustrate how events, actors and strategies are conceptualised within or between the discourses they identify as important. Discourse mapping will be

employed in this workshop to reveal environmental politics in the design industry, design education, design research and the design press.

Takeaways for The Participants

Participants will benefit from an introduction to discourse mapping and an opportunity to put this method into practice by mapping environmental discourses and what they reveal about various debates, events, strategies and actors in sustainable design.

I will photograph the workshop and all the maps at the end of the workshop (I will ask permission to photograph).

Results and Final Reflections for Consideration

Discourse mapping offers a means to interpret the politics associated with the design of sustainable future ways of living. This method informs the work of design educators and researchers as they develop capacities for sharper political analysis. The newly created discourse maps could potentially be used as educational resources.

Research Perspectives IN THE ERA OF Transformations

Discovering design narratives to humanize organizations

AUGSTEN Andrea[a]*; JYLKÄS Titta[b]; GEUY Bernadette[c]; HOLLOWGRASS Rachel[d] and MÄKELÄ KLIPPI Marjukka[e]

[a] University of Wuppertal, Germany
[b] University of Lapland, Finland
[c] Service Design Consultant, San Francisco
[d] University of California, Berkeley
[e] Aalto University, Finland
* corresponding author e-mail: mail@andreaaugsten.de
doi: 10.33114/adim.2019.w06.468

Workshop Purpose and Aims

Human-centered design approaches have emerged in business organizations since the rise of service design and design thinking. As a consequence, designers have been shifting their role from pure aesthetics towards innovating. Thus, in this workshop, we look at the role of design and designer in the frame of designing organizations. Lots of designers are becoming involved in strategic projects in the context of organizational change, such as creating a more creative, design-driven work attitude, bringing a human perspective into existing processes and acknowledging employee's individual diversity. But, do designers feel prepared for that? Are they aware of the organizational design narratives of companies?

Mostly, the introduction of new practices labeled as design thinking or service design is not adapted to the organizational circumstances, company values, habits, beliefs and experiences. However, we believe that each company would benefit from emphasizing its design narrative while introducing employees to new design practices in order to exploit its full potential and stay healthy as an organization.

Especially identifying solutions that fit both to the needs of users and to the organizational environment is challenging. Here, the lack of communication about an organizational design narrative challenges the work of a designer. Rather, the use of design activities is seen through new initiatives, such as labs, workspaces and innovation projects that aim to disrupt the organization towards more human-centric culture.

We, the workshop convenors, did a conceptual literature review to explore the topic of *humanizing an organization* by building upon co-created dimensions that have been developed with design scholars and practitioners in 2018. We identified four aggregated themes around management, design and organizational change. Each theme describes one aspect relevant to *humanizing an organization*.

During the workshop, participants use the two dimensions of pre-text and context of organizational design narratives as a basis for creating future scenarios for strategies to humanize an organization. The workshop aims to raise awareness for an organizational design narrative, to strengthen participants sensibility for organizational design practices and to deliver hands-on methods for experiencing and exploiting the approach.

Through a practical workshop approach, we are positioning and exploring the phenomena of humanizing organizations in design research by linking historical roots with complex issues currently arising in the context of design management and organizational change.

Theoretical Relation

The idea of reflecting and being aware of the organizational design narrative is firstly claimed by Junginger and Bailey in 2017. According to them (2017, p.39), a design narrative *aligns the design pre-*

text and the design context of an organization with other narratives and *reconstructs the organizational journey, the design practices, design principles and design methods*, as well as fosters its resilience.

Workshop Approach

Through the interactive workshop concept, we introduce a design framework built through a selection of tools and methods to help participants first to identify an organizational design narrative, and second, to create future scenarios with strategies for fitting the organizational design narrative to design activities for a more humanized organization.

The workshop structure is built through three main parts:

1. **Introduction:** The workshop topic is introduced by the convenors through synthesized results of the literature review in a presentation of maximum 20 minutes at the beginning of the workshop. The presentation also includes the introduction of the workshop agenda.
2. **Interactive team work:** After the introduction, the participants are divided into groups working on the given main themes identified in the literature review.
    a. The teams are given a description of their theme, as well as a predefined organizational context as a basis for the exercise.
    b. After getting familiar with the material, teams are guided through an exercise to (1) recognize and complete the dimensions of *pre-text* and *context* of the design narrative, and to (2) create a future scenario for humanizing the organization.
    c. All materials are provided as paper-based templates.
    d. Convenors are guiding the teams through the exercises step by step ending up in a block of 45 minutes in total.
3. **Wrap up:** At the end of the workshop, each team will present their results, sharing learnings and reflections utilizing the working templates as their structure. The presentations are filmed as short video clips for documentation purposes. (20 min)

The maximum number of participants for the workshop is 30 people. The participants will be divided into groups of maximum five people in each.

Takeaways for the Participants

The workshop exercises will result in narrated future scenarios of humanized organizations. The outcomes serve as a framework for the participants to take design actions in their own or their client's organizations for more humanized practice.

Results and Final Reflections for Consideration

The workshop facilitators are building the workshop upon a literature review in the context of humanizing organizations through design. By transferring the theoretical results in practical exercises and presentable design narratives, the fields of research and practice are linked in a collaborative format. The workshop results will be documented as a workshop report building on the literature review through the notes of the teams on paper templates accompanied by photos and short videos of the presentations.

Shelter after disaster management. New approaches by design driven Innovation

BENDITO Felix* and BRIS Pablo

Higher Technical School of Industrial Design and Engineering / Technical University of Madrid, Spain
* corresponding author e-mail: felix.bendito@upm.es
doi: 10.33114/adim.2019.w07.453

Workshop purpose and aims:

Despite several stakeholders involved in the shelter after disaster management, like academia or the private sector, are focused on the introduction of new products and on direct action, Innovation in shelter after disaster is today more likely to be concerned with improvements in process and more related with facilitation.

Design driven innovation (DDI) is increasingly applied on services, changing realities on individual, organizational or societal levels. It has clear potential in shelter after disaster management to lead the sector on interesting and important new directions, achieving breakthrough innovations and transforming the meaning of shelter as a product into a user's centered service.

The purpose of the workshop is to show a set of techniques from the DDI approach focused on service design projects and apply them in a disaster context to enhance current practices in shelter management.

The aim of this workshop is to establish a direction for the ideation of a new meaning of post-disaster shelter through the unique perspective of the participant through an ongoing value co-creation process.

Theoretical relationship:

Disasters occurs and causing destruction and homeless people in the need of shelter. With the aim of assist victims that have lost their homes he first thing that comes to mind is the delivery of thousands of tents or prefabricated units. But post-disaster shelter should be more than this.

Post disaster shelter is one of the most important sectors in Disaster Management. There is a large number of actions, activities and measures that must be carried out before, during and after a disastrous event, including emergency actions in order to save lives in the aftermath of the disaster, and recovery activities once the situation is stabilized- But it also has to include endless measures and activities of mitigation and preparedness, developed with the aim of decreasing vulnerabilities and increasing capacities, trying to reduce the consequences of the disaster. These procedures are interrelated and require a great deal of strategic planning.

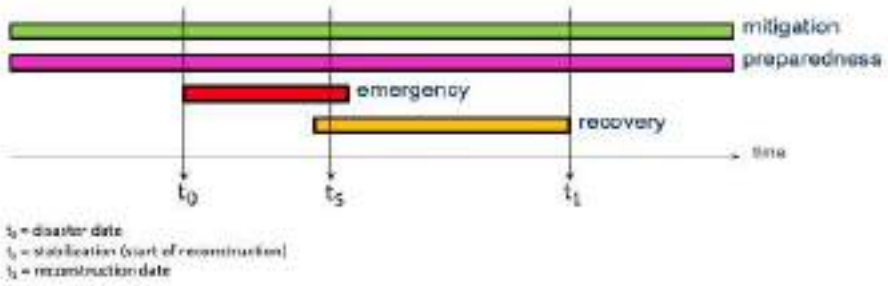

Figure 1 Disaster management diagram

When a disaster strikes, post-disaster shelter strategies begin with the implementation of emergency plans. Usually, they consist of moving homeless people from an affected area to a safer one, either sheltering them in existing structures: such as public buildings, schools, civic centers, sport facilities, and so on, or in new shelters such as tents, small structures, plastic covers, etc...

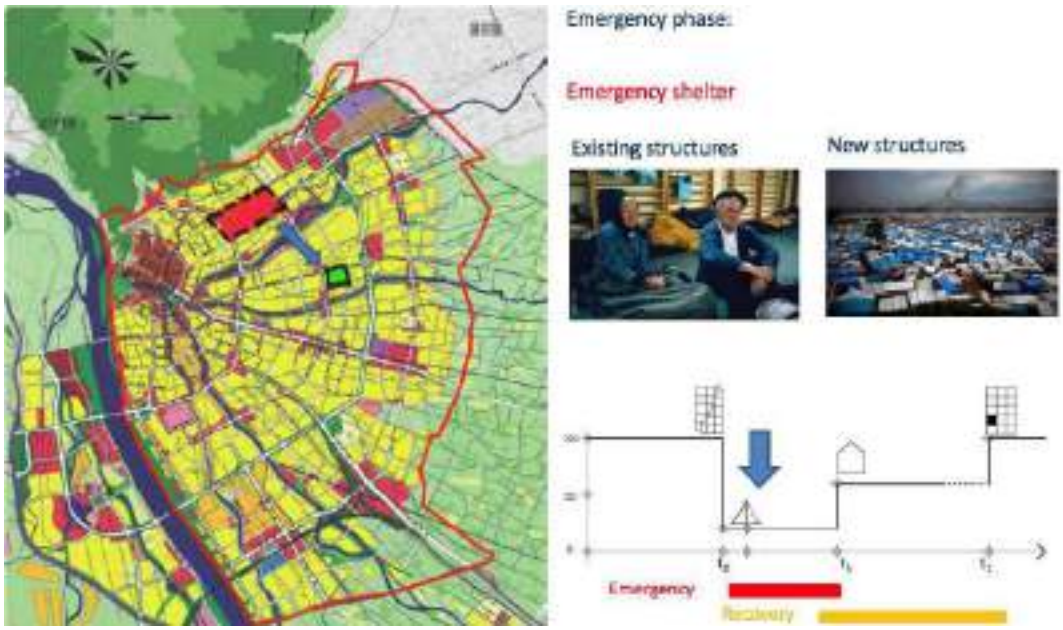

Figure 2 Shelter strategy during the emergency phase

Once the situation has been stabilized the recovery activities can start. Destroyed houses must be rebuild, and damaged ones repaired. This period may last long time. At least 2-3 years, but sometimes it can last more than ten. During this period, homeless people can't remain in an emergency shelter because living conditions are very limited; there is not enough privacy, comfort or security and its useful time is very short. It could be months, even weeks. Another kind of provisional shelter is needed to fill the gap between emergency and reconstruction. A temporary housing program offers a more durable solution and better living conditions than an emergency shelter. There is a wide range of temporary housing solutions; lodging, rental, prefabricated units, etc...

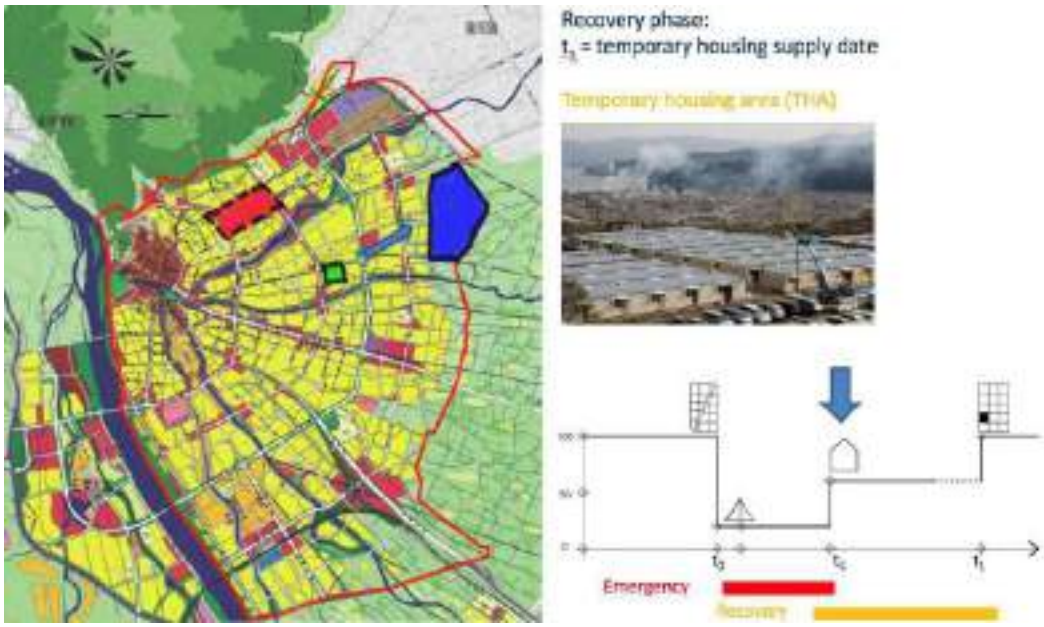

Figure 2 Shelter strategy during the recovery phase

The provision of temporary housing is crucial for an effective recovery process. It can provide not only physical protection, but also a certain sense of stability from a psychological point of view. It allows people to regain control over own lives. People are less vulnerable, and the community can increase their capacities, thus becoming more resilient. From this base point, the community can begin the reconstruction tasks, reducing the recovery time. Once the reconstruction is finished, people can return to their rebuilt permanent homes.

Unfortunately, most temporary housing strategies do not work properly, and this is the real problem in post-disaster shelter management. There are common failures in temporary housing programs:

- In most cases the recovery strategy hasn't been well planned. The housing plans are made during the emergency period without enough time, instead of being made in advance as part of the preparedness activities.

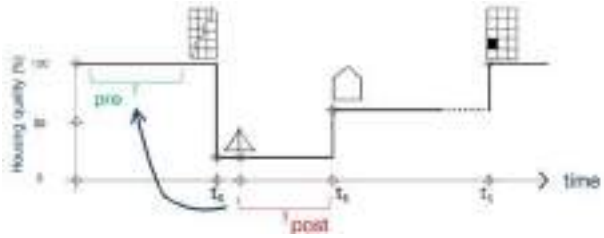

Figure 3 Post-disaster planned strategies enlarge the emergency period

- Many times, decisions are made in a very limited context, with only a few stakeholders, in a top-down approach, without any involvement of the people affected.

Figure 4 Top-down approach

- Usually, the quality and quantity requirements of shelter are based on feasibility and viability standards, such us lifespan, cost, m2, transport and assembly speed, etc., regardless of desirability, speaking in terms of human feelings or emotions.

Figure 5 Technocratic approach

- Most designs try to find a universal solution to adapt to any place, without taking into account contextual aspects such as the physical, economic or socio-cultural.

Figure 6 Universal approach

- Finally, the housing strategy generally consist in the delivery of a product or artifact, mainly a prefabricated unit designed to fit in a production chain, that hardly contributes to improving the recovery process.

Figure 7 Product approach

Losing our house is one of the most traumatic experience we can have. Homeless people are a risk group for mental illness such as depression, PTSD and even alcoholism. Experience shows that units designed as permanent houses, with the highest quality standards, are not enough for affected people to resume their normal lives. That is because they need more than a place to live. They need a home to build or rebuild relationships with other people and with the environment. They need to regain hope.

Post-disaster shelter management requires an innovative human centered approach to overcome the old technocratic approaches. We are talking about bottom-up participation processes, about standards based on requirements of desirability in terms of feelings and emotions, about designs adapted to different socio-cultural contexts and, finally, we are talking about temporary housing strategies that contribute to the community recovery process.

Design methodologies are comparatively different from technocratic in content, process and tools.

- In design, innovation becomes the centerpiece of strategy.
- Commensurating the feasibility, viability and desirability dimensions, design process can achieve a comprehensive picture of what a user really values in products and services, proposing new value configurations to create or innovate meaningful experiences.
- Design process and its tools emphasize innovation by collaboration, facilitation, argument and a multiplicity of views.
- Design can break through established boundaries and reconceptualize models, questioning existing assumptions, to frame things differently.

Design innovative methods are seen as a powerful toolset to deal with such wicked problems. Applied to shelter after disaster management, they can change realities at the individual, organizational or societal, and therefore strategically, helping the sector to satisfy the user desires throughout the recovery process in an integrated user experience.

Workshop approach:

This workshop proposes the change of meaning of housing in disaster management, reframing the context from the pre-disaster situation to a post-disaster situation.

In a first step, participants investigate the original context where the product (the house) is normally used. What a house is, front the user's point of view (how is it perceived), how the user interacts with it, with other people and with the environment, and why it is really necessary for the user.

Decomposing the house into the activities developed in it and analyzing the user behavior, we will try to discover the user's real desires in terms of feelings and emotions.

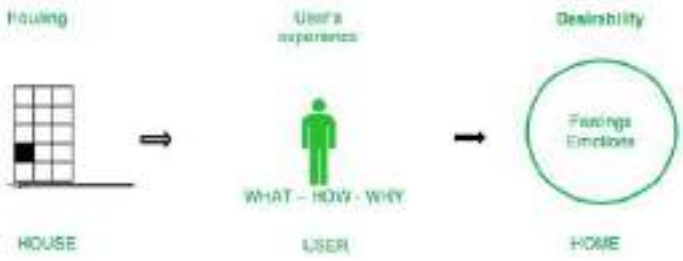

Figure 8 Stage 1; understanding the primary context

In a second step, participants try to unveil the underlying abstract values that make the user feel at home and then try to find the most important values to maintain the sense of home in a post-disaster situation (new context).

Figure 9 Stage 2; Reframing the context

In the last step, participants try to redefine, from this value conceptualization process, the meaning or purpose of temporary housing in the new context frame. Once the context has been reframed, it is possible to think about how to satisfy the user desires (not as a product, but as a service) and, therefore, define what kind of service should be provided to improve the user experience.

Figure 10 Stage 3; Redefining the mining

Takeaways for the participants:

Despite the brevity of the workshop, participants become aware of the complexity of the shelter sector in post-disaster management and realized the potential of design methods to generate innovative approaches to solve this kind of wicked problems.

Participants see how design can involve many stakeholders from different fields and with different points of view, expanding the context from which the problem arises, looking for new insights.

An interesting finding by the participants is how, taking into account the users' point of view, desirability becomes a key piece in the puzzle solution.

Another interesting finding is how feelings and emotions can be verbalized through the process of conceptualization and abstraction, so that deeper values can be uncovered, and users' true desires can be achieved.

Participants also realize that, in order to understand user behavior and discover new meanings, it is not so important what people do or how they do it, but the why of what they do.

Finally, through design-driven innovation and its powerful toolset, participants can develop their own vision of a possible alternative solution that can be proposed to people.

Figure 11 Participants acting as interpreters

Results and final reflections for consideration:

Houses shape and configuration are very different all over the world, depending on the climate, culture, local resources, the economy, the level of development, etc. The number of rooms, dimensions, windows or facilities depends on local customs. A house also hosts many functions such as resting, eating, sleeping, playing, working, protecting, cooking, caring for children, maintaining family unity or facilitating contact with family and friends. But housing context changes after a disaster and also housing requirements. To reduce the traumatic consequences of disasters other concepts come to mind more related to people's feelings and emotions and the feeling of being at home. Safety, security, love, sharing, sense of belonging or self-realization are strong desires related to why people need to establish relationships with each other and with the environment.

> *"Recovery is neither revival in economy, nor rebuilding houses. (…)*
>
> *What shape the recovery processes are relations: relations between human being and nature, relations between people, relations between ourselves and those we lost, including our ancestors, relations between our lives and local cultures and histories*."
>
> Uchiyama, 2011

In conclusion, the basic function of temporary housing should be to facilitate relations between people and between people and their environment, so that their desires can be satisfied. It should not simply be a product, but a human-centered service, capable of improving the user experience during the recovery process

This is an interesting starting point to obtain significant outputs in the definition of an innovative strategy in post-disaster shelter management

Research Perspectives IN THE ERA OF Transformations

Establishing Design Literacy International Network

NIELSEN Liv Merete[a]*; BOHEMIA Erik[a]; REITAN Janne Beate[a]; BRÆNNE Karen[a]; BRAVO Úrsula[b] and CORTÉS Catalina[b]

[a] Oslo Metropolitan University, Norway
[b] Universidad del Desarrollo, Santiago, Chile
* corresponding author: livmn@oslomet.no
doi: 10.33114/adim.2019.w08.435

The aims of the workshop where threefold:

a) establish an international network on Design Literacy,

b) articulate how network membership might support personal goals,

c) share information regarding how the participants might contribute into the network in terms of research expertise, funding, networks.

The workshop gathered a group of 21 international scholars who were interested in exploring the emerging area of the Design Literacy. Production and consumption are very much tight around human designed and made systems – how can citizens become aware of their vital role in shaping the world and support a better tomorrow for both people and planet? How does the uptake of design literacies evolve across diverse field of education (both universities and K12), policy development and commercial organisations?

Figure 1. Design Literacy workshop participants

A majority of the workshop participants had presented papers in the paper track 6b: Design Literacy enabling Critical Innovation Practices. Different perspectives on Design Literacy was presented during the four sessions of track 6b and proved a valuable point of departure for further discussions in the workshop. Two papers from the track were awarded TOP III at the conference: Úrsula Bravo for best student paper and Eva Lutnæs for best paper. In her paper, Lutnæs' raise the question of what it means to be design literate in a context of critical innovation and suggest the following definition:

> *Being design literate in a context of critical innovation means to be aware of both positive and negative impacts of design on people and the planet, approaching real-world problems as complex, voicing change through design processes, and judging the viability of any design ideas in terms of how they support a transition towards more sustainable ways of living (Lutnæs, 2019, p. 9)*

The definition was displayed on screen and the concept of Design Literacy debated. How is Design Literacy different from other types of literacies, such as visual literacy? Is it vital to be able to address the negative impacts of design? How could the concept be kept wide and open to evolve? What is design illiteracy? How could indicators of design literacy be developed rather than a definition?

After a plural session, the participants worked in groups and encouraged to articulate how network membership might support their personal goals, articulate research ideas and expertise. This is an important aspect as we envisage developing a proactive network that support international colleagues with diverse career paths and visions. Thus, recognising that members' context and diverse agendas will play an important part of how the Design Literacies will be taken up. Identifying the diversity provide a tipping point to succeed in the development of rich resources that can be adopted by the Design Literacy International Network members to develop specific research funding applications with a goal to produce tangible impact.

The workshop successfully established the Design Literacy International Network and a webpage for sharing information on members, papers, articles, conferences, applications, funding, grants and positions was regarded the next step. The webpage for the Design Literacy International Network will need to find its form. The address of the webpage is: www.designliteracy.net

Co-creating a visual thesaurus for the role of design thinking in management decision making

BEAUSOLEIL Angele*[a] and QUAYLE Moura[b]

[a] University of Toronto, Canada
[b] University of British Columbia, Canada
* e-mail: angele.beausoleil@rotman.utoront.ca
doi: 10.33114/adim.2019.w09.455

Introduction and Aim:

The workshop will engage participants to co-create concept maps and a visual thesaurus associated with 'design thinking'. For design researchers, scholars and practitioners this workshop aims to expose the epistemological challenges and opportunities associated with 'design thinking' in management and leadership contexts. Concept mapping is a tool and technique that aims to enable visual thinking and knowledge organization skills. It offers a way to externalize understanding of complex topics (i.e. design thinking) in terms of both intra- and inter-personal relationships (i.e. within the management domain). A visual thesaurus displays semantic connections using pictures or images, not words. It aids in recognizing visually similar events or visual synonyms. Workshop participants will be guided through a series of visual thinking and design techniques to develop concept maps and a visual thesaurus for 'design thinking' and design-related terminologies within the management discourse. The outputs generated from the workshop will reflect a multidisciplinary understanding of the subject for knowledge translation and identify future research goals.

Outline and Format:

The 90-minute workshop will engage participants in an active design research session. The facilitators will:

- first present a set of proposed theories and practices associated with design thinking and its role within a mixed economy system (30 min);
- then present a series of design prompts and probes to critically explore and capture the participants' diverse visual and semantic views on design thinking in relation to management resulting in a series of concept maps (30 min); and,
- guide participants to co-create a visual thesaurus of 'design thinking' (30 min).

Participant Benefits:

Participants will benefit from contributing their a priori knowledge of design-related terminology, to the workshop resulting in two co-designed artefacts – a visual thesaurus and a summative concept map. They will be introduced to visual thinking techniques such as concept mapping and visual thesaurus making. Participants will receive a final graphical representation of the collective output generated from the workshop.

Workshop Relevance:

This workshop proposes both an active learning experience and action research framework, to gain a deeper understanding of design thinking's perceived meaning and value in relation to managerial decision-making. Furthermore, the artefacts (i.e. visual models) generated from this workshop aim to inspire more research on the use and value of visual models in design-based decision studies.
